PRODUCT PROFILE SHEET

MB814265-60/-70

CMOS 256K X 16BIT HYPER PAGE MODE DYNAMIC RAM

CMOS 262,144 x 16 bit Hyper Page Mode Dynamic RAM

The Fujitsu MB814265 is a fully decoded CMOS Dynamic RAM (DRAM) that contains 4,194,304 memory cells accessible in 16–bit increments. The MB814265 features the ”hyper page” mode of operation which provides extended valid time for data output and higher speed random access of up to 512x16–bits of data within the same row than the fast page mode. The MB814265-60/-70 DRAMs are ideally suited for memory applications such as embedded control, buffer, portable computers, and video imaging equipment where very low power dissipation and high bandwidth are basic requirements of the design.

The MB814265 is fabricated using silicon gate CMOS and Fujitsu's advanced four–layer polysilicon process. This process, coupled with three–dimensional stacked capacitor memory cells, reduces the possibility of soft errors and extends the time interval between memory refreshes.

PRODUCT LINE & FEATURES

Parameter		MB814265-60	MB814265–70
$\overline{RAS}$ Access Time		60ns max.	70ns max.
$\overline{CAS}$ Access Time		20ns max.	20ns max.
Address Access Time		30ns max.	35ns max.
Randam Cycle Time		104ns max.	119ns min.
Hyper Page Mode Cycle Time		25ns min.	30ns min.
Low Power Dissipation	Operating current	523mW max.	462mw max.
	Standby current	11mW max. (TTL level) / 5.5mW max. (CMOS level)	

- 262,144 words x 16 bit organization
- Silicon gate, CMOS, Advanced Stacked Capacitor Cell
- All input and output are TTL compatible
- 512 refresh cycles every 8.2ms
- 9 rows x 9 columns, addressing scheme
- Early Write or $\overline{OE}$ controlled Write capability
- $\overline{RAS}$-only, $\overline{CAS}$-before-$\overline{RAS}$, or Hidden Refresh
- Hyper page mode, Read-Modify-Write capability
- On chip substrate bias generator for high performance

ABSOLUTE MAXIMUM RATINGS (see NOTE)

Parameter	Symbol	Value	Unit
Voltage at any pin relative to VSS	V_{IN} , V_{OUT}	–0.5 to +7	V
Voltage of V_{CC} supply relative to VSS	V_{CC}	–0.5 to +7	V
Power Dissipation	PD	1.0	W
Short Circuit Output Current	I_{OUT}	–50 to +50	mA
Storage Temperature	T_{STG}	–55 to +125	°C
Temperature under Bias	T_{BIAS}	0 to +70	°C

NOTE: Permanent device damage may occur if the above **Absolute Maximum Ratings** are exceeded. Functional operation should be restricted to the conditions as detailed in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package and Ordering Information

– 40–pin plastic (400mil) SOJ,
order as MB814265–xxPJ

– 44–pin plastic (400mil) TSOP–II
with normal bend leads,
order as MB814265–xxPFTN

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields. However, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit.

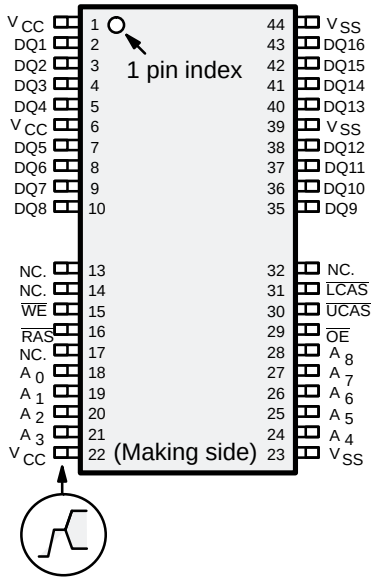
<Normal Bend>



Designator	Function
A0 to A8	Address inputs. row : A0 to A8 column : A0 to A8 refresh : A0 to A8
$\overline{RAS}$	Row address strobe.
$\overline{LCAS}$	Lower column address strobe
$\overline{UCAS}$	Upper column address strobe
$\overline{WE}$	Write enable
$\overline{OE}$	Output enable.
DQ1 to DQ16	Data Input/ Output
VCC	+5 volt power supply.
VSS	Circuit ground.
NC.	No connection

RECOMMENDED OPERATING CONDITIONS

Parameter	Notes	Symbol	Min	Typ	Max	Unit	Ambient Operating Temp
Supply Voltage	1	V_{CC}	4.5	5.0	5.5	V	0 °C to +70 °C
		V_{SS}	0	0	0		
Input High Voltage, all inputs	1	VIH	2.4	—	6.5	V	
Input Low Voltage, all inputs (*)	1	VIL	–0.3	—	0.8	V	

*** :** Undershoots of up to –2.0 volts with a pulse width not exceeding 20ns are acceptable.

FUNCTIONAL OPERATION

ADDRESS INPUTS

Eighteen input bits are required to decode any sixteen of 4,194,304 cell addresses in the memory matrix. Since only nine address bits (A0 to A8) are available, the column and row inputs are separately strobed by $\overline{LCAS}$ or $\overline{UCAS}$ and $\overline{RAS}$ as shown in Figure 1. First, nine row address bits are input on pins A0–through–A9 and latched with the row address strobe ($\overline{RAS}$) then, nine column address bits are input and latched with the column address strobe ($\overline{LCAS}$ or $\overline{UCAS}$). Both row and column addresses must be stable on or before the falling edges of $\overline{RAS}$ and $\overline{LCAS}$ or $\overline{UCAS}$, respectively. The address latches are of the flow-through type; thus, address information appearing after t_{RAH} (min) + t_T is automatically treated as the column address.

WRITE ENABLE

The read or write mode is determined by the logic state of $\overline{WE}$. When $\overline{WE}$ is active Low, a write cycle is initiated; when $\overline{WE}$ is High, a read cycle is selected. During the read mode, input data is ignored.

DATA INPUT

Input data is written into memory in either of three basic ways : an early write cycle, an $\overline{OE}$ (delayed) write cycle, and a read-modify-write cycle. The falling edge of $\overline{WE}$ or $\overline{LCAS}$ / $\overline{UCAS}$, whichever is later, serves as the input data-latch strobe. In an early write cycle, the input data of DQ1-DQ8 is strobed by LCAS and DQ9-DQ16 is strobed by $\overline{UCAS}$ and the setup/hold times are referenced to each $\overline{LCAS}$ and $\overline{UCAS}$ because $\overline{WE}$ goes Low before $\overline{LCAS}$ / $\overline{UCAS}$. in a delayed write or a read-modify-write cycle, $\overline{WE}$ goes Low after $\overline{LCAS}$ / $\overline{UCAS}$; thus, input data is strobed by $\overline{WE}$ and all setup/hold times are referenced to the write-enable signal.

DATA OUTPUT

The three-state buffers are TTL compatible with a fanout of two TTL loads. Polarity of the output data is identical to that of the input; the output buffers remain in the high-impedance state until the column address strobe goes Low. When a read or read-modify-write cycle is executed, valid outputs and High-Z state are obtained under the following conditions:

- t_{RAC} : from the falling edge of $\overline{RAS}$ when t_{RCD} (max) is satisfied.
- t_{CAC} : from the falling edge of $\overline{LCAS}$ (for DQ1–DQ8) $\overline{UCAS}$ (for DQ9–DQ16) when t_{RCD} is greater than t_{RCD} (max).
- t_{AA} : from column address input when t_{RAD} is greater than t_{RAD} (max), and t_{RCD} (max.) is satisfied.
- t_{OEA} : from the falling edge of $\overline{OE}$ when $\overline{OE}$ is brought Low after t_{RAC}, t_{CAC}, or t_{AA}.
- t_{OEZ} : from $\overline{OE}$ inactive.
- t_{OFF} : from $\overline{CAS}$ inactive while $\overline{RAS}$ inactive.
- t_{OFR} : from $\overline{RAS}$ inactive while $\overline{CAS}$ inactive.
- t_{WEZ} : from $\overline{WE}$ active while $\overline{CAS}$ inactive.

The data remains valid after either $\overline{OE}$ is inactive, or both $\overline{RAS}$ and $\overline{LCAS}$ (and/or $\overline{UCAS}$) are inactive, or $\overline{CAS}$ is reactived. When an early write is executed, the output buffers remain in a high-impedance state during the entire cycle.

HYPER PAGE MODE OPERATION

The hyper page mode operation provides faster memory access and lower power dissipation. The hyper page mode is implemented by keeping the same row address and strobing in successive column addresses. To satisfy these conditions, $\overline{RAS}$ is held Low for all contiguous memory cycles in which row addresses are common. For each page of memory (within column address locations), any of 512x16-bits can be accessed and, when multiple MB814265s are used, $\overline{CAS}$ is decoded to select the desired memory page. Hyper page mode operations need not be addressed sequentially and combinations of read, write, and/or read-modify-write cycles are permitted. Hyper page mode features that output remains valid when $\overline{CAS}$ is inactive until $\overline{CAS}$ is reactivated.

DC CHARACTERISTICS

(Recommended operating conditions unless otherwise noted) Notes 3

Parameter	Notes	Symbol	Conditions	Value Min	Value Max	Unit
Output high voltage	1	V_{OH}	I_{OH} = –5 mA	2.4	—	V
Output low voltage	1	V_{OL}	I_{OL} = 4.2 mA	—	0.4	V
Input leakage current (any input)		$I_{I(L)}$	0V≤V_{IN}≤ 5.5V; 4.5V≤V_{CC}≤ 5.5V; V_{SS} = 0V; All other pins not under test = 0V	–10	10	µA
Output leakage current		$I_{DQ(L)}$	0V≤V_{OUT}≤ 5.5V; Data out disabled	–10	10	µA

Notes:

1. Referenced to VSS. To all V_{CC}(V_{SS}) pins, the same supply voltage should be applied.
2. I_{CC} depends on the output load conditions and cycle rates; The specified values are obtained with the output open.
   I_{CC} depends on the number of address change as $\overline{RAS}$ = V_{IL} and $\overline{UCAS}$= V_{IH}, $\overline{LCAS}$= V_{IH}, V_{IL} > –0.3V.
   I_{CC1}, I_{CC3} and I_{CC5} are specified at one time of address change during $\overline{RAS}$ = V_{IL} and $\overline{UCAS}$= V_{IH}, $\overline{LCAS}$= V_{IH}.
   I_{CC4} is specified at one time of address change during one Page cycle.
3. An initial pause ($\overline{RAS}$ = $\overline{CAS}$ =VIH) of 200µs is required after power–up followed by any eight $\overline{RAS}$ –only cycles before proper device operation is achieved. In case of using internal refresh counter, a minimum of eight $\overline{CAS}$ –before–$\overline{RAS}$ initialization cycles instead of 8 $\overline{RAS}$ cycles are required.
4. AC characteristics assume t_T = 5ns.
5. V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Also transition times are measured between V_{IH} (min) and V_{IL} (max).
6. Assumes that $t_{RCD} \leq t_{RCD}$ (max), $t_{RAD} \leq t_{RAD}$ (max). If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will be increased by the amount that t_{RCD} exceeds the value shown. Refer to Fig. 2 and 3.
7. If $t_{RCD} \geq t_{RCD}$ (max), $t_{RAD} \geq t_{RAD}$ (max), and $t_{ASC} \geq t_{AA} - t_{CAC} - t_T$, access time is t_{CAC}.
8. If $t_{RAD} \geq t_{RAD}$ (max) and $t_{ASC} \leq t_{AA} - t_{CAC} - t_T$, access time is t_{AA}.
9. Measured with a load equivalent to two TTL loads and 100 pF.
10. t_{OFF} and t_{OEZ} are specified that output buffer change to high impedance state.
11. Operation within the t_{RCD} (max) limit ensures that t_{RAC} (max) can be met. t_{RCD} (max) is specified as a reference point only; if t_{RCD} is greater than the specified t_{RCD} (max) limit, access time is controlled exclusively by t_{CAC} or t_{AA}.
12. t_{RCD} (min) = t_{RAH} (min)+ 2t_T + t_{ASC} (min).
13. Operation within the t_{RAD} (max) limit ensures that t_{RAC} (max) can be met. t_{RAD} (max) is specified as a reference point only; if t_{RAD} is greater than the specified t_{RAD} (max) limit, access time is controlled exclusively by t_{CAC} or t_{AA}.
14. Either t_{RRH} or t_{RCH} must be satisfied for a read cycle.
15. t_{WCS} is specified as a reference point only. If $t_{WCS} \geq t_{WCS}$ (min) the data output pin will remain High-Z state through entire cycle.
16. Assumes that $t_{WCS} < t_{WCS}$ (min).
17. Either t_{DZC} or t_{DZO} must be satisfied.
18. t_{CPA} is access time from the selection of a new column address (that is caused by changing both $\overline{UCAS}$ and $\overline{LCAS}$ from “L” to “H”). Therefore, if t_{CP} is long, t_{CPA} is longer than t_{CPA} (max).
19. Assumes that $\overline{CAS}$ –before–$\overline{RAS}$ refresh.
20. The last $\overline{CAS}$ rising edge.
21. The first $\overline{CAS}$ falling edge.

