AT&T Products and Services

- To order documents from the Customer Information Center:
 - □ within the continental United States, call 1-800-432-6600
 - □ outside the continental United States, call 1-317-352-8557

 send mail orders to:
 AT&T Customer Information Center Customer Service Representative P.O. Box 19901 Indianapolis, Indiana 46219

To sign up for UNIX system or AT&T computer courses:

- within the continental United States, call 1-800-221-1647
- outside the continental United States, call 1-609-639-4593
- TELEX: 1-609-639-4756 Attention: Training Registration

For information on Intel hardware and software, contact the Intel sales office nearest you.

To find out about UNIX system source licenses:

- within the continental United States, except North Carolina, call 1-800-828-UNIX
- in North Carolina and outside the continental United States, call 1-919-855-2737
- or write to:

Software Licensing Guilford Center Salem Bldg. 4th Floor P.O. Box 25000 Greensboro, NC 27420

Introduction

This manual describes the programming features of the UNIX system. It provides neither a general overview of the UNIX system nor details of the implementation of the system.

Not all commands, features, and facilities described in this manual are available in every UNIX system. Some of the features require additional utilities which may not exist on your system.

This manual is divided into five sections, some containing interfiled subclasses:

- 1. Commands
- 2. System Calls
- 3. Subroutines:
 - 3C. C Programming Language Libraries
 - 3S. Standard I/O Library Routines
 - 3M. Mathematical Library Routines
 - 3N. Networking Support Utilities
 - 3X. Specialized Libraries
 - 3F. FORTRAN Programming Libraries
- 4. File Formats
- 5. Miscellaneous Facilities.

Section 1 (*Commands*) describes commands that support C and other programming languages.

Section 2 (*System Calls*) describes the access to the services provided by the UNIX system kernel, including the C language interface.

Section 3 (*Subroutines*) describes the available subroutines. Their binary versions reside in various system libraries in the directories **/lib** and **/usr/lib**. See *intro*(3) for descriptions of these libraries and the files in which they are stored.

Section 4 (*File Formats*) documents the structure of particular kinds of files; for example, the format of the output of the link editor is given in *a.out*(4). Excluded are files used by only one command (for example, the assembler's intermediate files). In general, the C language structures corresponding to these formats can be found in the directories **/usr/include** and **/usr/include/sys**.

Section 5 (*Miscellaneous Facilities*) contains a variety of things. Included are descriptions of character sets, macro packages, etc.

References with numbers other than those above mean that the utility is contained in the appropriate section of another manual. References with (1) following the command mean that the utility is contained in this manual or the User's Reference Manual. Those followed by (1M), (7), or (8) are contained in the System Administrator's Reference Manual.

Each section consists of a number of independent entries of a page or so each. Entries within each section are alphabetized, with the exception of the introductory entry that begins each section (also Section 3 is in alphabetical order by suffixes). Some entries may describe several routines, commands, etc. In such cases, the entry appears only once, alphabetized under its "primary" name, the name that appears at the upper corners of each manual page.

All entries are based on a common format, not all of whose parts always appear:

- The NAME part gives the name(s) of the entry and briefly states its purpose.
- The SYNOPSIS part summarizes the use of the program being described. A few conventions are used, particularly in Section 2 (System Calls):
 - □ **Boldface** strings are literals and are to be typed just as they appear.
 - Italic strings usually represent substitutable argument prototypes and program names found elsewhere in the manual.
 - Square brackets [] around an argument prototype indicate that the argument is optional. When an argument prototype is given as 'name' or 'file,' it always refers to a *file* name.
 - Ellipses ... are used to show that the previous argument prototype may be repeated.
 - □ A final convention is used by the commands themselves. An argument beginning with a minus -, plus +, or equal sign = is often taken to be some sort of flag argument, even if it appears in a position where a file name could appear. Therefore, it is unwise to have files whose names begin with -, +, or =.

2 PROGRAMMER'S REFERENCE MANUAL

- The DESCRIPTION part describes the utility.
- The EXAMPLE(S) part gives example(s) of usage, where appropriate.
- The FILES part gives the file names that are built into the program.
- The SEE ALSO part gives pointers to related information.
- The **DIAGNOSTICS** part discusses the diagnostic indications that may be produced. Messages that are intended to be self-explanatory are not listed.
- The NOTES part gives generally "helpful hints" about the use of the utility.
- The WARNINGS part points out potential pitfalls.
- The BUGS part gives known bugs and sometimes deficiencies.
- The CAVEATS part gives details of the implementation that might affect usage.

A "Table of Contents" and a "Permuted Index" derived from that table precede section 1. The "Permuted Index" is a list of keywords, given in the second of three columns, together with the context in which each keyword is found. Keywords are either topical keywords or the names of manual entries. Entries are identified with their section numbers shown in parentheses. This is important because there is considerable duplication of names among the sections, arising principally from components that exist only to exercise a particular system call. The right column lists the name of the manual page on which each keyword may be found. The left column contains useful information about the keyword. L

TABLE OF CONTENTS

1. Commands

intro(1)	
admin(1)	
ar(1)	archive and library maintainer for portable archives
as(1)	
as386.sed(1) .	sed script to convert Intel ASM386 source to as source
cb(1)	
cc(1)	
ccoff(1)	
cdc(1)	
cflow(1)	
comb(1)	
conv(1)	
convert(1) .	convert archive files to common formats
cpp(1)	
cprs(1)	
ctrace(1)	
$cxref(1) \dots$	
delta(1)	
dis(1)	
dump(1)	
gencc(1M) .	
get(1)	
i286emul(1) .	••••••••••••••••••••••••••••••••••••••
infocmp(1M)	
install(1M) .	
$Id(1) \dots$	
lex(1)	generate programs for simple lexical tasks
$lint(1) \dots$	
list(1)	
lorder(1)	
m4(1)	
make(1)	maintain, update, and regenerate groups of programs
mcs(1)	
mkshlib(1) .	
nm(1)	
omi(1)	
$\operatorname{prof}(1) \ldots$	
$prs(1) \cdot \cdot \cdot$	
$\operatorname{regcmp}(1)$.	
relogin(1M).	rename login entry to snow current layer
rmael(1)	
sact(1)	
sccsall(1)	
sub(1)	
$size(1) \dots$	
	. strip symbol and line number information from a common object file
uc(11VI)	

tsort(1)
unget(1)
val(1)
vc(1)
what(1)
wtinit(1M) object downloader for the 5620 DMD terminal
xtd(1M)
xts(1M)
xtt(1M)
yacc(1)

2. System Calls

.

intro(2) introduction to system calls and error numbers access(2)
chdir(2)
chmod(2)
chown(2) $change owner and group of a file$
chroot(2)
close(2)
creat(2) create a new file or rewrite an existing one
dup(2)
exec(2)
exit(2)
fcntl(2)
fork(2)
getmsg(2)
getpid(2)
getuid(2)
ioctl(2)
kill(2) send a signal to a process or a group of processes
link(2)
lseek(2)
mkdir(2)
mknod(2)
mount(2)
msgget(2)
msgop(2)
nice(2)
open(2)
msgct(2) get message control operations msgget(2) get message queue msgop(2) message operations nice(2) nessage operations pause(2) suspend process until signal pipe(2) nessage operations nessage operations nessage operations plock(2) nessage operations nessage operations nessage operations poll(2) nessage operations nessage operations nessage o
$p_1 p_2(z)$
process, text, or data in memory
noll(2) STREAMS input /output multipleving

profil(2)
profil(2)
putmsg(2)
read(2)
rmdir(2)
semctl(2)
semget(2)
semop(2)
setpgrp(2)
setuid(2)
setuid(2)
shmget(2)
shmop(2)
signal(2) specify what to do upon receipt of a signal
sigset(2)
stat(2)
statfs(2)
stime(2)
sync(2)
sysfs(2)
systab(2), s , s
time(2)
time(2)
uadmin(2)
ulimit(2)
umask(2)
umount(2)
uname(2)
unlink(2)
ustat(2)
unlink(2)
wait(2)
write(2)

3. Subroutines

intro(3) introduction to functions and libraries
a64l(3C) convert between long integer and base-64 ASCII string
abort(3C)
abort(3F)
abs(3C)
abs(3F)
acos(3F)
aimag(3F) FORTRAN imaginary part of complex argument
aint(3F)
asin(3F)
assert(3X)
atan(3F)
atan2(3F)

1 1/03.0	
$bessel(3M) \cdot \cdot$	Bessel functions
bool(3F) \ldots	FORTRAN Bitwise Boolean functions
bsearch(3C)	Bessel functions Bessel functions
$\operatorname{clock}(3\dot{C})$	report CPU time used
conig(3E)	
conjg(01)	translate characters
$\operatorname{conv}(\operatorname{SC})$	
$\cos(3F)$	FORTRAN cosine intrinsic function
$\cosh(3F)$	FORTRAN hyperbolic cosine intrinsic function
crypt(3C)	generate hashing encryption
crypt(3X)	generate hashing encryption
ctermid(3S)	generate file name for terminal
$ctime(3\dot{C})$, \ldots , \ldots , \ldots , \ldots , \ldots	convert date and time to string
ctype(3C)	
curses(3X)	. terminal screen handling and optimization package
curses(0X)	and optimization package
$\operatorname{cuseria}(55) \ldots \ldots \ldots \ldots$	
dial(3C)	establish an out-going terminal line connection
$\dim(3F) \cdot \cdot$	positive difference intrinsic functions
directory $(3X)$	directory operations
dprod(3F)	double precision product intrinsic function
drand48(3C)	nerate uniformly distributed pseudo-random numbers
dup2(3C)	
ecvt(3C)	convert floating-point number to string
eevi(3C)	
end(3C)	. error function and complementary error function
eri(3M)	error function and complementary error function
$\exp(3F)$	FORTRAN exponential intrinsic function
	exponential, logarithm, power, square root functions
fclose(3S)	
ferror(3S)	••••••••••••••••••••••••••••••••••••••
floor(3M)	floor, ceiling, remainder, absolute value functions
fopen(3S)	
fpgetround(3C)	IEEE floating point environment control
fread(3S)	hinary input/output
frown(3C)	binary input/output manipulate parts of floating-point numbers
facek(2S)	
$\operatorname{ISEek}(35) \ldots \ldots \ldots \ldots \ldots \ldots$	reposition a file pointer in a stream
$ftw(3C) \dots \dots \dots \dots \dots$	
$ftype(3F) \dots \dots \dots \dots \dots$	••••••••••••••••••••••••••••••••••••••
$gamma(3M) \ldots \ldots \ldots \ldots$	log gamma function
getarg(3F)	return FORTRAN command-line argument
getc(3S)	get character or word from a stream
getcwd(3C)	get path name of current working directory
getenv(3C)	return value for environment name
getenv(3F)	return FORTRAN environment variable
geterront(3C)	get group file optry
for form (QC)	
getopt(3C)	
getpass(3C)	••••••••••••••••••••••••••••••••••••••
getpw(3C)	••••• get name from UID
getpwent(3C)	
gets(3S)	get a string from a stream
	0 0

getut(3C)
hsearch(3C)
hypot(3M)
is reg(2E)
index(3F)
index(3F)
isnan(3C) test for floating point NaN (Not-A-Number)
13tol(3C)
Idahread $(3X)$ read the archive header of a member of an archive file
ldclose(3X)
ldfhread $(3X)$ read the file header of a common object file
ldgetname $(3X)$ retrieve symbol name for common object file symbol table entry
ldlread(3X) manipulate line number entries of a common object file function
Idlseek(3X) seek to line number entries of a section of a common object file
ldohseek(3X) seek to the optional file header of a common object file
ldopen(3X)
ldrseek(3X) seek to relocation entries of a section of a common object file
inseek(SA) seek to relocation entres of a section of a common object the
ldshread(3X) read an indexed/named section header of a common object file
ldsseek(3X) seek to an indexed/named section of a common object file
ldtbindex(3X) compute the index of a symbol table entry of a common object file
ldtbread(3X) read an indexed symbol table entry of a common object file
ldtbseek(3X) seek to the symbol table of a common object file
len(3F)
libwindows(3X)
lockf(3C)
log(3F) FORTRAN natural logarithm intrinsic function
log10(3F) FORTRAN common logarithm intrinsic function
$\log \log(3X)$
lsearch(3C)
search (3C)
malloc(3C)
malloc(3X)
matherr(3M)
max(3F)
mclock(3F)
memory(3C) memory operations
mil(3F)
min(3F)
mktemp(3C)
mod(3F)
monitor(3C)
nlist(3C)
norrow(3C)
perror(3C)
pio(3x)
popen(35)
printi(35)
popen(3S)
putenv(3C)
putpwent(3C)
putpwent(3C)
qsort(3C)

1/06	the former the second sec
rand(3C)	
rand(3F)	random number generator
regcmp $(3X)$	
round(3F)	FORTRAN nearest integer functions
scanf(3S)	
setbuf(3S)	
setimp(3C)	
sign(3F)	
signal(3E)	specify EORTRAN action on receipt of a system signal
$signal(01) \cdots \cdots$	EOPTRAN action on receipt of a system signal
$\operatorname{SIII}(\operatorname{SF})$	FORTRAN sine intrinsic function
sinn(3F)	FORTRAN hyperbolic sine intrinsic function
sinn(3M)	
sleep(3C)	suspend execution for interval
$sputl(3X)$ \ldots \ldots	access long integer data in a machine independent fashion
$\alpha_{m+1}(2E)$	ECIPTERAN aguara root intringia tunation
$ssignal(3C) \dots \dots \dots$	
stdio(3S)	
stdipc(3C)	
strcmp(3F)	
string(3C)	
strtod(3C)	
strtol(3C)	convert string to integer
$succession(0C)$ \cdots \cdots \cdots	ewan bytes
$swab(SC) \dots \dots \dots$	
system(3F)	icous a shall command
$system(55) \dots \dots \dots$	
tan(3F)	EODTRANSIC FORTRAIN tangent intrinsic function
tanh(3F)	FORTRAN hyperbolic tangent intrinsic function
tmpfile(3S)	
tmpnam(3S)	
trig(3M)	
tsearch(3C)	
ttyname(3C)	
ttyslot(3C)	
$t_accept(3N)$	
$t_{alloc}(3N)$	
$t_{\rm bind}(3N)$	bind an address to a transport endpoint
t close(3N)	
t connect(3NI)	establish a connection with another transport user
t error(3N)	produce error message
$t_{\rm free}(2NI)$	free a library structure
$t_{min}(SN) \cdots \cdots$	
$t_getinio(3N) \dots \dots$	get protocol-specific service information
t_getstate(SIN)	
$t_listen(3N)$	
$t \perp look(3N) \dots \dots \dots$	
$t_open(3N)$	establish a transport endpoint
$t_optmgmt(3N)$	
t_rcv(3N)	receive data or expedited data sent over a connection
t_rcvconnect(3N)	receive the confirmation from a connect request
t_rcvdis(3N)	retrieve information from disconnect

t_rcvrel(3N)
t_rcvudata(3N)
t_rcvuderr(3N) receive a unit data error indication
t_snd(3N) send data or expedited data over a connection
t_snddis(3N) send user-initiated disconnect request
t_sndrel(3N)
t_sndudata(3N)
t_sync(3N)
t_unbind(3N)
ungetc(3S)
vprintf(3S)

4. File Formats

sent over a/ t_rcv:	receive data or expedited data t_rcv(3N)
a connect/ t_rcvconnect:	receive the confirmation from t_rcvconnect(3N)
lockf:	record locking on files lockf(3C)
execute regular expression.	regcmp, regex: compile and regcmp(3X)
compile.	regcmp: regular expression regcmp(1)
make: maintain, update, and	regenerate groups of programs make(1)
regular expression. regcmp,	regex: compile and execute regcmp(3X)
compile and match routines.	regexp: regular expression regexp(5)
match routines. regexp:	regular expression compile and regexp(5)
regcmp:	regular expression compile regcmp(1)
regex: compile and execute	regular expression. regcmp, regcmp(3X)
lorder: find ordering	relation for an object/ lorder(1)
/receipt of an orderly	release indication t_rcvrel(3N)

t_sndrel: initiate an orderly	release
for a common object file.	reloc: relocation information reloc(4)
ldrseek, ldnrseek: seek to	relocation entries of a/ ldrseek(3X)
common object file. reloc:	relocation information for a reloc(4)
show current layer.	relogin: rename login entry to relogin(1M)
/fmod, fabs: floor, ceiling,	remainder, absolute value/ floor(3M)
mod, amod, dmod: FORTRAN	remaindering intrinsic/ mod(3F)
server master file. rfmaster:	Remote File Sharing name
file. rmdel:	remove a delta from an SCCS rmdel(1)
rmdir:	remove a directory
unlink:	remove directory entry
current layer. relogin:	rename login entry to show relogin(1M)
clock:	report CPU time used
stream. fseek, rewind, ftell:	reposition a file pointer in a fseek(3S)
t_accept: accept a connect	request. \ldots \ldots \ldots \ldots \ldots \ldots \ldots $t_accept(3N)$
t_listen: listen for a connect	request
confirmation from a connect	request. /receive the
send user-initiated disconnect	request. t_snddis: t_snddis(3N)
disconnect. t_rcvdis:	retrieve information from t_rcvdis(3N)
common object file/ ldgetname:	retrieve symbol name for
argument. getarg:	return FORTRAN command-line getarg(3F)
variable. getenv:	return FORTRAN environment getenv(3F)
accounting. mclock:	return FORTRAN time mclock(3F)
abs:	return integer absolute value
string. len:	return length of FORTRAN len(3F)
substring. index:	return location of FORTRAN index(3F)
logname:	return login name of user logname(3X)
line arguments. iargc:	return the number of command iargc(3F)
name. getenv:	return value for environment getenv(3C)
stat: data	returned by stat system call
file pointer in a/ fseek,	rewind, ftell: reposition a fseek(3S)
/readdir, telldir, seekdir,	rewinddir, closedir: directory/ directory(3X)
creat: create a new file or	rewrite an existing one
name server master file.	rfmaster: Remote File Sharing rfmaster(4)
SCCS file.	rmdel: remove a delta from an rmdel(1)
	rmdir: remove a directory rmdir(2)
chroot: change	root directory.
logarithm, power, square	root functions. /exponential, exp(3M)
/dsqrt, csqrt: FORTRAN square	root intrinsic function.
idnint: FORTRAN nearest/	round: anint, dnint, nint, round(3F)
common object file access	routines. ldfcn:
expression compile and match	routines. regexp: regular regexp(5)
and, or, xor, not, lshift,	rshift: FORTRAN Bitwise/ bool: bool(3F)
editing activity.	sact: print current SCCS file sact(1)
space allocation. brk,	sbrk: change data segment brk(2)
formatted input.	scanf, fscanf, sscanf: convert scanf(3S)
the delta commentary of an	SCCS delta. cdc: change
comb: combine	SCCS deltas
make a delta (change) to an	SCCS file. delta:
sact: print current	SCCS file editing activity
get: get a version of an	SCCS file
prs: print an	SCCS file
rmdel: remove a delta from an	SCCS file

commente truce complemente de com	
compare two versions of an	SCCS file. sccsdiff(1) SCCS file. sccsfile(4)
sccsfile: format of undo a previous get of an	
val: validate	SCCS file. unget:
admin: create and administer	SCCS files
what: identify	SCCS files.
of an SCCS file.	sccsdiff: compare two versions
of an occo me.	sccsfile: format of SCCS file.
common object file.	schhdr: section header for a
screen image file.	scr_dump: format of curses scr_dump(4)
optimization/ curses: terminal	screen handling and
scr_dump: format of curses	screen image file.
inittab:	script for the init process inittab(4)
source to as/ as386.sed: sed	script to convert Intel ASM386 as386.sed(1)
· ,	sdb: symbolic debugger
bsearch: binary	search a sorted table bsearch(3C)
lsearch, lfind: linear	search and update lsearch(3C)
hcreate, hdestroy: manage hash	search tables. hsearch, hsearch(3C)
tdelete, twalk: manage binary	search trees. tsearch, tfind, tsearch(3C)
object file. scnhdr:	section header for a common scnhdr(4)
object/ /read an indexed/named	section header of a common
the object file comment	section. mcs: manipulate mcs(1)
/to line number entries of a	section of a common object/
/to relocation entries of a	section of a common object/ ldrseek(3X)
/seek to an indexed/named	section of a common object/ ldsseek(3X)
common object/ size: print	section sizes in bytes of size(1)
ASM386 source to/ as386.sed:	sed script to convert Intel as386.sed(1)
/mrand48, jrand48, srand48,	seed48, lcong48: generate/ drand48(3C)
section of/ ldsseek, ldnsseek:	seek to an indexed/named ldsseek(3X)
a section/ ldlseek, ldnlseek:	seek to line number entries of ldlseek(3X)
a section/ ldrseek, ldnrseek:	seek to relocation entries of ldrseek(3X)
header of a common/ ldohseek:	seek to the optional file
common object file. ldtbseek:	seek to the symbol table of a
/opendir, readdir, telldir,	seekdir, rewinddir, closedir:/ directory(3X)
shmget: get shared memory	segment identifier
brk, sbrk: change data	segment space allocation
file. dump: dump	selected parts of an object dump(1)
semctl:	semaphore control operations semctl(2)
semop:	semaphore operations semop(2)
semget: get set of	semaphores semget(2)
operations.	semctl: semaphore control semctl(2)
	semget: get set of semaphores
t_sndudata:	semop: semaphore operations semop(2) send a data unit
putmsg:	send a message on a stream
a group of processes. kill:	send a signal to a process or
over a connection. t_snd:	send data or expedited data $\ldots \ldots \ldots$
request. t_snddis:	send user-initiated disconnect Lsnddis(3N)
/receive data or expedited data	sent over a connection.
Remote File Sharing name	server master file. rfmaster:

intro - introduction to programming commands

DESCRIPTION

This section describes, in alphabetical order, commands available for your computer. The top of each page indicates the utilities package to which the command belongs. The packages are:

Advanced C Utilities AT&T Windowing Utilities C Programming Language Utilities Directory and File Management Utilities Extended Software Generation System Utilities Software Generation System Utilities Source Code Control System Utilities Terminal Information Utilities

COMMAND SYNTAX

Unless otherwise noted, the commands described accept options and other arguments according to the following syntax:

name [option(s)] [cmdarg(s)]

where:

name is the name of an executable file

option is - noargletter(s) or - argletter<>optarg

where:

noargletter is a single letter representing an option without an option-argument

argletter is a single letter representing an option requiring an option-argument

<> is optional white space

optarg is an option-argument (character string) satisfying the preceding argletter.

cmdarg is a path name (or other command argument) *not* beginning with "-", or "-" by itself indicating the standard input.

Throughout the manual pages there are references to *TMPDIR*, *BINDIR*, *INCDIR*, *LIBDIR*, and *LLIBDIR*. These represent directory names whose value is specified on each manual page as necessary. For example, *TMPDIR* might refer to /tmp or /usr/tmp. These are not environment variables and cannot be set. [There is also an environment variable called **TMPDIR** which can be set. See *tmpnam*(3S).]

SEE ALSO

exit(2), wait(2), getopt(3C). getopts(1) in the User's Reference Manual,

DIAGNOSTICS

Upon termination, each command returns two bytes of status, one supplied by the system and giving the cause for termination, and (in the case of "normal" termination) one supplied by the program [see *wait*(2) and *exit*(2)]. The former byte is 0 for normal termination; the latter is customarily 0 for successful execution and non-zero to indicate troubles such as erroneous parameters, or bad or inaccessible data. It is called variously "exit code", "exit status", or "return code", and is described only where special conventions are involved.

WARNINGS

Some commands produce unexpected results when processing files containing null characters. These commands often treat text input lines as strings and therefore become confused upon encountering a null character (the string terminator) within a line.

admin - create and administer SCCS files

SYNOPSIS

admin [-n] [-i[name]] [-rrel] [-t[name]] [-fflag[flag-val]] [-dflag[flag-val]] [-alogin] [-elogin] [-m[mrlist]] [-y[comment]] [-h] [-z] files

DESCRIPTION

The *admin* command is used to create new SCCS files and change parameters of existing ones. Arguments to *admin*, which may appear in any order, consist of keyletter arguments, which begin with -, and named files (note that SCCS file names must begin with the characters **s**.). If a named file does not exist, it is created, and its parameters are initialized according to the specified keyletter arguments. Parameters not initialized by a keyletter argument are assigned a default value. If a named file does exist, parameters corresponding to specified keyletter arguments are changed, and other parameters are left as is.

If a directory is named, *admin* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.) and unreadable files are silently ignored. If a name of – is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed. Again, non-SCCS files and unreadable files are silently ignored.

The keyletter arguments are as follows. Each is explained as though only one named file is to be processed since the effects of the arguments apply independently to each named file.

- -n This keyletter indicates that a new SCCS file is to be created.
- -i[name] The name of a file from which the text for a new SCCS file is to be taken. The text constitutes the first delta of the file (see -r keyletter for delta numbering scheme). If the i keyletter is used, but the file name is omitted, the text is obtained by reading the standard input until an end-of-file is encountered. If this keyletter is omitted, then the SCCS file is created empty. Only one SCCS file may be created by an admin command on which the i keyletter is supplied. Using a single admin to create two or more SCCS files requires that they be created empty (no -i keyletter). Note that the -i keyletter implies the -n keyletter.
- -rrel The release into which the initial delta is inserted. This keyletter may be used only if the -i keyletter is also used. If the -r keyletter is not used, the initial delta is inserted into release 1. The level of the initial delta is always 1 (by default initial deltas are named 1.1).
- -t[name] The name of a file from which descriptive text for the SCCS file is to be taken. If the -t keyletter is used

and *admin* is creating a new SCCS file (the -n and/or -i keyletters also used), the descriptive text file name must also be supplied. In the case of existing SCCS files: (1) a -t keyletter without a file name causes removal of descriptive text (if any) currently in the SCCS file, and (2) a -t keyletter with a file name causes text (if any) in the named file to replace the descriptive text (if any) currently in the SCCS file.

- -fflag This keyletter specifies a flag, and, possibly, a value for the flag, to be placed in the SCCS file. Several **f** keyletters may be supplied on a single *admin* command line. The allowable flags and their values are:
 - **b** Allows use of the **-b** keyletter on a *get*(1) command to create branch deltas.
 - cceil The highest release (i.e., "ceiling"), a number greater than 0 but less than or equal to 9999, which may be retrieved by a *get*(1) command for editing. The default value for an unspecified **c** flag is 9999.
 - ffloor The lowest release (i.e., "floor"), a number greater than 0 but less than 9999, which may be retrieved by a get(1) command for editing. The default value for an unspecified f flag is 1.
 - **d**SID The default delta number (SIDs+1) to be used by a get(1) command.
 - i[str] Causes the "No id keywords (ge6)" message issued by get(1) or delta(1) to be treated as a fatal error. In the absence of this flag, the message is only a warning. The message is issued if no SCCS identification keywords [see get(1)] are found in the text retrieved or stored in the SCCS file. If a value is supplied, the keywords must exactly match the given string, however the string must contain a keyword, and no embedded newlines.
 - j Allows concurrent *get*(1) commands for editing on the same SID of an SCCS file. This allows multiple concurrent updates to the same version of the SCCS file.
 - llist A list of releases to which deltas can no longer be made (get -e against one of these "locked" releases fails). The list has the following syntax:
 - tist> ::= <range> | <list> , <range> <range>~::= | a

The character **a** in the *list* is equivalent to specifying *all releases* for the named SCCS file.

n

future.

Causes *delta*(1) to create a "null" delta in each of those releases (if any) being skipped when a delta is made in a *new* release (e.g., in making delta 5.1 after delta 2.7, releases 3 and 4 are skipped). These null deltas serve as "anchor points" so that branch deltas may later be created from them. The absence of this flag causes skipped releases to be non-existent in the SCCS file, preventing branch deltas from being created from them in the

- **q**text User-definable text substituted for all occurrences of the %Q% keyword in SCCS file text retrieved by get(1).
- **m**mod Module name of the SCCS file substituted for all occurrences of the %M% keyword in SCCS file text retrieved by *get*(1). If the **m** flag is not specified, the value assigned is the name of the SCCS file with the leading **s**. removed.
- *ttype Type* of module in the SCCS file substituted for all occurrences of %Y% keyword in SCCS file text retrieved by *get*(1).
- vpgm Causes delta(1) to prompt for Modification Request (MR) numbers as the reason for creating a delta. The optional value specifies the name of an MR number validity checking program [see delta(1)]. (If this flag is set when creating an SCCS file, the m keyletter must also be used even if its value is null.)
- -dflag
 Causes removal (deletion) of the specified flag from an SCCS file. The -d keyletter may be specified only when processing existing SCCS files. Several -d keyletters may be supplied on a single admin command. See the -f keyletter for allowable flag names.
 - **l***list* A *list* of releases to be "unlocked". See the **-f** keyletter for a description of the **1** flag and the syntax of a *list*.
- -alogin A login name, or numerical UNIX system group ID, to be added to the list of users which may make deltas (changes) to the SCCS file. A group ID is equivalent to specifying all *login* names common to that group ID. Several **a** keyletters may be used on a single *admin* command line. As many *logins*, or numerical group IDs, as desired may be on the list simultaneously. If the list of users is empty, then anyone may add deltas. If *login* or group ID is preceded by a 1 they are to be denied permission to make deltas.

ADMIN(1)

-elogin A login name, or numerical group ID, to be erased from the list of users allowed to make deltas (changes) to the SCCS file. Specifying a group ID is equivalent to specifying all *login* names common to that group ID. Several **e** keyletters may be used on a single *admin* command line.

-m[mrlist]The list of Modification Requests (MR) numbers is
inserted into the SCCS file as the reason for creating
the initial delta in a manner identical to delta(1). The
v flag must be set and the MR numbers are validated
if the v flag has a value (the name of an MR number
validation program). Diagnostics will occur if the v
flag is not set or MR validation fails.

-y[comment] The comment text is inserted into the SCCS file as a comment for the initial delta in a manner identical to that of delta(1). Omission of the -y keyletter results in a default comment line being inserted in the form:

date and time created YY /MM /DD HH:MM:SS by login

The **-y** keyletter is valid only if the **-i** and/or **-n** keyletters are specified (i.e., a new SCCS file is being created).

-h

-Z

Causes *admin* to check the structure of the SCCS file [see *sccsfile*(5)], and to compare a newly computed check-sum (the sum of all the characters in the SCCS file except those in the first line) with the check-sum that is stored in the first line of the SCCS file. Appropriate error diagnostics are produced.

> This keyletter inhibits writing on the file, so that it nullifies the effect of any other keyletters supplied, and is, therefore, only meaningful when processing existing files.

The SCCS file check-sum is recomputed and stored in the first line of the SCCS file (see -h, above).

Note that use of this keyletter on a truly corrupted file may prevent future detection of the corruption.

