FUNCTION DESCRIPTIONS

Pulse swallow function

The divide ratio can be calculated using the following equation:

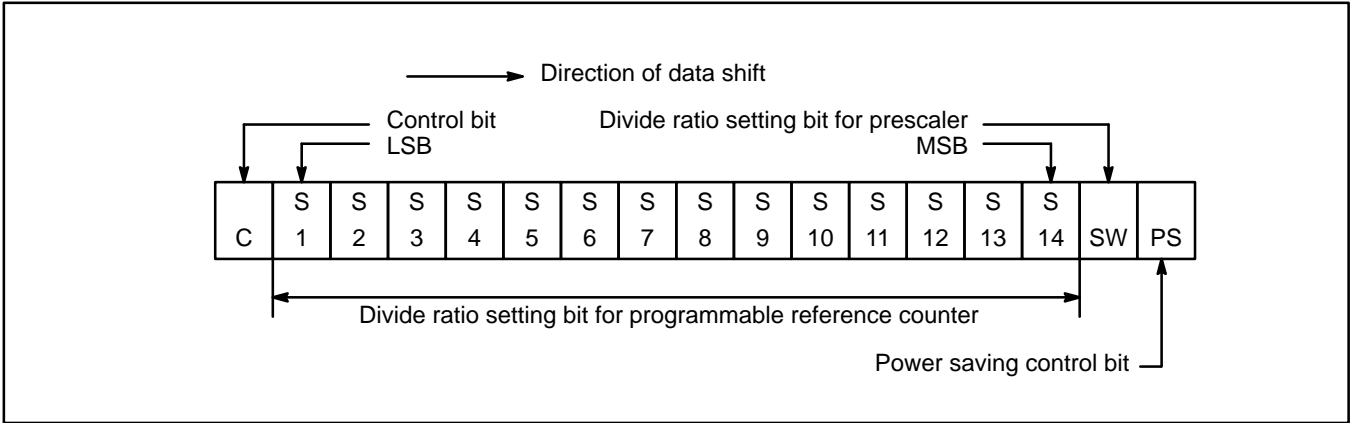

$$f_{VCO} = [(M \times N) + A] \times f_{OSC} \div R \quad (A < N)$$
  
 $f_{VCO}$  : Output frequency of external voltage controlled oscillator (VCO)  
 $N$  : Preset divide ratio of binary 11-bit programmable counter (5 to 2,047)  
 $A$  : Preset divide ratio of binary 7-bit swallow counter ( $0 \leq A \leq 127$ )  
 $f_{OSC}$  : Output frequency of the reference frequency oscillator  
 $R$  : Preset divide ratio of binary 14-bit programmable reference counter (6 to 16,383)  
 $M$  : Preset divide ratio of modules prescaler (64 or 128)

Serial data input

Serial data is processed using the Data, Clock, and LE pins. Serial data controls the 16-bit programmable reference divider and 18-bit programmable divider separately.  
Binary serial data is entered via the Data pin.  
One bit of data is shifted into the internal shift register on the rising edge of the clock. When the load enable pin is high or open, stored data is latched depending on the control data as follows:

Control data	Destination of serial data
H	16 bit latch
L	18 bit latch

- (a) Programmable reference divider ratio  
The programmable reference divider consists of a 16-bit latch and a 14-bit reference counter. The serial 17-bit data format is shown below:

Serial data input timing

### Power saving mode (Intermittent operation control circuit)

Setting PS bit to Low, MB1516A enters into power saving mode resultatly current sonsumption can be limited to 100 $\mu$ A (typ.). Setting PS bit to High, power saving mode is released so that the device works normally. In addition, the intermittent operation control circuit is included which helps smooth start up from stand by mode. The power consumption can be reduced by the intermittent operation that powering down or waking up parts of the PLL circuitry. If a PLL is powered up uncontrolled, the resulting phase comparator output signal is unpredictable due to an undefined phase relation between reference frequency ( $f_R$ ) and comparison frequency ( $f_P$ ) and may in the worst case take longer time for lock up of the loop. To prevent this, the intermittent operation control circuit enforces a limited error signal output of the phase detector during power up, thus keeping the loop locked.