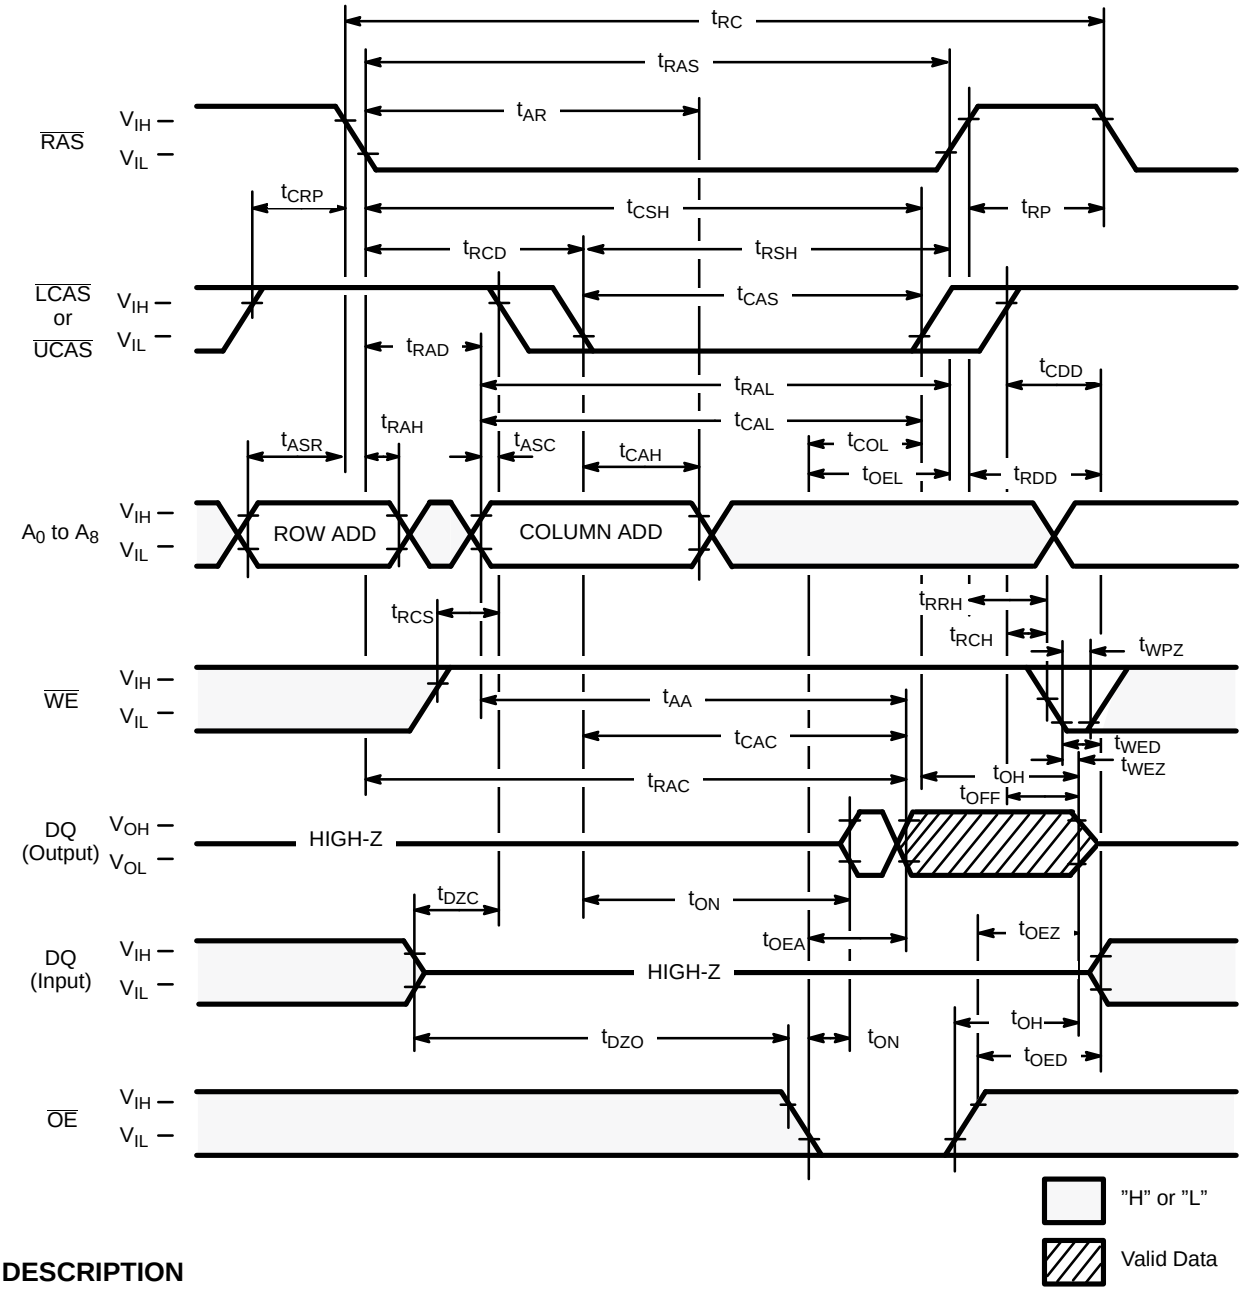
Fig. 5 – READ CYCLE



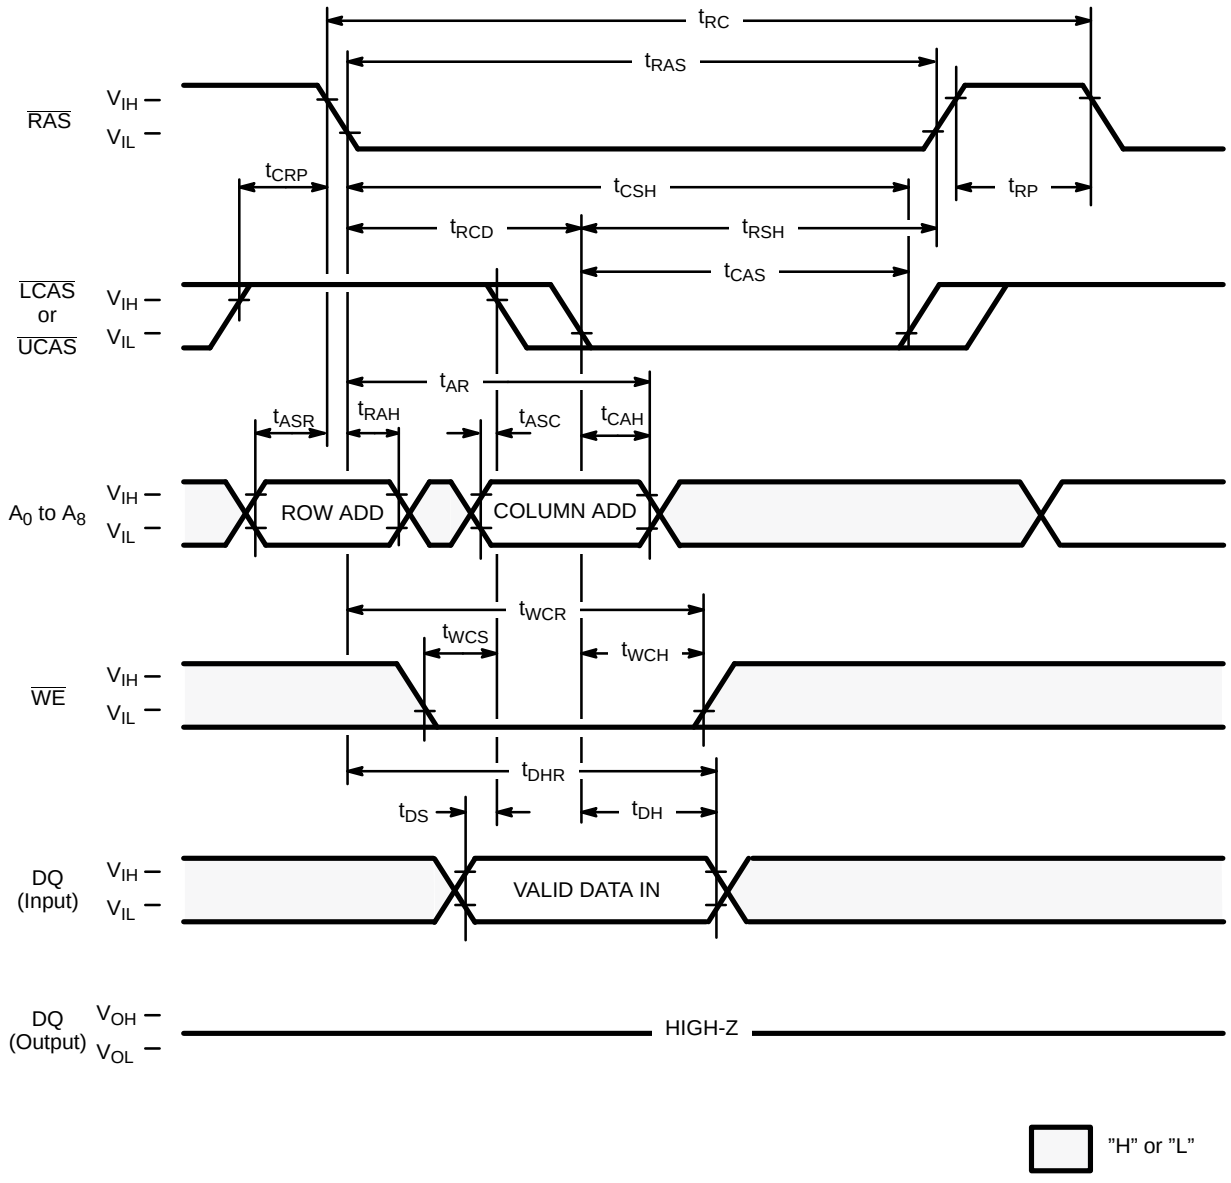
DESCRIPTION

To implement a read operation, a valid address is latched by the $\overline{RAS}$ and $\overline{LCAS}$ or $\overline{UCAS}$ address strobes and with $\overline{WE}$ set to a High level and $\overline{OE}$ set to a low level, the output is valid once the memory access time has elapsed. DQ8–DQ16 pins is valid when $\overline{RAS}$ and $\overline{CAS}$ are High or until $\overline{OE}$ goes High. The access time is determined by RAS(t_{RAC}), $\overline{LCAS}$/$\overline{UCAS}$(t_{CAC}), $\overline{OE}$(t_{OEA}) or column addresses (t_{AA}) under the following conditions:

If $t_{RCD} > t_{RCD}$(max), access time = t_{CAC}.
If $t_{RAD} > t_{RAD}$(max), access time = t_{AA}
If $\overline{OE}$ is brought Low after t_{RAC}, t_{CAC}, or t_{AA}(whichever occurs later), access time = t_{OEA}.

However, if either $\overline{LCAS}$/$\overline{UCAS}$ or $\overline{OE}$ goes High, the output returns to a high-impedance state after t_{OH} is satisfied.