The last component of all SCCS file names must be of the form s.filename. New SCCS files are given mode 444 [see chmod(1)]. Write permission in the pertinent directory is, of course, required to create a file. All writing done by *admin* is to a temporary x-file, called x.file-name, [see get(1)], created with mode 444 if the *admin* command is creating a new SCCS file, or with the same mode as the SCCS file if it exists. After successful execution of *admin*, the SCCS file is removed (if it exists), and the x-file is renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occurred. It is recommended that directories containing SCCS files be mode 755 and that SCCS files themselves be mode 444. The mode of the directories allows only the owner to modify SCCS files contained in the directories. The mode of the SCCS files prevents any modification at all except by SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner allowing use of ed(1). *Care must be taken!* The edited file should *always* be processed by an **admin** –**h** to check for corruption followed by an **admin** –**z** to generate a proper check-sum. Another **admin** –**h** is recommended to ensure the SCCS file is valid.

The *admin* command also makes use of a transient lock file (called *z.file-name*), which is used to prevent simultaneous updates to the SCCS file by different users. See get(1) for further information.

FILES

g-file	Existed before the execution of <i>delta</i> ; removed after completion of <i>delta</i> .
p-file	Existed before the execution of <i>delta</i> ; may exist after completion of <i>delta</i> .
q-file	Created during the execution of <i>delta</i> ; removed after completion of <i>delta</i> .
x-file	Created during the execution of <i>delta</i> ; renamed to SCCS file after completion of <i>delta</i> .
z-file	Created during the execution of <i>delta</i> ; removed during the execution of <i>delta</i> .
d-file	Created during the execution of <i>delta</i> ; removed after completion of <i>delta</i> .

DIAGNOSTICS

Use help(1) for explanations.

ar – archive and library maintainer for portable archives

SYNOPSIS

ar key [posname] afile [name] ...

DESCRIPTION

The *ar* command maintains groups of files combined into a single archive file. Its main use is to create and update library files as used by the link editor. It can be used, though, for any similar purpose. The magic string and the file headers used by *ar* consist of printable ASCII characters. If an archive is composed of printable files, the entire archive is printable. Archives of text files created by *ar* are portable between implementations of System V.

When *ar* creates an archive, it creates headers in a format that is portable across all machines. The portable archive format and structure is described in detail in ar(4). The archive symbol table [described in ar(4)] is used by the link editor [ld(1)] to effect multiple passes over libraries of object files in an efficient manner. An archive symbol table is only created and maintained by *ar* when there is at least one object file in the archive. The archive symbol table is in a specially named file which is always the first file in the archive. This file is never mentioned nor is accessible to the user. Whenever the ar(1) command is used to create or update the contents of such an archive, the symbol table is rebuilt. The **s** option, described in the following, text will force the symbol table to be rebuilt.

Unlike command options, the command key is a required part of ar's command line. The key (which may begin with a –) is formed with one of the following letters: **drqtpmx**. Arguments to the *key*, alternatively, are made with one of more of the following set: **vuaibcls**. *Posname* is an archive member name used as a reference point in positioning other files in the archive. *Afile* is the archive file. The *names* are constituent files in the archive file. The meanings of the *key* characters are as follows:

- **d** Delete the named files from the archive file.
- **r** Replace the named files in the archive file. If the optional character
 u is used with **r**, then only those files with dates of modification later than the archive files are replaced. If an optional positioning character from the set **abi** is used, then the *posname* argument must be present and specifies that new files are to be placed after (**a**) or before (**b** or **i**) *posname*. Otherwise new files are placed at the end.
- **q** Quickly append the named files to the end of the archive file. Optional positioning characters are invalid. The command does not check whether the added members are already in the archive. This option is useful to avoid quadratic behavior when creating a large archive piece-by-piece. Unchecked, the file may grow exponentially up to the second degree.

t Print a table of contents of the archive file. If no names are given, all files in the archive are tabled. If names are given, only those files are tabled.

- **m** Move the named files to the end of the archive. If a positioning character is present, then the *posname* argument must be present and, as in **r**, specifies where the files are to be moved.
- **x** Extract the named files. If no names are given, all files in the archive are extracted. In neither case does **x** alter the archive file.

The meanings of the key arguments are as follows:

- **v** Give a verbose file-by-file description of the making of a new archive file from the old archive and the constituent files. When used with **t**, give a long listing of all information about the files. When used with **x**, precede each file with a name.
- **c** Suppress the message that is produced by default when *afile* is created.
- Place temporary files in the local (current working) directory rather than in the default temporary directory, *TMPDIR*.
- **s** Force the regeneration of the archive symbol table even if ar(1) is not invoked with a command which will modify the archive contents. This command is useful to restore the archive symbol table after the *strip*(1) command has been used on the archive.

FILES

\$TMPDIR/* temporary files

\$TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

ld(1), lorder(1), strip(1), tmpnam(3S), a.out(4), ar(4) in the *Programmer's Reference Manual*.

NOTES

If the same file is mentioned twice in an argument list, it may be put in the archive twice.

as - common assembler

SYNOPSIS

as [options] file name

DESCRIPTION

The *as* command assembles the named file. The following flags may be specified in any order:

- -o *objfile* Put the output of the assembly in *objfile*. By default, the output file name is formed by removing the .s suffix, if there is one, from the input file name and appending a .o suffix.
- -n Turn off long/short address optimization. By default, address optimization takes place.
- -m Run the *m*4 macro processor on the input to the assembler.
- -**R** Remove (unlink) the input file after assembly is completed.
- -dl Do not produce line number information in the object file.
- -MI (80286 only) Assemble the program using the large memory model. See *Programming Procedures for UNIX System V/286*.
- -Ms (80286 only) Assemble the program using the small memory model. This model is used by default when no memory model is specified. See *Programming Procedures for UNIX System V/286*.
- -V Write the version number of the assembler being run on the standard error output.

-Y [md],dir

Find the **m4** preprocessor (**m**) and/or the file of predefined macros (**d**) in directory *dir* instead of in the customary place.

FILES

TMPDIR/* temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

cc(1), ld(1), m4(1), nm(1), strip(1), tmpnam(3S), a.out(4)

WARNING

If the $-\mathbf{m}$ (m4 macro processor invocation) option is used, keywords for m4 [see m4(1)] cannot be used as symbols (variables, functions, labels) in the input file since m4 cannot determine which are assembler symbols and which are real m4 macros.

BUGS

The **.align** assembler directive may not work in the **.text** section when optimization is performed.

CAVEATS

Arithmetic expressions may only have one forward referenced symbol per expression.

NOTES

Wherever possible, the assembler should be accessed through a compilation system interface program [such as cc(1)].

as386.sed - sed script to convert Intel ASM386 source to as source

SYNOPSIS

sed -f as386.sed < input-file >output-file

DESCRIPTION

The *as386.sed* sed script is used to convert an Intel ASM386 assembler source file to a form acceptable to the UNIX system *as* assembler.

The sed script does not attempt to convert 100% of the ASM386 source code; it cannot handle the following constructs:

- Macros.
- Strange segmentation schemes.
- Data declarations beyond the simple db/dw/dd/dp with simple constant *init* list.
- Quoted ASCII strings.
- Structure or record template addressing (i.e., [ebp].foo).
- Complex expressions (parentheses and operators other than simple + and -).
- Immediate operands that are not simple constants.
- Immediate operands with automatically typed memory operands.
- Source files with opcodes in upper case.
- Source files with continued lines.

The sed script will preserve all comments, it will also transform certain ASM386 directives into comments (like EXTERN, SEGMENT, etc.) Since it translates the ASM386 NAME directive into the .file directive, it is best to put the NAME directive as the first line of the source file.

EXAMPLES

The following command will read an uppercase ASM386 formatted file named *misc.asm* and produce a UNIX system *as* formatted file named *misc.s.*

tr "[A-Z]" "[a-z]" <misc.asm | sed -f as386.sed >misc.s

SEE ALSO

sed(1)

BUGS

Except for the limitations mentioned above, there are no known bugs.

CB(1)

NAME

cb – C program beautifier

SYNOPSIS

cb [-**s**] [-**j**] [-**l** leng] [file ...]

DESCRIPTION

The *cb* comand reads C programs either from its arguments or from the standard input, and writes them on the standard output with spacing and indentation that display the structure of the code. Under default options, *cb* preserves all user new-lines.

The *cb* command accepts the following options.

-s	Canonicalizes the code to the style of Kernighan and Ritchie in
	The C Programming Language.

-j Causes split lines to be put back together.

-1 *leng* Causes *cb* to split lines that are longer than *leng*.

SEE ALSO

cc(1).

The C Programming Language. Prentice-Hall, 1978.

BUGS

Punctuation that is hidden in preprocessor statements will cause indentation errors.

cc – C compiler

SYNOPSIS

cc [options] files

DESCRIPTION

The *cc* command is the interface to the C Compilation System. The compilation tools consist of a preprocessor, compiler, optimizer, assembler, and link editor. The *cc* command processes the supplied options and then executes the various tools with the proper arguments. The *cc* command accepts several types of files as arguments.

Files whose names end with **.c** are taken to be C source programs and may be preprocessed, compiled, optimized, assembled and link edited. The compilation process may be stopped after the completion of any pass if the appropriate options are supplied. If the compilation process runs through the assembler, then an object program is produced and is left in the file whose name is that of the source with **.o** substituted for **.c.** However, the **.o** file is normally deleted if a single C program is compiled and then immediately link edited. In the same way, files whose names end in **.s** are taken to be assembly source programs and may be assembled and link edited; and files whose names end in .i are taken to be preprocessed C source programs and may be compiled, optimized, assembled, and link edited. Files whose names do not end in **.c. .s**, or **.i** are handed to the link editor.

Since the *cc* command usually creates files in the current directory during the compilation process, it is necessary to run the *cc* command in a directory in which a file can be created.

The following options are interpreted by *cc*: .

- -c Suppress the link editing phase of the compilation and do not remove any produced object files.
- -ds Do not generate symbol attribute information for the symbolic debugger.
- -dl Do not generate symbolic debugging line number information. This and the above flag may be used in conjunction as -dsl (-dsl is the default unless the -g flag is given).
- -g Cause the compiler to generate additional information needed for the use of sdb(1).
- -MI (80286 only) Compile the program using the large memory model. See *Programming Procedures for UNIX System V/286 for details.*
- -Ms (80286 only) Compile the program using the small memory model. This memory model is used by default when no memory model is specified. See *Programming Procedures for UNIX System V/286 for details.*
- -o outfile

Produce an output object file by the name *outfile*. The name of the default file is **a.out**. This is a link editor option.

- -p Arrange for the compiler to produce code that counts the number of times each routine is called; also, if link editing takes place, profiled versions of libc.a and libm.a (with -lm option) are linked and *monitor*(3C) is automatically called. A **mon.out** file will then be produced at normal termination of execution of the object program. An execution profile can then be generated by use of *prof*(1).
- -**qp** Arrange for profiled code to be produced where the **p** argument produces identical results to the -**p** option [allows profiling with *prof*(1)].

-Bstring

-t/p02al)

These options will be removed in the next release. Use the -Y option.

- -E Run only *cpp*(1) on the named C programs, and send the result to the standard output.
- -F Cause the compiler to generate code for single precision arithmetic whenever an expression contains float variables and no doubles.
- -H Print out on *stderr* the path name of each file included during the current compilation.
- -O Do compilation phase optimization. This option will not have any effect on **.s** files.
- -P Run only *cpp*(1) on the named C programs and leave the result in corresponding files suffixed **.i**. This option is passed to *cpp*(1).
- -S Compile and do not assemble the named C programs, and leave the assembler-language output in corresponding files suffixed **.s**.
- -V Print the version of the compiler, optimizer, assembler and/or link editor that is invoked.

-Wc,arg1[,arg2...]

Hand off the argument[s] *argi* to pass c where c is one of [**p02al**] indicating the preprocessor, compiler, optimizer, assembler, or link editor, respectively. For example: **-Wa,-m** passes **-m** to the assembler.

-Y [p02alSILU], dirname

Specify a new path name, *dirname*, for the locations of the tools and directories designated in the first argument. **[p02alSILU]** represents:

- **p** preprocessor
- 0 compiler
- 2 optimizer

a assembler

1 link editor

S directory containing the start-up routines

I default include directory searched by *cpp*(1)

L first default library directory searched by ld(1)

U second default library directory searched by ld(1)

If the location of a tool is being specified, then the new path name for the tool will be *dirname/tool*. If more than one -Y option is applied to any one tool or directory, then the last occurrence holds.

The *cc* command also recognizes -C, -D, -H, -I and -U and passes these options and their arguments directly to the preprocessor without using the -W option. Similarly, the *cc* command recognizes -a, -l, -m, -o, -r, -s, -t, -u, -x, -z, -L, -M and -V and passes these options and their arguments directly to the loader. See the manual pages for *cpp*(1) and *ld*(1) for descriptions.

Other arguments are taken to be C compatible object programs, typically produced by an earlier *cc* run, or perhaps libraries of C compatible routines and are passed directly to the link editor. These programs, together with the results of any compilations specified, are link edited (in the order given) to produce an executable program with name **a.out** unless the $-\mathbf{0}$ option of the link editor is used.

If the cc command is put in a file *prefix*cc the prefix will be parsed off the command and used to call the tools, i.e., *prefix*tool. For example, OLDcc will call OLDcpp, OLDcomp, OLDoptim, OLDas, and OLDld and will link OLDcrt1.o. Therefore, one MUST be careful when moving the cc command around. The prefix will apply to the preprocessor, compiler, optimizer, assembler, link editor, and the start-up routines.

The C language standard was extended to allow arbitrary length variable names. The option pair "-**Wp**,-**T** -**W0**,-**XT**" will cause cc to truncate arbitrary length variable names.

FILES

file.c	C source file
file.i	preprocessed C source file
file.o	object file
file.s	assembly language file
a.out	link edited output
LIBDIR/*crt1.0	start-up routine
LIBDIR/ <model>/*crt1.o</model>	start-up routine (80286 only; model is either
	small or large)
LIBDIR/crtn.o	start-up routine
LIBDIR/ <model>/crtn.o</model>	start-up routine (80286 only; model is either
	small or large)
TMPDIR/*	temporary files
<i>LIBDIR</i> /cpp	preprocessor, <i>cpp</i> (1)
LIBDIR/comp	compiler
LIBDIR/optim	optimizer
BINDIR/as	assembler, <i>as</i> (1)
BINDIR/ld	link editor, <i>ld</i> (1)
LIBDIR/libc.a	standard C library
LIBDIR/ <model>/libc.a</model>	standard C library (80286 only; model is either
	small or large)
LIBDIR/libc_s.a	standard C shared library

LIBDIR/<model>/libc_s.a standard C shared library (80286 only; model is large)

LIBDIR is usually /lib

LIBDIR/*<model>* is usually /lib (80286 only; model is either small or large) *BINDIR* is usually /bin

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

Kernighan, B. W., and Ritchie, D. M., The C Programming Language, Prentice-Hall, 1978.

DIAGNOSTICS

The diagnostics produced by the C compiler are sometimes cryptic.

NOTES

By default, the return value from a compiled C program is completely random. The only two guaranteed ways to return a specific value is to explicitly call *exit*(2) or to leave the function **main**() with a *"return expression;"* construct.

CC(1)

CCOFF(1)

NAME

ccoff - convert a COFF file

SYNOPSIS

ccoff [-r] [-v] file ...

DESCRIPTION

The *ccoff* command converts a COFF file by byte-swapping all multi-byte integers in the file. Thus, if the COFF file has been built by a cross compiler running on a big-endian development machine (Motorola 68000, etc.), ccoff will convert the file to a format suitable for running on the target (80386) machine. The *ccoff* command will convert relocated executables, non-relocated objects, and archives (libraries). The –r flag performs the reverse conversion, so that a file that has already been run through *ccoff* can be restored to its original state; or a file that has been built on a target machine can be manipulated on the development machine. The –v flag causes *ccoff* to operate verbosely.

convert(1)

cdc - change the delta commentary of an SCCS delta

SYNOPSIS

cdc -rSID [-m[mrlist]] [-y[comment]] files

DESCRIPTION

The *cdc* command changes the *delta commentary*, for the SID (SCCS IDentification string) specified by the $-\mathbf{r}$ keyletter, of each named SCCS file.

Delta commentary is defined to be the Modification Request (MR) and comment information normally specified via the delta(1) command (-m and -y keyletters).

If a directory is named, *cdc* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.) and unreadable files are silently ignored. If a name of – is given, the standard input is read (see *WARNINGS*) and each line of the standard input is taken to be the name of an SCCS file to be processed.

Arguments to *cdc*, which may appear in any order, consist of *keyletter* arguments and file names.

All the described *keyletter* arguments apply independently to each named file:

- -rSID Used to specify the SCCS IDentification (SID) string of a delta for which the delta commentary is to be changed.
- -**m***mrlist* If the SCCS file has the **v** flag set [see *admin*(1)] then a list of MR numbers to be added and/or deleted in the delta commentary of the SID specified by the -**r** keyletter *may* be supplied. A null MR list has no effect.

MR entries are added to the list of MRs in the same manner as that of *delta*(1). In order to delete an MR, precede the MR number with the character ! (see *EXAMPLES*). If the MR to be deleted is currently in the list of MRs, it is removed and changed into a "comment" line. A list of all deleted MRs is placed in the comment section of the delta commentary and preceded by a comment line stating that they were deleted.

If **-m** is not used and the standard input is a terminal, the prompt **MRs?** is issued on the standard output before the standard input is read; if the standard input is not a terminal, no prompt is issued. The **MRs?** prompt always precedes the **comments?** prompt (see **-y** keyletter). **MRs** in a list are separated by blanks and/or tab characters. An unescaped new-line character terminates the MR list.

Note that if the **v** flag has a value [see admin(1)], it is taken to be the name of a program (or shell procedure) which validates the correctness of the MR numbers. If a non-zero exit status is returned from the MR number validation program, *cdc* terminates and the delta commentary remains unchanged.

-y[comment] Arbitrary text used to replace the comment(s) already existing for the delta specified by the -r keyletter. The previous comments are kept and preceded by a comment line stating that they were changed. A null comment has no effect.

If -y is not specified and the standard input is a terminal, the prompt **comments?** is issued on the standard output before the standard input is read; if the standard input is not a terminal, no prompt is issued. An unescaped new-line character terminates the *comment* text.

Simply stated, the keyletter arguments are either (1) if you made the delta, you can change its delta commentary; or (2) if you own the file and directory, you can modify the delta commentary.

EXAMPLES

cdc -r1.6 -m "bl78-12345 !bl77-54321 bl79-00001 " -ytrouble s.file

adds bl78-12345 and bl79-00001 to the MR list, removes bl77-54321 from the MR list, and adds the comment **trouble** to delta **1.6** of s.file.

cdc -r1.6 s.file MRs? !b177-54321 b178-12345 b179-00001 comments? trouble

does the same thing.

WARNINGS

If SCCS file names are supplied to the *cdc* command via the standard input (- on the command line), then the $-\mathbf{m}$ and $-\mathbf{y}$ keyletters must also be used.

FILES

x-file	[see delta(1)]
z-file	[see delta(1)]

DIAGNOSTICS

Use *help*(1) for explanations.

- 2 -

cflow - generate C flowgraph

SYNOPSIS

cflow [-r] [-ix] [-i_] [-dnum] files

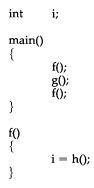

DESCRIPTION

The *cflow* command analyzes a collection of C, yacc, lex, assembler, and object files and attempts to build a graph charting the external references. Files suffixed with .y, .l, and .c are yacced, lexed, and C-preprocessed as appropriate. The results of the preprocessed files, and files suffixed with .i, are then run through the first pass of *lint*(1). Files suffixed with .s are assembled. Assembled files, and files suffixed with .o, have information extracted from their symbol tables. The results are collected and turned into a graph of external references which is displayed upon the standard output.

Each line of output begins with a reference number, followed by a suitable number of tabs indicating the level, then the name of the global symbol followed by a colon and its definition. Normally only function names that do not begin with an underscore are listed (see the -i options below). For information extracted from C source, the definition consists of an abstract type declaration (e.g., **char** *), and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the file name and location counter under which the symbol appeared (e.g., *text*). Leading underscores in C-style external names are deleted.

Once a definition of a name has been printed, subsequent references to that name contain only the reference number of the line where the definition may be found. For undefined references, only <> is printed.

As an example, given the following in *file.c*:

the command

cflow –ix file.c

produces the output

 1
 main: int(), <file.c 4>

 2
 f: int(), <file.c 11>

 3
 h: <>

 4
 i: int, <file.c 1>

 5
 g: <>

When the nesting level becomes too deep, the output of cflow can be piped to pr(1), using the -e option, to compress the tab expansion to something less than every eight spaces.

In addition to the **-D**, **-I**, and **-U** options [which are interpreted just as they are by *cc*(1) and *cpp*(1)], the following options are interpreted by *cflow*:

- **-r** Reverse the "caller:callee" relationship producing an inverted listing showing the callers of each function. The listing is also sorted in lexicographical order by callee.
- -ix Include external and static data symbols. The default is to include only functions in the flowgraph.
- -i_ Include names that begin with an underscore. The default is to exclude these functions (and data if -*ix* is used).
- -dnum The *num* decimal integer indicates the depth at which the flowgraph is cut off. By default this is a very large number. Attempts to set the cutoff depth to a nonpositive integer will be ignored.

DIAGNOSTICS

Complains about bad options. Complains about multiple definitions and only believes the first. Other messages may come from the various programs used (e.g., the C-preprocessor).

SEE ALSO

as(1), cc(1), cpp(1), lex(1), lint(1), nm(1), yacc(1). pr(1) in the *User's Reference Manual*.

BUGS

Files produced by lex(1) and yacc(1) cause the reordering of line number declarations which can confuse cflow. To get proper results, feed cflow the *yacc* or *lex* input.

comb - combine SCCS deltas

SYNOPSIS

comb files

DESCRIPTION

The *comb* command generates a shell procedure [see sh(1)] which, when run, will reconstruct the given SCCS files. The reconstructed files will, hopefully, be smaller than the original files. The arguments may be specified in any order, but all keyletter arguments apply to all named SCCS files. If a directory is named, *comb* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.) and unreadable files are silently ignored. If a name of – is given, the standard input is read; each line of the input is taken to be the name of an SCCS file to be processed; non-SCCS files and unreadable files are silently ignored. The generated shell procedure is written on the standard output.

The keyletter arguments are as follows. Each is explained as though only one named file is to be processed, but the effects of any keyletter argument apply independently to each named file.

-0	For each get – e generated, this argument causes the reconstructed file to be accessed at the release of the delta to be created, otherwise the reconstructed file would be accessed at the most recent ancestor. Use of the – o keyletter may decrease the size of the reconstructed SCCS file. It may also alter the shape of the delta tree of the original file.
-pSID	The SCCS <i>ID</i> entification string (SID) of the oldest delta to be preserved. All older deltas are discarded in the reconstructed file.
- S	This argument causes <i>comb</i> to generate a shell procedure which, when run, will produce a report giving, for each file: the file name, size (in blocks) after combining, original size (also in blocks), and percentage change computed by: 100 * (original – combined) / original It is recommended that before any SCCS files are actually combined, one should use this option to determine exactly how much space is saved by the combining process.
If no keyletter arguments are specified, <i>comb</i> will preserve only leaf deltas and the minimal number of ancestors needed to preserve the tree.	
s COMB	The name of the reconstructed SCCS file

FILES

s.COMB	The name of the reconstructed SCCS file.
comb?????	Temporary.

SEE ALSO

admin(1), delta(1), get(1), prs(1), sccsfile(4). help(1), sh(1) in the User's Reference Manual. COMB(1)

DIAGNOSTICS

Use *help*(1) for explanations.

BUGS

The *comb* command may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

conv – common object file converter

SYNOPSIS

conv [-a] [-o] [-p] -t target [- | files]

DESCRIPTION

The *conv* command converts object files in the common object file format from their current byte ordering to the byte ordering of the *target* machine. The converted file is written to *file.v*. The *conv* command can be used on either the source (sending) or target (receiving) machine.

Command line options are:

- Indicates that the names of *files* should be read from the standard input.
- -a If the input file is an archive, produce the output file in the UNIX System V Release 2.0 portable archive format.
- -o If the input file is an archive, produce the output file in the old (pre- UNIX System V) archive format.
- -p If the input file is an archive, produce the output file in the UNIX System V Release 1.0 random access archive format.
- -t target Convert the object file to the byte ordering of the machine (*target*) to which the object file is being shipped. This may be another host or a target machine. Legal values for *target* are: pdp, vax, ibm, x86, b16, n3b, mc68, and m32.

The *conv* command is meant to ease the problems created by a multi-host cross-compilation development environment. The *conv* command is best used within a procedure for shipping object files from one machine to another.

The *conv* command will recognize and produce archive files in three formats: the pre-UNIX System V format, the UNIX System V Release 1.0 random access format, and the UNIX System V Release 2.0 portable ASCII format. By default, *conv* will create the output archive file in the same format as the input file. To produce an output file in a different format than the input file, use the **-a**, **-o**, or **-p** option. If the output archive format is the same as the input format, the archive symbol table will be converted, otherwise the symbol table will be stripped from the archive. The *ar*(1) command with its **-t** and **-s** options must be used on the target machine to recreate the archive symbol table.

EXAMPLE

To ship object files from a VAX computer sytem to a 3B2 computer, execute the following commands:

conv -t m32 *.out

uucp *.out.v my3b2!~/rje/

DIAGNOSTICS

The diagnostics are self-explanatory. Fatal diagnostics on the command lines cause termination. Fatal diagnostics on an input file cause the program to continue to the next input file.

CAVEATS

The *conv* command will not convert archives from one format to another if both the source and target machines have the same byte ordering. The UNIX system tool *convert*(1) should be used for this purpose.

SEE ALSO

ar(1), convert(1), ar(4), a.out(4).

CONVERT(1)

NAME

convert - convert archive files to common formats

SYNOPSIS

convert infile outfile

DESCRIPTION

The *convert* command transforms input *infile* to output *outfile*. *Infile* must be a UNIX System V Release 1.0 archive file and *outfile* will be the equivalent UNIX System V Release 2.0 archive file. All other types of input to the *convert* command will be passed unmodified from the input file to the output file (along with appropriate warning messages).

Infile must be different from outfile.

FILES

TMPDIR/conv* temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

ar(1), tmpnam(3S), a.out(4), ar(4)

cpp – the C language preprocessor

SYNOPSIS

LIBDIR/cpp [option ...] [ifile [ofile]]

DESCRIPTION

The C language preprocessor, cpp, is invoked as the first pass of any C compilation by the cc(1) command. Thus cpp's output is designed to be in a form acceptable as input to the next pass of the C compiler. As the C language evolves, cpp and the rest of the C compilation package will be modified to follow these changes. Therefore, the use of cpp other than through the cc(1) command is not suggested, since the functionality of cpp may someday be moved elsewhere. See m4(1) for a general macro processor.

The *cpp* command optionally accepts two file names as arguments. *Ifile* and *ofile* are respectively the input and output for the preprocessor. They default to standard input and standard output if not supplied.

The following *options* to *cpp* are recognized:

- -P Preprocess the input without producing the line control information used by the next pass of the C compiler.
- -C By default, *cpp* strips C-style comments. If the -C option is specified, all comments (except those found on *cpp* directive lines) are passed along.

–**U**name

Remove any initial definition of *name*, where *name* is a reserved symbol that is predefined by the particular preprocessor. Following is the current list of these possibly reserved symbols. On the 80286 and 80386, *unix* and one of *i286* or *i386* are defined.

operating system:	unix, dmert, gcos, ibm, os, tss
hardware:	i286, i386, interdata, pdp11, u370, u3b,
	u3b5, u3b2, u3b20d, vax
UNIX system variant:	RES, RT
lint(1):	lint
(-)	

-**D**name

-Dname=def

Define *name* with value *def* as if by a **#define**. If no =*def* is given, *name* is defined with value 1. The –**D** option has lower precedence than the –**U** option. That is, if the same name is used in both a –**U** option and a –**D** option, the name will be undefined regardless of the order of the options.

- -T The -T option forces *cpp* to use only the first eight characters to distinguish preprocessor symbols and is included for backward compatibility.
- -Idir Change the algorithm for searching for **#include** files whose names do not begin with / to look in *dir* before looking in the directories on the standard list. Thus, **#include** files whose names are

enclosed in " " will be searched for first in the directory of the file with the **#include** line, then in directories named in **-I** options, and last in directories on a standard list. For **#include** files whose names are enclosed in <>, the directory of the file with the **#include** line is not searched.

- -Ydir Use directory dir in place of the standard list of directories when searching for **#include** files.
- -H Print, one per line on standard error, the path names of included files.

Two special names are understood by *cpp*. The name __LINE__ is defined as the current line number (as a decimal integer) as known by *cpp*, and __FILE__ is defined as the current file name (as a C string) as known by *cpp*. They can be used anywhere (including in macros) just as any other defined name.

All *cpp* directive lines start with **#** in column 1. Any number of blanks and tabs is allowed between the **#** and the directive. The directives are:

#define name token-string

Replace subsequent instances of name with token-string.

#define name(arg, ..., arg) token-string

Notice that there can be no space between *name* and the (. Replace subsequent instances of *name* followed by a (, a list of comma-separated sets of tokens, and a) followed by *token-string*, where each occurrence of an *arg* in the *token-string* is replaced by the corresponding set of tokens in the comma-separated list. When a macro with arguments is expanded, the arguments are placed into the expanded *token-string* unchanged. After the entire *token-string* has been expanded, *cpp* re-starts its scan for names to expand at the beginning of the newly created *token-string*.

#undef name

Cause the definition of *name* (if any) to be forgotten from now on. No additional tokens are permitted on the directive line after *name*.

#ident "string"

Put string into the .comment section of an object file.

#include "filename"

#include <filename>

Include at this point the contents of *filename* (which will then be run through *cpp*). When the <*filename* > notation is used, *filename* is only searched for in the standard places. See the -I and -Y options above for more detail. No additional tokens are permitted on the directive line after the final " or >.

#line integer-constant "filename"

Causes *cpp* to generate line control information for the next pass of the C compiler. *Integer-constant* is the line number of the next line and *filename* is the file from which it comes. If "*filename*" is not given, the current file name is unchanged. No additional tokens are permitted on the directive line after the optional *filename*.

#endif

Ends a section of lines begun by a test directive (**#if**, **#ifdef**, or **#ifndef**). Each test directive must have a matching **#endif**. No additional tokens are permitted on the directive line.

#ifdef name

The lines following will appear in the output if and only if *name* has been the subject of a previous **#define** without being the subject of an intervening **#undef**. No additional tokens are permitted on the directive line after *name*.

#ifndef name

The lines following will appear in the output if and only if *name* has not been the subject of a previous **#define**. No additional tokens are permitted on the directive line after *name*.

#if constant-expression

Lines following will appear in the output if and only if the *constant-expression* evaluates to non-zero. All binary non-assignment C operators, the **?**: operator, the unary –, **!**, and [~] operators are all legal in *constant-expression*. The precedence of the operators is the same as defined by the C language. There is also a unary operator **defined**, which can be used in *constant-expression* in these two forms: **defined** (*name*) or **defined** *name*. This allows the utility of **#ifdef** and **#ifndef** in a **#if** directive. Only these operators, integer constants, and names which are known by *cpp* should be used in *constant-expression*. In particular, the **sizeof** operator is not available.

