# SHORTCUTS IN SELECTION OF TAPE WOUND CORES FOR MAGNETCC CIRCUITRY 

## FOR MAGNETIC CIRCUITRY

Magnetics Inc. has developed three sets of curves helpful to design engineers working in the areas of INVERTERS, MAGNETIC AMPLIFIERS, and TRANSFORMERS. There is a characteristic curve for each of three materials...Magnesil, Orthonol, and Permalloy 80...in each device area. The curves were developed by solving Faraday's Law and using specific basic assumptions in solving this equation.

Magnetics Inc. core tables (Bulletin TWC-PN and TWC-300) contain a column headed " $W_{a} A_{c}$ ". This column lists the value of the relative power handling capacity of each core. By equating this value against Faraday's Law, the following relationships have been obtained:

I Solving for Saturating Type Inverter Designs

$$
\text { Faraday's Law }=E=4 \mathrm{Bm} \mathrm{Ac} N f \times 10^{-8}
$$

Solving for $N A c=\frac{E}{4 \mathrm{Bm} \mathrm{f} \mathrm{x} 10^{-8}}$
However, the Window Utilization Factor

$$
\begin{aligned}
& \mathrm{K}=\frac{\mathrm{NAW}}{\mathrm{Wa}}=.1 \\
& \mathrm{NAW}=.1 \mathrm{Wa}
\end{aligned}
$$

Multiply both sides by $A c$ and transpose

$$
\mathrm{NAc}=\frac{.1 \mathrm{WaAc}}{\mathrm{Aw}}
$$

Combining and solving for WaAc

$$
\begin{aligned}
& .1 \mathrm{WaAc}=\frac{\mathrm{E}}{4 \times \mathrm{Bm} \times \mathrm{f} \times 10^{-8}} \\
& \mathrm{WaAc}=\frac{\mathrm{EAW}}{.4 \times \mathrm{Bm} \times \mathrm{f} \times 10^{-8}} \\
& \mathrm{WaAc}=\frac{2.5 \times \mathrm{E} \times \mathrm{Aw}}{\mathrm{Bm} \times \mathrm{f} \times 10^{-8}}
\end{aligned}
$$

Assume $85 \%$ efficiency and $750 \frac{\text { cir mils }}{\text { amp }}$ current capacity of wire.

However the primary winding has a $50 \%$ duty factor giving a current capacity of $375 \frac{\text { cir mils. }}{a m p}$.

Therefore the formula becomes:

$$
\text { WaAc }=\frac{1.1 \times \text { Power Output }}{B m \times f \times 10^{-11}}
$$

Since the inverter is a saturating device,

$$
\begin{array}{ll}
\mathrm{Bm}=17000 & (\text { Magnesi1) } \\
\mathrm{Bm}=14500 & \text { (Orthono1) } \\
\mathrm{Bm}=7000 & \text { (Perma11oy 80) }
\end{array}
$$

Formulas used for inverter curves are:

$$
\begin{aligned}
& \text { WaAc }=\frac{6.5 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Magnesil) } \\
& \text { WaAc }=\frac{7.6 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Orthonol) } \\
& \text { WaAc }=\frac{14.3 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Perma1loy 80) }
\end{aligned}
$$

Solving for Typical Sine Wave Magnetic Amplifier Designs

$$
\text { Faraday Law }=4.44 \mathrm{BmAcN} \mathrm{f} \times 10^{-8}
$$

$$
\mathrm{K}=.3 \text { and } \mathrm{WaAc}=\frac{.75 \times \mathrm{E} \times \mathrm{AW}}{\mathrm{Bm} \times \mathrm{f} \times 10^{-8}}
$$

Assume $94 \%$ efficiency and 750 cir mils/amp.
Therefore formula becomes:

$$
\text { WaAc }=\frac{.60 \times \text { Power Output }}{\operatorname{Bm} \times \mathrm{f} \times 10^{-11}}
$$

Since magnetic amplifiers are saturating devices use Bm noted for Inverters.

Formulas used for Magnetic Amplifier curves are:

$$
\text { WaAc }=\frac{3.5 \times \text { Power Output } \times 10^{6}}{\text { frequency }}
$$

$$
\begin{aligned}
& \text { WaAc }=\frac{4.15 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Orthono1) } \\
& \text { WaAc }=\frac{9.35 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Perma11oy 80) }
\end{aligned}
$$

## III Solving for Typical Transformer Design

Where Flux Swing Doesn't Exceed . 5 Bm.

$$
\begin{aligned}
& \text { Faraday's Law }=\mathrm{E}=4.44 \mathrm{BAc} \mathrm{~N} \mathrm{f} \times 10^{-8} \\
& \mathrm{~K}=.2 \text { and WaAc }=\frac{.89 \times \mathrm{E} \times \mathrm{Aw}}{\mathrm{~B} \times \mathrm{f} \times 10^{-8}}
\end{aligned}
$$

Assume $95 \%$ efficiency and 750 cir mils/amp.
Therefore formula becomes:

$$
\text { WaAc }=\frac{.70 \times \text { Power Output }}{B \times \mathrm{f} \times 10^{-11}}
$$

Since $B$ is only $1 / 2$ of the $B m$ value for each core material,

$$
\begin{array}{ll}
B=8500 & \text { (Magnesi1) } \\
B=7250 & \text { (Orthono1) } \\
B=3500 & \text { (Perma11oy 80) }
\end{array}
$$

Formulas used for Transformer curves are:

$$
\begin{aligned}
& \text { WaAc }=\frac{8.25 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Magnesi1) } \\
& \text { WaAc }=\frac{9.7 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Orthono1) } \\
& \text { WaAc } \left.=\frac{20 \times \text { Power Output } \times 10^{6}}{\text { frequency }} \quad \text { (Perma1loy } 80\right)
\end{aligned}
$$

To use the curves, the output power and operating frequency must be known. Select the proper frequency curve from the family of curves chosen. Read across from the power output to the intercept point on the frequency curve. Read down to the proper WaAc value. Refer to TWC-300 or TWC-PN for the selection of the proper core by its WaAc.

Relationship of Core $\mathrm{W}_{\mathrm{a}} \mathrm{A}_{\mathrm{c}}$ to Output Power Capability
Magnesil -- Magnetic Amplifiers - Reactors

$W_{a} A_{C}\left(x 10^{+6}\right)$ (Cir. mils $\left.\mathrm{cm}^{2}\right)$
NOTE: These graphs can be used to select a tape wound core from core tables listing the $W_{a} A_{c}$ in terms of circular mils centimeters ${ }^{2}$. To use, determine the material to be used, the operating frequency, and the output power. Locate the proper frequency curve and its intercept point at the output power required. Read down from this intercept point to obtain the $\mathrm{Wa}_{\mathrm{a}} \mathrm{C}_{\mathrm{c}}$ from the graph.

Orthonol -- Magnetic Amplifiers - Reactors

$\mathrm{W}_{\mathrm{a}} \mathrm{A}_{\mathrm{C}}\left(\mathrm{x} 10^{+6}\right)\left(\right.$ Cir. mils cm $\left.{ }^{2}\right)$