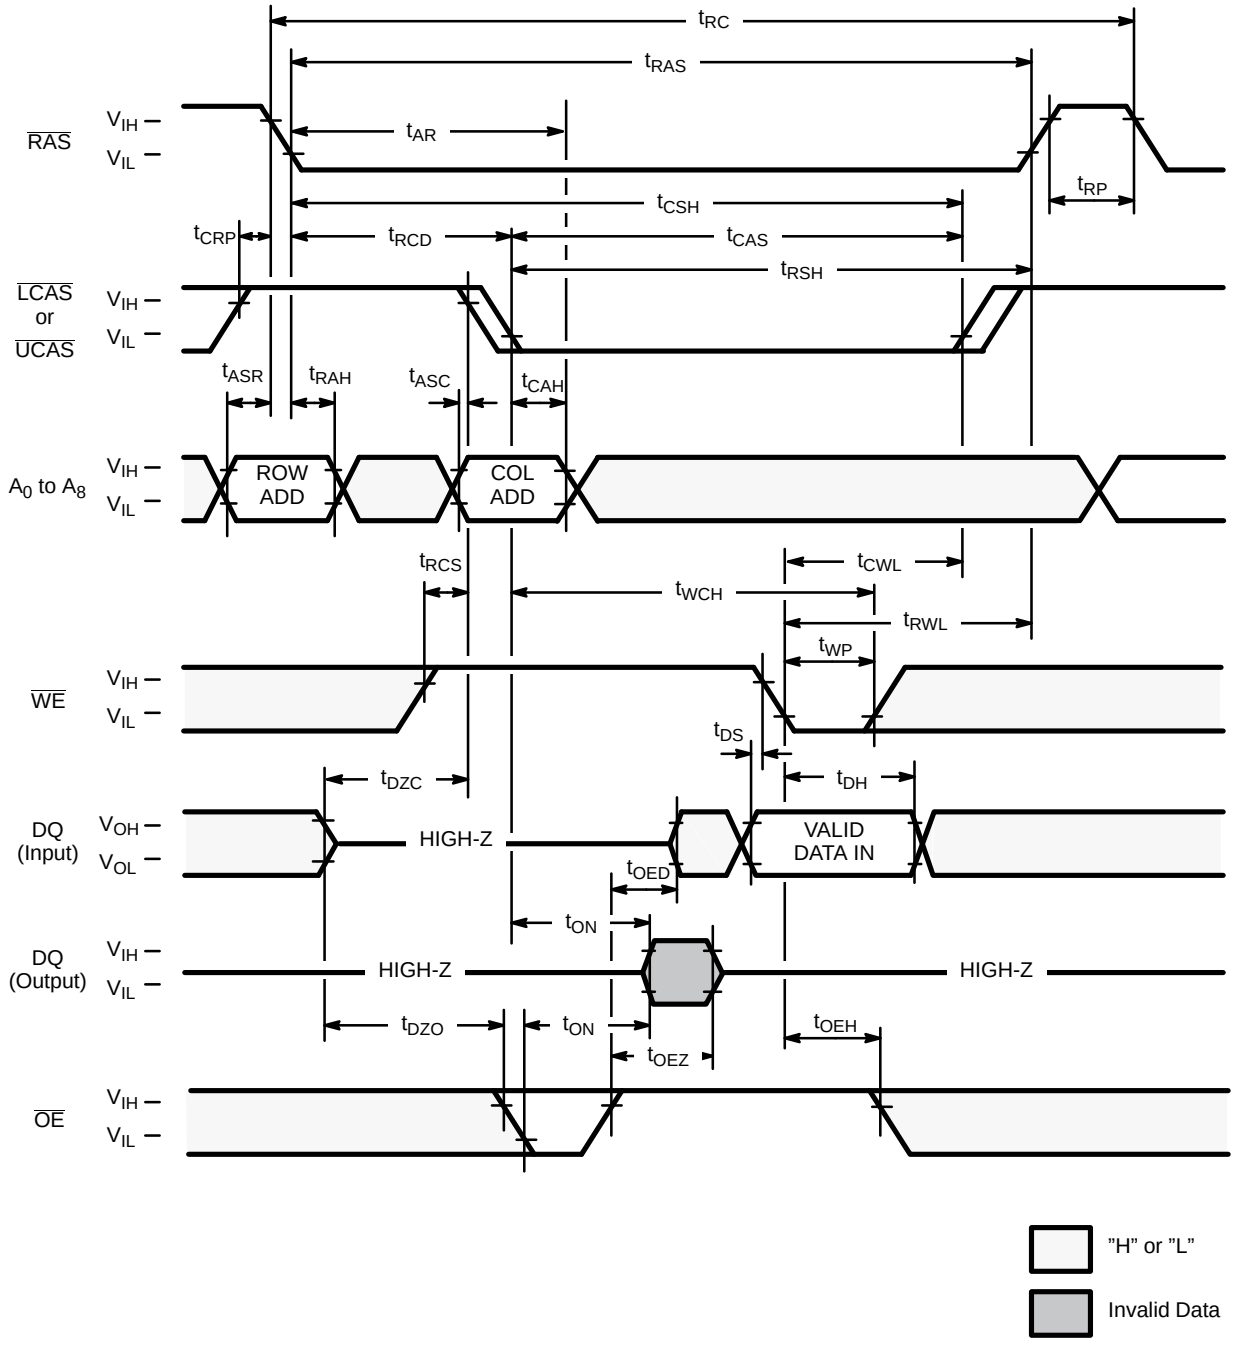
Fig. 6 – EARLY WRITE CYCLE



DESCRIPTION

A write cycle is similar to a read cycle except $\overline{WE}$ is set to a Low state and $\overline{OE}$ is an "H" or "L" signal. A write cycle can be implemented in either of three ways – early write, delayed write, or read-modify-write. During all write cycles, timing parameters t_{RWL}, t_{CWL}, t_{RAL} and t_{CAL} must be satisfied. In the early write cycle shown above t_{WCS} satisfied, data on the DQ pins are latched with the falling edge of $\overline{LCAS}$ or $\overline{UCAS}$ and written into memory.

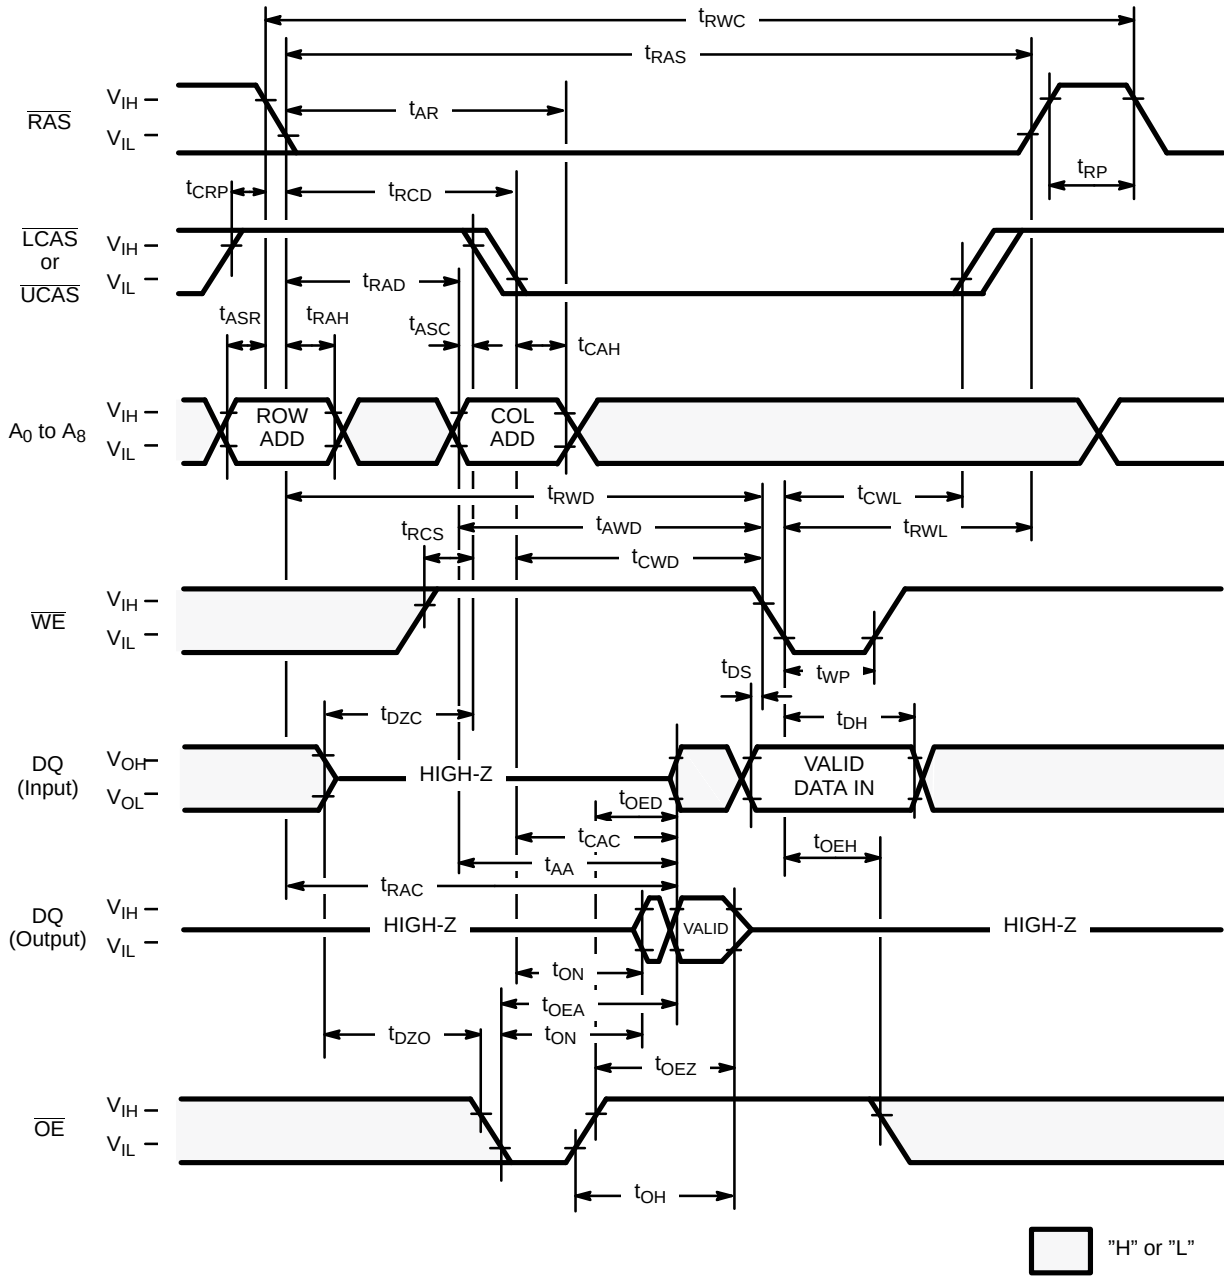
Fig. 7 – DELAYED WRITE CYCLE ($\overline{OE}$ CONTROLLED)



DESCRIPTION

In the delayed write cycle, t_{WCS} is not satisfied; thus, the data on the DQ pins are latched with the falling edge of $\overline{WE}$ and written into memory. The Output Enable ($\overline{OE}$) signal must be changed from Low to High before $\overline{WE}$ goes Low ($t_{OED} + t_T + t_{DS}$).