To test whether either of two symbols, foo and fum, are defined, use

#if defined(foo) # defined(fum)

#elif constant-expression

An arbitrary number of **#elif** directives is allowed between a **#if**, **#ifdef**, or **#ifndef** directive and a **#else** or **#endif** directive. The lines following the **#elif** directive will appear in the output if and only if the preceding test directive evaluates to zero, all intervening **#elif** directives evaluate to zero, and the *constant-expression* evaluates to non-zero. If *constant-expression* evaluates to non-zero, all succeeding **#elif** and **#else** directives will be ignored. Any *constant-expression* allowed in a **#if** directive is allowed in a **#elif** directive.

#else The lines following will appear in the output if and only if the preceding test directive evaluates to zero, and all intervening **#elif** directives evaluate to zero. No additional tokens are permitted on the directive line.

The test directives and the possible **#else** directives can be nested.

FILES

INCDIR	standard directory list for #include files, usually
	/usr/include
LIBDIR	usually /lib

SEE ALSO

cc(1), lint(1), m4(1).

DIAGNOSTICS

The error messages produced by cpp are intended to be self-explanatory. The line number and file name where the error occurred are printed along with the diagnostic.

NOTES

The unsupported **-W** option enables the **#class** directive. If it encounters a **#class** directive, *cpp* will exit with code 27 after finishing all other processing. This option provides support for "C with classes".

Because the standard directory for included files may be different in different environments, this form of **#include** directive:

#include <file.h>

should be used, rather than one with an absolute path, like:

#include "/usr/include/file.h"

The *cpp* commnad warns about the use of the absolute path name.

CPRS(1)

NAME

cprs - compress a common object file

SYNOPSIS

cprs [-p] file1 file2

DESCRIPTION

The *cprs* command reduces the size of a common object file, *file1*, by removing duplicate structure and union descriptors. The reduced file, *file2*, is produced as output.

The sole option to *cprs* is:

-p Print statistical messages including: total number of tags, total duplicate tags, and total reduction of *file1*.

SEE ALSO

strip(1), a.out(4), syms(4).

ctrace - C program debugger

SYNOPSIS

ctrace [options] [file]

DESCRIPTION

The *ctrace* command allows you to follow the execution of a C program, statement-by-statement. The effect is similar to executing a shell procedure with the -x option. The *ctrace* command reads the C program in *file* (or from standard input if you do not specify *file*), inserts statements to print the text of each executable statement and the values of all variables referenced or modified, and writes the modified program to the standard output. You must put the output of *ctrace* into a temporary file because the *cc*(1) command does not allow the use of a pipe. You then compile and execute this file.

As each statement in the program executes it will be listed at the terminal, followed by the name and value of any variables referenced or modified in the statement, followed by any output from the statement. Loops in the trace output are detected and tracing is stopped until the loop is exited or a different sequence of statements within the loop is executed. A warning message is printed every 1000 times through the loop to help you detect infinite loops. The trace output goes to the standard output so you can put it into a file for examination with an editor or the bfs(1) or tail(1) commands.

The options commonly used are:

-f functions	Trace only these functions.
-v functions	Trace all but these functions.

You may want to add to the default formats for printing variables. Long and pointer variables are always printed as signed integers. Pointers to character arrays are also printed as strings if appropriate. Char, short, and int variables are also printed as signed integers and, if appropriate, as characters. Double variables are printed as floating point numbers in scientific notation. You can request that variables be printed in additional formats, if appropriate, with these options:

- -o Octal
- -x Hexadecimal
- -u Unsigned
- -e Floating point

These options are used only in special circumstances:

- -1 *n* Check *n* consecutively executed statements for looping trace output, instead of the default of 20. Use 0 to get all the trace output from loops.
- -s Suppress redundant trace output from simple assignment statements and string copy function calls. This option can hide a bug caused by use of the = operator in place of the == operator.
- -t *n* Trace *n* variables per statement instead of the default of 10 (the maximum number is 20). The Diagnostics section explains when to

use this option.

-P Run the C preprocessor on the input before tracing it. You can also use the -D, -I, and -U *cpp*(1) options.

These options are used to tailor the run-time trace package when the traced program will run in a non-UNIX System environment:

-b Use only basic functions in the trace code, that is, those in *ctype*(3C), *printf*(3S), and *string*(3C). These are usually available even in cross-compilers for microprocessors. In particular, this option is needed when the traced program runs under an operating system that does not have *signal*(2), *fflush*(3S), *longjmp*(3C), or *setjmp*(3C).

-p string

- Change the trace print function from the default of 'printf('. For example, 'fprintf(stderr,' would send the trace to the standard error output.
- **-r** *f* Use file *f* in place of the *runtime.c* trace function package. This lets you change the entire print function, instead of just the name and leading arguments (see the **-p** option).

EXAMPLE

If the file *lc.c* contains this C program:

```
1 #include <stdio.h>
2 main()
             /* count lines in input */
3 {
4
        int c, nl;
5
6
        nl = 0:
7
        while ((c = getchar()) != EOF)
8
                if (c = ' \setminus n')
                        ++nl;
9
10
        printf("%d\n", nl);
11 }
```

and you enter these commands and test data:

cc lc.c a.out 1

(cntl-d)

the program will be compiled and executed. The output of the program will be the number **2**, which is not correct because there is only one line in the test data. The error in this program is common, but subtle. If you invoke *ctrace* with these commands:

ctrace lc.c >temp.c cc temp.c a.out the output will be: 2 main() 6 nl = 0; /* nl == 0 */

- 2 -

7 while ((c = getchar()) != EOF)The program is now waiting for input. If you enter the same test data as before, the output will be:

/* c == 49 or '1' */ if $(c = ' \setminus n')$ 8 /* c == 10 or '\n' */ 9 ++nl;/* nl == 1 */ 7 while ((c = getchar()) != EOF)/* c == 10 or '\n' */ 8 if $(c = ' \setminus n')$ /* c == 10 or '\n' */ 9 ++nl;/* nl == 2 */

7 while ((c = getchar()) != EOF)

If you now enter an end-of-file character (cntl-d) the final output will be: $(* \circ -- - 1 * i)$

Note that the program output printed at the end of the trace line for the **nl** variable. Also note the **return** comment added by *ctrace* at the end of the trace output. This shows the implicit return at the terminating brace in the function.

The trace output shows that variable **c** is assigned the value '1' in line 7, but in line 8 it has the value '\n'. Once your attention is drawn to this **if** statement, you will probably realize that you used the assignment operator (=) in place of the equality operator (==). You can easily miss this error during code reading.

EXECUTION-TIME TRACE CONTROL

The default operation for *ctrace* is to trace the entire program file, unless you use the -f or -v options to trace specific functions. This does not give you statement-by-statement control of the tracing, nor does it let you turn the tracing off and on when executing the traced program.

You can do both of these by adding *ctroff(*) and *ctron(*) function calls to your program to turn the tracing off and on, respectively, at execution time. Thus, you can code arbitrarily complex criteria for trace control with *if* statements, and you can even conditionally include this code because *ctrace* defines the **CTRACE** preprocessor variable. For example:

```
#ifdef CTRACE
    if (c == '!' && i > 1000)
        ctron();
#endif
```

You can also call these functions from sdb(1) if you compile with the -g option. For example, to trace all but lines 7 to 10 in the main function, enter:

```
sdb a.out
main:7b ctroff()
main:11b ctron()
r
```

You can also turn the trace off and on by setting static variable $tr_ct_$ to 0 and 1, respectively. This is useful if you are using a debugger that cannot call these functions directly.

DIAGNOSTICS

This section contains diagnostic messages from both *ctrace* and cc(1), since the traced code often gets some cc warning messages. You can get cc error messages in some rare cases, all of which can be avoided.

ctrace Diagnostics

warning: some variables are not traced in this statement

Only 10 variables are traced in a statement to prevent the C compiler "out of tree space; simplify expression" error. Use the -t option to increase this number.

warning: statement too long to trace

This statement is over 400 characters long. Make sure that you are using tabs to indent your code, not spaces.

cannot handle preprocessor code, use -P option

This is usually caused by #ifdef/#endif preprocessor statements in the middle of a C statement, or by a semicolon at the end of a #define preprocessor statement.

'if ... else if' sequence too long

Split the sequence by removing an **else** from the middle.

possible syntax error, try –P option

Use the -P option to preprocess the *ctrace* input, along with any appropriate -D, -I, and -U preprocessor options. If you still get the error message, check the Warnings section below.

Cc Diagnostics

warning: illegal combination of pointer and integer warning: statement not reached warning: sizeof returns 0

Ignore these messages.

compiler takes size of function

See the *ctrace* "possible syntax error" message above.

yacc stack overflow

See the *ctrace* "'if ... else if' sequence too long" message above.

- 4 -

out of tree space; simplify expression

Use the -t option to reduce the number of traced variables per statement from the default of 10. Ignore the "ctrace: too many variables to trace" warnings you will now get.

redeclaration of signal

Either correct this declaration of *signal*(2), or remove it and #include <signal.h>.

SEE ALSO

signal(2), ctype(3C), fclose(3S), printf(3S), setjmp(3C), string(3C). bfs(1), tail(1) in the User's Reference Manual.

WARNINGS

You will get a *ctrace* syntax error if you omit the semicolon at the end of the last element declaration in a structure or union, just before the right brace (}). This is optional in some C compilers. Defining a function with the same name as a system function may cause a syntax error if the number of arguments is changed. Just use a different name.

The *ctrace* command assumes that BADMAG is a preprocessor macro, and that EOF and NULL are #defined constants. Declaring any of these to be variables, e.g., "int EOF;", will cause a syntax error.

BUGS

The *ctrace* command does not know about the components of aggregates like structures, unions, and arrays. It cannot choose a format to print all the components of an aggregate when an assignment is made to the entire aggregate. *ctrace* may choose to print the address of an aggregate or use the wrong format (e.g., 3.149050e-311 for a structure with two integer members) when printing the value of an aggregate.

Pointer values are always treated as pointers to character strings.

The loop trace output elimination is done separately for each file of a multifile program. This can result in functions called from a loop still being traced, or the elimination of trace output from one function in a file until another in the same file is called.

FILES

/usr/lib/ctrace/runtime.c

run-time trace package

cxref - generate C program cross-reference

SYNOPSIS

cxref [options] files

DESCRIPTION

The *cxref* command analyzes a collection of C files and attempts to build a cross-reference table. The *cxref* command uses a special version of *cpp* to include **#define**'d information in its symbol table. It produces a listing on standard output of all symbols (auto, static, and global) in each file separately, or, with the **-c** option, in combination. Each symbol contains an asterisk (*) before the declaring reference.

In addition to the **-D**, **-I**, and **-U** options [which are interpreted just as they are by *cc*(1) and *cpp*(1)], the following *options* are interpreted by *cxref*:

-c Print a combined cross-reference of all input files.

-w<*num*>

Width option which formats output no wider than <num> (decimal) columns. This option will default to 80 if <num> is not specified or is less than 51.

- **-o** file Direct output to *file*.
- -s Operate silently; do not print input file names.
- -t Format listing for 80-column width.

FILES

LLIBDIR usually /usr/lib

LLIBDIR/xcpp special version of the C preprocessor.

SEE ALSO

cc(1), cpp(1).

DIAGNOSTICS

Error messages are unusually cryptic, but usually mean that you cannot compile these files.

BUGS

The *cxref* command considers a formal argument in a *#define* macro definition to be a declaration of that symbol. For example, a program that *#includes* **ctype.h**, will contain many declarations of the variable **c**.

delta – make a delta (change) to an SCCS file

SYNOPSIS

delta [-rSID] [-s] [-n] [-glist] [-m[mrlist]] [-y[comment]] [-p] files

DESCRIPTION

The *delta* command is used to permanently introduce into the named SCCS file changes that were made to the file retrieved by get(1) (called the *g*-file, or generated file).

The *delta* command makes a delta to each named SCCS file. If a directory is named, *delta* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.) and unreadable files are silently ignored. If a name of – is given, the standard input is read (see *WARNINGS*); each line of the standard input is taken to be the name of an SCCS file to be processed.

The *delta* command may issue prompts on the standard output depending upon certain keyletters specified and flags [see admin(1)] that may be present in the SCCS file (see **-m** and **-y** keyletters below).

Keyletter arguments apply independently to each named file.

- -rSID Uniquely identifies which delta is to be made to the SCCS file. The use of this keyletter is necessary only if two or more outstanding gets for editing (get -e) on the same SCCS file were done by the same person (login name). The SID value specified with the -r keyletter can be either the SID specified on the get command line or the SID to be made as reported by the get command [see get(1)]. A diagnostic results if the specified SID is ambiguous, or, if necessary and omitted on the command line.
- -s Suppresses the issue, on the standard output, of the created delta's SID, as well as the number of lines inserted, deleted, and unchanged in the SCCS file.
- **-n** Specifies retention of the edited *g*-*file* (normally removed at completion of delta processing).
- -glist a list [see get(1) for the definition of list] of deltas which are to be *ignored* when the file is accessed at the change level (SID) created by this delta.
- -**m**[*mrlist*] If the SCCS file has the **v** flag set [see *admin*(1)] then a Modification Request (**MR**) number *must* be supplied as the reason for creating the new delta.

If **-m** is not used and the standard input is a terminal, the prompt **MRs?** is issued on the standard output before the standard input is read; if the standard input is not a terminal, no prompt is issued. The **MRs?** prompt always precedes the **comments?** prompt (see **-y** keyletter). **MR**s in a list are separated by blanks and/or tab characters. An unescaped new-line character terminates the **MR** list.

Note that if the **v** flag has a value [see admin(1)], it is taken to be the name of a program (or shell procedure) which will validate the correctness of the **MR** numbers. If a non-zero exit status is returned from the **MR** number validation program, *delta* terminates. (It is assumed that the **MR** numbers were not all valid.)

-y[comment] Arbitrary text used to describe the reason for making the delta. A null string is considered a valid comment.

If -y is not specified and the standard input is a terminal, the prompt **comments?** is issued on the standard output before the standard input is read; if the standard input is not a terminal, no prompt is issued. An unescaped new-line character terminates the comment text.

-p Causes *delta* to print (on the standard output) the SCCS file differences before and after the delta is applied in a *diff*(1) format.

FILES

g-file	Existed before the execution of <i>delta</i> ; removed after com-
-	pletion of <i>delta</i> .

- p-file Existed before the execution of *delta*; may exist after completion of *delta*.
- q-file Created during the execution of *delta*; removed after completion of *delta*.
- x-file Created during the execution of *delta*; renamed to SCCS file after completion of *delta*.
- z-file Created during the execution of *delta*; removed during the execution of *delta*.
- d-file Created during the execution of *delta*; removed after completion of *delta*.

/usr/bin/bdiff Program to compute differences between the "gotten" file and the *g*-file.

WARNINGS

Lines beginning with an **SOH** ASCII character (binary 001) cannot be placed in the SCCS file unless the **SOH** is escaped. This character has special meaning to SCCS [see *sccsfile*(4)] and will cause an error.

A get of many SCCS files, followed by a *delta* of those files, should be avoided when the get generates a large amount of data. Instead, multiple get/delta sequences should be used.

If the standard input (-) is specified on the *delta* command line, the $-\mathbf{m}$ (if necessary) and $-\mathbf{y}$ keyletters *must* also be present. Omission of these keyletters causes an error to occur.

Comments are limited to text strings of at most 512 characters.

DIAGNOSTICS

Use *help*(1) for explanations.

dis – object code disassembler

SYNOPSIS

dis [-o] [-V] [-L] [-s] [-d sec] [-da sec] [-F function] [-t sec] [-l string] file ...

DESCRIPTION

The *dis* command produces an assembly language listing of *file*, which may be an object file or an archive of object files. The listing includes assembly statements and an octal or hexadecimal representation of the binary that produced those statements.

The following *options* are interpreted by the disassembler and may be specified in any order.

- -o Print numbers in octal. The default is hexadecimal.
- -V Print, on standard error, the version number of the disassembler being executed.
- -L Look up source labels in the symbol table for subsequent printing. This option works only if the file was compiled with additional debugging information [e.g., the **-g** option of *cc*(1)].
- -s Perform symbolic disassembly, i.e., specify source symbol names for operands where possible. Symbolic disassembly output will appear on the line following the instruction. For maximal symbolic disassembly to be performed, the file must be compiled with additional debugging information [e.g., the -g option of cc(1)]. Symbol names will be printed using C syntax.
- -d sec Disassemble the named section as data, printing the offset of the data from the beginning of the section.
- -da sec Disassemble the named section as data, printing the actual address of the data.
- **-F** *function* Disassemble only the named function in each object file specified on the command line. The **-F** option may be specified multiple times on the command line.
- -t sec Disassemble the named section as text.
- -1 string Disassemble the library file specified by string. For example, one would issue the command dis $-1 \times -1 \times 1$ to disassemble libx.a and libz.a. All libraries are assumed to be in *LIBDIR*.

If the **-d**, **-da** or **-t** options are specified, only those named sections from each user-supplied file name will be disassembled. Otherwise, all sections containing text will be disassembled.

On output, a number enclosed in brackets at the beginning of a line, such as [5], represents that the break-pointable line number starts with the following instruction. These line numbers will be printed only if the file was compiled with additional debugging information [e.g., the **-g** option of cc(1)]. An expression such as **<40>** in the operand field or in the symbolic

disassembly, following a relative displacement for control transfer instructions, is the computed address within the section to which control will be transferred. A function name will appear in the first column, followed by ().

FILES

LIBDIR usually /lib.

SEE ALSO

as(1), cc(1), ld(1), a.out(4).

DIAGNOSTICS

The self-explanatory diagnostics indicate errors in the command line or problems encountered with the specified files.

dump – dump selected parts of an object file

SYNOPSIS

dump [options] files

DESCRIPTION

The *dump* command dumps selected parts of each of its object *file* arguments.

This command will accept both object files and archives of object files. It processes each file argument according to one or more of the following options:

- -a Dump the archive header of each member of each archive file argument.
- -g Dump the global symbols in the symbol table of an archive.
- -f Dump each file header.
- -o Dump each optional header.
- -h Dump section headers.
- -s Dump section contents.
- **-r** Dump relocation information.
- -1 Dump line number information.
- -t Dump symbol table entries.
- -z name Dump line number entries for the named function.
- -c Dump the string table.
- -L Interpret and print the contents of the *.lib* sections.

The following *modifiers* are used in conjunction with the options listed above to modify their capabilities.

- -d number Dump the section number, *number*, or the range of sections starting at *number* and ending at the *number* specified by +d.
- +d number Dump sections in the range either beginning with first section or beginning with section specified by -d.
- -**n** name Dump information pertaining only to the named entity. This *modifier* applies to -**h**, -**s**, -**r**, -**l**, and -**t**.
- -p Suppress printing of the headers.
- -t index Dump only the indexed symbol table entry. The -t used in conjunction with +t, specifies a range of symbol table entries.
- +t index Dump the symbol table entries in the range ending with the indexed entry. The range begins at the first symbol table entry or at the entry specified by the -t option.
- -u Underline the name of the file for emphasis.

Dump information in symbolic representation rather than -v numeric (e.g., C_STATIC instead of 0x02). This modifier can be used with all the above options except -s and -o options of dump.

-z name, number

Dump line number entry or range of line numbers starting at number for the named function.

+z number Dump line numbers starting at either function *name* or *number* specified by -z, up to number specified by +z.

Blanks separating an option and its modifier are optional. The comma separating the name from the number modifying the -z option may be replaced by a blank.

The *dump* command attempts to format the information it dumps in a meaningful way, printing certain information in character, hex, octal, or decimal representation as appropriate.

a.out(4), ar(4).

gence – create a front-end to the cc command

SYNOPSIS

gencc

DESCRIPTION

The gencc command is an interactive command designed to aid in the creation of a front-end to the cc command. Since hard-coded path names have been eliminated from the C Compilation System (CCS), it is possible to move pieces of the CCS to new locations without recompiling the CCS. The new locations of moved pieces can be specified through the **-Y** option to the cc command. However, it is inconvenient to supply the proper **-Y** options with every invocation of the cc command. Further, if a system administrator moves pieces of the CCS, such movement should be invisible to users.

The front-end to the *cc* command which *gencc* generates is a one-line shell script which calls the *cc* command with the proper $-\mathbf{Y}$ options specified. The front-end to the *cc* command will also pass all user supplied options to the *cc* command.

The gencc command prompts for the location of each tool and directory which can be respecified by a -Y option to the *cc* command. If no location is specified, it assumes that that piece of the CCS has not been relocated. After all the locations have been prompted for, *gencc* will create the frontend to the *cc* command.

The *gencc* command creates the front-end to the *cc* command in the current working directory and gives the file the same name as the *cc* command. Thus, *gencc* can not be run in the same directory containing the actual *cc* command. Further, if a system administrator has redistributed the CCS, the actual *cc* command should be placed somewhere which is not typically in a user's PATH (e.g., /lib). This will prevent users from accidentally invoking the *cc* command without using the front-end.

CAVEATS

The *gencc* command does not produce any warnings if a tool or directory does not exist at the specified location. Also, *gencc* does not actually move any files to new locations.

FILES

./cc

front-end to cc

cc(1).

get - get a version of an SCCS file

SYNOPSIS

get [-rSID] [-ccutoff] [-ilist] [-xlist] [-wstring] [-aseq-no.] [-k] [-e] [-l[p] [-p] [-m] [-n] [-s] [-b] [-g] [-t] file ...

DESCRIPTION

The get command generates an ASCII text file from each named SCCS file according to the specifications given by its keyletter arguments, which begin with –. The arguments may be specified in any order, but all keyletter arguments apply to all named SCCS files. If a directory is named, get behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.) and unreadable files are silently ignored. If a name of – is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed. Again, non-SCCS files and unreadable files are silently ignored.

The generated text is normally written into a file called the *g*-file whose name is derived from the SCCS file name by simply removing the leading **s**.; (see also *FILES*, below).

Each of the keyletter arguments is explained below as though only one SCCS file is to be processed, but the effects of any keyletter argument applies independently to each named file.

-rSID The SCCS IDentification string (SID) of the version (delta) of an SCCS file to be retrieved. Table⁻¹ below shows, for the most useful cases, what version of an SCCS file is retrieved [as well as the SID of the version to be eventually created by delta(1) if the -e keyletter is also used], as a function of the SID specified.

-c*cutoff Cutoff* date-time, in the form:

YY[MM[DD[HH[MM[SS]]]]]

No changes (deltas) to the SCCS file which were created after the specified *cutoff* date-time are included in the generated ASCII text file. Units omitted from the date-time default to their maximum possible values; that is, -c7502 is equivalent to -c750228235959. Any number of non-numeric characters may separate the various 2-digit pieces of the *cut-off* date-time. This feature allows one to specify a *cutoff* date in the form: "-c77/2/2 9:22:25". Note that this implies that one may use the %E% and %U% identification keywords (see below) for nested *gets*.

~!get "-c%E% %U%" s.file

-ilist

A *list* of deltas to be included (forced to be applied) in the creation of the generated file. The *list* has the following syntax:

t> ::= <range> | <list> , <range> <range> ::= SID | SID - SID

SID, the SCCS Identification of a delta, may be in any form shown in the "SID Specified" column of Table 1.

A *list* of deltas to be excluded in the creation of the generated file. See the -i keyletter for the *list* format.

-е

-b

-k

-xlist

Indicates that the *get* is for the purpose of editing or making a change (delta) to the SCCS file via a subsequent use of *delta*(1). The -e keyletter used in a *get* for a particular version (SID) of the SCCS file prevents further *gets* for editing on the same SID until *delta* is executed or the **j** (joint edit) flag is set in the SCCS file [see *admin*(1)]. Concurrent use of **get** -e for different SIDs is always allowed.

If the *g*-file generated by get with an $-\mathbf{e}$ keyletter is accidentally ruined in the process of editing it, it may be regenerated by re-executing the get command with the $-\mathbf{k}$ keyletter in place of the $-\mathbf{e}$ keyletter.

SCCS file protection specified via the ceiling, floor, and authorized user list stored in the SCCS file [see admin(1)] are enforced when the -e keyletter is used.

Used with the -e keyletter to indicate that the new delta should have an SID in a new branch as shown in Table 1. This keyletter is ignored if the **b** flag is not present in the file [see *admin*(1)] or if the retrieved *delta* is not a leaf *delta*. (A leaf *delta* is one that has no successors on the SCCS file tree.)

Note: A branch *delta* may always be created from a non-leaf *delta*. Partial SIDs are interpreted as shown in the "SID Retrieved" column of Table 1.

- Suppresses replacement of identification keywords (see below) in the retrieved text by their value. The $-\mathbf{k}$ keyletter is implied by the $-\mathbf{e}$ keyletter.
- -l[p] Causes a delta summary to be written into an *l-file*. If -lp is used, then an *l-file* is not created; the delta summary is written on the standard output instead. See *FILES* for the format of the *l-file*.
- -p Causes the text retrieved from the SCCS file to be written on the standard output. No *g-file* is created. All output which normally goes to the standard output goes to file descriptor 2 instead, unless the -s keyletter is used, in which case it disappears.

- -s Suppresses all output normally written on the standard output. However, fatal error messages (which always go to file descriptor 2) remain unaffected.
- -m Causes each text line retrieved from the SCCS file to be preceded by the SID of the delta that inserted the text line in the SCCS file. The format is: SID, followed by a horizontal tab, followed by the text line.
- -n Causes each generated text line to be preceded with the %M% identification keyword value (see below). The format is: %M% value, followed by a horizontal tab, followed by the text line. When both the -m and -n keyletters are used, the format is: %M% value, followed by a horizontal tab, followed by the -m keyletter generated format.
- -g Suppresses the actual retrieval of text from the SCCS file. It is primarily used to generate an *l-file*, or to verify the existence of a particular SID.
- -t Used to access the most recently created delta in a given release (e.g., -r1), or release and level (e.g., -r1.2).
- -w string Substitute string for all occurrences of %W% when getting the file.
- -aseq-no. The delta sequence number of the SCCS file delta (version) to be retrieved [see sccsfile(5)]. This keyletter is used by the comb(1) command; it is not a generally useful keyletter. If both the -r and -a keyletters are specified, only the -a keyletter is used. Care should be taken when using the -a keyletter in conjunction with the -e keyletter, as the SID of the delta to be created may not be what one expects. The -r keyletter can be used with the -a and -e keyletters to control the naming of the SID of the delta to be created.

For each file processed, *get* responds (on the standard output) with the SID being accessed and with the number of lines retrieved from the SCCS file.

If the -e keyletter is used, the SID of the delta to be made appears after the SID accessed and before the number of lines generated. If there is more than one named file or if a directory or standard input is named, each file name is printed (preceded by a new-line) before it is processed. If the -i keyletter is used, included deltas are listed following the notation "Included"; if the -x keyletter is used, excluded deltas are listed following the notation "Excluded".

	IADLE I. De	termination of SCCS I	dentification 5	tring

R.L.B.S		Branch succ.	R.L.B.S	R.L.(mB+1).1

TABLE 1. Determination of SCCS Identification String

"R", "L", "B", and "S" are the "release", "level", "branch", and "sequence" components of the SID, respectively; "m" means "maximum". Thus, for example, "R.mL" means "the maximum level number within release R"; "R.L.(mB+1).1" means "the first sequence number on the *new* branch (i.e., maximum branch number plus one) of level L within release R". Note that if the SID specified is of the form "R.L", "R.L.B", or "R.L.B.S", each of the specified components *must* exist.

** "hR" is the highest *existing* release that is lower than the specified, *nonexistent*, release R.

*** This is used to force creation of the *first* delta in a *new* release.

Successor.

*

† The -b keyletter is effective only if the b flag [see admin(1)] is present in the file. An entry of - means "irrelevant".

‡ This case applies if the **d** (default SID) flag is *not* present in the file. If the **d** flag *is* present in the file, then the SID obtained from the **d** flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

IDENTIFICATION KEYWORDS

Identifying information is inserted into the text retrieved from the SCCS file by replacing *identification keywords* with their value wherever they occur. The following keywords may be used in the text stored in an SCCS file:

Keyword Value %**M**% Module name: either the value of the **m** flag in the file [see admin(1)], or if absent, the name of the SCCS file with the leading s. removed. SCCS identification (SID) (%R%.%L%.%B%.%S%) of the **%I%** retrieved text. %**R**% Release. %L% Level. %**B**% Branch. %S% Sequence. %D% Current date (YY/MM/DD). %**H**% Current date (MM/DD/YY). %T% Current time (HH:MM:SS). %E% Date newest applied delta was created (YY/MM/DD). %G% Date newest applied delta was created (MM/DD/YY). %U% Time newest applied delta was created (HH:MM:SS). %Y% Module type: value of the t flag in the SCCS file [see admin(1)]. %F% SCCS file name. %**P**% Fully qualified SCCS file name. %**O**% The value of the **q** flag in the file [see admin(1)]. %C% Current line number. This keyword is intended for identifying messages output by the program such as "this should not have happened" type errors. It is *not* intended to be used on every line to provide sequence numbers. %Z% The 4-character string $(\mathbf{a}(\mathbf{#}))$ recognizable by what(1). %W% A shorthand notation for constructing what(1) strings for UNIX W% = %Z% M%-horizontalsystem program files. tab>%I% %A% Another shorthand notation for constructing what(1) strings for non-UNIX system program files. A% = %Z%%Y%%M%%I%%Z%

Several auxiliary files may be created by get. These files are known generically as the g-file, l-file, p-file, and z-file. The letter before the hyphen is called the tag. An auxiliary file name is formed from the SCCS file name: the last component of all SCCS file names must be of the form s.module-name, the auxiliary files are named by replacing the leading s with the tag. The g-file is an exception to this scheme: the g-file is named by removing the s. prefix. For example, s.xyz.c, the auxiliary file names would be xyz.c, l.xyz.c, p.xyz.c, and z.xyz.c, respectively.

The *g*-file, which contains the generated text, is created in the current directory (unless the $-\mathbf{p}$ keyletter is used). A *g*-file is created in all cases, whether or not any lines of text were generated by the *get*.

It is owned by the real user. If the -k keyletter is used or implied, its mode is 644; otherwise its mode is 444. Only the real user need have write permission in the current directory.

The *l-file* contains a table showing which deltas were applied in generating the retrieved text. The *l-file* is created in the current directory if the -1 keyletter is used; its mode is 444 and it is owned by the real user. Only the real user need have write permission in the current directory.

Lines in the *l-file* have the following format:

- a. A blank character if the delta was applied;
 - * otherwise.
- b. A blank character if the delta was applied or was not applied and ignored;
 - * if the delta was not applied and was not ignored.
- c. A code indicating a "special" reason why the delta was or was not applied:
 - "I": Included.
 - "X": Excluded.
 - "C": Cut off (by a **-c** keyletter).
- d. Blank.
- e. SCCS identification (SID).
- f. Tab character.
- g. Date and time (in the form YY/MM/DD HH:MM:SS) of creation.
- h. Blank.
- i. Login name of person who created *delta*.

The comments and **MR** data follow on subsequent lines, indented one horizontal tab character. A blank line terminates each entry.