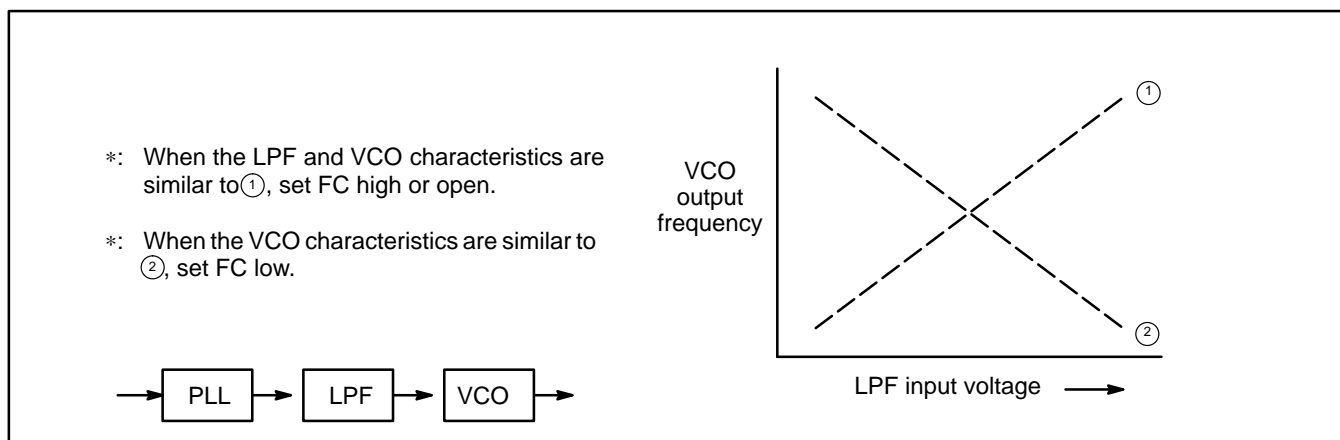

### Relation between the FC input and phase characteristics

The FC pin changes the phase characteristics of the phase comparator. Both the internal charge pump output level ( $D_O$ ) and the phase comparator output ( $\Phi_R$ ,  $\Phi_P$ ) are reversed depending on the FC pin input level. Also, the monitor pin ( $f_{OUT}$ ) output is controlled by the FC pin. The relationship between the FC input level and each of  $D_O$ ,  $\Phi_R$ , and  $\Phi_P$  is shown below:

	FC = High or open				FC = Low			
	$D_O$	$\Phi_R$	$\Phi_P$	$f_{OUT}$	$D_O$	$\Phi_R$	$\Phi_P$	$f_{OUT}$
$f_R > f_P$	H	L	L	(fr)	L	H	Z(*1)	(fp)
$f_R < f_P$	L	H	Z(*1)	(fr)	H	L	L	(fp)
$f_R = f_P$	Z(*1)	L	Z(*1)	(fr)	Z(*1)	L	Z(*1)	(fp)

\*1: High impedance

When designing a synthesizer, the FC pin setting depends on the VCO and LPF characteristics.

Phase comparator output waveforms

[ FC = "H" ]

[ FC = "L" ]

- Notes:**
1. Phase difference detection range:  $-2\pi$  to  $+2\pi$
  2.  $LD$  output becomes low when phase is  $twu$  or more.  $LD$  output becomes high when phase error is  $twl$  or less and continues to be so for three cycles or more.
  3.  $twu$  and  $twl$  depend on  $OSCin$  input frequency.  
 $twu \geq 8/fosc$  (e. g.  $twu \geq 625ns$ ,  $foscin = 12.8$  MHz)  
 $twl \leq 16/fosc$  (e. g.  $twl \leq 1250ns$ ,  $foscin = 12.8$  MHz)