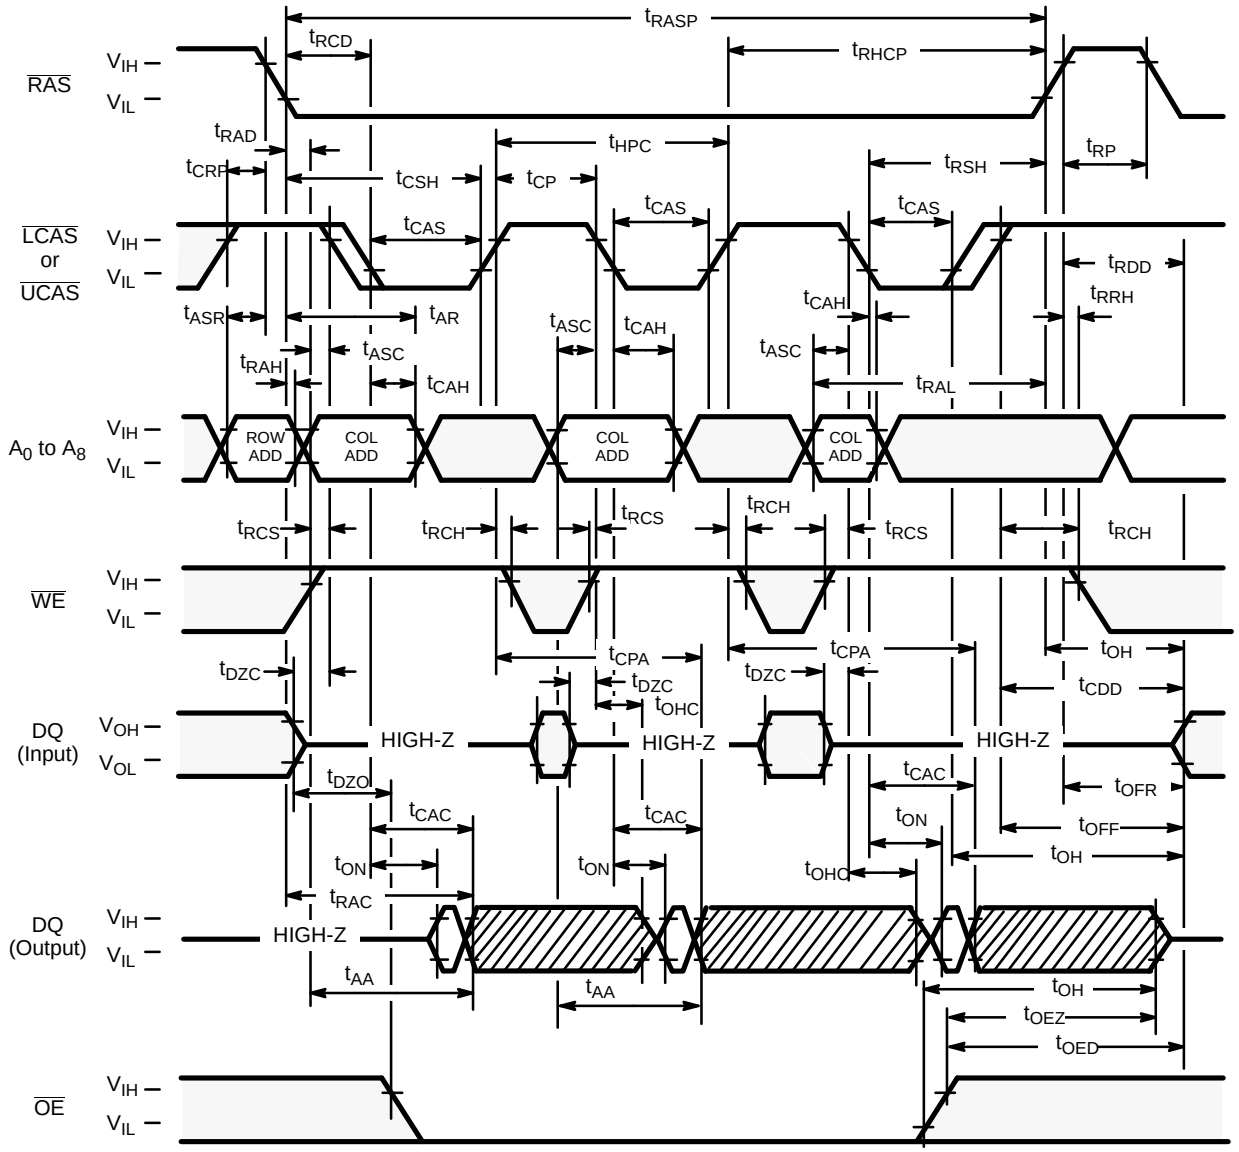
Fig. 8 – READ-MODIFY-WRITE-CYCLE



DESCRIPTION

The read-modify-write cycle is executed by changing $\overline{WE}$ from High to Low after the data appears on the DQ pins. In the read-modify-write cycle, $\overline{OE}$ must be changed from Low to High after the memory access time.

Fig. 9 – HYPER PAGE MODE READ CYCLE



During one cycle is achieved, the input/output timing apply the same manner as the former cycle.

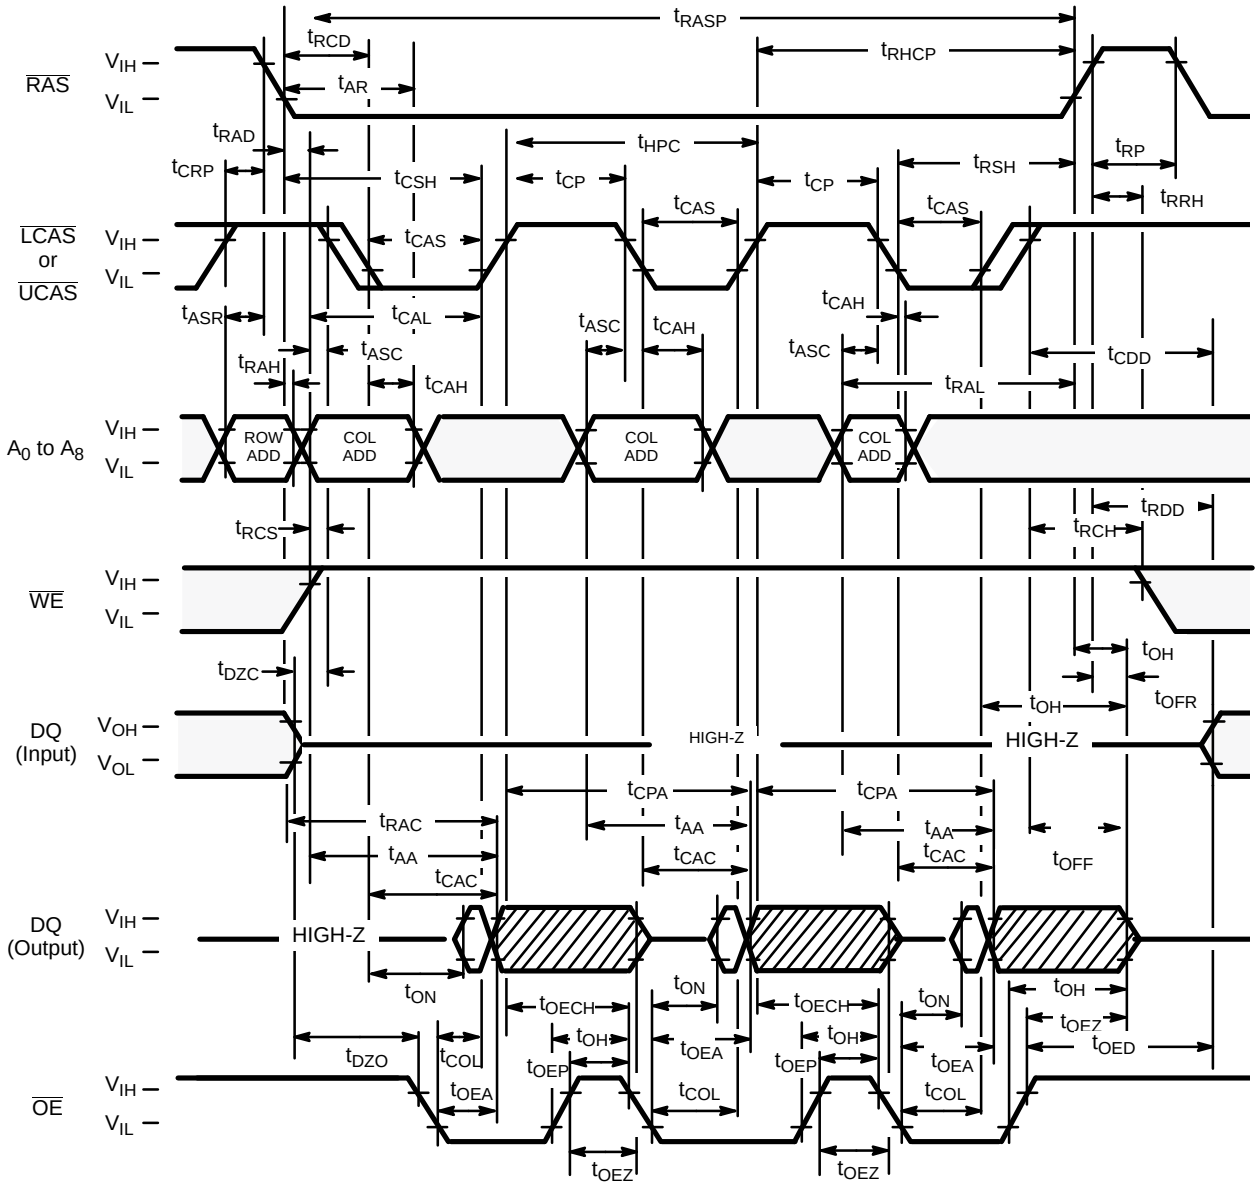
”H” or ”L”

Valid Data

DESCRIPTION

The hyper page mode of operation permits faster successive memory operations at multiple column locations of the same row address. This operation is performed by strobing in the row address and maintaining $\overline{RAS}$ at a Low level and $\overline{WE}$ at a High level during all successive memory cycles in which the row address is latched. The address time is determined by t_{CAC}, t_{AA}, t_{CPA}, or t_{OEA}, whichever one is the latest in occurring.

Fig. 10 – HYPER PAGE MODE READ CYCLE ($\overline{OE}$ = "H" or "L")



During one cycle is achieved, the input/output timing apply the same manner as the former cycle.