The *p*-file is used to pass information resulting from a get with a -e keyletter along to delta. Its contents are also used to prevent a subsequent execution of get with a -e keyletter for the same SID until delta is executed or the joint edit flag, **j**, [see admin(1)] is set in the SCCS file. The *p*-file is created in the directory containing the SCCS file and the effective user must have write permission in that directory. Its mode is 644 and it is owned by the effective user. The format of the *p*-file is: the gotten SID, followed by a blank, followed by the SID that the new delta will have when it is made, followed by a blank, followed by the login name of the real user, followed by a blank and the -i keyletter argument if it was present, followed by a blank. There can be an arbitrary number of lines in the *p*-file at any time; no two lines can have the same new delta SID.

The *z*-file serves as a lock-out mechanism against simultaneous updates. Its contents are the binary (2 bytes) process ID of the command (i.e., get) that created it. The *z*-file is created in the directory containing the SCCS file for the duration of get. The same protection restrictions as those for the *p*-file apply for the *z*-file. The *z*-file is created mode 444.

FILES

g-file	Existed before the execution of <i>delta</i> ; removed after completion of <i>delta</i> .
p-file	Existed before the execution of <i>delta</i> ; may exist after completion of <i>delta</i> .
q-file	Created during the execution of <i>delta</i> ; removed after completion of <i>delta</i> .
x-file	Created during the execution of <i>delta</i> ; renamed to SCCS file after completion of <i>delta</i> .
z-file	Created during the execution of <i>delta</i> ; removed during the execution of <i>delta</i> .
d-file	Created during the execution of <i>delta</i> ; removed after completion of <i>delta</i> .
/usr/bin/bdiff	Program to compute differences between the "gotten" file and the <i>g-file</i> .

SEE ALSO

DIAGNOSTICS

Use *help*(1) for explanations.

BUGS

If the effective user has write permission (either explicitly or implicitly) in the directory containing the SCCS files, but the real user does not, then only one file may be named when the -e keyletter is used.

i286emul - emulate 80286

SYNOPSIS

i286emul [arg ...] prog286

DESCRIPTION

1286emul is an emulator that allows programs from UNIX System V Release 2 or Release 3 on the Intel 80286 to run on UNIX System V Release 3 on the Intel 80386.

The UNIX system recognizes an attempt to exec(2) a 286 program, and automatically *exec's* the 286 emulator with the 286 program name as an additional argument. It is not necessary to specify the *i286emul* emulator on the command line. The 286 programs can be invoked using the same command format as on the 286 UNIX System V.2 or V.3.

1286emul reads the 286 program's text and data into memory and maps them through the LDT [via sysi86(2)] as 286 text and data segments. It also sets callgate 89 in the GDT (which is used by 286 programs for system calls) to point to a routine in *i286emul*. *1286emul* starts the 286 program by jumping to its entry point.

When the 286 program attempts to do a system call, *i286emul* takes control. It does any conversions needed between the 286 system call and the equivalent 386 system call, and performs the 386 system call. The results are converted to the form the 286 program expects, and the 286 program is resumed.

The following are some of the differences between a program running on a 286 and a 286 program using *i286emul* on a 386:

A 286 program under *i286emul* always has 64k in the stack segment if it is a large-model process, or 64k in the data segment if it is a small-model process.

System calls and signal handling use more space on the stack under *i286emul* than it does on a 286.

Attempts to unlink or write on the 286 program will fail on the 286 with ETXTBSY. Under *i286emul*, they will not fail.

Ptrace(2) is not supported under *i286emul*.

The 286 program must be readable for the emulator to read it.

FILES

/bin/i286emul

The emulator must have this name and be in **/bin** if it is to be automatically invoked when exec(2) is used on a 286 program.

BUGS

The signal mechanism under the emulator is the System V release 2 signal mechanism rather than the System V release 3 mechanism.

infocmp - compare or print out terminfo descriptions

SYNOPSIS

infocmp [-d] [-c] [-n] [-I] [-L] [-C] [-r] [-u] [-s dliilic] [-v] [-V] [-1] [-w width] [-A directory] [-B directory] [termname ...]

DESCRIPTION

infocmp can be used to compare a binary terminfo(4) entry with other terminfo entries, rewrite a terminfo(4) description to take advantage of the **use**= terminfo field, or print out a terminfo(4) description from the binary file (term(4)) in a variety of formats. In all cases, the boolean fields will be printed first, followed by the numeric fields, followed by the string fields.

Default Options

If no options are specified and zero or one *termnames* are specified, the $-\mathbf{I}$ option will be assumed. If more than one *termname* is specified, the $-\mathbf{d}$ option will be assumed.

Comparison Options [-d] [-c] [-n]

infocmp compares the terminfo(4) description of the first terminal termname with each of the descriptions given by the entries for the other terminal's termnames. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: **F** for boolean variables, -1 for integer variables, and NULL for string variables.

- -d produce a list of each capability that is different. In this manner, if one has two entries for the same terminal or similar terminals, using *infocmp* will show what is different between the two entries. This is sometimes necessary when more than one person produces an entry for the same terminal and one wants to see what is different between the two.
- -c produce a list of each capability that is common between the two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the -u option is worth using.
- -n produce a list of each capability that is in neither entry. If no termnames are given, the environment variable TERM will be used for both of the termnames. This can be used as a quick check to see if anything was left out of the description.

Source Listing Options [-I] [-L] [-C] [-r]

The -I, -L, and -C options will produce a source listing for each terminal named.

- -I use the *terminfo*(4) names
- -L use the long C variable name listed in <term.h>
- -C use the *termcap* names
- **-r** when using **-C**, put out all capabilities in *termcap* form

If no *termnames* are given, the environment variable **TERM** will be used for the terminal name.

The source produced by the -C option may be used directly as a *termcap* entry, but not all of the parameterized strings may be changed to the *termcap* format. *infocmp* will attempt to convert most of the parameterized information, but that which it doesn't will be plainly marked in the output and commented out. These should be edited by hand.

All padding information for strings will be collected together and placed at the beginning of the string where *termcap* expects it. Mandatory padding (padding information with a trailing '/') will become optional.

All *termcap* variables no longer supported by *terminfo*(4), but which are derivable from other *terminfo*(4) variables, will be output. Not all *terminfo*(4) capabilities will be translated; only those variables which were part of *termcap* will normally be output. Specifying the $-\mathbf{r}$ option will take off this restriction, allowing all capabilities to be output in *termcap* form.

Note that because padding is collected to the beginning of the capability, not all capabilities are output, mandatory padding is not supported, and *termcap* strings were not as flexible, it is not always possible to convert a *terminfo*(4) string capability into an equivalent *termcap* format. Not all of these strings will be able to be converted. A subsequent conversion of the *termcap* file back into *terminfo*(4) format will not necessarily reproduce the original *terminfo*(4) source.

Some common *terminfo* parameter sequences, their *termcap* equivalents, and some terminal types which commonly have such sequences, are:

Terminfo	Termcap	Representative Terminals
%p1%c	%.	adm
%p1%d %p1%'x'%+%c	%d %+x	hp, ANSI standard, vt100
%p1% x %+%c	%+x %i	concept ANSI standard, vt100
%p1%?%'x'%>%t%p1%'y'%+%;	%>xy	concept
%p2 is printed before %p1	%r	hp

Use= Option [-u]

-11

produce a *terminfo*(4) source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals *termnames*. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with **use**= fields for the other terminals. In this manner, it is possible to retrofit generic terminals exist, but were coded at different times or by different people so that each description is a full description, using *infocmp* will show what can be done to change one description to be relative to the other.

A capability will get printed with an at-sign (@) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value gets printed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other

-s

termname entries that has this capability gives a different value for the capability than that in the first *termname*.

The order of the other *termname* entries is significant. Since the terminfo compiler **tic**(1M) does a left-to-right scan of the capabilities, specifying two **use**= entries that contain differing entries for the same capabilities will produce different results depending on the order that the entries are given in. *infocmp* will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a **use**= entry that contains that capability will cause the second specification to be ignored. Using *infocmp* to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying extra **use**= fields that are superfluous. *infocmp* will flag any other *termname* **use**= fields that were not needed.

Other Options [-s dlillc] [-v] [-V] [-1] [-w width]

sort the fields within each type according to the argument below:

- **d** leave fields in the order that they are stored in the *terminfo* database.
- **i** sort by *terminfo* name.
- **1** sort by the long C variable name.
- **c** sort by the *termcap* name.

If no -s option is given, the fields printed out will be sorted alphabetically by the *terminfo* name within each type, except in the case of the -C or the -L options, which cause the sorting to be done by the *termcap* name or the long C variable name, respectively.

- -v print out tracing information on standard error as the program runs.
- -V print out the version of the program in use on standard error and exit.
- -1 cause the fields to printed out one to a line. Otherwise, the fields will be printed several to a line to a maximum width of 60 characters.
- **-w** change the output to width characters.

Changing Databases [-A directory] [-B directory]

The location of the compiled terminfo(4) database is taken from the environment variable **TERMINFO**. If the variable is not defined, or the terminal is not found in that location, the system terminfo(4) database, usually in /usr/lib/terminfo, will be used. The options **-A** and **-B** may be used to override this location. The **-A** option will set **TERMINFO** for the first *termname* and the **-B** option will set **TERMINFO** for the other *termnames*. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing

descriptions for the same terminal created by different people. Otherwise the terminals would have to be named differently in the *terminfo*(4) database for a comparison to be made.

FILES

/usr/lib/terminfo/?/* compiled terminal description database

DIAGNOSTICS

malloc is out of space!

There was not enough memory available to process all the terminal descriptions requested. Run *infocmp* several times, each time including a subset of the desired *termnames*.

use= order dependency found:

A value specified in one relative terminal specification was different from that in another relative terminal specification.

'use=*term*' did not add anything to the description.

A relative terminal name did not contribute anything to the final description.

must have at least two terminal names for a comparison to be done.

The -u, -d and -c options require at least two terminal names.

NOTE

The *termcap* database (from earlier releases of UNIX System V) may not be supplied in future releases.

install – install commands

SYNOPSIS

/etc/install [-c dira] [-f dirb] [-i] [-n dirc] [-m mode] [-u user] [-g
group] [-0] [-s] file [dirx ...]

DESCRIPTION

The *install* command is most commonly used in "makefiles" [see make(1)] to install a *file* (updated target file) in a specific place within a file system. Each *file* is installed by copying it into the appropriate directory, thereby retaining the mode and owner of the original command. The program prints messages telling the user exactly what files it is replacing or creating and where they are going.

If no options or directories ($dirx \dots$) are given, *install* will search a set of default directories (**/bin**, **/usr/bin**, **/etc**, **/lib**, and **/usr/lib**, in that order) for a file with the same name as *file*. When the first occurrence is found, *install* issues a message saying that it is overwriting that file with *file*, and proceeds to do so. If the file is not found, the program states this and exits without further action.

If one or more directories (dirx ...) are specified after *file*, those directories will be searched before the directories specified in the default list.

The meanings of the options are:

. meanings of the	options are.
-c dira	Installs a new command (<i>file</i>) in the directory speci- fied by <i>dira</i> , only if it is not found. If it is found, <i>install</i> issues a message saying that the file already exists, and exits without overwriting it. May be used alone or with the $-s$ option.
-f dirb	Forces <i>file</i> to be installed in given directory, whether or not one already exists. If the file being installed does not already exist, the mode and owner of the new file will be set to 755 and bin , respectively. If the file already exists, the mode and owner will be that of the already existing file. May be used alone or with the -0 or $-\mathbf{s}$ options.
-i	Ignores default directory list, searching only through the given directories ($dirx$). May be used alone or with any other options except $-c$ and $-f$.
-n dirc	If <i>file</i> is not found in any of the searched directories, it is put in the directory specified in <i>dirc</i> . The mode and owner of the new file will be set to 755 and bin , respectively. May be used alone or with any other options except $-c$ and $-f$.
-m mode	The mode of the new file is set to <i>mode</i> . Only available to the superuser.
-u user	The owner of the new file is set to <i>user</i> . Only available to the superuser.

INSTALL(1M) (Extended Software Generation System Utilities) INSTALL(1M)

- -g group The group id of the new file is set to group. Only available to the superuser.
- -0 If *file* is found, this option saves the "found" file by copying it to OLD*file* in the directory in which it was found. This option is useful when installing a frequently used file such as */bin/sh* or */etc/getty*, where the existing file cannot be removed. May be used alone or with any other options except -c.
- -s Suppresses printing of messages other than error messages. May be used alone or with any other options.

SEE ALSO make(1).

- 2 -

ld – link editor for common object files

SYNOPSIS

ld [options] file name

DESCRIPTION

The *ld* command combines several object files into one, performs relocation, resolves external symbols, and supports symbol table information for symbolic debugging. In the simplest case, the names of several object programs are given, and *ld* combines the objects, producing an object module that can either be executed or, if the **-r** option is specified, used as input for a subsequent *ld* run. The output of *ld* is left in **a.out**. By default this file is executable if no errors occurred during the load. If any input file, *filename*, is not an object file, *ld* assumes it is either an archive library or a text file containing link editor directives. [See *Link Editor Directives* in the *UNIX System V Programmer's Guide* for a discussion of input directives.]

If any argument is a library, it is searched exactly once at the point it is encountered in the argument list. The library may be either a relocatable archive library or a shared library. [See *Shared Libraries* in the UNIX System V Programmer's Guide for a discussion of shared libraries.] Only those routines defining an unresolved external reference are loaded. The library (archive) symbol table [see ar(4)] is searched sequentially with as many passes as are necessary to resolve external references which can be satisfied by library members. Thus, the ordering of library members is functionally unimportant, unless there exist multiple library members defining the same external symbol.

The following options are recognized by *ld*:

-e epsym

Set the default entry point address for the output file to be that of the symbol *epsym*.

- -f fill Set the default fill pattern for "holes" within an output section as well as initialized *bss* sections. The argument fill is a two-byte constant.
- -kx (80286 only) Set the allocated stack area to x, where x is the number of bytes you wish to allocate for the stack. The value entered will be rounded up to a multiple of 512 bytes.
- -1x Search a library **lib***x***.a**, where *x* is up to nine characters. A library is searched when its name is encountered, so the placement of a -1 is significant. By default, libraries are located in *LIBDIR* or *LLIBDIR*.
- -m Produce a map or listing of the input/output sections on the standard output.

-o outfile

Produce an output object file by the name *outfile*. The name of the default object file is **a.out**.

-r Retain relocation entries in the output object file. Relocation entries must be saved if the output file is to become an input file in a

LD(1)

subsequent *ld* run. The link editor will not complain about unresolved references, and the output file will not be executable.

- -a Create an absolute file. This is the default if the -r option is not used. Used with the -r option, -a allocates memory for common symbols.
- -s Strip line number entries and symbol table information from the output object file.
- -t Turn off the warning about multiply-defined symbols that are not the same size.
- -u symnare

Enter *symname* as an undefined symbol in the symbol table. This is useful for loading entirely from a library, since initially the symbol table is empty and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the *ld* line is significant; it must be placed before the library which will define the symbol.

- -x Do not preserve local symbols in the output symbol table; enter external and static symbols only. This option saves some space in the output file.
- -z Do not bind anything to address zero. This option will allow runtime detection of null pointers.
- -L dir Change the algorithm of searching for libx.a to look in dir before looking in LIBDIR and LLIBDIR. This option is effective only if it precedes the -l option on the command line.
- -M Output a message for each multiply-defined external definition.
- -N Put the text section at the beginning of the text segment rather than after all header information, and put the data section immediately following text in the core image.
- -R (80286 only) Real address mode linkage.
- -V Output a message giving information about the version of ld being used.
- -VS num

Use *num* as a decimal version stamp identifying the **a.out** file that is produced. The version stamp is stored in the optional header.

-Y[LU],dir

Change the default directory used for finding libraries. If L is specified the first default directory which *ld* searches, *LIBDIR*, is replaced by *dir*. If U is specified and ld has been built with a second default directory, *LLIBDIR*, then that directory is replaced by *dir*. If ld was built with only one default directory and U is specified a warning is printed and the option is ignored.

FILES

LIBDIR/libx.a	libraries
LLIBDIR/libx.a	libraries
a.out	output file
LIBDIR	usually /lib
LLIBDIR	usually /usr/lib
/lib/ <model>/libx.a</model>	libraries (80286 only)
/usr/lib/ <model>/libx.a</model>	libraries (80286 only)
where " <model>" is either small or large.</model>	

SEE ALSO

as(1), cc(1), mkshlib(1), exit(2), end(3C), a.out(4), ar(4), and Link Editor Directives and Shared Libraries in the Programmer's Guide.

CAVEATS

Through its options and input directives, the common link editor gives users great flexibility; however, those who use the input directives must assume some added responsibilities. Input directives and options should insure the following properties for programs:

- C defines a zero pointer as null. A pointer to which zero has been assigned must not point to any object. To satisfy this, users must not place any object at virtual address zero in the program's address space.
- When the link editor is called through *cc*(1), a startup routine is linked with the user's program. This routine calls exit() [see *exit*(2)] after execution of the main program. If the user calls the link editor directly, then the user must insure that the program always calls exit() rather than falling through the end of the entry routine.

The symbols *etext*, *edata*, and *end* [see *end*(3C)] are reserved and are defined by the link editor. It is incorrect for a user program to redefine them.

If the link editor does not recognize an input file as an object file or an archive file, it will assume that it contains link editor directives and will attempt to parse it. This will occasionally produce an error message complaining about "syntax errors".

Arithmetic expressions may only have one forward referenced symbol per expression.

lex – generate programs for simple lexical tasks

SYNOPSIS

lex [-rctvn] [file] ...

DESCRIPTION

The *lex* command generates programs to be used in simple lexical analysis of text.

The input *files* (standard input default) contain strings and expressions to be searched for, and C text to be executed when strings are found.

A file **lex.yy.c** is generated which, when loaded with the library, copies the input to the output except when a string specified in the file is found; then the corresponding program text is executed. The actual string matched is left in yytext, an external character array. Matching is done in order of the strings in the file. The strings may contain square brackets to indicate character classes, as in [abx-z] to indicate a, b, x, y, and z; and the operators *, +, and ? mean respectively any non-negative number of, any positive number of, and either zero or one occurrence of, the previous character or character class. The character . is the class of all ASCII characters except new-line. Parentheses for grouping and vertical bar for alternation are also supported. The notation $r\{d,e\}$ in a rule indicates between d and e instances of regular expression r. It has higher precedence than I, but lower than *, ?, +, and concatenation. Thus [a-zA-Z]+ matches a string of letters. The character at the beginning of an expression permits a successful match only immediately after a new-line, and the character \$ at the end of an expression requires a trailing new-line. The character / in an expression indicates trailing context; only the part of the expression up to the slash is returned in *yytext*, but the remainder of the expression must follow in the input stream. An operator character may be used as an ordinary symbol if it is within " symbols or preceded by \setminus .

Three subroutines defined as macros are expected: **input()** to read a character; **unput(c)** to replace a character read; and **output(c)** to place an output character. They are defined in terms of the standard streams, but you can override them. The program generated is named **yylex()**, and the library contains a **main()** which calls it. The action REJECT on the right side of the rule causes this match to be rejected and the next suitable match executed; the function **yymore()** accumulates additional characters into the same *yytext*; and the function **yyless(***p***)** pushes back the portion of the string matched beginning at *p*, which should be between *yytext* and *yytext+yyleng*. The macros *input* and *output* use files **yyin** and **yyout** to read from and write to, defaulted to **stdin** and **stdout**, respectively.

Any line beginning with a blank is assumed to contain only C text and is copied; if it precedes %%, it is copied into the external definition area of the **lex.yy.c** file. All rules should follow a %%, as in YACC. Lines preceding %% which begin with a non-blank character define the string on the left to be the remainder of the line; it can be called out later by surrounding it with {}. Note that curly brackets do not imply parentheses; only string substitution is done.

EXAMPLE

D	[0-9]
%%	
if	<pre>printf("IF statement\n");</pre>
[a-z]+	printf("tag, value %s\n",yytext);
	printf("octal number %s\n",yytext);
	printf("decimal number %s\n",yytext);
`++"	
"+"	
"/*"	skipcommnts();
%%	1 07
skipcor	nmnts()
{	v
,	for (;;)
	{
	while (input() != '*')
	;
	if (input() != '/')
	unput(yytext[yyleng-1]);
	else
	return;
	}
}	

The external names generated by *lex* all begin with the prefix yy or YY.

The flags must appear before any files. The flag $-\mathbf{r}$ indicates RATFOR actions, $-\mathbf{c}$ indicates C actions and is the default, $-\mathbf{t}$ causes the **lex.yy.c** program to be written instead to standard output, $-\mathbf{v}$ provides a one-line summary of statistics, $-\mathbf{n}$ will not print out the $-\mathbf{v}$ summary. Multiple files are treated as a single file. If no files are specified, standard input is used.

Certain table sizes for the resulting finite state machine can be set in the definitions section:

- p n number of positions is *n* (default 2500)
- %**n** number of states is *n* (500)
- **%e** n number of parse tree nodes is n (1000)
- %a *n* number of transitions is *n* (2000)
- % k n number of packed character classes is n (1000)
- **%0** *n* size of output array is n (3000)

The use of one or more of the above automatically implies the $-\mathbf{v}$ option, unless the $-\mathbf{n}$ option is used.

yacc(1). Programmer's Guide.

BUGS

The **-r** option is not yet fully operational.

lint - a C program checker

SYNOPSIS

lint [option] ... file ...

DESCRIPTION

The *lint* command attempts to detect features of the C program files that are likely to be bugs, non-portable, or wasteful. It also checks type usage more strictly than the compilers. Among the things that are currently detected are unreachable statements, loops not entered at the top, automatic variables declared and not used, and logical expressions whose value is constant. Moreover, the usage of functions is checked to find functions that return values in some places and not in others, functions called with varying numbers or types of arguments, and functions whose values are not used or whose values are used but none returned.

Arguments whose names end with .c are taken to be C source files. Arguments whose names end with .ln are taken to be the result of an earlier invocation of *lint* with either the -c or the -o option used. The .ln files are analogous to .o (object) files that are produced by the cc(1) command when given a .c file as input. Files with other suffixes are warned about and ignored.

The *lint* command will take all the .c, .ln, and **llib-lx.ln** (specified by -lx) files and process them in their command line order. By default, *lint* appends the standard C lint library (**llib-lc.ln**) to the end of the list of files. However, if the -p option is used, the portable C lint library (**llib-port.ln**) is appended instead. When the -c option is not used, the second pass of *lint* checks this list of files for mutual compatibility. When the -c option is used, the .ln and the **llib-lx.ln** files are ignored.

Any number of *lint* options may be used, in any order, intermixed with file-name arguments. The following options are used to suppress certain kinds of complaints:

- -a Suppress complaints about assignments of long values to variables that are not long.
- -b Suppress complaints about **break** statements that cannot be reached. (Programs produced by *lex* or *yacc* will often result in many such complaints.)
- -h Do not apply heuristic tests that attempt to intuit bugs, improve style, and reduce waste.
- -u Suppress complaints about functions and external variables used and not defined, or defined and not used. (This option is suitable for running *lint* on a subset of files of a larger program.)
- -v Suppress complaints about unused arguments in functions.
- -x Do not report variables referred to by external declarations but never used.

The following arguments alter *lint*'s behavior:

- -lx Include additional lint library llib-lx.ln. For example, you can include a lint version of the math library llib-lm.ln by inserting -lm on the command line. This argument does not suppress the default use of llib-lc.ln. These lint libraries must be in the assumed directory. This option can be used to reference local lint libraries and is useful in the development of multifile projects.
- -n Do not check compatibility against either the standard or the portable lint library.
- -p Attempt to check portability to other dialects (IBM and GCOS) of C. Along with stricter checking, this option causes all non-external names to be truncated to eight characters and all external names to be truncated to six characters and one case.
- -c Cause *lint* to produce a .ln file for every .c file on the command line. These .ln files are the product of *lint*'s first pass only, and are not checked for inter-function compatibility.
- -o lib Cause *lint* to create a lint library with the name llib-llib.ln. The -c option nullifies any use of the -o option. The lint library produced is the input that is given to *lint's* second pass. The -o option simply causes this file to be saved in the named lint library. To produce a llib-llib.ln without extraneous messages, use of the -x option is suggested. The -v option is useful if the source file(s) for the lint library are just external interfaces (for example, the way the file llib-lc is written). These option settings are also available through the use of "lint comments" (see below).

The -D, -U, and -I options of cpp(1) and the -g and -O options of cc(1) are also recognized as separate arguments. The -g and -O options are ignored, but, by recognizing these options, *lint*'s behavior is closer to that of the cc(1) command. Other options are warned about and ignored. The preprocessor symbol "lint" is defined to allow certain questionable code to be altered or removed for *lint*. Therefore, the symbol "lint" should be thought of as a reserved word for all code that is planned to be checked by *lint*.

Certain conventional comments in the C source will change the behavior of *lint*:

/*NOTREACHED*/

at appropriate points stops comments about unreachable code. [This comment is typically placed just after calls to functions like *exit*(2)].

/*VARARGSn*/

suppresses the usual checking for variable numbers of arguments in the following function declaration. The data types of the first n arguments are checked; a missing n is taken to be 0.

/*ARGSUSED*/

turns on the **-v** option for the next function.

LINT(1)

/*LINTLIBRARY*/

at the beginning of a file shuts off complaints about unused functions and function arguments in this file. This is equivalent to using the -v and -x options.

The *lint* command produces its first output on a per-source-file basis. Complaints regarding included files are collected and printed after all source files have been processed. Finally, if the -c option is not used, information gathered from all input files is collected and checked for consistency. At this point, if it is not clear whether a complaint stems from a given source file or from one of its included files, the source file name will be printed followed by a question mark.

The behavior of the -c and the -o options allows for incremental use of *lint* on a set of C source files. Generally, one invokes *lint* once for each source file with the -c option. Each of these invocations produces a **.In** file which corresponds to the **.c** file, and prints all messages that are about just that source file. After all the source files have been separately run through *lint*, it is invoked once more (without the -c option), listing all the **.In** files with the needed -Ix options. This will print all the interfile inconsistencies. This scheme works well with *make*(1); it allows *make* to be used to *lint* only the source files that have been modified since the last time the set of source files were *lint*ed.

FILES

LLIBDIR	the directory where the lint libraries specified by the
	-lx option must exist, usually /usr/lib
LLIBDIR/lint[12]	first and second passes
LLIBDIR/llib-lc.ln	declarations for C Library functions (binary format; source is in <i>LLIBDIR</i> /llib-lc)
LLIBDIR/llib-port.ln	declarations for portable functions (binary format; source is in <i>LLIBDIR</i> /llib-port)
LLIBDIR/llib-lm.ln	declarations for Math Library functions (binary for- mat; source is in LLIBDIR/llib-lm)
TMPDIR/*lint*	temporaries
TMPDIR	usually /usr/tmp but can be redefined by setting the environment variable TMPDIR [see <i>tempnam</i> () in <i>tmpnam</i> (3S)].

SEE ALSO

BUGS

exit(2), setjmp(3C), and other functions that do not return are not understood; this causes various lies.

list – produce C source listing from a common object file

SYNOPSIS

list [-V] [-h] [-F function] source-file . . . [object-file]

DESCRIPTION

The *list* command produces a C source listing with line number information attached. If multiple C source files were used to create the object file, *list* will accept multiple file names. The object file is taken to be the last non-C source file argument. If no object file is specified, the default object file, **a.out**, will be used.

Line numbers will be printed for each line marked as breakpoint inserted by the compiler (generally, each executable C statement that begins a new line of source). Line numbering begins anew for each function. Line number 1 is always the line containing the left curly brace ({) that begins the function body. Line numbers will also be supplied for inner block redeclarations of local variables so that they can be distinguished by the symbolic debugger.

The following options are interpreted by *list* and may be given in any order:

- -V Print, on standard error, the version number of the *list* command executing.
- -h Suppress heading output.
- -Ffunction List only the named function. The -F option may be specified multiple times on the command line.

SEE ALSO

as(1), cc(1), ld(1).

CAVEATS

Object files given to *list* must have been compiled with the -g option of cc(1).

Since *list* does not use the C preprocessor, it may be unable to recognize function definitions whose syntax has been distorted by the use of C preprocessor macro substitutions.

DIAGNOSTICS

The *list* command will produce the error message "list: name: cannot open" if *name* cannot be read. If the source file names do not end in .c , the message is "list: name: invalid C source name". An invalid object file will cause the message "list: name: bad magic" to be produced. If some or all of the symbolic debugging information is missing, one of the following messages will be printed: "list: name: symbols have been stripped, cannot proceed", "list: name: cannot read line numbers", and "list: name: not in symbol table". The following messages are produced when *list* has become confused by **#ifdef's** in the source file: "list: name: cannot find function in symbol table". The error message "list: name: missing or inappropriate line numbers" means that either symbol debugging information is missing, or *list* has been confused by C preprocessor statements.

lorder - find ordering relation for an object library

SYNOPSIS

lorder file ...

DESCRIPTION

The input is one or more object or library archive *files* [see ar(1)]. The standard output is a list of pairs of object file or archive member names, meaning that the first file of the pair refers to external identifiers defined in the second. The output may be processed by tsort(1) to find an ordering of a library suitable for one-pass access by ld(1). Note that the link editor ld(1) is capable of multiple passes over an archive in the portable archive format [see ar(4)] and does not require that lorder(1) be used when building an archive. The usage of the lorder(1) command may, however, allow for a slightly more efficient access of the archive during the link edit process.

The following example builds a new library from existing **.o** files.

ar -cr library 'lorder *.o | tsort'

FILES

TMPDIR/*symref temporary files

TMPDIR/*symdef temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

ar(1), ld(1), tsort(1), ar(4).

CAVEAT

The *lorder* command will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be **.o**.

m4 – macro processor

SYNOPSIS

m4 [options] [files]

DESCRIPTION

The m4 command is a macro processor intended as a front end for Ratfor, C, and other languages. Each of the argument files is processed in order; if there are no files, or if a file name is –, the standard input is read. The processed text is written on the standard output.

The options and their effects are as follows:

- -e Operate interactively. Interrupts are ignored and the output is unbuffered.
- -s Enable line sync output for the C preprocessor (#line ...)
- -Bint Change the size of the push-back and argument collection buffers from the default of 4,096.
- -Hint Change the size of the symbol table hash array from the default of 199. The size should be prime.
- -Sint Change the size of the call stack from the default of 100 slots. Macros take three slots, and non-macro arguments take one.
- -Tint Change the size of the token buffer from the default of 512 bytes.

To be effective, these flags must appear before any file names and before any **-D** or **-U** flags:

-Dname[=val]

Defines name to val or to null in val's absence.

-Uname

Undefines name.

Macro calls have the form:

name(arg1,arg2, ..., argn)

The (must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphabetic letters, digits, and underscore __, where the first character is not a digit.

Leading unquoted blanks, tabs, and new-lines are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.

When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be null. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses which happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned. The *m4* command makes available the following built-in macros. They may be redefined, but once this is done, the original meaning is lost. Their values are null unless otherwise stated.

- define the second argument is installed as the value of the macro whose name is the first argument. Each occurrence of \$n in the replacement text, where n is a digit, is replaced by the nth argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; \$# is replaced by the number of arguments; \$* is replaced by a list of all the arguments separated by commas; \$@ is like \$*, but each argument is quoted (with the current quotes).
- undefine removes the definition of the macro named in its argument.
- defn returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.
- pushdef like *define*, but saves any previous definition.
- popdef removes current definition of its argument(s), exposing the previous one, if any.
- if def if the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is null. The word unix is predefined on UNIX system versions of m4.
- shift returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.
- changequote change quote symbols to the first and second arguments. The symbols may be up to five characters long. *Changequote* without arguments restores the original values (i.e., '').
- changecom change left and right comment markers from the default # and new-line. With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes newline. With two arguments, both markers are affected. Comment markers may be up to five characters long.
- divert *m4* maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The *divert* macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.
- undivert causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.

divnum returns the value of the current output stream.

dnl reads and discards characters up to and including the next new-line.

- ifelse has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6, and 7. Otherwise, the value is either the fourth string, or, if it is not present, null.
- incr returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.

decr returns the value of its argument decremented by 1.

- eval evaluates its argument as an arithmetic expression, using 32bit arithmetic. Operators include +, -, *, /, %, (exponentiation), bitwise &, |, ^, and ~; relationals; parentheses. Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
- len returns the number of characters in its argument.
- index returns the position in its first argument where the second argument begins (zero origin), or -1 if the second argument does not occur.
- substr returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.
- translit transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.

include returns the contents of the file named in the argument.

- sinclude is identical to *include*, except that it says nothing if the file is inaccessible.
- syscmd executes the UNIX system command given in the first argument. No value is returned.
- sysval is the return code from the last call to *syscmd*.

maketemp fills in a string of XXXXX in its argument with the current process ID.

m4exit causes immediate exit from m4. Argument 1, if given, is the exit code; the default is 0.

M4(1)		(Software Generation System Utilities) M4(1)
	m4wrap	argument 1 will be pushed back at final EOF; example: m4wrap('cleanup()')
	errprint	prints its argument on the diagnostic output file.
	dumpdef	prints current names and definitions, for the named items, or for all if no arguments are given.
	traceon	with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.
	traceoff	turns off trace globally and for any macros specified. Macros specifically traced by <i>traceon</i> can be untraced only by specific calls to <i>traceoff</i> .

make - maintain, update, and regenerate groups of programs

SYNOPSIS

make [-f makefile] [-p] [-i] [-k] [-s] [-r] [-n] [-b] [-e] [-u] [-t] [-q] [names]

DESCRIPTION

The *make* command allows the programmer to maintain, update, and regenerate groups of computer programs. The following is a brief description of all options and some special names:

- -f makefile Description file name. makefile is assumed to be the name of a description file.
- -p Print out the complete set of macro definitions and target descriptions.
- -i Ignore error codes returned by invoked commands. This mode is entered if the fake target name .IGNORE appears in the description file.
- -k Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry.
- -s Silent mode. Do not print command lines before executing. This mode is also entered if the fake target name .SILENT appears in the description file.
- **-r** Do not use the built-in rules.
- -n No execute mode. Print commands, but do not execute them. Even lines beginning with an **@** are printed.
- -b Compatibility mode for old makefiles.
- -e Environment variables override assignments within makefiles.
- **-u** Force an unconditional update.
- -t Touch the target files (causing them to be up-to-date) rather than issue the usual commands.
- -q Question. The *make* command returns a zero or non-zero status code depending on whether the target file is or is not up-to-date.
- .DEFAULT If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name .DEFAULT are used if it exists.
- **.PRECIOUS** Dependents of this target will not be removed when quit or interrupt are hit.
- **.SILENT** Same effect as the **-s** option.
- **.IGNORE** Same effect as the **-i** option.

The *make* command executes commands in *makefile* to update one or more target *names*. *Name* is typically a program. If no -f option is present, **makefile**, **Makefile**, and the Source Code Control System(SCCS) files

s.makefile, and **s.Makefile** are tried in order. If *makefile* is –, the standard input is taken. More than one – *makefile* argument pair may appear.

The *make* command updates a target only if its dependents are newer than the target (unless the $-\mathbf{u}$ option is used to force an unconditional update). All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be out-of-date.

The *makefile* file contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a :, then a (possibly null) list of prerequisite files or dependencies. Text following a ; and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or *#* begins a new dependency or macro definition. Shell commands may be continued across lines with the
sequence. Everything printed by make (except the initial tab) is passed directly to the shell as is. Thus,

echo a∖ b

will produce

ab

exactly the same as the shell would.

Sharp (#) and new-line surround comments.