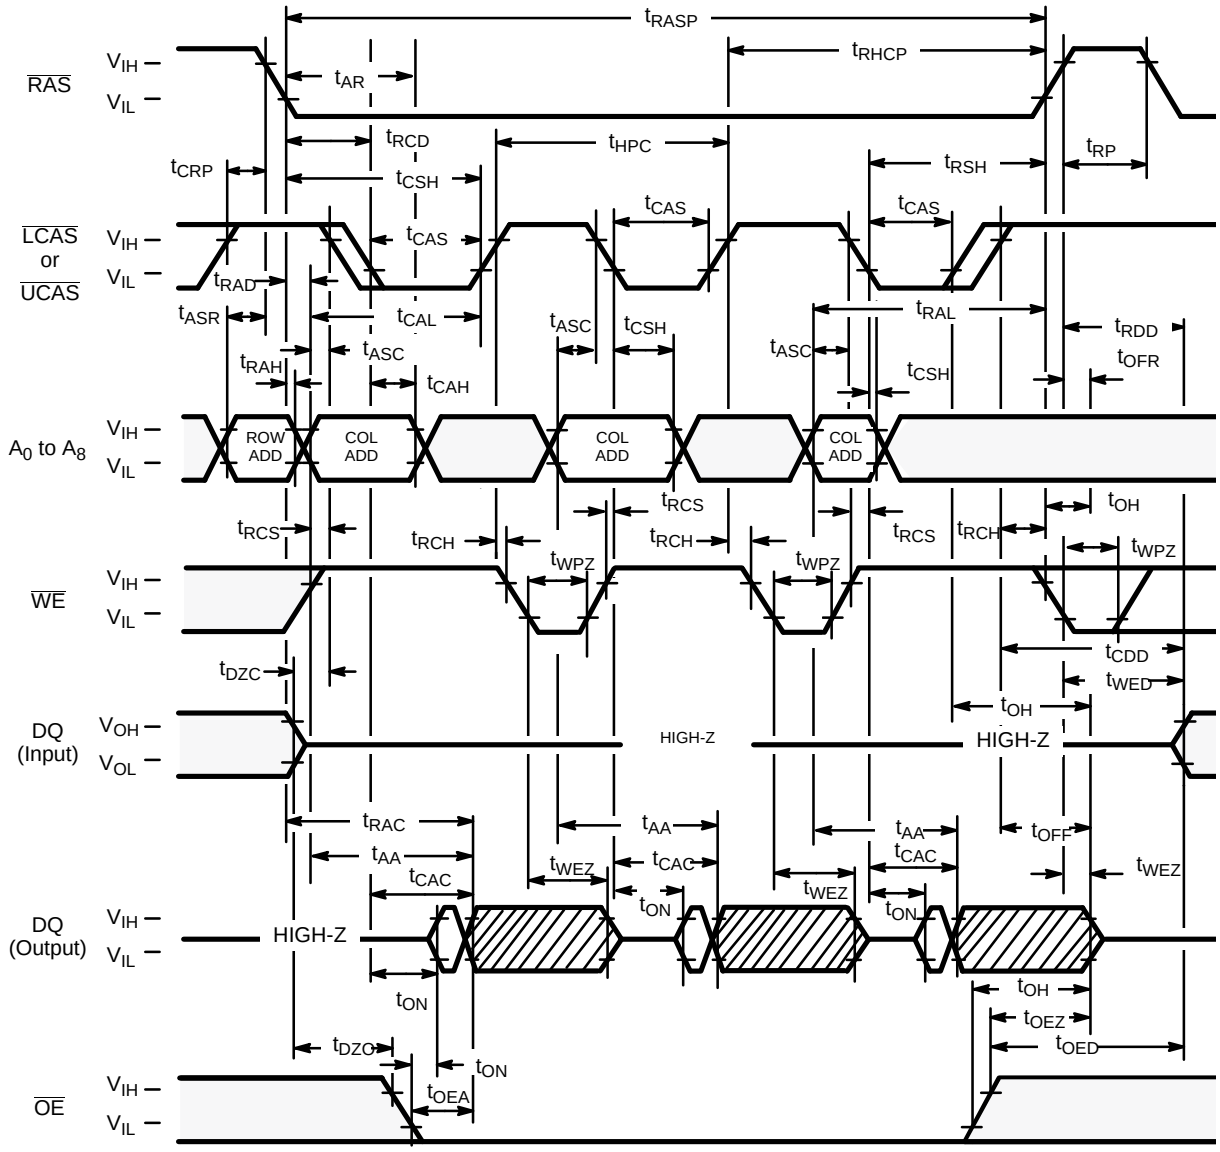
"H" or "L"

Valid Data

DESCRIPTION

The hyper page mode of operation permits faster successive memory operations at multiple column locations of the same row address. This operation is performed by strobing in the row address and maintaining $\overline{RAS}$ at a Low level and $\overline{WE}$ at a High level during all successive memory cycles in which the row address is latched. The address time is determined by t_{CAC}, t_{AA}, t_{CPA}, or t_{OEA}, whichever one is the latest in occurring.

Fig. 11 – HYPER PAGE MODE READ CYCLE ($\overline{WE}$ = "H" or "L")



During one cycle is achieved, the input/output timing apply the same manner as the former cycle.

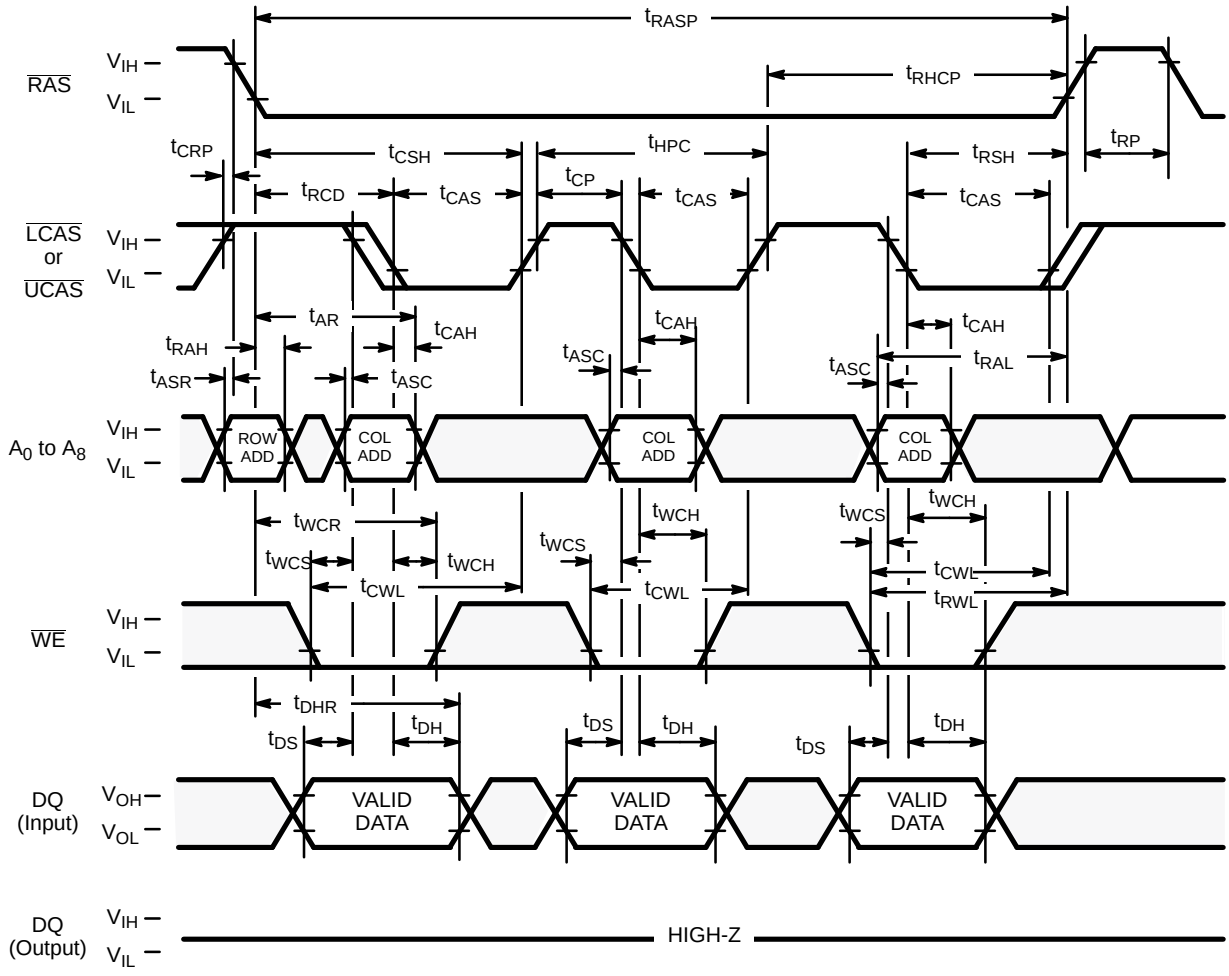
"H" or "L"

Valid Data

DESCRIPTION

The hyper page mode of operation permits faster successive memory operations at multiple column locations of the same row address. This operation is performed by strobing in the row address and maintaining $\overline{RAS}$ at a Low level and $\overline{WE}$ at a High level during all successive memory cycles in which the row address is latched. The address time is determined by t_{CAC}, t_{AA}, t_{CPA}, or t_{OEA}, whichever one is the latest in occurring.

Fig. 12 – HYPER PAGE MODE EARLY WRITE CYCLE



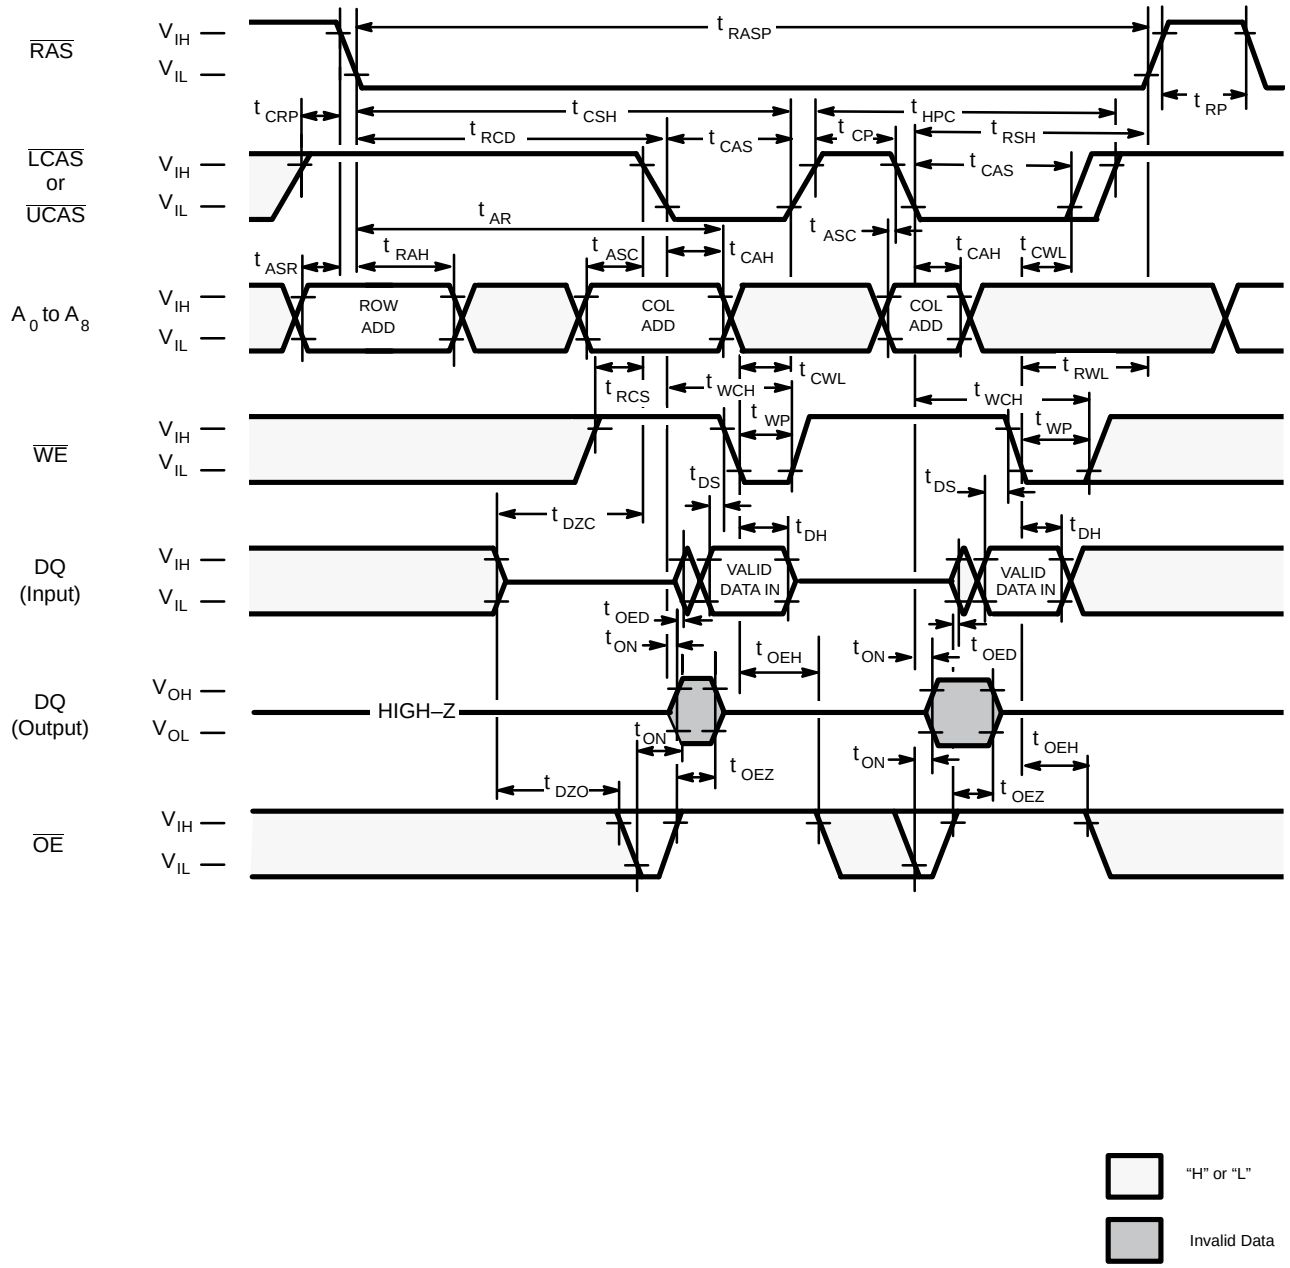
During one cycle is achieved, the input/output timing apply the same manner as the former cycle.

"H" or "L"

DESCRIPTION

The hyper page mode early write cycle is executed in the same manner as the hyper page mode read cycle except the states of WE and $\overline{OE}$ are reversed. Data appearing on the DQ1 to DQ8 is latched on the falling edge of $\overline{LCAS}$ and one appearing on the DQ9 to DQ16 is latched on the falling edge of $\overline{UCAS}$ and the data is written into the memory. During the hyper page mode early write cycle, including the delayed ($\overline{OE}$) write and read-modify-write cycles, t_{CWL} must be satisfied.

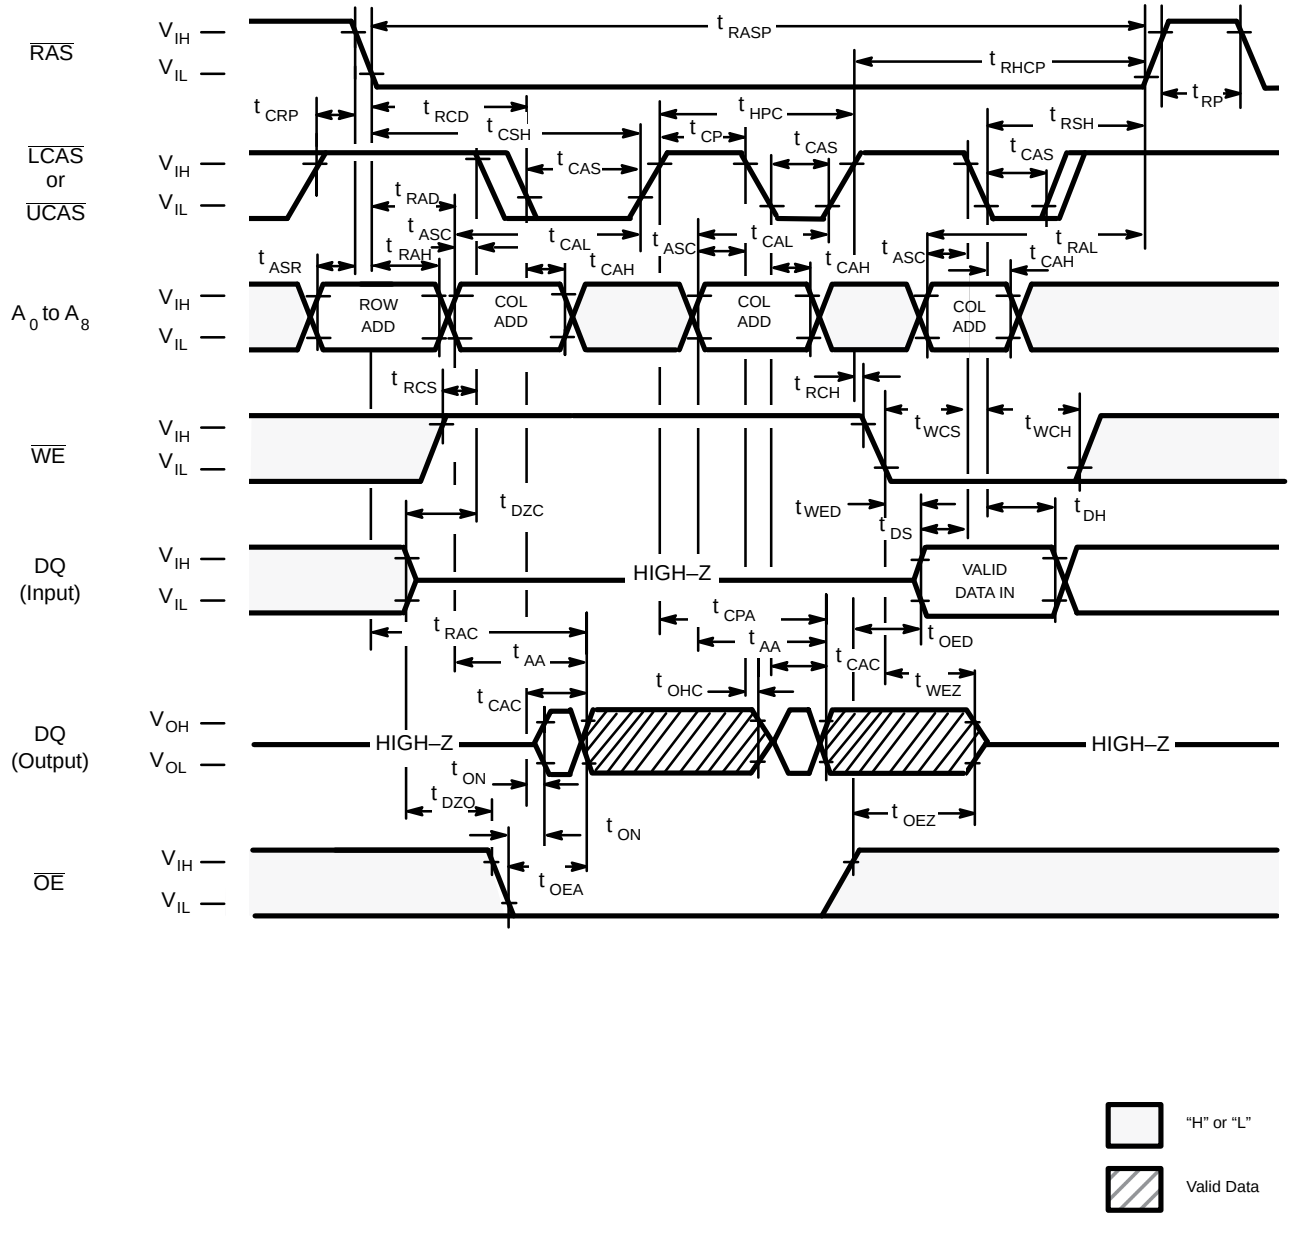
Fig. 13 – HYPER PAGE MODE DELAYED WRITE CYCLE



DESCRIPTION

The hyper page mode delayed write cycle is executed in the same manner as the hyper page mode early write cycle except for the states of $\overline{WE}$ and $\overline{OE}$. Input data on the DQ pins are latched on the falling edge of $\overline{WE}$ and written into memory. In the hyper page mode delayed write cycle, $\overline{OE}$ must be changed from Low to High before $\overline{WE}$ goes Low ($t_{OED} + t_T + t_{DS}$).

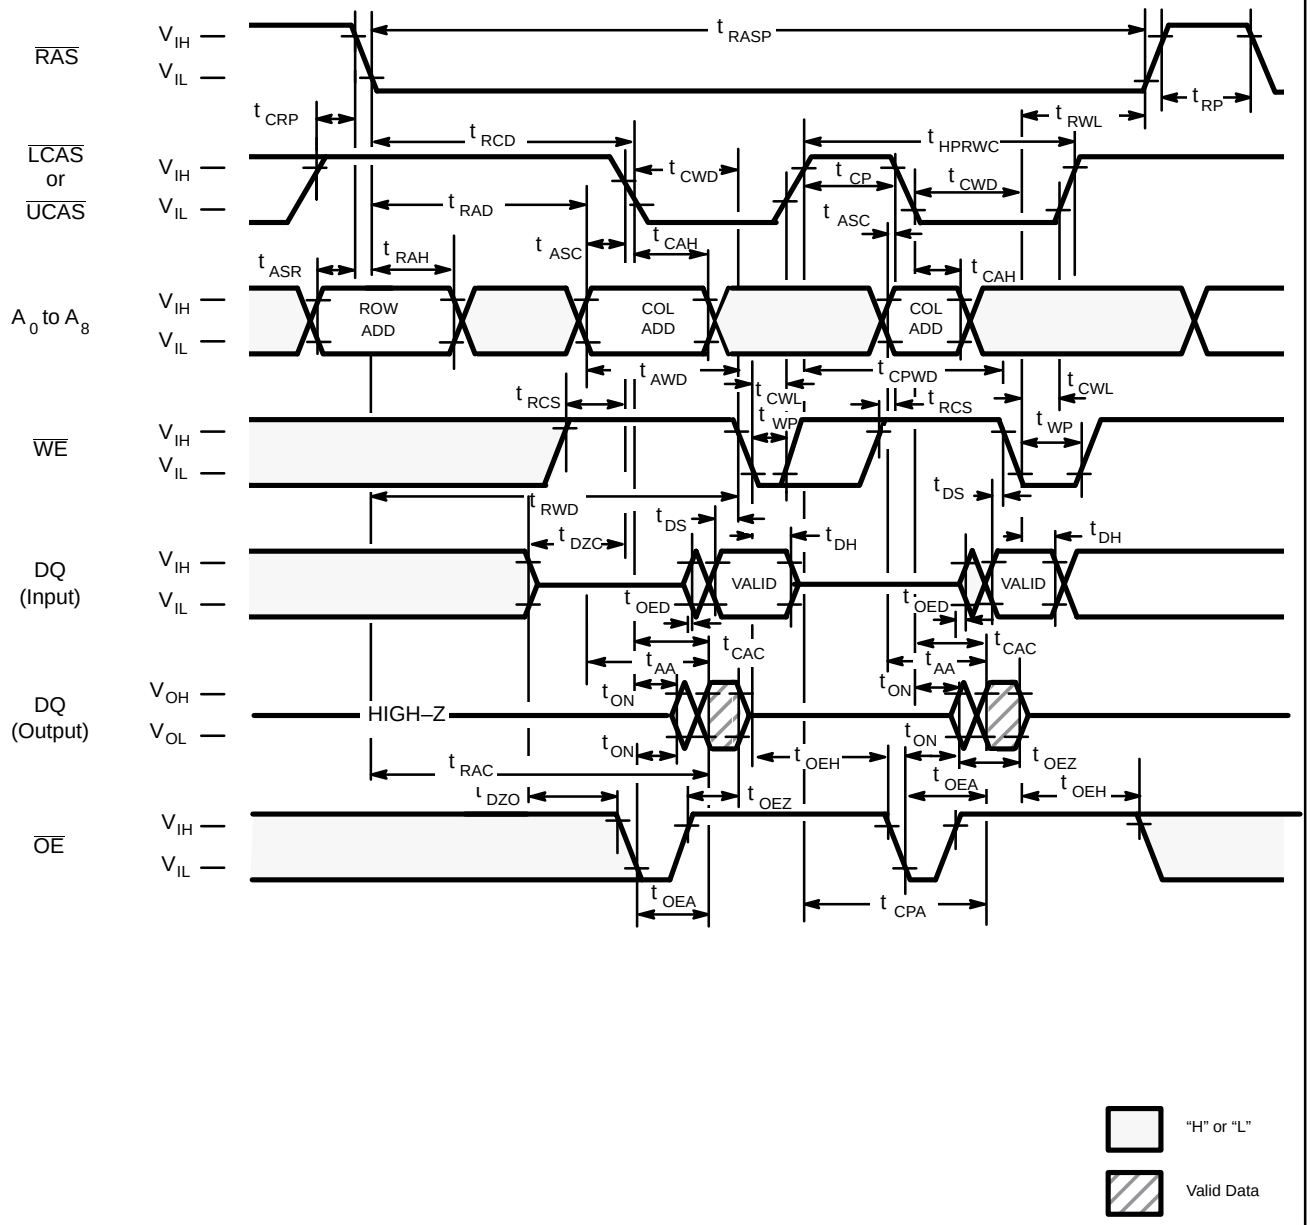
Fig. 14 – HYPER PAGE MODE READ/WRITE MIXED CYCLE



DESCRIPTION

The hyper page mode performs read/write operations repetitively during one $\overline{RAS}$ cycle. At this time, t_{HPC} (min.) is invalid.