The following *makefile* says that **pgm** depends on two files **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**) and a common file **incl.h**:

```
pgm: a.o b.o
cc a.o b.o -o pgm
a.o: incl.h a.c
cc -c a.c
b.o: incl.h b.c
cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The SHELL environment variable can be used to specify which shell *make* should use to execute commands. The default is /bin/sh. The first one or two characters in a command can be the following: -, @, -@, or @-. If @ is present, printing of the command is suppressed. If - is present, *make* ignores an error. A line is printed when it is executed unless the -s option is present, or the entry .SILENT: is in *makefile*, or unless the initial character sequence contains a @. The -n option specifies printing without execution; however, if the command line has the string (MAKE) in it, the line is always executed (see discussion of the MAKEFLAGS macro under *Environment*). The -t (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate *make*. If the **-i** option is present, or the entry **.IGNORE:** appears in *makefile*, or the initial character sequence of the command contains –. the error is ignored. If the

-k option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

The **-b** option allows old makefiles (those written for the old version of *make*) to run without errors.

Interrupt and quit cause the target to be deleted unless the target is a dependent of the special name **.PRECIOUS**.

Environment

The environment is read by *make*. All variables are assumed to be macro definitions and processed as such. The environment variables are processed before any makefile and after the internal rules; thus, macro assignments in a makefile override environment variables. The -e option causes the environment to override the macro assignments in a makefile. Suffixes and their associated rules in the makefile will override any identical suffixes in the built-in rules.

The MAKEFLAGS environment variable is processed by *make* as containing any legal input option (except **-f** and **-p**) defined for the command line. Further, upon invocation, *make* "invents" the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, MAKEFLAGS always contains the current input options. This proves very useful for "super-makes". In fact, as noted above, when the **-n** option is used, the command **\$(MAKE)** is executed anyway; hence, one can perform a **make -n** recursively on a whole software system to see what would have been executed. This is because the **-n** is put in MAKEFLAGS and passed to further invocations of **\$(MAKE)**. This is one way of debugging all of the makefiles for a software project without actually doing anything.

Include Files

If the string *include* appears as the first seven letters of a line in a *makefile*, and is followed by a blank or a tab, the rest of the line is assumed to be a file name and will be read by the current invocation, after substituting for any macros.

Macros

Entries of the form string1 = string2 are macro definitions. String2 is defined as all characters up to a comment character or an unescaped newline. Subsequent appearances of (string1[:subst1=[subst2]]) are replaced by string2. The parentheses are optional if a single character macro name is used and there is no substitute sequence. The optional :subst1=subst2 is a substitute sequence. If it is specified, all non-overlapping occurrences of subst1 in the named macro are replaced by subst2. Strings (for the purposes of this type of substitution) are delimited by blanks, tabs, new-line characters, and beginnings of lines. An example of the use of the substitute sequence is shown under *Libraries*.

Internal Macros

There are five internally maintained macros which are useful for writing rules for building targets.

- \$* The macro \$* stands for the file name part of the current dependent with the suffix deleted. It is evaluated only for inference rules.
- \$@ The \$@ macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.
- \$< The \$< macro is only evaluated for inference rules or the .DEFAULT rule. It is the module which is out-of-date with respect to the target (i.e., the "manufactured" dependent file name). Thus, in the .c.o rule, the \$< macro would evaluate to the .c file. An example for making optimized .o files from .c files is:</p>

.c.o:

.c.o:

or:

cc –c –O \$<

- **\$?** The **\$?** macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are out-of-date with respect to the target; essentially, those modules which must be rebuilt.
- \$% The \$% macro is only evaluated when the target is an archive library member of the form lib(file.o). In this case, \$@ evaluates to lib and \$% evaluates to the library member, file.o.

Four of the five macros can have alternative forms. When an uppercase **D** or **F** is appended to any of the four macros, the meaning is changed to "directory part" for **D** and "file part" for **F**. Thus, (0D) refers to the directory part of the string (0). If there is no directory part, ./ is generated. The only macro excluded from this alternative form is ?.

Suffixes

Certain names (for instance, those ending with **.o**) have inferable prerequisites such as **.c**, **.s**, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, *make* has inference rules which allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

> .c .c .f .f .sh .sh .c.o .c.a .c .o .c .c .c .a .f.o .f.a .f .o .f .f .f .a .h .h .s.o .s .o .s .s .s .a .sh .sh .l.o .l.c .l .o .l .l .l .c .y.o .y.c .y .o .y .y .y .c

The internal rules for *make* are contained in the source file **rules.c** for the *make* program. These rules can be locally modified. To print out the rules compiled into the *make* on any machine in a form suitable for recompilation, the following command is used:

make -fp - 2>/dev/null </dev/null

A tilde in the above rules refers to an SCCS file [see sccsfile(4)]. Thus, the rule **.c**^{*}.**o** would transform an SCCS C source file into an object file (.**o**). Because the **s**. of the SCCS files is a prefix, it is incompatible with *make*'s suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (i.e., .c:) is the definition of how to build x from x.c. In effect, the other suffix is null. This is useful for building targets from only one source file (e.g., shell procedures, simple C programs).

Additional suffixes are given as the dependency list for **.SUFFIXES**. Order is significant; the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

.SUFFIXES: .o .c .c .y .y .l .l .s .s .sh .sh .h .h .f .f

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; **.SUFFIXES:** with no dependencies clears the list of suffixes.

Inference Rules

The first example can be done more briefly.

pgm: a.o b.o cc a.o b.o -o pgm a.o b.o: incl.h

This is because *make* has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, CFLAGS, LFLAGS, and YFLAGS are used for compiler options to cc(1), lex(1), and yacc(1), respectively. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix **.o** from a file with suffix **.c** is specified as an entry with **.c.o**: as the target and no dependents. Shell commands associated with the target define the rule for making a **.o** file from a **.c** file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus **lib(file.o)** and **\$(LIB)(file.o)** both refer to an archive library which contains **file.o**. (This assumes the **LIB** macro has been previously defined.) The expression **\$(LIB)(file1.o file2.o)** is not legal. Rules pertaining to archive libraries have the form .XX.a where the XX is the suffix from which the archive member is to be made. An unfortunate byproduct of the current implementation requires the XX to be different from the suffix of the

archive member. Thus, one cannot have **lib(file.o)** depend upon **file.o** explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

.c.a:

\$(CC) -c \$(CFLAGS) \$< \$(AR) \$(ARFLAGS) \$@ \$*.0 rm -f \$*.0

In fact, the **.c.a** rule listed above is built into *make* and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

lib: lib(file1.o) lib(file2.o) lib(file3.o)
\$(CC) -c \$(CFLAGS) \$(?:.o=.c)
\$(AR) \$(ARFLAGS) lib \$?
rm \$? @echo lib is now up-to-date

.c.a:;

Here the substitution mode of the macro expansions is used. The **\$?** list is defined to be the set of object file names (inside **lib**) whose C source files are out-of-date. The substitution mode translates the **.o** to **.c**. (Unfortunately, one cannot as yet transform to **.c**[~]; however, this may become possible in the future.) Note also, the disabling of the **.c.a**: rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

FILES

[Mm]akefile and s.[Mm]akefile /bin/sh

SEE ALSO

cc(1), lex(1), yacc(1), printf(3S), sccsfile(4). cd(1), sh(1) in the User's Reference Manual.

NOTES

Some commands return non-zero status inappropriately; use **-i** to overcome the difficulty.

BUGS

File names with the characters = : **(a)** will not work. Commands that are directly executed by the shell, notably cd(1), are ineffectual across new-lines in *make*. The syntax **(lib(file1.0 file2.0 file3.0)** is illegal. You cannot build **lib(file.0)** from **file.0**. The macro **\$(a:.0=.c⁻)** does not work. Named pipes are not handled well.

mcs - manipulate the object file comment section

SYNOPSIS

mcs [options] object-file ...

DESCRIPTION

The *mcs* command manipulates the comment section, normally the ".comment" section, in an object file. It is used to add to, delete, print, and compress the contents of the comment section in a UNIX system object file. The *mcs* command must be given one or more of the options described below. It takes each of the options given and applies them in order to the *object-files*.

If the object file is an archive, the file is treated as a set of individual object files. For example, if the -a option is specified, the string is appended to the comment section of each archive element.

The following options are available.

-a string

Append *string* to the comment section of the *object-files*. If *string* contains embedded blanks, it must be enclosed in quotation marks.

- -c Compress the contents of the comment section. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.
- -d Delete the contents of the comment section from the object file. The object file comment section header is removed also.

-n name

Specify the name of the section to access. By default, *mcs* deals with the section named *.comment*. This option can be used to specify another section.

-p Print the contents of the comment section on the standard output. If more than one name is specified, each entry printed is tagged by the name of the file from which it was extracted, using the format "filename:string."

EXAMPLES

mcs -p file # Print *file's comment* section.

mcs -a string file # Append string to file's comment section

FILES

TMPDIR/mcs* temporary files

TMPDIR/* temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

cpp(1), a.out(4).

MCS(1)

NOTES

The *mcs* command cannot add new sections or delete existing sections to executable objects with magic number 0413 [see *a.out*(4)].

mkshlib – create a shared library

SYNOPSIS

mkshlib -s specfil [-t target] [-h host] [-n] [-q]

DESCRIPTION

The *mkshlib* command builds both the host and target shared libraries. A shared library is similar in function to a normal, non-shared library, except that programs which link with a shared library will share the library code during execution, whereas programs which link with a non-shared library will get their own copy of each library routine used.

The host shared library is an archive which is used to link-edit user programs with the shared library [see ar(4)]. A host shared library can be treated exactly like a non-shared library and should be included on cc(1)command lines in the usual way [see cc(1)]. Further, all operations which can be performed on an archive can also be performed on the host shared library.

The target shared library is an executable module which is attached to the user's process during execution of a program using the shared library. The target shared library contains the code for all the routines in the library and must be fully resolved. The target will be brought into memory during execution of a program using the shared library, and subsequent processes which use the shared library will share the copy of code already in memory. The text of the target is always shared, but each process will get its own copy of the data.

The user interface to *mkshlib* consists of command line options and a shared library specification file. The shared library specification file describes the contents of the shared library.

The *mkshlib* command invokes other tools such as the archiver, ar(1), the assembler, as(1), and the loader, ld(1). Tools are invoked through the use of *system*(3S) which searches directories in the user's PATH. Also, prefixes to *mkshlib* are parsed in the same manner as prefixes to the cc(1) command, and invoked tools are given the prefix, where appropriate. For example, *i386mkshlib* or *i286mkshlib* will invoke *i386ld* or *i286ld*, respectively.

The following command line options are recognized by *mkshlib*:

-s specfil Specifies the shared library specification file, *specfil*. This file contains the information necessary to build a shared library. Its contents include the branch table specifications for the target, the path name in which the target should be installed, the start addresses of text and data for the target, the initialization specifications for the host, and the list of object files to be included in the shared library (see details below).

- -t target Specifies the name, *target*, of the target shared library produced on the host machine. When *target* is moved to the target machine, it should be installed at the location given in the specification file (see the **#target** directive below). If the **-n** option is used, then a new target shared library will not be generated.
- -h host Specifies the name of the host shared library, *host*. If this option is not given, then the host shared library will not be produced.
- -n Do not generate a new target shared library. This option is useful when producing only a new host shared library. The -t option must still be supplied since a version of the target shared library is needed to build the host shared library.
- -q Quiet warning messages. This option is useful when warning messages are expected but not desired.

The shared library specification file contains all the information necessary to build both the host and target shared libraries. The contents and format of the specification file are given by the following directives:

#address sectname address

Specifies the start address, *address*, of section *sectname* for the target. This directive typically is used to specify the start addresses of the .text and .data sections.

#target pathname

Specifies the absolute path name, *pathname*, of the target shared library on the target machine. This pathname is copied to **a.out** files and is the location where the operating system will look for the shared library when executing a file which uses it.

#branch

Specifies the start of the branch table specifications. The lines following this directive are taken to be branch table specification lines.

Branch table specification lines have the following format:

funcname <white space> position

where *funcname* is the name of the symbol given a branch table entry and *position* specifies the position of *funcname*'s branch table entry. *Position* may be a single integer or a range of integers of the form *position1-position2*. Each *position* must be greater than or equal to one, the same position cannot be specified more than once, and every position from one to the highest given position must be accounted for.

If a symbol is given more than one branch table entry by associating a range of positions with the symbol or by specifying the same symbol on more than one branch table specification line, then the symbol is defined to have the address of the highest associated branch table entry. All other branch table entries for the symbol can be thought of as "empty" slots and can be replaced by new entries in future versions of the shared library.

Finally, only functions should be given branch table entries, and those functions must be external.

This directive can be specified only once per shared library specification file.

#objects

Specifies the names of the object files constituting the target shared library. The lines following this directive are taken to be the list of input object files in the order they are to be loaded into the target. The list simply consists of each file name followed by white space. This list is also used to determine the input object files for the host shared library, but the order for the host is given by running the list through *lorder*(1) and *tsort*(1).

This directive can be specified only once per shared library specification file.

#init object

Specifies that the object file, *object*, requires initialization code. The lines following this directive are taken to be initialization specification lines.

Initialization specification lines have the following format:

pimport <white space> import

Pimport is a pointer to the associated imported symbol, *import*, and must be defined in the current specified object file, *object*. The initialization code generated for each such line is of the form:

pimport = &import;

where *pimpaddr* is the absolute address of *pimport*.

All initializations for a particular object file must be given at once and multiple specifications of the same object file are not allowed.

#ident string

Specifies a string, *string*, to be included in the .comment section of the target shared library. This directive can be specified only once per shared library specification file.

##

Specifies a comment. All information on a line following this directive is ignored.

All directives which may be followed by multiline specifications are valid until the next directive or the end of the file.

FILES

TEMPDIR/* temporary files

TEMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

NM(1)

NAME

nm – print name list of common object file

SYNOPSIS

nm [-oxhvnefurpVT] file name ...

DESCRIPTION

The *nm* command displays the symbol table of each common object file, *filename*. *Filename* may be a relocatable or absolute common object file; or it may be an archive of relocatable or absolute common object files. For each symbol, the following information will be printed:

- Name The name of the symbol.
- Value Its value expressed as an offset or an address depending on its storage class.
- **Class** Its storage class.
- **Type** Its type and derived type. If the symbol is an instance of a structure or of a union, then the structure or union tag will be given following the type (e.g., struct-tag). If the symbol is an array, then the array dimensions will be given following the type (e.g., char[n][m]). Note that the object file must have been compiled with the $-\mathbf{g}$ option of the cc(1) command for this information to appear.
- Size Its size in bytes, if available. Note that the object file must have been compiled with the -g option of the cc(1) command for this information to appear.
- **Line** The source line number at which it is defined, if available. Note that the object file must have been compiled with the $-\mathbf{g}$ option of the cc(1) command for this information to appear.
- **Section** For storage classes static and external, the object file section containing the symbol (e.g., text, data, or bss).

The output of *nm* may be controlled using the following options:

- -o Print the value and size of a symbol in octal instead of decimal.
- -x Print the value and size of a symbol in hexadecimal instead of decimal.
- -h Do not display the output header data.
- -v Sort external symbols by value before they are printed.
- -n Sort external symbols by name before they are printed.
- -e Print only external and static symbols.
- -f Produce full output. Print redundant symbols (.text, .data, .lib, and .bss), normally suppressed.
- -u Print undefined symbols only.
- **-r** Prepend the name of the object file or archive to each output line.

-p Produce easily parsable, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters U (undefined), A (absolute), T (text segment symbol), D (data segment symbol), S (user-defined segment symbol), R (register symbol), F (file symbol), or C (common symbol). If the symbol is local (non-external), the type letter is in lower case.

- -V Print the version of the nm command executing on the standard error output.
- -T By default, *nm* prints the entire name of the symbols listed. Since object files can have symbols names with an arbitrary number of characters, a name that is longer than the width of the column set aside for names will overflow its column, forcing every column after the name to be misaligned. The -T option causes *nm* to truncate every name which would otherwise overflow its column and place an asterisk as the last character in the displayed name to mark it as truncated.

Options may be used in any order, either singly or in combination, and may appear anywhere in the command line. Therefore, both **nm name –e –v** and **nm –ve name** print the static and external symbols in *name*, with external symbols sorted by value.

FILES

TMPDIR/* temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam(*) in *tmpnam(*3S)].

BUGS

When all the symbols are printed, they must be printed in the order they appear in the symbol table in order to preserve scoping information. Therefore, the $-\mathbf{v}$ and $-\mathbf{n}$ options should be used only in conjunction with the $-\mathbf{e}$ option.

SEE ALSO

as(1), cc(1), ld(1), tmpnam(3S), a.out(4), ar(4).

DIAGNOSTICS

"nm: name: cannot open"

if *name* cannot be read.

"nm: name: bad magic"

if *name* is not a common object file.

"nm: name: no symbols"

if the symbols have been stripped from *name*.

omf - convert an object module from COFF to OMF

SYNOPSIS

omf [-i input-file] [-o output-file] -G gdt_limit,gdt_base -I idt_limit,idt_base -T tss_selector [-3]

DESCRIPTION

The omf command is used to convert an object module from AT&T's COFF (Common Object File Format) to Xenix's OMF (Object Module Format). The following options may be given in any order:

input-file is the name of the COFF file. If it is missing then *omf* will attempt to read from a file named *a.out*.

output-file is the name of the OMF file. If it is missing then *omf* will attempt to write to a file named *x.out*.

gdt_limit,gdt_base are the limit and base of the Global Descriptor Table (GDT); these numbers are separated by a comma.

idt_limit,idt_base are the limit and base of the Interrupt Descriptor Table (IDT); these numbers are separated by a comma.

tss_selector is a selector into the GDT for the initial task state.

By default, *omf* will convert a file to the format of an Intel 80286 bootloadable file. The -3 argument causes *omf* to produce an 80386 bootloadable file.

EXAMPLES

The following command will read a COFF formatted file named "a.out" and produce an 80286 boot-loadable file named "x.out". "x.out" will have a GDT limit of 100, a GDT base of 1000, an IDT limit of 200, an IDT base of 2000, and a TSS selector of 32:

omf -G100,1000 -I200,2000 -T32

The following command will read a COFF formatted file named "test" and produce an 80386 boot-loadable file named "x.out". "x.out" will have a GDT limit of 256, a GDT base of 0, an IDT limit of 512, an IDT base of 256, and a TSS selector of 64:

omf -i test -G256,0 -I512,256 -T64 -3

SEE ALSO

a.out(4)

DIAGNOSTICS

The error messages are intended to be self-explanatory.

prof – display profile data

SYNOPSIS

prof [-tcan] [-ox] [-g] [-z] [-h] [-s] [-m mdata] [prog]

DESCRIPTION

The *prof* command interprets a profile file produced by the *monitor*(3C) function. The symbol table in the object file *prog* (a.out by default) is read and correlated with a profile file (mon.out by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.

The mutually exclusive options t, c, a, and n determine the type of sorting of the output lines:

- -t Sort by decreasing percentage of total time (default).
- -c Sort by decreasing number of calls.
- -a Sort by increasing symbol address.
- **-n** Sort lexically by symbol name.

The mutually exclusive options \mathbf{o} and \mathbf{x} specify the printing of the address of each symbol monitored:

- -o Print each symbol address (in octal) along with the symbol name.
- -x Print each symbol address (in hexadecimal) along with the symbol name.

The following options may be used in any combination:

- -g Include non-global symbols (static functions).
- -z Include all symbols in the profile range [see *monitor*(3C)], even if associated with zero number of calls and zero time.
- -h Suppress the heading normally printed on the report. (This is useful if the report is to be processed further.)
- -s Print a summary of several of the monitoring parameters and statistics on the standard error output.

-m mdata

Use file *mdata* instead of **mon.out** as the input profile file.

A program creates a profile file if it has been loaded with the $-\mathbf{p}$ option of cc(1). This option to the cc command arranges for calls to *monitor*(3C) at the beginning and end of execution. It is the call to *monitor* at the end of execution that causes a profile file to be written. The number of calls to a function is tallied if the $-\mathbf{p}$ option was used when the file containing the function was compiled.

The name of the file created by a profiled program is controlled by the environment variable PROFDIR. If PROFDIR does not exist, "mon.out" is produced in the directory that is current when the program terminates. If

PROFDIR = string, "string/pid.progname" is produced, where *progname* consists of argv[0] with any path prefix removed, and *pid* is the program's process id. If PROFDIR is the null string, no profiling output is produced.

A single function may be split into subfunctions for profiling by means of the MARK macro [see *prof*(5)].

FILES

mon.out for profile a.out for namelist

SEE ALSO

cc(1), exit(2), profil(2), monitor(3C), prof(5).

WARNING

The times reported in successive identical runs may show variances of 20% or more, because of varying cache-hit ratios due to sharing of the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements.

Call counts are always recorded precisely.

The times for static functions are attributed to the preceding external text symbol if the -g option is not used. However, the call counts for the preceding function are still correct, i.e., the static function call counts are not added in with the call counts of the external function.

CAVEATS

Only programs that call exit(2) or return from *main* will cause a profile file to be produced, unless a final call to monitor is explicitly coded.

The use of the **-p** option to cc(1) to invoke profiling imposes a limit of 600 functions that may have call counters established during program execution. For more counters you must call *monitor*(3C) directly. If this limit is exceeded, other data will be overwritten and the **mon.out** file will be corrupted. The number of call counters used will be reported automatically by the *prof* command whenever the number exceeds 5/6 of the maximum.

prs – print an SCCS file

-a

SYNOPSIS

prs [-d[dataspec]] [-r[SID]] [-e] [-l] [-c[date-time]] [-a] files

DESCRIPTION

The *prs* command prints, on the standard output, parts or all of an SCCS file [see *sccsfile*(4)] in a user-supplied format. If a directory is named, *prs* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s**.), and unreadable files are silently ignored. If a name of – is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file or directory to be processed; non-SCCS files and unreadable files are silently ignored.

Arguments to *prs*, which may appear in any order, consist of *keyletter* arguments and file names.

All the described *keyletter* arguments apply independently to each named file:

- d [dataspec]	Used to specify the output data specification. The
	dataspec is a string consisting of SCCS file data key-
	words (see DATA KEYWORDS) interspersed with
	optional user-supplied text.
-r[SID]	Used to specify the SCCS IDentification (SID) string of

- a delta for which information is desired. If no SID is specified, the SID of the most recently created delta is assumed.
- -e Requests information for all deltas created *earlier* than and including the delta designated via the -r keyletter or the date given by the -c option.
- -1 Requests information for all deltas created *later* than and including the delta designated via the -**r** keyletter or the date given by the -**c** option.

-**c**[*date-time*] The cutoff date-time -**c**[cutoff]] is in the form:

YY[MM[DD[HH[MM[SS]]]]]

Units omitted from the date-time default to their maximum possible values; that is, -c7502 is equivalent to -c750228235959. Any number of non-numeric characters may separate the various 2-digit pieces of the *cut*off date in the form: "-c77/2/2 9:22:25".

Requests printing of information for both removed, i.e., delta type = R, [see *rmdel*(1)] and existing, i.e., delta type = D, deltas. If the **-a** keyletter is not specified, information for existing deltas only is provided.

DATA KEYWORDS

Data keywords specify which parts of an SCCS file are to be retrieved and output. All parts of an SCCS file [see sccsfile(4)] have an associated data keyword. There is no limit on the number of times a data keyword may appear in a *dataspec*.

The information printed by *prs* consists of: (1) the user-supplied text; and (2) appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in the *dataspec*. The format of a data keyword value is either *Simple* (S), in which keyword substitution is direct, or *Multiline* (M), in which keyword substitution is followed by a carriage return.

User-supplied text is any text other than recognized data keywords.

A tab is specified by t and carriage return/new-line is specified by n. The default data keywords are:

":Dt:\t:DL:\nMRs:\n:MR:COMMENTS:\n:C:"

regcmp – regular expression compile

SYNOPSIS

regcmp [–] files

DESCRIPTION

The regcmp command performs a function similar to regcmp(3X) and, in most cases, precludes the need for calling regcmp(3X) from C programs. This saves on both execution time and program size. The command regcmp compiles the regular expressions in *file* and places the output in *file*.i. If the - option is used, the output will be placed in *file.c.* The format of entries in file is a name (C variable) followed by one or more blanks followed by a regular expression enclosed in double quotes. The output of regcmp is C source code. Compiled regular expressions are represented as extern char vectors. File.i files may thus be included in C programs, or file.c files may be compiled and later loaded. In the C program which uses the regcmp output, regex(abc,line) will apply the regular expression named abc to line. Diagnostics are self-explanatory.

EXAMPLES

name

"([A-Za-z][A-Za-z0-9_]*)\$0" telno "\({0,1}([2-9][01][1-9])\$0\){0,1} *"

"([2-9][0-9]{2})\$1[-]{0,1} " "([0-9]{4})\$2"

In the C program that uses the *regcmp* output,

regex(telno, line, area, exch, rest)

will apply the regular expression named *telno* to *line*.

SEE ALSO

regcmp(3X).

relogin – rename login entry to show current layer

SYNOPSIS

/usr/lib/layersys/relogin [-s] [line]

DESCRIPTION

The *relogin* command changes the terminal *line* field of a user's utmp(4) entry to the name of the windowing terminal layer attached to standard input. *write*(1) messages sent to this user are directed to this layer. In addition, the *who*(1) command will show the user associated with this layer. *relogin* may only be invoked under *layers*(1).

The *relogin* command is invoked automatically by *layers*(1) to set the utmp(4) entry to the terminal line of the first layer created upon startup, and to reset the utmp(4) entry to the real line on termination. It may be invoked by a user to designate a different layer to receive *write*(1) messages.

- -s Suppress error messages.
- *line* Specifies which utmp(4) entry to change. The utmp(4) file is searched for an entry with the specified *line* field. That field is changed to the line associated with the standard input. (To learn what lines are associated with a given user, say **jdoe**, type **ps f u jdoe** and note the values shown in the **TTY** field [see ps(1)].

FILES

/etc/utmp data base of users versus terminals

EXIT STATUS

Returns **0** upon successful completion, **1** otherwise.

SEE ALSO

utmp(4) in the Programmer's Reference Manual.

layers(1), mesg(1), ps(1), who(1), write(1) in the User's Reference Manual.

NOTES

If *line* does not belong to the user issuing the *relogin* command or standard input is not associated with a terminal, *relogin* will fail.

rmdel - remove a delta from an SCCS file

SYNOPSIS

rmdel -rSID files

DESCRIPTION

The *rmdel* command removes the delta specified by the *SID* from each named SCCS file. The delta to be removed must be the newest (most recent) delta in its branch in the delta chain of each named SCCS file. In addition, the specified must *not* be that of a version being edited for the purpose of making a delta (i. e., if a *p*-file [see get(1)] exists for the named SCCS file, the specified must *not* appear in any entry of the *p*-file).

The **-r** option is used for specifying the *SID* (SCCS **ID**entification) level of the delta to be removed.

If a directory is named, *rmdel* behaves as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with s.) and unreadable files are silently ignored. If a name of – is given, the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed; non-SCCS files and unreadable files are silently ignored.

Simply stated, they are either (1) if you make a delta you can remove it; or (2) if you own the file and directory you can remove a delta.

FILES

DIAGNOSTICS

Use *help*(1) for explanations.

- 1 -

sact - print current SCCS file editing activity

SYNOPSIS

sact files

DESCRIPTION

The *sact* command informs the user of any impending deltas to a named SCCS file. This situation occurs when get(1) with the -e option has been previously executed without a subsequent execution of delta(1). If a directory is named on the command line, *sact* behaves as though each file in the directory were specified as a named file, except that non-SCCS files and unreadable files are silently ignored. If a name of - is given, the standard input is read with each line being taken as the name of an SCCS file to be processed.

The output for each named file consists of five fields separated by spaces.

- Field 1 specifies the SID of a delta that currently exists in the SCCS file to which changes will be made to make the new delta.
- Field 2 specifies the SID for the new delta to be created.
- Field 3 contains the logname of the user who will make the delta (i.e., executed a *get* for editing).
- Field 4 contains the date that **get –e** was executed.
- Field 5 contains the time that **get -e** was executed.

SEE ALSO

delta(1), get(1), unget(1).

DIAGNOSTICS

Use *help*(1) for explanations.

sccsdiff - compare two versions of an SCCS file

SYNOPSIS

sccsdiff -rSID1 -rSID2 [-p] [-sn] files

DESCRIPTION

The *sccsdiff* command compares two versions of an SCCS file and generates the differences between the two versions. Any number of SCCS files may be specified, but arguments apply to all files.

- -rSID? SID1 and SID2 specify the deltas of an SCCS file that are to be compared. Versions are passed to *bdiff*(1) in the order given.
- **-p** pipe output for each file through *pr*(1).
- -sn *n* is the file segment size that *bdiff* will pass to *diff*(1). This is useful when *diff* fails due to a high system load.

FILES

DIAGNOSTICS

"file: No differences" If the two versions are the same. Use *help*(1) for explanations.

sdb – symbolic debugger

SYNOPSIS

sdb [-w] [-W] [objfil [corfil [directory-list]]]

DESCRIPTION

The *sdb* command calls a symbolic debugger that can be used with C and F77 programs. It may be used to examine their object files and core files and to provide a controlled environment for their execution.

Objfil is an executable program file which has been compiled with the $-\mathbf{g}$ (debug) option. If it has not been compiled with the $-\mathbf{g}$ option, the symbolic capabilities of *sdb* will be limited, but the file can still be examined and the program debugged. The default for *objfil* is **a.out**. *Corfil* is assumed to be a core image file produced after executing *objfil*; the default for *corfil* is **core**. The core file need not be present. A – in place of *corfil* will force *sdb* to ignore any core image file. The colon-separated list of directories (*directory-list*) is used to locate the source files used to build *objfil*.

It is useful to know that at any time there is a *current line* and *current file*. If *corfil* exists, then they are initially set to the line and file containing the source statement at which the process terminated. Otherwise, they are set to the first line in *main()*. The current line and file may be changed with the source file examination commands.

By default, warnings are provided if the source files used in producing *objfil* cannot be found, or are newer than *objfil*. This checking feature and the accompanying warnings may be disabled by the use of the **-W** flag.

Names of variables are written just as they are in C or F77. *sdb* does not truncate names. Variables local to a procedure may be accessed using the form *procedure:variable*. If no procedure name is given, the procedure containing the current line is used by default.

It is also possible to refer to structure members as variable.member, pointers to structure members as variable->member, and array elements as Pointers may be dereferenced by using the form variable [number]. pointer[0]. Combinations of these forms may also be used. F77 common variables may be referenced by using the name of the common block instead of the structure name. Blank common variables may be named by the form *.variable*. A number may be used in place of a structure variable name, in which case the number is viewed as the address of the structure, and the template used for the structure is that of the last structure referenced by sdb. An unqualified structure variable may also be used with various commands. Generally, sdb will interpret a structure as a set of variables. Thus, sdb will display the values of all the elements of a structure when it is requested to display a structure. An exception to this interpretation occurs when displaying variable addresses. An entire structure does have an address, and it is this value *sdb* displays, not the addresses of individual elements.

Elements of a multidimensional array may be referenced as variable [number][number]..., or as variable [number,number,...]. In place of number,

the form *number;number* may be used to indicate a range of values, * may be used to indicate all legitimate values for that subscript, or subscripts may be omitted entirely if they are the last subscripts and the full range of values is desired. As with structures, *sdb* displays all the values of an array or of the section of an array if trailing subscripts are omitted. It displays only the address of the array itself or of the section specified by the user if subscripts are omitted. A multidimensional parameter in an F77 program cannot be displayed as an array, but it is actually a pointer, whose value is the location of the array. The array itself can be accessed symbolically from the calling function.

A particular instance of a variable on the stack may be referenced by using the form *procedure:variable,number*. All the variations mentioned in naming variables may be used. *Number* is the occurrence of the specified procedure on the stack, counting the top, or most current, as the first. If no procedure is specified, the procedure currently executing is used by default.

It is also possible to specify a variable by its address. All forms of integer constants which are valid in C may be used, so that addresses may be input in decimal, octal, or hexadecimal.

Line numbers in the source program are referred to as *file-name:number* or *procedure:number*. In either case the number is relative to the beginning of the file. If no procedure or file name is given, the current file is used by default. If no number is given, the first line of the named procedure or file is used.

While a process is running under *sdb*, all addresses refer to the executing program; otherwise they refer to *objfil* or *corfil*. An initial argument of -w permits overwriting locations in *objfil*.

Addresses

The address in a file associated with a written address is determined by a mapping associated with that file. Each mapping is represented by two triples (b1, e1, f1) and (b2, e2, f2) and the *file address* corresponding to a written *address* is calculated as follows:

b1≤address<e1 then file address=address+f1-b1 otherwise

> b2≤address<e2 then file address=address+f2-b2

otherwise, the requested *address* is not legal. In some cases (e.g., for programs with separated I and D space) the two segments for a file may overlap.

The initial setting of both mappings is suitable for normal **a.out** and **core** files. If either file is not of the kind expected then, for that file, b1 is set to 0, e1 is set to the maximum file size, and f1 is set to 0; in this way the whole file can be examined with no address translation.

In order for sdb to be used on large files, all appropriate values are kept as signed 32-bit integers.

Commands

The commands for examining data in the program are:

- t Print a stack trace of the terminated or halted program.
- **T** Print the top line of the stack trace.

variable /clm

Print the value of *variable* according to length l and format m. A numeric count c indicates that a region of memory, beginning at the address implied by *variable*, is to be displayed. The length specifiers are:

- **b** one byte
- **h** two bytes (half word)
- 1 four bytes (long word)

Legal values for *m* are:

- c character
- d decimal
- **u** decimal, unsigned
- o octal
- **x** hexadecimal
- f 32-bit single precision floating point
- **g** 64-bit double precision floating point
- **s** Assume *variable* is a string pointer and print characters starting at the address pointed to by the variable.
- **a** Print characters starting at the variable's address. This format may not be used with register variables.
- **p** pointer to procedure
- i disassemble machine-language instruction with addresses printed numerically and symbolically.
- I disassemble machine-language instruction with addresses just printed numerically.

Length specifiers are only effective with the c, d, u, o, and x formats. Any of the specifiers, c, l, and m, may be omitted. If all are omitted, *sdb* chooses a length and a format suitable for the variable's type as declared in the program. If m is specified, then this format is used for displaying the variable. A length specifier determines the output length of the value to be displayed, sometimes resulting in truncation. A count specifier c tells *sdb* to display that many units of memory, beginning at the address of *variable*. The number of bytes in one such unit of memory is determined by the length specifier l, or if no length is given, by the size associated with the *variable*. If a count specifier is used for the **s** or **a** command, then that many characters are printed. Otherwise successive characters are printed until either a null byte is reached or 128 characters are printed. The last variable may be redisplayed with the command ./. The sh(1) metacharacters * and ? may be used within procedure and variable names, providing a limited form of pattern matching. If no procedure name is given, variables local to the current procedure and global variables are matched; if a procedure name is specified, then only variables local to that procedure are matched. To match only global variables, the form :*pattern* is used.

linenumber?lm

variable:?lm

Print the value at the address from **a.out** or I space given by *linenumber* or *variable* (procedure name), according to the format lm. The default format is 'i'.

variable=lm

linenumber=lm

number=lm

Print the address of *variable* or *linenumber*, or the value of *number*, in the format specified by lm. If no format is given, then lx is used. The last variant of this command provides a convenient way to convert between decimal, octal, and hexadecimal.

variable!value

Set *variable* to the given *value*. The value may be a number, a character constant, or a variable. The value must be well defined; expressions which produce more than one value, such as structures, are not allowed. Character constants are denoted *'character*. Numbers are viewed as integers unless a decimal point or exponent is used. In this case, they are treated as having the type double. Registers are viewed as integers. The *variable* may be an expression which indicates more than one variable, such as an array or structure name. If the address of a variable is given, it is regarded as the address of a variable of type *int*. C conventions are used in any type conversions necessary to perform the indicated assignment.

- **x** Print the machine registers and the current machine-language instruction.
- **X** Print the current machine-language instruction.

The commands for examining source files are:

- e procedure
- e file-name
- e directory/
- e directory file-name

The first two forms set the current file to the file containing *procedure* or to *file-name*. The current line is set to the first line in the named procedure or file. Source files are assumed to be in *directory*. The default is the current working directory. The latter two forms change the value of *directory*. If no procedure, file name, or directory is given, the current procedure name and file name are reported.

/regular expression /

Search forward from the current line for a line containing a string matching *regular expression* as in ed(1). The trailing / may be deleted.

?regular expression?

Search backward from the current line for a line containing a string matching *regular expression* as in ed(1). The trailing ? may be deleted.

- **p** Print the current line.
- **z** Print the current line followed by the next 9 lines. Set the current line to the last line printed.

w Window. Print the 10 lines around the current line.

number

Set the current line to the given line number. Print the new current line.

count +

Advance the current line by *count* lines. Print the new current line.

count –

Retreat the current line by *count* lines. Print the new current line.

The commands for controlling the execution of the source program are:

count **r** args

count **R**

Run the program with the given arguments. The **r** command with no arguments reuses the previous arguments to the program while the **R** command runs the program with no arguments. An argument beginning with < or > causes redirection for the standard input or output, respectively. If *count* is given, it specifies the number of breakpoints to be ignored.

linenumber **c** count

linenumber C count

Continue after a breakpoint or interrupt. If *count* is given, the program will stop when *count* breakpoints have been encountered. The signal which caused the program to stop is reactivated with the C command and ignored with the c command. If a line number is specified, then a temporary breakpoint is placed at the line and execution is continued. The breakpoint is deleted when the command finishes.

linenumber g count

Continue after a breakpoint with execution resumed at the given line. If *count* is given, it specifies the number of breakpoints to be ignored.

S count

Single-step the program through *count* lines. If no count is given, then the program is run for one line. **S** is equivalent to **s** except it steps through procedure calls.

s count

i T

SDB(1)

Single-step by one machine-language instruction. The signal which caused the program to stop is reactivated with the I command and ignored with the i command.

variable\$**m** count

address:**m** count

Single-step (as with s) until the specified location is modified with a new value. If *count* is omitted, it is effectively infinity. *Variable* must be accessible from the current procedure. Since this command is done by software, it can be very slow.

level v

Toggle verbose mode, for use when single-stepping with S, s, or m. If *level* is omitted, then just the current source file and/or subroutine name is printed when either changes. If *level* is 1 or greater, each C source line is printed before it is executed; if *level* is 2 or greater, each assembler statement is also printed. A v turns verbose mode off if it is on for any level.

k Kill the program being debugged.

procedure(arg1,arg2,...)

procedure(arg1,arg2,...)/m

Execute the named procedure with the given arguments. Arguments can be integer, character, or string constants or names of variables accessible from the current procedure. The second form causes the value returned by the procedure to be printed according to format m. If no format is given, it defaults to **d**. This facility is only available if the program was loaded with the -g option.

linenumber **b** commands

Set a breakpoint at the given line. If a procedure name without a line number is given (e.g., "proc:"), a breakpoint is placed at the first line in the procedure even if it was not compiled with the $-\mathbf{g}$ option. If no *linenumber* is given, a breakpoint is placed at the current line. If no *commands* are given, execution stops just before the breakpoint and control is returned to *sdb*. Otherwise the *commands* are executed when the breakpoint is encountered and execution continues. Multiple commands are specified by separating them with semicolons. If \mathbf{k} is used as a command to execute at a breakpoint, control returns to *sdb*, instead of continuing execution.

B Print a list of the currently active breakpoints.

linenumber **d**

Delete a breakpoint at the given line. If no *linenumber* is given, then the breakpoints are deleted interactively. Each breakpoint location is printed and a line is read from the standard input. If the line begins with a \mathbf{y} or \mathbf{d} , then the breakpoint is deleted.

- **D** Delete all breakpoints.
- **1** Print the last executed line.

linenumber **a**

Announce. If *linenumber* is of the form *proc:number*, the command effectively does a *linenumber* b **l**. If *linenumber* is of the form *proc:*, the command effectively does a *proc*: b T.

Miscellaneous commands:

!command

The command is interpreted by sh(1).

new-line

If the previous command printed a source line, then advance the current line by one line and print the new current line. If the previous command displayed a memory location, then display the next memory location.

end-of-file character

Scroll. Print the next 10 lines of instructions, source or data depending on which was printed last. The end-of-file character is usually control-D.

< filename

Read commands from *filename* until the end of file is reached, and then continue to accept commands from standard input. When *sdb* is told to display a variable by a command in such a file, the variable name is displayed along with the value. This command may not be nested; < may not appear as a command in a file.

- **M** Print the address maps.
- **M** [?/] [*] b e f

Record new values for the address map. The arguments ? and / specify the text and data maps, respectively. The first segment (b1, e1, f1) is changed unless * is specified; in which case, the second segment (b2, e2, f2) of the mapping is changed. If fewer than three values are given, the remaining map parameters are left unchanged.

" string

Print the given string. The C escape sequences of the form \character are recognized, where character is a nonnumeric character.

q Exit the debugger.

The following commands also exist and are intended only for debugging the debugger:

- V Print the version number.
- **Q** Print a list of procedures and files being debugged.
- Y Toggle debug output.

FILES

a.out

lore

SEE ALSO

cc(1), a.out(4), core(4), syms(4). sh(1) in the User's Reference Manual.

SDB(1)

WARNINGS

When *sdb* prints the value of an external variable for which there is no debugging information, a warning is printed before the value. The size is assumed to be **int** (integer).

Data which are stored in text sections are indistinguishable from functions.

Line number information in optimized functions is unreliable, and some information may be missing.

BUGS

If a procedure is called when the program is *not* stopped at a breakpoint (such as when a core image is being debugged), all variables are initialized before the procedure is started. This makes it impossible to use a procedure which formats data from a core image.

The *sdb* command cannot print the value of an F77 parameter. It will erroneously print the address.

Tracebacks containing F77 subprograms with multiple entry points may print too many arguments in the wrong order, but their values are correct.

The range of an F77 array subscript is assumed to be 1 to n, where n is the dimension corresponding to that subscript. This is only significant when the user omits a subscript, or uses * to indicate the full range. There is no problem in general with arrays having subscripts whose lower bounds are not 1.

SIZE(1)

NAME

size - print section sizes in bytes of common object files

SYNOPSIS

size [-n] [-f] [-o] [-x] [-V] files

DESCRIPTION

The *size* command produces section size information in bytes for each loaded section in the common object files. The size of the text, data, and bss (uninitialized data) sections is printed, as well as the sum of the sizes of these sections. If an archive file is input to the *size* command, the information for all archive members is displayed.

The **-n** option includes NOLOAD sections in the size.

The **-f** option produces full output, that is, it prints the size of every loaded section, followed by the section name in parentheses.

Numbers will be printed in decimal unless either the -o or the -x option is used, in which case they will be printed in octal or in hexadecimal, respectively.

The **-V** flag will supply the version information on the *size* command.

SEE ALSO

as(1), cc(1), ld(1), a.out(4), ar(4).

CAVEAT

Since the size of bss sections is not known until link-edit time, the *size* command will not give the true total size of pre-linked objects.

DIAGNOSTICS

size: name: cannot open if *name* cannot be read.

size: name: bad magic

if name is not an appropriate common object file.

strip – strip symbol and line number information from a common object file

SYNOPSIS

strip [-1] [-x] [-b] [-r] [-V] filename ...

DESCRIPTION

The *strip* command strips the symbol table and line number information from common object files, including archives. Once this has been done, no symbolic debugging access will be available for that file; therefore, this command is normally run only on production modules that have been debugged and tested.

The amount of information stripped from the symbol table can be controlled by using any of the following options:

- -1 Strip line number information only; do not strip any symbol table information.
- -x Do not strip static or external symbol information.
- -b Same as the -x option, but also do not strip scoping information (e.g., beginning and end of block delimiters).
- **-r** Do not strip static or external symbol information, or relocation information.
- -V Print the version of the strip command executing on the standard error output.

If there are any relocation entries in the object file and any symbol table information is to be stripped, *strip* will complain and terminate without stripping *filename* unless the $-\mathbf{r}$ option is used.

If the *strip* command is executed on a common archive file [see ar(4)] the archive symbol table will be removed. The archive symbol table must be restored by executing the ar(1) command with the **s** option before the archive can be link-edited by the ld(1) command. *strip* will produce appropriate warning messages when this situation arises.

The *strip* command is used to reduce the file storage overhead taken by the object file.

FILES

TMPDIR/strp* temporary files

TMPDIR is usually /usr/tmp but can be redefined by setting the environment variable **TMPDIR** [see *tempnam*() in *tmpnam*(3S)].

SEE ALSO

ar(1), as(1), cc(1), ld(1), tmpnam(3S), a.out(4), ar(4).

DIAGNOSTICS

strip: name: cannot open

if *name* cannot be read.

strip: name: bad magic

if name is not an appropriate common object file.

strip: name: relocation entries present; cannot strip if *name* contains relocation entries and the -r flag is not used, the symbol table information cannot be stripped.

tic – terminfo compiler

SYNOPSIS

tic [-v[n]] [-c] file

DESCRIPTION

tic translates a *terminfo*(4) file from the source format into the compiled format. The results are placed in the directory */usr/lib/terminfo*. The compiled format is necessary for use with the library routines described in *curses*(3X).

- **-vn** (verbose) output to standard error trace information showing tic's progress. The optional integer n is a number from 1 to 10, inclusive, indicating the desired level of detail of information. If n is omitted, the default level is 1. If n is specified and greater than 1, the level of detail is increased.
- -c only check *file* for errors. Errors in **use**= links are not detected.
- file contains one or more *terminfo*(4) terminal descriptions in source format (see *terminfo*(4)). Each description in the file describes the capabilities of a particular terminal. When a **use**=*entry-name* field is discovered in a terminal entry currently being compiled, *tic* reads in the binary from */usr/lib/terminfo* to complete the entry. (Entries created from *file* will be used first. If the environment variable **TERMINFO** is set, that directory is searched instead of */usr/lib/terminfo*.) *tic* duplicates the capabilities in *entry-name* for the current entry, with the exception of those capabilities that explicitly are defined in the current entry.

If the environment variable **TERMINFO** is set, the compiled results are placed there instead of */usr/lib/terminfo*.

FILES

/usr/lib/terminfo/?/* compiled terminal description data base

SEE ALSO

curses(3X), term(4), terminfo(4) in the Programmer's Reference Manual. Chapter 10 in the Programmer's Guide.

WARNINGS

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes.

Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

When the -c option is used, duplicate terminal names will not be diagnosed; however, when -c is not used, they will be.

BUGS

To allow existing executables from the previous release of the UNIX System to continue to run with the compiled terminfo entries created by the new terminfo compiler, cancelled capabilities will not be marked as cancelled within the terminfo binary unless the entry name has a '+' within it. (Such terminal names are only used for inclusion within other entries via a **use**=

entry. Such names would not be used for real terminal names.)

For example:

4415+nl, kf1@, kf2@,

4415+base, kf1=\EOc, kf2=\EOd,

4415-nll4415 terminal without keys, use=4415+nl, use=4415+base,

The above example works as expected; the definitions for the keys do not show up in the 4415-nl entry. However, if the entry 4415+nl did not have a plus sign within its name, the cancellations would not be marked within the compiled file and the definitions for the function keys would not be cancelled within 4415-nl.

DIAGNOSTICS

Most diagnostic messages produced by *tic* during the compilation of the source file are preceded with the approximate line number and the name of the terminal currently being worked on.

mkdir ... returned bad status

The named directory could not be created.

File does not start with terminal names in column one

The first thing seen in the file, after comments, must be the list of terminal names.

Token after a *lseek*(2) not NAMES

Somehow the file being compiled changed during the compilation.

Not enough memory for use_list element

or

Out of memory

Not enough free memory was available (*malloc*(3C) failed).

Can't open ...

The named file could not be created.

Error in writing ...

The named file could not be written to.

Can't link ... to ...

A link failed.

Error in re-reading compiled file ...

The compiled file could not be read back in.

Premature EOF

The current entry ended prematurely.

Backspaced off beginning of line

This error indicates something wrong happened within tic.

Unknown Capability - "..."

The named invalid capability was found within the file.

Wrong type used for capability "..."

For example, a string capability was given a numeric value.

Unknown token type

Tokens must be followed by '@' to cancel, ',' for booleans, '#' for numbers, or '=' for strings.

"...": bad term name

or

Line ...: Illegal terminal name - "..."

Terminal names must start with a letter or digit

The given name was invalid. Names must not contain white space or slashes, and must begin with a letter or digit.

"...": terminal name too long.

An extremely long terminal name was found.

"...": terminal name too short.

A one-letter name was found.

"..." filename too long, truncating to "..."

The given name was truncated to 14 characters due to UNIX file name length limitations.

"..." defined in more than one entry. Entry being used is "...". An entry was found more than once.

Terminal name "..." synonym for itself

A name was listed twice in the list of synonyms.

At least one synonym should begin with a letter.

At least one of the names of the terminal should begin with a letter.

Illegal character - "..."

The given invalid character was found in the input file.

Newline in middle of terminal name

The trailing comma was probably left off of the list of names.

Missing comma

A comma was missing.

Missing numeric value

The number was missing after a numeric capability.

NULL string value

The proper way to say that a string capability does not exist is to cancel it.

Very long string found. Missing comma? self-explanatory