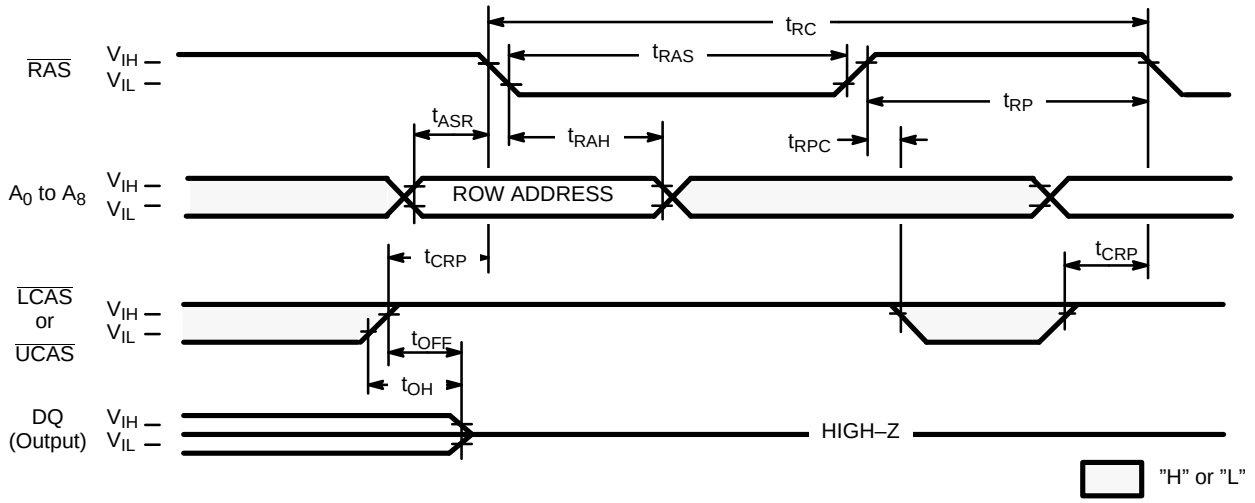
Fig. 15 – HYPER PAGE MODE READ MODIFY WRITE CYCLE



DESCRIPTION

During the hyper page mode of operation, the read-modify-write cycle can be executed by switching $\overline{WE}$ from High to Low after input data appears at the DQ pins during a normal cycle.

Fig. 16 – $\overline{RAS}$-ONLY REFRESH ($\overline{WE}$ = $\overline{OE}$ = "H"or "L")

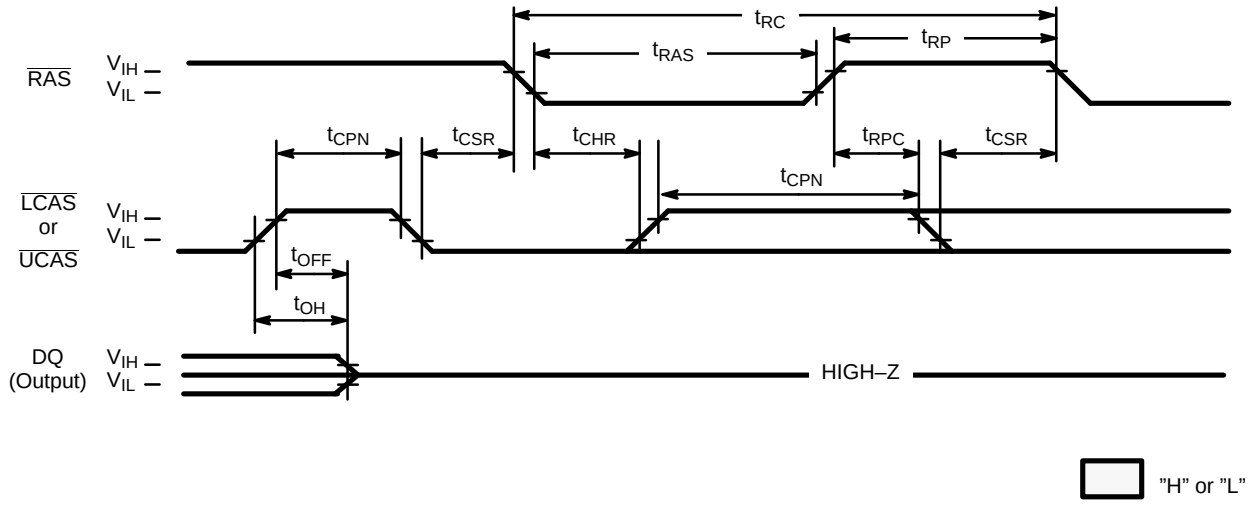


DESCRIPTION

Refresh of RAM memory cells is accomplished by performing a read, a write, or a read-modify-write cycle at each of 512 row addresses every 8.2–milliseconds. Three refresh modes are available: $\overline{RAS}$-only refresh, $\overline{CAS}$-before-$\overline{RAS}$ refresh, and hidden refresh.

$\overline{RAS}$-only refresh is performed by keeping $\overline{RAS}$ Low and $\overline{LCAS}$ and $\overline{UCAS}$ High throughout the cycle; the row address to be refreshed is latched on the falling edge of RAS. During $\overline{RAS}$-only refresh, DQ pins are kept in a high-impedance state.

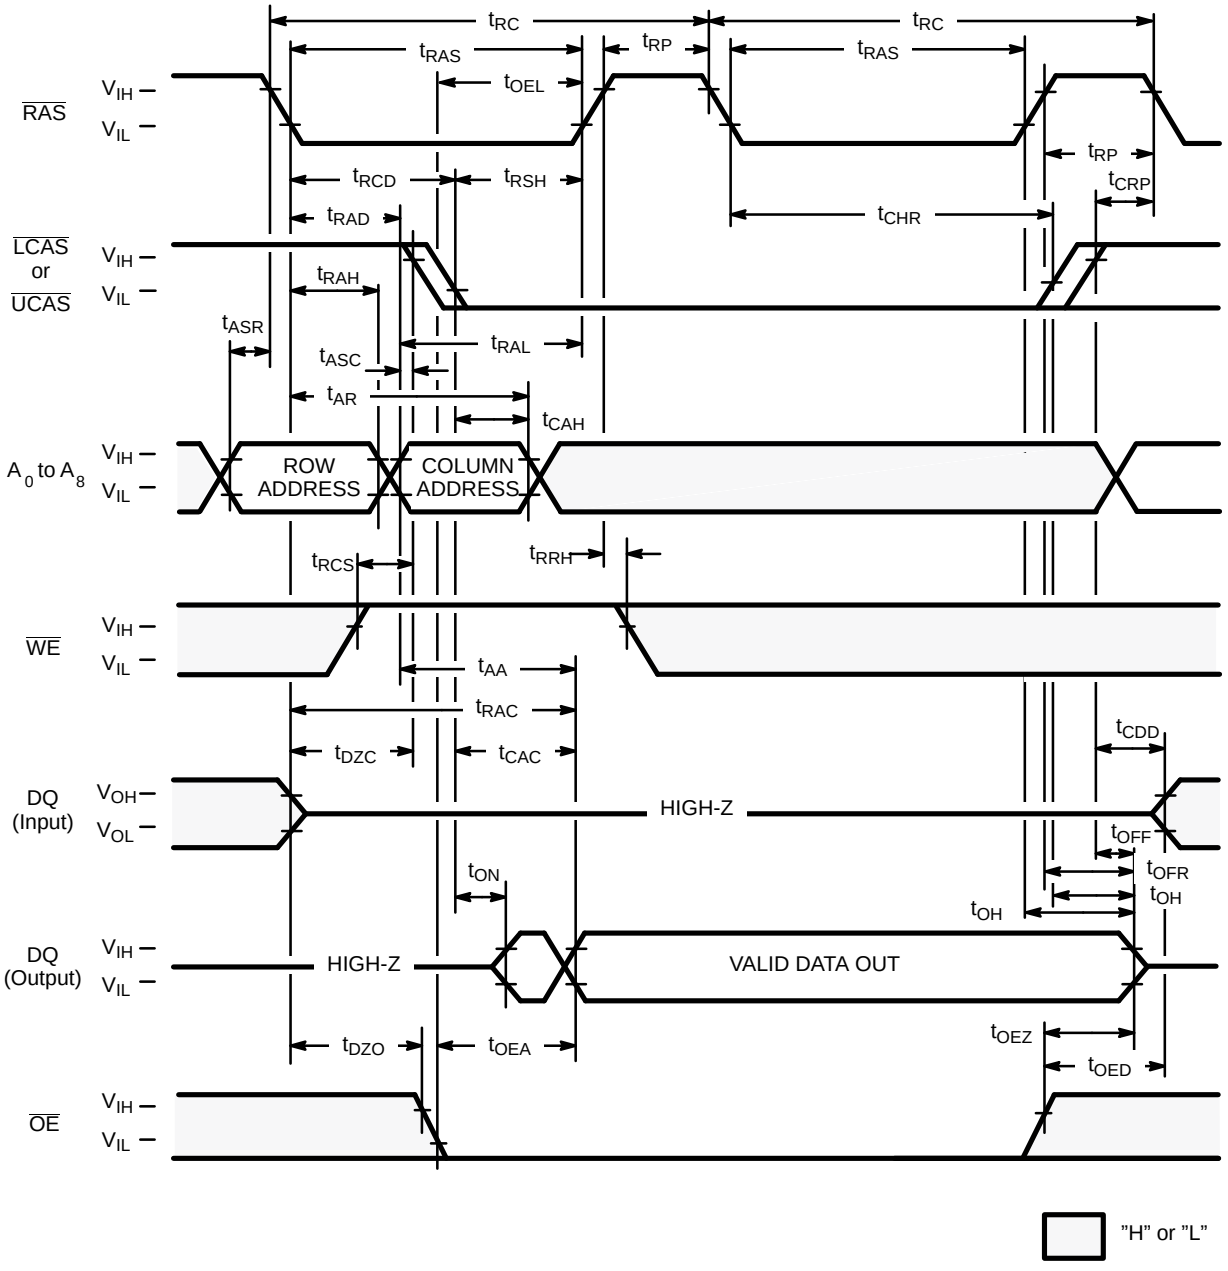
Fig. 17 – $\overline{CAS}$-BEFORE-$\overline{RAS}$ REFRESH (ADDRESSES = $\overline{WE}$ = $\overline{OE}$ = "H"or "L")



DESCRIPTION

$\overline{CAS}$-before-$\overline{RAS}$ refresh is an on-chip refresh capability that eliminates the need for external refresh addresses. If $\overline{LCAS}$ or $\overline{UCAS}$ is held Low for the specified setup time (t_{CSR}) before $\overline{RAS}$ goes Low, the on-chip refresh control clock generators and refresh address counter are enabled. An internal refresh operation automatically occurs and the refresh address counter is internally incremented in preparation for the next $\overline{CAS}$-before-$\overline{RAS}$ refresh operation.

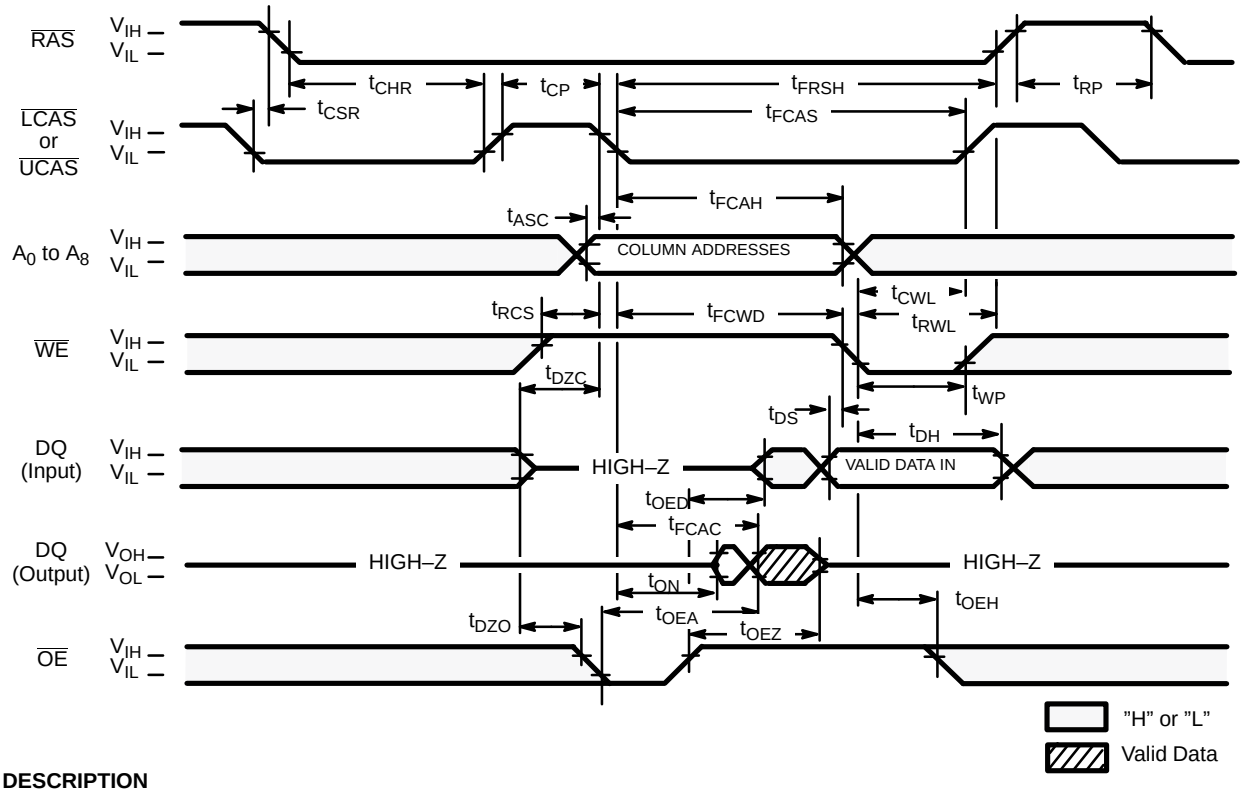
Fig. 18 – HIDDEN REFRESH CYCLE



DESCRIPTION

A hidden refresh cycle may be performed while maintaining the latest valid data at the output by extending the active time of $\overline{LCAS}$ or $\overline{UCAS}$ and cycling $\overline{RAS}$. The refresh row address is provided by the on-chip refresh address counter. This eliminates the need for the external row address that is required by DRAMs that do not have $\overline{CAS}$-before-$\overline{RAS}$ refresh capability.

Fig. 19 – $\overline{CAS}$–BEFORE–$\overline{RAS}$ REFRESH COUNTER TEST CYCLE



DESCRIPTION

A special timing sequence using the $\overline{CAS}$-before-$\overline{RAS}$ refresh counter test cycle provides a convenient method to verify the functionality of $\overline{CAS}$-before-$\overline{RAS}$ refresh circuitry. After a $\overline{CAS}$-before-$\overline{RAS}$ refresh cycle, if $\overline{LCAS}$ or $\overline{UCAS}$ makes a transition from High to Low while $\overline{RAS}$ is held Low, read and write operations are enabled as shown above. Row and column addresses are defined as follows:

Row Address: Bits A0 through A8 are defined by the on-chip refresh counter.
Column Address: Bits A0 through A8 are defined by latching levels on A0–A8 at the second falling edge of $\overline{LCAS}$ or $\overline{UCAS}$.

The $\overline{CAS}$-before-$\overline{RAS}$ Counter Test procedure is as follows ;

1) Normalize the internal refresh address counter by using 8 $\overline{RAS}$ only refresh cycles.
2) Use the same column address throughout the test.
3) Write “0” to all 512 row addresses at the same column address by using CBR refresh counter test cycles.
4) Read “0” written in procedure 3) by using normal read cycle and check; After reading ”0” and check are completed (or simultaneously), write “1” to the same addresses by using normal write cycle (or read–modify–write cycle).
5) Read and check data ”1” written in procedure 4) by using CBR refresh counter test cycle for all 512 memory locations.
6) Reverse test data and repeat procedures 3), 4), and 5).

(At recommended operating conditions unless otherwise noted.)

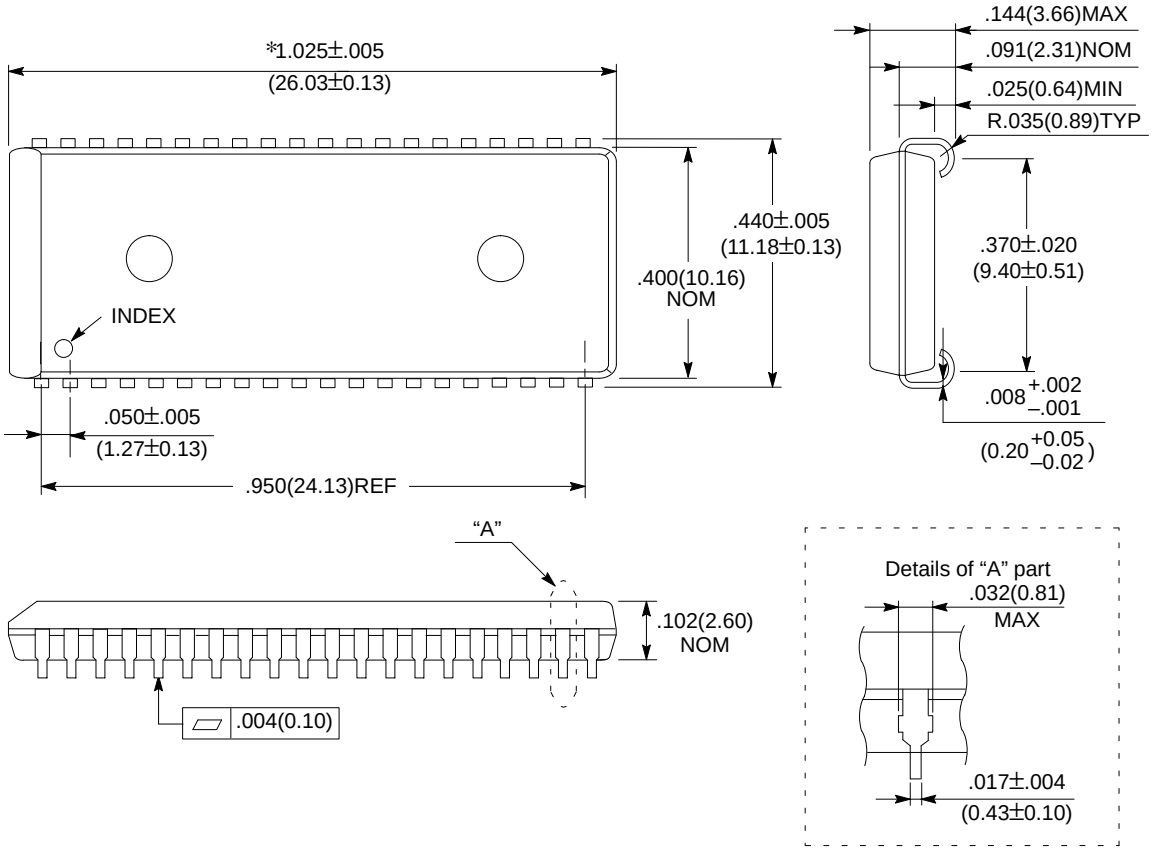
No.	Parameter	Symbol	MB814265-60		MB814265-70		Unit
			Min	Max	Min	Max	
90	Access Time from $\overline{CAS}$	t_{FCAC}	—	55	—	55	µs
91	Column Adress Hold Time	t_{FCAH}	30	—	30	—	ns
92	$\overline{CAS}$ to $\overline{WE}$ Delay Time	t_{FCWD}	80	—	80	—	ns
93	$\overline{CAS}$ pulse Width	t_{FCAS}	55	—	55	—	µs
94	$\overline{RAS}$ Hold Time	t_{FRSH}	55	—	55	—	ns
95	$\overline{CAS}$ Hold Time	t_{FCSH}	85	—	85	—	ns

Note: Assumes that $\overline{CAS}$-before-$\overline{RAS}$ refresh counter test cycle only.

PACKAGE DIMENSIONS

(Suffix : –PJ)

40-LEAD PLASTIC LEADED CHIP CARRIER
(CASE No.: LCC-40P-M01)



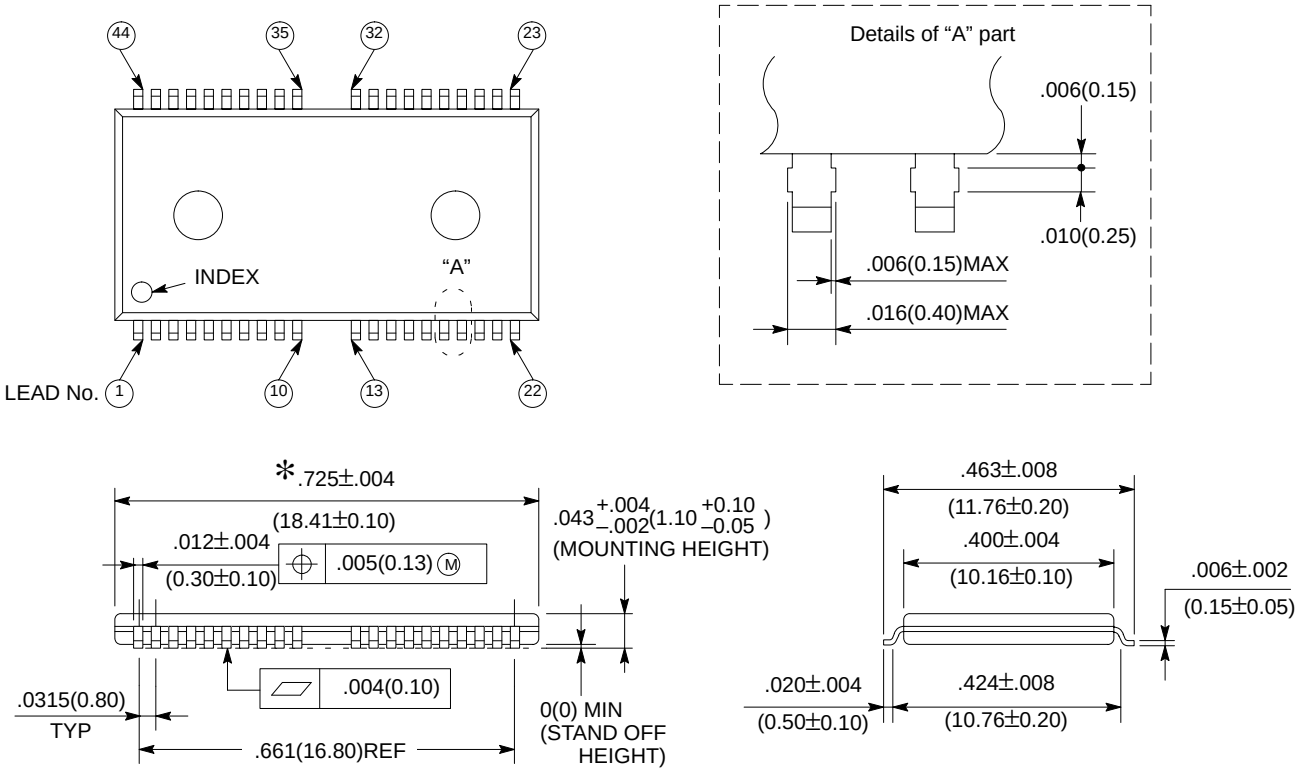
*: This dimension exclude resin protrusion(Each side:.006(0.15)MAX.).

Dimensions in
inches (millimeters)

PACKAGE DIMENSIONS (Continued)

(Suffix : –PFTN)

44-LEAD PLASTIC FLAT PACKAGE
(CASE No.: FPT-44P-M07)



*: This dimension exclude resin protrusion(Each side : .006(0.15) MAX).

Dimensions in
inches (millimeters)