Unknown option. Usage is: An invalid option was entered.

Too many file names. Usage is:

self-explanatory

. .

TIC(1M)

- "..." non-existant or permission denied The given directory could not be written into.
- "..." is not a directory self-explanatory
- "...": Permission denied access denied.
- "...": Not a directory *tic* wanted to use the given name as a directory, but it already exists as a file
- SYSTEM ERROR!! Fork failed!!! A fork(2) failed.

Error in following up use-links. Either there is a loop in the links or they reference non-existant terminals. The following is a list of the entries involved:

A *terminfo*(4) entry with a **use**=*name* capability either referenced a non-existant terminal called *name* or *name* somehow referred back to the given entry.

tsort - topological sort

SYNOPSIS

tsort [file]

DESCRIPTION

The *tsort* command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input *file*. If no *file* is specified, the standard input is understood.

The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

SEE ALSO

lorder(1).

DIAGNOSTICS

Odd data: there is an odd number of fields in the input file.

unget – undo a previous get of an SCCS file

SYNOPSIS

unget [-rSID] [-s] [-n] files

DESCRIPTION

The *unget* command undoes the effect of a **get** –**e** done prior to creating the intended new delta. If a directory is named, *unget* behaves as though each file in the directory were specified as a named file, except that non-SCCS files and unreadable files are silently ignored. If a name of – is given, the standard input is read with each line being taken as the name of an SCCS file to be processed.

Keyletter arguments apply independently to each named file.

- -rSID Uniquely identifies which delta is no longer intended. (This would have been specified by get as the "new delta"). The use of this keyletter is necessary only if two or more outstanding gets for editing on the same SCCS file were done by the same person (login name). A diagnostic results if the specified *SID* is ambiguous, or if it is necessary and omitted on the command line.
- -s Suppresses the printout, on the standard output, of the intended delta's *SID*.

-n Causes the retention of the gotten file which would normally be removed from the current directory.

SEE ALSO

delta(1), get(1), sact(1). help(1) in the User's Reference Manual.

DIAGNOSTICS

Use help(1) for explanations.

val - validate SCCS file

SYNOPSIS

val -

val [-s] [-rSID] [-mname] [-ytype] files

DESCRIPTION

The *val* command determines if the specified *file* is an SCCS file meeting the characteristics specified by the optional argument list. Arguments to *val* may appear in any order. The arguments consist of keyletter arguments, which begin with a -, and named files.

The *val* command has a special argument, –, which causes reading of the standard input until an end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.

The *val* command generates diagnostic messages on the standard output for each command line and file processed, and also returns a single 8-bit code upon exit as described below.

The keyletter arguments are defined as follows. The effects of any keyletter argument apply independently to each named file on the command line.

-s The presence of this argument silences the diagnostic message normally generated on the standard output for any error that is detected while processing each named file on a given command line.

-rSID The argument value SID (SCCS IDentification String) is an SCCS delta number. A check is made to determine if the SID is ambiguous (e. g., r1 is ambiguous because it physically does not exist but implies 1.1, 1.2, etc., which may exist) or invalid (e. g., r1.0 or r1.1.0 are invalid because neither case can exist as a valid delta number). If the SID is valid and not ambiguous, a check is made to determine if it actually exists.

-mname The argument value *name* is compared with the SCCS %M% keyword in *file*.

-ytype The argument value *type* is compared with the SCCS %Y% keyword in *file*.

The 8-bit code returned by *val* is a disjunction of the possible errors, i. e., can be interpreted as a bit string where (moving from left to right) set bits are interpreted as follows:

- bit 0 = missing file argument;
- bit 1 = unknown or duplicate keyletter argument;

bit 2 = corrupted SCCS file;

bit 3 = cannot open file or file not SCCS;

bit 4 = SID is invalid or ambiguous;

bit 5 = SID does not exist;

bit 6 = % Y%, **-y** mismatch;

bit 7 = %M%, **-m** mismatch;

Note that *val* can process two or more files on a given command line and in turn can process multiple command lines (when reading the standard input). In these cases an aggregate code is returned – a logical **OR** of the codes generated for each command line and file processed.

SEE ALSO

admin(1), delta(1), get(1), prs(1). help(1) in the User's Reference Manual.

DIAGNOSTICS

Use *help*(1) for explanations.

BUGS

The *val* command can process up to 50 files on a single command line. Any number above 50 will produce a **core** dump.

vc – version control

SYNOPSIS

vc [-a] [-t] [-cchar] [-s] [keyword=value ... keyword=value]

DESCRIPTION

The vc command copies lines from the standard input to the standard output under control of its *arguments* and *control statements* encountered in the standard input. In the process of performing the copy operation, user declared *keywords* may be replaced by their string *value* when they appear in plain text and/or control statements.

The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as *vc* command arguments.

A control statement is a single line beginning with a control character, except as modified by the **-t** keyletter (see below). The default control character is colon (:), except as modified by the **-c** keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.

A keyword is composed of 9 or less alphanumerics; the first must be alphabetic. A value is any ASCII string that can be created with ed(1); a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.

Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The **-a** keyletter (see below) forces replacement of keywords in *all* lines of text. An uninterpreted control character may be included in a value by preceding it with \backslash . If a literal \backslash is desired, then it too must be preceded by \backslash .

Keyletter Arguments

-a Forces replacement of keywords surrounded by control characters with their assigned value in *all* text lines and not just in *vc* statements.

- -t All characters from the beginning of a line up to and including the first *tab* character are ignored for the purpose of detecting a control statement. If one is found, all characters up to and including the *tab* are discarded.
- -cchar Specifies a control character to be used in place of :.
- -s Silences warning messages (not error) that are normally printed on the diagnostic output.

Version Control Statements

:dcl keyword[, ..., keyword]

Used to declare keywords. All keywords must be declared.

- 1 -

:asg keyword=value

Used to assign values to keywords. An **asg** statement overrides the assignment for the corresponding keyword on the *vc* command line and all previous **asg**'s for that keyword. Keywords declared, but not assigned values have null values.

:if condition

:end

Used to skip lines of the standard input. If the condition is true, all lines between the *if* statement and the matching *end* statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note that intervening *if* statements and matching *end* statements are recognized solely for the purpose of maintaining the proper *if-end* matching. The syntax of a condition is:

<cond></cond>	:: = ["not"] <or></or>
<or></or>	:= <and> <and> " " <or></or></and></and>
<and></and>	:: = <exp> <exp> "&" <and></and></exp></exp>
<exp></exp>	::= "(" <or> ")" <value> <op> <value></value></op></value></or>
<op></op>	:= "=" "!=" "<" ">"
<value></value>	:: = <arbitrary ascii="" string=""> <numeric string=""></numeric></arbitrary>

The available operators and their meanings are:

=	equal
!=	not equal
&	and
	or
>	greater than
<	less than
()	used for logical groupings
not	may only occur immediately after the <i>if</i> , and
	when present, inverts the value of the entire condition

The > and < operate only on unsigned integer values (e.g., : 012 > 12 is false). All other operators take strings as arguments (e.g., : 012 != 12 is true). The precedence of the operators (from highest to lowest) is:

= != > < all of equal precedence &

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

VC(1)

::text

Used for keyword replacement on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the -a keyletter.

:on

:off

Turn on or off keyword replacement on all lines.

:ctl char

Change the control character to char.

:msg message

Prints the given message on the diagnostic output.

:err message

Prints the given message followed by:

ERROR: err statement on line ... (915)

on the diagnostic output. vc halts execution and returns an exit code of 1.

SEE ALSO

ed(1), help(1) in the User's Reference Manual.

DIAGNOSTICS

Use *help*(1) for explanations.

EXIT CODES

0 – normal

1 – any error

what - identify SCCS files

SYNOPSIS

what [-s] files

DESCRIPTION

The *what* command searches the given files for all occurrences of the pattern that get(1) substitutes for %Z% (this is **@(#)** at this printing) and prints out what follows until the first $\tilde{}$, >, new-line, \backslash , or null character. For example, if the C program in file **f.c** contains

char ident[] = "@(#)identification information ";

and f.c is compiled to yield f.o and a.out, then the command

what f.c f.o a.out

will print

f.c:

identification information

f.o:

identification information

a.out:

-s

identification information

The *what* command is intended to be used in conjunction with the command get(1), which automatically inserts identifying information, but it can also be used where the information is inserted manually. Only one option exists:

Quit after finding the first occurrence of pattern in each file.

SEE ALSO

get(1).

help(1) in the User's Reference Manual.

DIAGNOSTICS

Exit status is 0 if any matches are found, otherwise 1. Use help(1) for explanations.

BUGS

It is possible that an unintended occurrence of the pattern @(#) could be found just by chance, but this causes no harm in nearly all cases.

wtinit - object downloader for the 5620 DMD terminal

SYNOPSIS

/usr/lib/layersys/wtinit [-d] [-p] file

DESCRIPTION

The *wtinit* utility downloads the named *file* for execution in the AT&T Teletype 5620 DMD terminal connected to its standard output. *file* must be a DMD object file. *wtinit* performs all necessary bootstrap and protocol procedures.

There are two options.

- -d Prints out the sizes of the text, data, and bss portions of the down-loaded *file* on standard error.
- -p Prints the down-loading protocol statistics and a trace on standard error.

The environment variable **JPATH** is the analog of the shell's **PATH** variable to define a set of directories in which to search for *file*.

If the environment variable **DMDLOAD** has the value **hex**, *wtinit* will use a hexadecimal download protocol that uses only printable characters.

Terminal Feature Packages for specific versions of AT&T windowing terminals will include terminal-specific versions of *wtinit* under those installation sub-directories. */usr/lib/layersys/wtinit* is used for *layers*(1) initialization only when no Terminal Feature Package is in use.

EXIT STATUS

Returns **0** upon successful completion, **1** otherwise.

WARNING

Standard error should be redirected when using the -d or -p options.

SEE ALSO

layers(1) in the User's Reference Manual.

xtd - extract and print xt driver link structure

SYNOPSIS

xtd [-f] [-n ...]

DESCRIPTION

The *xtd* command is a debugging tool for the *xt*(7) driver. It performs an **XTIOCDATA** *ioctl*(2) call on its standard input file to extract the *Link* data structure for the attached group of channels. This call will fail if data extraction has not been configured in the driver or the standard input is not attached to an *xt*(7) channel. The data are printed one item per line on the standard output. The output should probably be formatted via **pr** -3.

The optional flags affect output as follows:

- -n *n* is a number in the range 0 to 7. Channel *n* is included in the list of channels to be printed. The default prints all channels, whereas the occurrence of one or more channel numbers implies a subset.
- -f Causes a "formfeed" character to be put out at the end of the output, for the benefit of page-display programs.

EXIT STATUS

Returns **0** upon successful completion, **1** otherwise.

SEE ALSO

xts(1M), xtt(1M), ioctl(2), xtproto(5) xt(7) in the System Administrator's Reference Manual. pr(1) in the User's Reference Manual.

xts - extract and print xt driver statistics

SYNOPSIS

xts [-f]

DESCRIPTION

The *xts* command is a debugging tool for the xt(7) driver. It performs an **XTIOCSTATS** *ioctl*(2) call on its standard input file to extract the accumulated statistics for the attached group of channels. This call will fail if statistics have not been configured in the driver, or the standard input is not attached to an xt(7) channel. The statistics are printed, one item per line, on the standard output.

-f Causes a "formfeed" character to be put out at the end of the output, for the benefit of page-display programs.

EXIT STATUS

Returns **0** upon successful completion, **1** otherwise.

SEE ALSO

xtd(1M), xtt(1M), ioctl(2), xtproto(5)

xt(7) in the System Administrator's Reference Manual.

xtt - extract and print xt driver packet traces

SYNOPSIS

xtt [-f] [-0]

DESCRIPTION

The *xtt* command is a debugging tool for the xt(7) driver. It performs an **XTIOCTRACE** *ioctl*(2) call on its standard input file to turn on tracing and extract the circular packet trace buffer for the attached group of channels. This call will fail if tracing has not been configured in the driver, or the standard input is not attached to an xt(7) channel. The packets are printed on the standard output.

The optional flags are:

- -f Causes a "formfeed" character to be put out at the end of the output, for the benefit of page-display programs.
- -o Turns off further driver tracing.

EXIT STATUS

Returns 0 upon successful completion, 1 otherwise.

NOTE

If driver tracing has not been turned on for the terminal session by invoking *layers*(1) with the -t option, *xtt* will not generate any output the first time it is executed.

SEE ALSO

xtd(1M), xts(1M), ioctl(2), layers(5) xt(7) in the System Administrator's Reference Manual. layers(1) in the User's Reference Manual. YACC(1)

NAME

yacc – yet another compiler-compiler

SYNOPSIS

yacc [-vdlt] grammar

DESCRIPTION

The *yacc* command converts a context-free grammar into a set of tables for a simple automaton which executes an LR(1) parsing algorithm. The grammar may be ambiguous; specified precedence rules are used to break ambiguities.

The output file, **y.tab.c**, must be compiled by the C compiler to produce a program *yyparse*. This program must be loaded with the lexical analyzer program, *yylex*, as well as *main* and *yyerror*, an error-handling routine. These routines must be supplied by the user; lex(1) is useful for creating lexical analyzers usable by *yacc*.

If the -v flag is given, the file **y.output** is prepared, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.

If the -d flag is used, the file **y.tab.h** is generated with the **#define** statements that associate the *yacc*-assigned "token codes" with the user-declared "token names". This allows source files other than **y.tab.c** to access the token codes.

If the **-1** flag is given, the code produced in **y.tab.c** will *not* contain any **#line** constructs. This should only be used after the grammar and the associated actions are fully debugged.

Runtime debugging code is always generated in **y.tab.c** under conditional compilation control. By default, this code is not included when **y.tab.c** is compiled. However, when *yacc*'s **-t** option is used, this debugging code will be compiled by default. Independent of whether the **-t** option was used, the runtime debugging code is under the control of **YYDEBUG**, a preprocessor symbol. If **YYDEBUG** has a non-zero value, then the debugging code is included. If its value is zero, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster.

FILES

y.output y.tab.c y.tab.h defines for token names yacc.tmp, yacc.debug, yacc.acts temporary files /usr/lib/yaccpar parser prototype for C programs

SEE ALSO

lex(1). *Programmer's Guide*.

YACC(1)

DIAGNOSTICS

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output; a more detailed report is found in the **y.output** file. Similarly, if some rules are not reachable from the start symbol, this is also reported.

CAVEAT

Because file names are fixed, at most one *yacc* process can be active in a given directory at a given time.

intro - introduction to system calls and error numbers

SYNOPSIS

#include <errno.h>

DESCRIPTION

This section describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value. This is almost always -1 or the NULL pointer; the individual descriptions specify the details. An error number is also made available in the external variable *errno*. *Errno* is not cleared on successful calls, so it should be tested only after an error has been indicated.

Each system call description attempts to list all possible error numbers. The following is a complete list of the error numbers and their names as defined in $\langle errno.h \rangle$.

1 EPERM Not owner

Typically this error indicates an attempt to modify a file in some way forbidden except to its owner or super-user. It is also returned for attempts by ordinary users to do things allowed only to the super-user.

2 ENOENT No such file or directory

This error occurs when a file name is specified and the file should exist but doesn't, or when one of the directories in a path name does not exist.

3 ESRCH No such process

No process can be found corresponding to that specified by *pid* in *kill*(2) or *ptrace*(2).

4 EINTR Interrupted system call

An asynchronous signal (such as interrupt or quit), which the user has elected to catch, occurred during a system call. If execution is resumed after processing the signal, it will appear as if the interrupted system call returned this error condition.

5 EIO I/O error

Some physical I/O error has occurred. This error may in some cases occur on a call following the one to which it actually applies.

6 ENXIO No such device or address

I/O on a special file refers to a subdevice which does not exist, or beyond the limits of the device. It may also occur when, for example, a tape drive is not on-line or no disk pack is loaded on a drive.

7 E2BIG Arg list too long

An argument list longer than 5,120 bytes is presented to a member of the exec(2) family.

8 ENOEXEC Exec format error

A request is made to execute a file which, although it has the appropriate permissions, does not start with a valid magic number [see a.out(4)].

9 EBADF Bad file number

Either a file descriptor refers to no open file, or a *read*(2) [respectively, *write*(2)] request is made to a file which is open only for writing (respectively, reading).

10 ECHILD No child processes

A *wait* was executed by a process that had no existing or unwaitedfor child processes.

11 EAGAIN No more processes

A *fork* failed because the system's process table is full or the user is not allowed to create any more processes. Or a system call failed because of insufficient memory or swap space.

12 ENOMEM Not enough space

During an exec(2), brk(2), or sbrk(2), a program asks for more space than the system is able to supply. This may not be a temporary condition; the maximum space size is a system parameter. The error may also occur if the arrangement of text, data, and stack segments requires too many segmentation registers, or if there is not enough swap space during a *fork*(2). If this error occurs on a resource associated with Remote File Sharing (RFS), it indicates a memory depletion wich may be temporary, dependent on system activity at the time the call was invoked.

13 EACCES Permission denied

An attempt was made to access a file in a way forbidden by the protection system.

- 14 EFAULT Bad address The system encountered a hardware fault in attempting to use an argument of a system call.
- 15 ENOTBLK Block device required

A non-block file was mentioned where a block device was required, e.g., in *mount*(2).

16 EBUSY Device or resource busy

An attempt was made to mount a device that was already mounted or an attempt was made to dismount a device on which there is an active file (open file, current directory, mounted-on file, active text segment). It will also occur if an attempt is made to enable accounting when it is already enabled. The device or resource is currently unavailable.

17 EEXIST File exists

An existing file was mentioned in an inappropriate context, e.g., *link*(2).

18 EXDEV Cross-device link

A link to a file on another device was attempted.

19 ENODEV No such device

An attempt was made to apply an inappropriate system call to a device; e.g., read a write-only device.

20 ENOTDIR Not a directory

A non-directory was specified where a directory is required, for example in a path prefix or as an argument to *chdir*(2).

21 EISDIR Is a directory

An attempt was made to write on a directory.

22 EINVAL Invalid argument

Some invalid argument (e.g., dismounting a non-mounted device; mentioning an undefined signal in *signal*(2) or *kill*(2); reading or writing a file for which *lseek*(2) has generated a negative pointer). Also set by the math functions described in the (3M) entries of this manual.

23 ENFILE File table overflow

The system file table is full, and temporarily no more *opens* can be accepted.

- 24 EMFILE Too many open files No process may have more than NOFILES (default 20) descriptors open at a time.
- 25 ENOTTY Not a character device (or) Not a typewriter

An attempt was made to *ioctl*(2) a file that is not a special character device.

26 ETXTBSY Text file busy

An attempt was made to execute a pure-procedure program that is currently open for writing. Also an attempt to open for writing or to remove a pure-procedure program that is being executed.

27 EFBIG File too large

The size of a file exceeded the maximum file size or ULIMIT [see *ulimit*(2)].

28 ENOSPC No space left on device

During a write(2) to an ordinary file, there is no free space left on the device. In fcntl(2), the setting or removing of record locks on a file cannot be accomplished because there are no more record entries left on the system.

29 ESPIPE Illegal seek

An lseek(2) was issued to a pipe.

30 EROFS Read-only file system

An attempt to modify a file or directory was made on a device mounted read-only.

31 EMLINK Too many links

An attempt to make more than the maximum number of links (1000) to a file.

32 EPIPE Broken pipe

A write on a pipe for which there is no process to read the data. This condition normally generates a signal; the error is returned if the signal is ignored. 33 EDOM Math argument

The argument of a function in the math package (3M) is out of the domain of the function.

34 ERANGE Result too large

The value of a function in the math package (3M) is not representable within machine precision.

35 ENOMSG No message of desired type

An attempt was made to receive a message of a type that does not exist on the specified message queue [see msgop(2)].

36 EIDRM Identifier removed

This error is returned to processes that resume execution due to the removal of an identifier from the file system's name space [see *msgctl*(2), *semctl*(2), and *shmctl*(2)].

- 37-44 Reserved numbers
- 45 EDEADLK Deadlock

A deadlock situation was detected and avoided. This error pertains to file and record locking.

46 ENOLCK No lock

In *fcntl*(2) the setting or removing of record locks on a file cannot be accomplished because there are no more record entries left on the system.

- 60 ENOSTR Not a stream A *putmsg*(2) or *getmsg*(2) system call was attempted on a file descriptor that is not a STREAMS device.
- 62 ETIME Stream ioctl timeout

The timer set for a STREAMS *ioctl*(2) call has expired. The cause of this error is device specific and could indicate either a hardware or software failure, or perhaps a timeout value that is too short for the specific operation. The status of the *ioctl*(2) operation is indeterminate.

63 ENOSR No stream resources

During a STREAMS *open*(2), either no STREAMS queues or no STREAMS head data structures were available.

64 ENONET Machine is not on the network

This error is Remote File Sharing (RFS)-specific. It occurs when users try to advertise, unadvertise, mount, or unmount remote resources while the machine has not done the proper start-up to connect to the network.

65 ENOPKG No package

This error occurs when users attempt to use a system call from a package which has not been installed.

66 EREMOTE Resource is remote

This error is RFS-specific. It occurs when users try to advertise a resource which is not on the local machine, or try to mount/unmount a device (or path name) that is on a remote machine.

67 ENOLINK Virtual circuit is gone

This error is RFS-specific. It occurs when the link (virtual circuit) connecting to a remote machine is gone.

68 EADV Advertise error

This error is RFS-specific. It occurs when users try to advertise a resource which has been advertised already, or try to stop the RFS while there are resources still advertised, or try to force unmount a resource when it is still advertised.

69 ESRMNT Srmount error

This error is RFS-specific. It occurs when users try to stop RFS while there are resources still mounted by remote machines.

70 ECOMM Communication error

This error is RFS-specific. It occurs when trying to send messages to remote machines but no virtual circuit can be found.

71 EPROTO Protocol error

Some protocol error occurred. This error is device-specific, but is generally not related to a hardware failure.

74 EMULTIHOP Multihop attempted

This error is RFS-specific. It occurs when users try to access remote resources which are not directly accessible.

77 EBADMSG Bad message

During a *read*(2), *getmsg*(2), or *ioctl*(2) L_RECVFD system call to a STREAMS device, something has come to the head of the queue that can't be processed. That something depends on the system call:

read(2)—control information or a passed file descriptor.

getmsg(2)—passed file descriptor.

ioctl(2)—control or data information.

83 ELIBACC Cannot access a needed shared library

Trying to *exec*(2) an *a.out* that requires a shared library (to be linked in) and the shared library doesn't exist or the user doesn't have permission to use it.

84 ELIBMAX Accessing a corrupted shared library

Trying to *exec*(2) an *a.out* that requires a shared library (to be linked in) and *exec*(2) could not load the shared library. The shared library is probably corrupted.

85 ELIBSCN .lib section in a.out corrupted

Trying to exec(2) an *a.out* that requires a shared library (to be linked in) and there was erroneous data in the .lib section of the *a.out*. The .lib section tells exec(2) what shared libraries are needed. The *a.out* is probably corrupted.

- 86 ELIBMAX Attempting to link in more shared libraries than system limit Trying to *exec*(2) an *a.out* that requires more shared libraries (to be linked in) than is allowed on the current configuration of the system. See the System Administrator's Guide.
- 87 ELIBEXEC Cannot exec a shared library directly
 - Trying to *exec*(2) a shared library directly. This is not allowed.

DEFINITIONS

Process ID. Each active process in the system is uniquely identified by a positive integer called a process ID. The range of this ID is from 1 to 30,000. By convention, process-ID 0 and 1 are reserved for special system processes.

Parent Process ID. A new process is created by a currently active process [see fork(2)]. The parent process ID of a process is the process ID of its creator.

Process Group ID. Each active process is a member of a process group that is identified by a positive integer called the process group ID. This ID is the process ID of the group leader. This grouping permits the signaling of related processes [see kill(2)].

Process Group Leader. A process group leader is any process whose process group ID is the same as its process ID. Any process that is not a process group leader may detach itself from its current process group and become a new process group leader by calling the setpgrp(2).

Tty Group ID. Each active process can be a member of a terminal group that is identified by a positive integer called the tty group ID. This grouping is used to terminate a group of related processes upon termination of one of the processes in the group [see *exit*(2) and *signal*(2)].

Real User ID and Real Group ID. Each user allowed on the system is identified by a positive integer (0 to 65535) called a real user ID.

Each user is also a member of a group. The group is identified by a positive integer called the real group ID.

An active process has a real user ID and real group ID that are set to the real user ID and real group ID, respectively, of the user responsible for the creation of the process.

Effective User ID and Effective Group ID. An active process has an effective user ID and an effective group ID that are used to determine file access permissions (see below). The effective user ID and effective group ID are equal to the process's real user ID and real group ID respectively, unless the process or one of its ancestors evolved from a file that had the set-user-ID bit or set-group ID bit set [see *exec*(2)].

Super-user. A process is recognized as a *super-user* process and is granted special privileges, such as immunity from file permissions, if its effective user ID is 0.

Special Processes. The processes with a process ID of 0 and a process ID of 1 are special processes and are referred to as *proc0* and *proc1*.

Proc0 is the scheduler. *Proc1* is the initialization process (*init*). Proc1 is the ancestor of every other process in the system and is used to control the process structure.

File Descriptor. A file descriptor is a small integer used to do I/O on a file. The value of a file descriptor is from 0 to (NOFILES - 1). A process may have no more than NOFILES file descriptors open simultaneously. A file descriptor is returned by system calls such as open(2), or pipe(2). The file descriptor is used as an argument by calls such as read(2), write(2), ioctl(2), and close(2).

File Name. Names consisting of 1 to 14 characters may be used to name an ordinary file, special file or directory.

These characters may be selected from the set of all character values excluding 0 (null) and the ASCII code for / (slash).

Note that it is generally unwise to use *, ?, [, or] as part of file names because of the special meaning attached to these characters by the shell [see sh(1)]. Other characters to avoid are the hypen, blank, tab, <, >, blackslash, single and double quotes, accent grave, vertical bar, caret, curly braces, and parentheses. Although permitted, the use of unprintable characters in file names should be avoided.

Path Name and Path Prefix. A path name is a null-terminated character string starting with an optional slash (/), followed by zero or more directory names separated by slashes, optionally followed by a file name.

If a path name begins with a slash, the path search begins at the *root* directory. Otherwise, the search begins from the current working directory.

A slash by itself names the root directory. An attempt to create or delete the path-name slash by itself is undefined and may be considered an error. The meaning of . and .. are defined under directory.

Unless specifically stated otherwise, the null path name is treated as if it named a non-existent file.

Directory. Directories organize files into a hierarchical system of files where directories are the nodes in the hierarchy. A directory is a file that catalogues the list of files, including directories (sub-directories), that are directly beneath it in the hierarchy. Directory entries are called links. By convention, a directory contains at least two links, . and ..., referred to as *dot*

and *dot-dot* respectively. Dot refers to the directory itself and dot-dot refers to its parent directory. The root-directory, which is the top-most node of the hierarchy, has itself as its parent-directory. The path-name of the root-directory is / and the parent directory of the root-directory is /.

Root Directory and Current Working Directory. Each process has associated with it a concept of a root directory and a current working directory for the purpose of resolving path name searches. The root directory of a process need not be the root directory of the root file system.

File Access Permissions. Read, write, and execute/search permissions on a file are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches the user ID of the owner of the file; and the appropriate access bit of the "owner" portion (0700) of the file mode is set.

The effective user ID of the process does not match the user ID of the owner of the file; and the effective group ID of the process matches the group of the file; and the appropriate access bit of the "group" portion (0070) of the file mode is set.

The effective user ID of the process does not match the user ID of the owner of the file; and the effective group ID of the process does not match the group ID of the file; and the appropriate access bit of the "other" portion (0007) of the file mode is set.

Otherwise, the corresponding permissions are denied.

Message Queue Identifier. A message queue identifier (msqid) is a unique positive integer created by a *msgget*(2) system call. Each msqid has a message queue and a data structure associated with it. The data structure is referred to as *msqid_ds* and contains the following members:

struct	<pre>ipc_perm msg_perm;</pre>
struct	msg *msg_first;
struct	msg *msg_last;
ushort	msg_cbytes;
ushort	msg_qnum;
ushort	msg_qbytes;
ushort	msg_lspid;
ushort	msg_lrpid;
time_t	msgstime;
time_t	msg_rtime;
time_t	msg_ctime;

msg_perm is an ipc_perm structure that specifies the message operation permission (see below). This structure includes the following members:

ushort	cuid;	/* creator user id */
ushort	cgid;	/* creator group id */

ushort	uid;	/* user id */
ushort	gid;	/* group id */
ushort	mode;	/* r/w permission */
ushort	seq;	/* slot usage sequence # */
key_t	key;	/* key */

msg *msg_first

is a pointer to the first message on the queue.

msg *msg_last

is a pointer to the last message on the queue.

msg_cbytes

is the current number of bytes on the queue.

msg_qnum

is the number of messages currently on the queue.

msg_qbytes

is the maximum number of bytes allowed on the queue.

msg_lspid

is the process id of the last process that performed a *msgsnd* operation.

msg_lrpid

is the process id of the last process that performed a *msgrcv* operation.

msg_stime

is the time of the last *msgsnd* operation.

msg__rtime

is the time of the last *msgrcv* operation.

msg_ctime

is the time of the last *msgctl*(2) operation that changed a member of the above structure.

Message Operation Permissions. In the *msgop*(2) and *msgctl*(2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed, interpreted as follows:

00400	Read by user
00200	Write by user
00040	Read by group
00020	Write by group
00004	Read by others
00002	Write by others

Read and write permissions on a msqid are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches **msg_perm.cuid** or **msg_perm.uid** in the data structure associated with *msqid* and the appropriate bit of the "user" portion (0600) of **msg_perm.mode** is set.

The effective group ID of the process matches **msg_perm.cgid** or **msg_perm.gid** and the appropriate bit of the "group" portion (060) of **msg_perm.mode** is set.

The appropriate bit of the "other" portion (006) of **msg_perm.mode** is set.

Otherwise, the corresponding permissions are denied.

Semaphore Identifier. A semaphore identifier (semid) is a unique positive integer created by a *semget*(2) system call. Each semid has a set of semaphores and a data structure associated with it. The data structure is referred to as *semid_ds* and contains the following members:

struct	<pre>ipc_perm sem_perm;</pre>	/* operation permission struct */
struct	sem *sem_base;	/* ptr to first semaphore in set */
ushort	semnsems;	/* number of sems in set */
time_t	sem_otime;	/* last operation time */
timet	sem_ctime;	/* last change time */
		/* Times measured in secs since */
		/* 00:00:00 GMT, Jan. 1, 1970 */

sem_perm is an ipc_perm structure that specifies the semaphore operation permission (see below). This structure includes the following members:

ushort	uid;	/* user id */
ushort	gid;	/* group id */
ushort	cuid;	/* creator user id */
ushort	cgid;	/* creator group id */
ushort	mode;	/* r/a permission */
ushort	seq;	/* slot usage sequence number */
key_t	key;	/* key */

sem_nsems

is equal to the number of semaphores in the set. Each semaphore in the set is referenced by a positive integer referred to as a *sem_num*. Sem_num values run sequentially from 0 to the value of sem_nsems minus 1.

sem_otime

is the time of the last *semop*(2) operation.

sem_ctime

is the time of the last *semctl*(2) operation that changed a member of the above structure.

A semaphore is a data structure called *sem* that contains the following members:

ushort	semval;	/* semaphore value */
short	sempid;	/* pid of last operation */

ushort semncnt; /* # awaiting semval > cval */ ushort semzcnt; /* # awaiting semval = 0 */

semval

is a non-negative integer which is the actual value of the semphore.

sempid

is equal to the process ID of the last process that performed a semaphore operation on this semaphore.

semncnt

is a count of the number of processes that are currently suspended awaiting this semaphore's semval to become greater than its current value.

semzcnt

is a count of the number of processes that are currently suspended awaiting this semaphore's semval to become zero.

Semaphore Operation Permissions. In the *semop*(2) and *semctl*(2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed, interpreted as follows:

00400	Read by user
00200	Alter by user
00040	Read by group
00020	Alter by group
00004	Read by others
00002	Alter by others

Read and alter permissions on a *semid* are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches **sem_perm.cuid** or **sem_perm.uid** in the data structure associated with *semid*, and the appropriate bit of the "user" portion (0600) of **sem_perm.mode** is set.

The effective group ID of the process matches **sem_perm.cgid** or **sem_perm.gid** and the appropriate bit of the "group" portion (060) of **sem_perm.mode** is set.

The appropriate bit of the "other" portion (006) of **sem_perm.mode** is set.

Otherwise, the corresponding permissions are denied.

Shared Memory Identifier. A shared memory identifier (*shmid*) is a unique positive integer created by a *shmget*(2) system call. Each *shmid* has a segment of memory (referred to as a shared memory segment) and a data structure associated with it. (Note that these shared memory segments must be explicitly removed by the user after the last reference to them is removed.)

INTRO(2)

The data structure is referred to as *shmid_ds* and contains the following members:

struct	ipc_perm shm_perm	; /* operation permission struct */
int	shm_segsz;	/* size of segment */
struct	region *shm_reg;	/*ptr to region structure */
char	pad[4];	/* for swap compatibility */
ushort	shm_lpid;	/* pid of last operation */
ushort	shm_cpid;	/* creator pid */
ushort	shm_nattch;	/* number of current attaches */
ushort	shmcnattch;	/* used only for shminfo */
time_t	shm_atime;	/* last attach time */
timet	shm_dtime;	/* last detach time */
timet	shm_ctime;	/* last change time */
		/* Times measured in secs since */
		/* 00:00:00 GMT, Jan. 1, 1970 */

shm_perm is an ipc_perm structure that specifies the shared memory operation permission (see below). This structure includes the following members:

ushort	cuid;	/* creator user id */
ushort	cgid;	/* creator group id */
ushort	uid;	/* user id */
ushort	gid;	/* group id */
ushort	mode;	/* r/w permission */
ushort	seq;	/* slot usage sequence # */
key_t	key;	/* key */

shm_segsz

specifies the size of the shared memory segment in bytes.

shm_cpid

is the process id of the process that created the shared memory identifier.

shm_lpid

is the process id of the last process that performed a shmop(2) operation.

shm_nattch

is the number of processes that currently have this segment attached.

shm_atime

is the time of the last *shmat*(2) operation,

shm_dtime

is the time of the last *shmdt*(2) operation.

shm_ctime

is the time of the last *shmctl*(2) operation that changed one of the members of the above structure.

Shared Memory Operation Permissions. In the *shmop*(2) and *shmctl*(2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed, interpreted as follows:

00400	Read by user
00200	Write by user
00040	Read by group
00020	Write by group
00004	Read by others
00002	Write by others

Read and write permissions on a shmid are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches **shm_perm.cuid** or **shm_perm.uid** in the data structure associated with *shmid* and the appropriate bit of the "user" portion (0600) of **shm_perm.mode** is set.

The effective group ID of the process matches **shm_perm.cgid** or **shm_perm.gid** and the appropriate bit of the "group" portion (060) of **shm_perm.mode** is set.

The appropriate bit of the "other" portion (06) of **shm_perm.mode** is set.

Otherwise, the corresponding permissions are denied.

STREAMS. A set of kernel mechanisms that support the development of network services and data communication *drivers*. It defines interface standards for character input/output within the kernel and between the kernel and user-level processes. The STREAMS mechanism is composed of utility routines, kernel facilities, and a set of data structures.

Stream. A stream is a full-duplex data path within the kernel between a user process and driver routines. The primary components are a *stream head*, a *driver*, and zero or more *modules* between the *stream head* and *driver*. A *stream* is analogous to a Shell pipeline except that data flow and processing are bidirectional.

Stream Head. In a *stream*, the *stream head* is the end of the *stream* that provides the interface between the *stream* and a user process. The principle functions of the *stream head* are processing STREAMS-related system calls, and passing data and information between a user process and the *stream*.

Driver. In a *stream*, the *driver* provides the interface between peripheral hardware and the *stream*. A *driver* can also be a pseudo-*driver*, such as a *multiplexer* or log *driver* [see *log*(7)], which is not associated with a hardware device.

Module. A module is an entity containing processing routines for input and output data. It always exists in the middle of a *stream*, between the stream's head and a *driver*. A *module* is the STREAMS counterpart to the commands in a Shell pipeline except that a module contains a pair of functions which allow independent bidirectional (*downstream* and *upstream*) data flow and processing.

Downstream. In a stream, the direction from stream head to driver.

Upstream. In a *stream*, the direction from *driver* to *stream head*.

Message. In a *stream*, one or more blocks of data or information, with associated STREAMS control structures. *Messages* can be of several defined types, which identify the *message* contents. *Messages* are the only means of transferring data and communicating within a *stream*.

Message Queue. In a stream, a linked list of messages awaiting processing by a module or driver.

Read Queue. In a stream, the message queue in a module or driver containing messages moving upstream.

Write Queue. In a stream, the message queue in a module or driver containing messages moving downstream.

Multiplexer. A multiplexer is a driver that allows *streams* associated with several user processes to be connected to a single *driver*, or several *drivers* to be connected to a single user process. STREAMS does not provide a general multiplexing *driver*, but does provide the facilities for constructing them, and for connecting multiplexed configurations of *streams*.

SEE ALSO

intro(3).

ACCESS(2)

NAME

access – determine accessibility of a file

SYNOPSIS

#include <unistd.h>

int access (path, amode) char *path; int amode;

DESCRIPTION

The *path* argument points to a path name naming a file. The *access* function checks the named file for accessibility according to the bit pattern contained in *amode*, using the real user ID in place of the effective user ID and the real group ID in place of the effective group ID. The bit pattern contained in *amode* is constructed as follows:

04 read

02 write

- 01 execute (search)
- 00 check existence of file

The symbolic constants for the argument **amode** are defined by the **<unistd.h>** header file and are as follows:

Name Description

R_OK test for *read* permission.

W_OK test for *write* permission.

X_OK test for *execute* (*search*) permission.

F_OK test for existence of file.

The argument **amode** is either the logical OR of one or more of the values of the symbolic constants for **R_OK**, **W_OK**, and **X_OK** or is the value of the symbolic constant **F_OK**.

Access to the file is denied if one or more of the following are true:

[ENOTDIR]	A component of the path prefix is not a directory.
[ENOENT]	Read, write, or execute (search) permission is
	requested for a null path name.
[ENOENT]	The named file does not exist.
[EACCES]	Search permission is denied on a component of the path prefix.
[EROFS]	Write access is requested for a file on a read-only file system.
[ETXTBSY]	Write access is requested for a pure procedure (shared text) file that is being executed.
[EACCES]	Permission bits of the file mode do not permit the requested access.
[EFAULT]	<i>Path</i> points outside the allocated address space for the process.
[EINTR]	A signal was caught during the <i>access</i> system call.
[ENOLINK]	<i>Path</i> points to a remote machine and the link to that machine is no longer active.

[EMULTIHOP] Components of *path* require hopping to multiple remote machines.

The owner of a file has permission checked with respect to the "owner" read, write, and execute mode bits. Members of the file's group other than the owner have permissions checked with respect to the "group" mode bits, and all others have permissions checked with respect to the "other" mode bits.

SEE ALSO

chmod(2), stat(2).

DIAGNOSTICS

If the requested access is permitted, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

ACCT(2)

NAME

acct - enable or disable process accounting

SYNOPSIS

int acct (path) char *path;

DESCRIPTION

acct is used to enable or disable the system process accounting routine. If the routine is enabled, an accounting record will be written on an accounting file for each process that terminates. Termination can be caused by one of two things: an *exit* call or a signal [see *exit*(2) and *signal*(2)]. The effective user ID of the calling process must be super-user to use this call.

path points to a pathname naming the accounting file. The accounting file format is given in acct(4).

The accounting routine is enabled if *path* is non-zero and no errors occur during the system call. It is disabled if *path* is zero and no errors occur during the system call.

acct will fail if one or more of the following are true:

[EPERM]	The effective user of	the callir	ng process is not super-user.
---------	-----------------------	------------	-------------------------------

- [EBUSY] An attempt is being made to enable accounting when it is already enabled.
- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] One or more components of the accounting file path name do not exist.
- [EACCES] The file named by *path* is not an ordinary file.
- [EROFS] The named file resides on a read-only file system.
- [EFAULT] *Path* points to an illegal address.

SEE ALSO

exit(2), signal(2), acct(4).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

alarm - set a process alarm clock

SYNOPSIS

unsigned alarm (sec) unsigned sec;

DESCRIPTION

The *alarm* system call instructs the alarm clock of the calling process to send the signal **SIGALRM** to the calling process after the number of real time seconds specified by *sec* have elapsed [see *signal*(2)].

Alarm requests are not stacked; successive calls reset the alarm clock of the calling process.

If sec is 0, any previously made alarm request is canceled. The fork(2) system call sets the alarm clock of a new process to 0. A process created by the exec(2) family of calls inherits the time left on the old process's alarm clock.

SEE ALSO

exec(2), fork(2), pause(2), signal(2), sigpause(2), sigset(2).

DIAGNOSTICS

The *alarm* system call returns the amount of time previously remaining in the alarm clock of the calling process.

BRK(2)

NAME

brk, sbrk - change data segment space allocation

SYNOPSIS

int brk (endds) char *endds; char *sbrk (incr)

int incr;

DESCRIPTION

The *brk* and *sbrk* system calls are used to change dynamically the amount of space allocated for the calling process's data segment [see *exec*(2)]. The change is made by resetting the process's break value and allocating the appropriate amount of space. The break value is the address of the first location beyond the end of the data segment. The amount of allocated space increases as the break value increases. Newly allocated space is set to zero. If, however, the same memory space is reallocated to the same process, its contents are undefined.

The *brk* system call sets the break value to *endds* and changes the allocated space accordingly.

The *sbrk* system call adds *incr* bytes to the break value and changes the allocated space accordingly. *Incr* can be negative, in which case the amount of allocated space is decreased.

For the 80286 computer *endds* and *incr* are rounded up to the next multiple of 512 in large model programs.

The *brk* and *sbrk* system calls will fail without making any change in the allocated space if one or more of the following are true:

- [ENOMEM] (For 80386 and 80286 computers) Such a change would result in more space being allocated than is allowed by the system-imposed maximum process size [see *ulimit*(2)].
- [ENOMEM] (For the 80286 computer only) Such a change would result in the segment selector of the break location being greater than or equal to the segment selector of any attached shared memory segment [see *shmop*(2)].
- [ENOMEM] (For the 80286 computer only) A large model process attempts to *brk* to an *endds* that has a segment selector which is greater than one more than the segment selector of the old break value.
- [ENOMEM] (For the 80286 computer only) Such a change would result in the break value being in the stack or text areas of the process.
- [ENOMEM] (For the 80286 computer only) Such a change would result in the break value being placed within an unallocated area between two currently allocated segments.

[EAGAIN] (For the 80386 computer only) Total amount of system memory available for a read during physical IO is temporarily insufficient [see shmop(2)]. This may occur even though the space requested was less than the system-imposed maximum process size [see ulimit(2)].

The following table summarizes the actions of brk(2), and sbrk(2) in the different memory models (S = small, L = large). The table is applicable to the 80286 computer only.

Operation	Model	Action
sbrk(0)	S	Returns current break value.
	L	Returns starting address of NEXT data
		segment.
sbrk(+incr)	S	Allocates incr bytes in current segment.
	L	Allocates incr bytes in next data segment
		(space from old break value* to end of
		old segment is not allocated).
	S,L	Returns the same value as sbrk (0).
sbrk(-incr)	S	Frees incr bytes in current segment.
	L	Frees incr bytes from as many segments
		as needed.
	<u>S,L</u>	Returns the same value as sbrk (0).
brk(endds)	S,L	Sets break value to endds and allocates
(current segment)		or frees memory to that point.
brk(endds)	L	Sets break value to endds and frees
(previous segment)		memory between old break value and endds.
		Endds must be an allocated location.
		Can free multiple segments.
brk(endds)	L	Sets break value to endds in next segment.
(new segment)	L	Can allocate up to one segment per call.
	L	Space from old break value to end of
		old segment is not allocated.

* "Old break value" is the break value previous to the execution of the current operation.

RETURN VALUE

On the 80386 computer, upon successful completion brk returns a value of 0, and sbrk returns the old break value. On the 80286 computer, upon successful completion brk returns a value of 0, and sbrk returns either the current break value (small model) or the starting address of the next data segment (large model). Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

CAVEATS (80286 computer only)

Brk(2) and sbrk(2) are not intended for general use: The malloc(3C) function is the recommended way to obtain arbitrary amounts of memory.

Processes must not assume that the allocated address space is contiguous. When large model processes perform any *sbrk* with a non-negative *incr* or a brk to a new segment, the area between the old segment's break location offset and the end of the old segment (offset 65535) is not accessible. Any reference to this area will cause a segmentation violation.

SEE ALSO

exec(2), shmop(2), ulimit(2), end(3C).

•

chdir – change working directory

SYNOPSIS

int chdir (path) char *path;

DESCRIPTION

Path points to the path name of a directory. *chdir* causes the named directory to become the current working directory, the starting point for path searches for path names not beginning with /.

chdir will fail and the current working directory will be unchanged if one or more of the following are true:

[ENOTDIR] A component of the path name is not a directory.

[ENOENT] The named directory does not exist.

- [EACCES] Search permission is denied for any component of the path name.
- [EFAULT] *Path* points outside the allocated address space of the process.

[EINTR] A signal was caught during the *chdir* system call.

- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

SEE ALSO

chroot(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

CHMOD(2)

NAME

chmod – change mode of file

SYNOPSIS

#include <sys/types.h>
#include <sys/stat.h>

int chmod (path, mode) char *path; int mode;

DESCRIPTION

The *path* argument points to a path name naming a file. The *chmod* system call sets the access permission portion of the named file's mode according to the bit pattern contained in *mode*.

Access permission bits are interpreted as follows:

04000	Set user ID on execution.				
020#0	Set group ID on execution if # is 7, 5, 3, or 1				
	Enable mandatory file/record locking if # is 6, 4, 2, or 0				
01000	Save text image after execution.				
00400	Read by owner.				
00200	Write by owner.				
00100	Execute (search if a directory) by owner.				
00070	Read, write, execute (search) by group.				
00007	Read, write, execute (search) by others.				

Symbolic constants defining the access permission bits are in the *<sys/stat.h>* header file and should be used to construct the argument *mode*. The value of the argument *mode* should be the logical OR of the values of the desired permissions:

Name	Description
S_ISUID	Set user-ID on execution.
S_ISGID	Set group-ID on execution.
S_ISVTX	Reserved.
S_IRUSR	Read by owner.
S_IWUSR	Write by owner.
S_IXUSR	Execute (search) by owner.
S_IRGRP	Read by group.
S_IWGRP	Write by group.
S_IXGRP	Execute (search) by group.
SIROTH	Read by others (i.e., anyone else).
S_IWOTH	Write by others.
S_IXOTH	Execute (search) by others.

S_ENFMT Record locking enforced.

The effective user ID of the process must match the owner of the file or be super-user to change the mode of a file.

If the effective user ID of the process is not super-user, mode bit 01000 (save text image on execution) is cleared.

If the effective user ID of the process is not super-user and the effective group ID of the process does not match the group ID of the file, mode bit 02000 (set group ID on execution) is cleared.

If a 410 executable file has the sticky bit (mode bit 01000) set, the operating system will not delete the program text from the swap area when the last user process terminates. If a 413 executable file has the sticky bit set, the operating system will not delete the program text from memory when the last user process terminates. In either case, if the sticky bit is set, the text will already be available (either in a swap area or in memory) when the next user of the file executes it, thus making execution faster.

If the mode bit 02000 (set group ID on execution) is set and the mode bit 00010 (execute or search by group) is not set, mandatory file/record locking will exist on a regular file. This may effect future calls to open(2), creat(2), read(2), and write(2) on this file.

The *chmod* system call will fail and the file mode will be unchanged if one or more of the following are true:

[ENOTDIR]	A component of the path prefix is not a directory.
[ENOENT]	The named file does not exist.
[EACCES]	Search permission is denied on a component of the path prefix.
[EPERM]	The effective user ID does not match the owner of the file and the effective user ID is not super-user.
[EROFS]	The named file resides on a read-only file system.
[EFAULT]	The <i>path</i> argument points outside the allocated address space of the process.
[EINTR]	A signal was caught during the <i>chmod</i> system call.
[ENOLINK]	The <i>path</i> argument points to a remote machine and the link to that machine is no longer active.
[EMULTIHOP]	Components of <i>path</i> require hopping to multiple remote machines.

SEE ALSO

chown(2), creat(2), fcntl(2), mknod(2), open(2), read(2), write(2). chmod(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

CHOWN(2)

NAME

chown – change owner and group of a file

SYNOPSIS

int chown (path, owner, group) char *path; int owner, group;

DESCRIPTION

Path points to a path name naming a file. The owner ID and group ID of the named file are set to the numeric values contained in *owner* and *group* respectively.

Only processes with effective user ID equal to the file owner or super-user may change the ownership of a file.

If *chown* is invoked by other than the super-user, the set-user-ID and setgroup-ID bits of the file mode, 04000 and 02000 respectively, will be cleared.

chown will fail and the owner and group of the named file will remain unchanged if one or more of the following are true:

- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] The named file does not exist.
- [EACCES] Search permission is denied on a component of the path prefix.
- [EPERM] The effective user ID does not match the owner of the file and the effective user ID is not super-user.
- [EROFS] The named file resides on a read-only file system.
- [EFAULT] *Path* points outside the allocated address space of the process.
- [EINTR] A signal was caught during the *chown* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

SEE ALSO

chmod(2).

chown(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

chroot – change root directory

SYNOPSIS

int chroot (path) char *path;

DESCRIPTION

The *path* argument points to a path name naming a directory. The *chroot* system call causes the named directory to become the root directory, the starting point for path searches for path names beginning with /. The user's working directory is unaffected by the *chroot* system call.

The effective user ID of the process must be super-user to change the root directory.

The .. entry in the root directory is interpreted to mean the root directory itself. Thus, .. cannot be used to access files outside the subtree rooted at the root directory.

The *chroot* system call will fail and the root directory will remain unchanged if one or more of the following are true:

- [ENOTDIR] Any component of the path name is not a directory.
- [ENOENT] The named directory does not exist.
- [EPERM] The effective user ID is not super-user.
- [EFAULT] The *path* argument points outside the allocated address space of the process.
- [EINTR] A signal was caught during the *chroot* system call.
- [ENOLINK] The *Path* argument points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

SEE ALSO

chdir(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

CLOSE(2)

NAME

close - close a file descriptor

SYNOPSIS

int close (fildes) int fildes;

DESCRIPTION

The *fildes* argument is a file descriptor obtained from a *creat*, *open*, *dup*, *fcntl*, or *pipe* system call. The *close* system call closes the file descriptor indicated by *fildes*. All outstanding record locks owned by the process (on the file indicated by *fildes*) are removed.

If a STREAMS [see *intro*(2)] file is closed, and the calling process had previously registered to receive a SIGPOLL signal [see *signal*(2) and *sigset*(2)] for events associated with that file [see L_SETSIG in *streamio*(7)], the calling process will be unregistered for events associated with the file. The last *close* for a *stream* causes the *stream* associated with *fildes* to be dismantled. If O_NDELAY is not set and there have been no signals posted for the *stream*, *close* waits up to 15 seconds, for each module and driver, for any output to drain before dismantling the *stream*. If the O_NDELAY flag is set or if there are any pending signals, *close* does not wait for output to drain and dismantles the *stream* immediately.

The named file is closed unless one or more of the following are true:

[EBADF]	The fildes	argument is	not a	valid o	open f	file descriptor.
---------	------------	-------------	-------	---------	--------	------------------

- [EINTR] A signal was caught during the *close* system call.
- [ENOLINK] *Fildes* is on a remote machine and the link to that machine is no longer ctive.

SEE ALSO

creat(2), dup(2), exec(2), fcntl(2), intro(2), open(2), pipe(2), signal(2), sigset(2).

streamio(7) in the System Administrator's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

creat - create a new file or rewrite an existing one

SYNOPSIS

```
#include <sys/types.h>
#include <sys/stat.h>
```

```
int creat (path, mode)
char *path;
int mode;
```

DESCRIPTION

The *creat* system call creates a new ordinary file or prepares to rewrite an existing file named by the path name pointed to by *path*.

If the file exists, the length is truncated to 0 and the mode and owner are unchanged. Otherwise, the file's owner ID is set to the effective user ID of the process; the group ID of the process is set to the effective group ID of the process; and the low-order 12 bits of the file mode are set to the value of *mode* modified as follows:

All bits set in the process's file mode creation mask are cleared [see *umask*(2)].

The "save text image after execution bit" of the mode is cleared [see *chmod*(2)].

Upon successful completion, a write-only file descriptor is returned and the file is open for writing, even if the mode does not permit writing. The file pointer is set to the beginning of the file. The file descriptor is set to remain open across *exec* system calls [see fcntl(2)]. No process may have more than 20 files open simultaneously. A new file may be created with a mode that forbids writing.

Symbolic constants defining the access permission bits are specified in the *<sys/stat.h>* header file and should be used to construct *mode* [see *chmod*(2)].

The call creat(path, mode) is equivalent to the following [see open(2)]:

open(path, O_WRONLY | O_CREAT | O_TRUNC, mode)

The creat system call fails if one or more of the following are true:

[ENOTDIR] A	component of the	path prefix is no	t a directory.
-------------	------------------	-------------------	----------------

- [ENOENT] A component of the path prefix does not exist.
- [EACCES] Search permission is denied on a component of the path prefix.
- [ENOENT] The path name is null.
- [EACCES] The file does not exist and the directory in which the file is to be created does not permit writing.
- [EROFS] The named file resides or would reside on a read-only file system.

 The file is a executed.	pure	procedure	(shared	text)	file	that	is	being

- [EACCES] The file exists and write permission is denied.
- [EISDIR] The named file is an existing directory.
- [EMFILE] NOFILES file descriptors are currently open.
- [EFAULT] The *path* argument points outside the allocated address space of the process.
- [ENFILE] The system file table is full.
- [EAGAIN] The file exists, mandatory file/record locking is set, and there are outstanding record locks on the file [see *chmod*(2)].
- [EINTR] A signal was caught during the *creat* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.
- [ENOSPC] The file system is out of inodes.

SEE ALSO

chmod(2), close(2), dup(2), fcntl(2), lseek(2), open(2), read(2), umask(2), write(2).

DIAGNOSTICS

Upon successful completion, a non-negative integer, namely the file descriptor, is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

dup – duplicate an open file descriptor

SYNOPSIS

int dup (fildes) int fildes;

DESCRIPTION

The *fildes* argument is a file descriptor obtained from a *creat*, *open*, *dup*, *fcntl*, or *pipe* system call. The *dup* system call returns a new file descriptor having the following in common with the original:

Same open file (or pipe).

Same file pointer (i.e., both file descriptors share one file pointer).

Same access mode (read, write, or read/write).

The new file descriptor is set to remain open across *exec* system calls [see *fcntl*(2)].

The file descriptor returned is the lowest one available.

The *dup* system call will fail if one or more of the following are true:

[EBADF] The *fildes* argument is not a valid open file descriptor.

[EINTR] A signal was caught during the *dup* system call.

[EMFILE] NOFILES file descriptors are currently open.

[ENOLINK] *Fildes* is on a remote machine and the link to that machine is no longer active.

SEE ALSO

close(2), creat(2), exec(2), fcntl(2), open(2), pipe(2), lockf(3C).

DIAGNOSTICS

Upon successful completion a non-negative integer, namely the file descriptor, is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

exec: execl, execv, execle, execve, execlp, execvp - execute a file

SYNOPSIS

```
int execl (path, arg0, arg1, ..., argn, (char *)0)
char *path, *arg0, *arg1, ..., *argn;
int execv (path, argv)
char *path, *argv[ ];
int execle (path, arg0, arg1, ..., argn, (char *)0, envp)
char *path, *arg0, *arg1, ..., *argn, *envp[ ];
int execve (path, argv, envp)
char *path, *argv[ ], *envp[ ];
int execlp (file, arg0, arg1, ..., argn, (char *)0)
char *file, *arg0, *arg1, ..., *argn;
int execvp (file, argv)
char *file, *argv[ ];
```

DESCRIPTION

The *exec* system call in all its forms transforms the calling process into a new process. The new process is constructed from an ordinary, executable file called the *new process file*. This file consists of a header [see *a.out*(4)], a text segment, and a data segment. The data segment contains an initialized portion and an uninitialized portion (bss). There can be no return from a successful *exec* because the calling process is overlaid by the new process.

When a C program is executed, it is called as follows:

main (argc, argv, envp) int argc; char **argv, **envp;

where *argc* is the argument count, *argv* is an array of character pointers to the arguments themselves, and *envp* is an array of character pointers to the environment strings. As indicated, *argc* is conventionally at least one and the first member of the array points to a string containing the name of the file.

The *path* argument points to a path name that identifies the new process file.

The *file* argument points to the new process file. The path prefix for this file is obtained by a search of the directories passed as the *environment* line "PATH =" [see *environ*(5)]. The environment is supplied by the shell [see sh(1)].

The *arg0*, *arg1*, ..., *argn* are pointers to null-terminated character strings. These strings constitute the argument list available to the new process. By convention, at least *arg0* must be present and point to a string that is the same as *path* (or its last component).

The *argv* is an array of character pointers to null-terminated strings. These strings constitute the argument list available to the new process. By convention, *argv* must have at least one member, and it must point to a string

that is the same as *path* (or its last component). The *argv* is terminated by a null pointer.

The *envp* is an array of character pointers to null-terminated strings. These strings constitute the environment for the new process. The *envp* is terminated by a null pointer. For *execl* and *execv*, the C run-time start-off routine places a pointer to the environment of the calling process in the global cell:

extern char **environ;

and it is used to pass the environment of the calling process to the new process.

File descriptors open in the calling process remain open in the new process, except for those whose close-on-exec flag is set; see *fcntl*(2). For those file descriptors that remain open, the file pointer is unchanged.

Signals set to terminate the calling process will be set to terminate the new process. Signals set to be ignored by the calling process will be set to be ignored by the new process. Signals set to be caught by the calling process will be set to terminate new process; see *signal*(2).

For signals set by *sigset*(2), *exec* will ensure that the new process has the same system signal action for each signal type whose action is SIG_DFL, SIG_IGN, or SIG_HOLD as the calling process. However, if the action is to catch the signal, then the action will be reset to SIG_DFL, and any pending signal for this type will be held.

If the set-user-ID mode bit of the new process file is set [see *chmod*(2)], *exec* sets the effective user ID of the new process to the owner ID of the new process file. Similarly, if the set-group-ID mode bit of the new process file is set, the effective group ID of the new process is set to the group ID of the new process file. The real user ID and real group ID of the new process remain the same as those of the calling process.

The shared memory segments attached to the calling process will not be attached to the new process [see *shmop*(2)].

Profiling is disabled for the new process; see *profil*(2).

The new process also inherits the following attributes from the calling process:

nice value [see *nice*(2)] process ID parent process ID process group ID semadj values [see *semop*(2)] tty group ID [see *exit*(2) and *signal*(2)] trace flag [see *ptrace*(2) request 0] time left until an alarm clock signal [see *alarm*(2)] current working directory root directory file mode creation mask [see *umask*(2)] file size limit [see *ulimit*(2)] EXEC(2)

utime, *stime*, *cutime*, and *cstime* [see *times*(2)] file-locks [see *fcntl*(2) and *lockf*(3C)]

The *exec* system call will fail and return to the calling process if one or more of the following are true:

- [ENOENT] One or more components of the new process path name of the file do not exist.
- [ENOTDIR] A component of the new process path of the file prefix is not a directory.
- [EACCES] Search permission is denied for a directory listed in the new process file's path prefix.
- [EACCES] The new process file is not an ordinary file.
- [EACCES] The new process file mode denies execution permission.
- [ENOEXEC] The exec is not an *execlp* or *execvp*, and the new process file has the appropriate access permission but an invalid magic number in its header.
- [ETXTBSY] The new process file is a pure procedure (shared text) file that is currently open for writing by some process.
- [ENOMEM] The new process requires more memory than is allowed by the system-imposed maximum MAXMEM.
- [E2BIG] The number of bytes in the new process's argument list is greater than the system-imposed limit of 5120 bytes.
- [EFAULT] Required hardware is not present.
- [EFAULT] Path, argv, or envp point to an illegal address.
- [EAGAIN] Not enough memory.
- [ELIBACC] Required shared library does not have execute permission.
- [ELIBEXEC] Trying to *exec*(2) a shared library directly.
- [EINTR] A signal was caught during the *exec* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

DIAGNOSTICS

If *exec* returns to the calling process, an error has occurred; the return value will be -1 and *errno* will be set to indicate the error.

exit, __exit – terminate process

SYNOPSIS

void exit (status) int status; void __exit (status) int status;

DESCRIPTION

The *exit* system call terminates the calling process with the following consequences:

All of the file descriptors open in the calling process are closed.

If the parent process of the calling process is executing a *wait*, it is notified of the calling process's termination and the low order eight bits (i.e., bits 0377) of *status* are made available to it [see *wait*(2)].

If the parent process of the calling process is not executing a *wait*, the calling process is transformed into a zombie process. A *zombie process* is a process that only occupies a slot in the process table. It has no other space allocated either in user or kernel space. The process table slot that it occupies is partially overlaid with time accounting information (see **<sys/proc.h**>) to be used by *times*.

The parent process ID of all of the calling processes' existing child processes and zombie processes is set to 1. This means the initialization process [see *intro*(2)] inherits each of these processes.

Each attached shared memory segment is detached and the value of **shm_nattach** in the data structure associated with its shared memory identifier is decremented by 1.

For each semaphore for which the calling process has set a semadj value [see semop(2)], that semadj value is added to the semval of the specified semaphore.

If the process has a process, text, or data lock, an *unlock* is performed [see *plock*(2)].

An accounting record is written on the accounting file if the system's accounting routine is enabled [see acct(2)].

If the process ID, tty group ID, and process group ID of the calling process are equal, the **SIGHUP** signal is sent to each process that has a process group ID equal to that of the calling process.

A death of child signal is sent to the parent.

The C function *exit* may cause cleanup actions before the process exits. The function *__exit* circumvents all cleanup.

SEE ALSO

acct(2), intro(2), plock(2), semop(2), signal(2), sigset(2), wait(2).

WARNING

See WARNING in signal(2).

DIAGNOSTICS None. There can be no return from an *exit* system call.

,

fcntl - file control

SYNOPSIS

#include <fcntl.h>

int fcntl (fildes, cmd, arg) int fildes, cmd;

DESCRIPTION

The *fcntl* system call provides for control over open files. The *fildes* argument is an open file descriptor obtained from a *creat*, *open*, *dup*, *fcntl*, or *pipe* system call. The data type and value of *arg* are specific to the type of command specified by *cmd*. The symbolic names for commands and file status flags are defined by the <**fcntl.h**> header file.

The commands available are:

FDUPFD	Return a nev	v file descriptor	as follows:

Lowest numbered available file descriptor greater than or equal to *arg*.

Same open file (or pipe) as the original file.

Same file pointer as the original file (i.e., both file descriptors share one file pointer).

Same access mode (read, write, or read/write).

Same file status flags (i.e., both file descriptors share the same file status flags).

The close-on-exec flag associated with the new file descriptor is set to remain open across *exec*(2) system calls.

- F_GETFD Get the close-on-exec flag associated with the file descriptor *fildes*. If the low-order bit is **0** the file will remain open across *exec*; otherwise the file will be closed upon execution of *exec*.
- F_SETFD Set the close-on-exec flag associated with *fildes* to the low-order bit of *arg* (**0** or **1** as above).
- F_GETFL Get file status flags [see open(2)].
- F_SETFL Set *file* status flags to *arg*. Only certain flags can be set [see *fcntl*(5)].

The following commands are used for file-locking and record-locking. Locks may be placed on an entire file or segments of a file.

F_GETLK

Get the first lock which blocks the lock description given by the variable of type *struct flock* pointed to by *arg*. The information retrieved overwrites the information passed to *fcntl* in the *flock* structure. If no lock is found that would prevent this lock from being created, then the structure is passed back unchanged except for the lock type which will be set to F_UNLCK.

F_SETLK

Set or clear a file segment lock according to the variable of type *struct flock* pointed to by *arg* [see *fcntl*(5)]. The *cmd* F_SETLK is used to establish read (F_RDLCK) and write (F_WRLCK) locks, as well as remove either type of lock (F_UNLCK). If a read or write lock cannot be set, *fcntl* will return immediately with an error value of -1.

F_SETLKW

This *cmd* is the same as F_SETLK except that if a read or write lock is blocked by other locks, the process will sleep until the segment is free to be locked.

A read lock prevents any process from write locking the protected area. More than one read lock may exist for a given segment of a file at a given time. The file descriptor on which a read lock is being placed must have been opened with read access.

A write lock prevents any process from read-locking or write-locking the protected area. Only one write lock may exist for a given segment of a file at a given time. The file descriptor on which a write lock is being placed must have been opened with write access.

The structure *flock* defined by the <**fcntl.h**> header file describes a lock. It describes the type (*l_type*), starting offset (*l_whence*), relative offset (*l_start*), size (*l_len*), and process-ID (*l_pid*):

short <i>l_type</i> ;	/* F_RDLCK, F_WRLCK, F_UNLCK */
short <i>l_whence</i> ;	/* flag for starting offset */
long <i>l_start</i> ;	'* relative offset in bytes */
long <i>l_len</i> ;	/* if 0 then until EOF */
short <i>l_pid</i> ;	/* returned with F_GETLK */

The value of *l_whence* is 0, 1, or 2 to indicate that the relative offset, *l_start* bytes, will be measured from the start of the file, current position, or end of file, respectively. The value of *l_len* is the number of consecutive bytes to be locked. The process id is used only with the F_GETLK *cmd* to return the values for a blocking lock. Locks may start and extend beyond the current end of a file, but may not be negative relative to the beginning of the file. A lock may be set to always extend to the end of file by setting *l_len* to zero (0). If such a lock also has *l_whence* and *l_start* set to zero (0), the whole file will be locked. Changing or unlocking a segment from the middle of a larger locked segment leaves two smaller segments for either end. Locking a segment that is already locked by the calling process causes the old lock type to be removed and the new lock type to take effect. All locks associated with a file for a given process are removed when a file descriptor for that file is closed by that process or the process holding that file descriptor terminates. Locks are not inherited by a child process in a fork(2) system call.

When mandatory file and record locking is active on a file, [see *chmod*(2)], *read* and *write* system calls issued on the file will be affected by the record locks in effect.

The *fcntl* system call will fail if one or more of the following are true:

- [EBADF] The *fildes* argument is not a valid open file descriptor.
- [EINVAL] The *cmd* argument is F_DUPFD. The *arg* argument is either negative, or greater than or equal to the configured value for the maximum number of open file descriptors allowed each user.
- [EINVAL] The *cmd* argument is F_GETLK, F_SETLK, or SETLKW and *arg* or the data it points to is not valid.
- [EACCES] The *cmd* argument is F_SETLK the type of lock (l_type) is a read (F_RDLCK) lock and the segment of a file to be locked is already write locked by another process or the type is a write (F_WRLCK) lock and the segment of a file to be locked is already read or write locked by another process.
- [ENOLCK] The *cmd* argument is F_SETLK or F_SETLKW, the type of lock is a read or write lock, and there are no more record locks available (too many file segments locked) because the system maximum has been exceeded.
- [EMFILE] The *cmd* argument is F_DUPFD and file-descriptors are currently open in the calling-process.
- [EBADF] The *cmd* argument is F_SETLK of F_SETLKW, the type of lock (*l_type*) is a read-lock (F_RDLCK), and *fildes* is not a valid file-descriptor open for reading.
- [EBADF] The *cmd* argument is F_SETLK or F_SETLKW, the type of lock (*l_type*) is a write-lock (F_WRLCK), and *fildes* is not a valid file-descriptor open for writing.
- [EDEADLK] The *cmd* argument is F_SETLKW, the lock is blocked by some lock from another process, and putting the calling-process to sleep, waiting for that lock to become free, would cause a deadlock.
- [EFAULT] The *cmd* argument is F_SETLK, *arg* points outside the program address space.
- [EINTR] A signal was caught during the *fcntl* system call.
- [ENOLINK] *Fildes* is on a remote machine and the link to that machine is no longer active.

SEE ALSO

close(2), creat(2), dup(2), exec(2), fork(2), open(2), pipe(2), fcntl(5).

DIAGNOSTICS

Upon successful completion, the value returned depends on *cmd* as follows:

A new file descriptor.
Value of flag (only the low-order bit is defined).
Value other than -1.
Value of file flags.

F_SETFL	Value other than -1.
F_GETLK	Value other than –1.
F_SETLK	Value other than –1.
F_SETLKW	Value other than -1 .

Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

WARNINGS

Because in the future the variable *errno* will be set to EAGAIN rather than EACCES when a section of a file is already locked by another process, portable application programs should expect and test for either value.

fork – create a new process

SYNOPSIS

int fork ()

DESCRIPTION

The *fork* system call causes creation of a new process. The new process (child process) is an exact copy of the calling process (parent process). This means the child process inherits the following attributes from the parent process:

environment close-on-exec flag [see *exec*(2)] signal handling settings (i.e., **SIG_DFL**, **SIG_IGN**, **SIG_HOLD**, function address) set-user-ID mode bit set-group-ID mode bit profiling on/off status nice value [see *nice*(2)] all attached shared memory segments [see *shmop*(2)] process group ID tty group ID [see *exit*(2)] current working directory root directory file mode creation mask [see *umask*(2)] file size limit [see *ulimit*(2)]

The child process differs from the parent process in the following ways:

The child process has a unique process ID.

The child process has a different parent process ID (i.e., the process ID of the parent process).

The child process has its own copy of the parent's file descriptors. Each of the child's file descriptors shares a common file pointer with the corresponding file descriptor of the parent.

All semadj values are cleared [see *semop*(2)].

Process locks, text locks, and data locks are not inherited by the child [see *plock*(2)].

The child process's *utime*, *stime*, *cutime*, and *cstime* are set to 0. The time left until an alarm clock signal is reset to 0.

The *fork* system call will fail and no child process will be created if one or more of the following are true:

- [EAGAIN] The system-imposed limit on the total number of processes under execution would be exceeded.
- [EAGAIN] The system-imposed limit on the total number of processes under execution by a single user would be exceeded.

[EAGAIN]	Total amount of system memory available when reading via raw IO is temporarily insufficient.
[ENOMEM]	The process requires more space than the system is able to supply.

SEE ALSO

exec(2), nice(2), plock(2), ptrace(2), semop(2), shmop(2), signal(2), sigset(2), times(2), ulimit(2), umask(2), wait(2).

DIAGNOSTICS

Upon successful completion, *fork* returns a value of 0 to the child process and returns the process ID of the child process to the parent process. Otherwise, a value of -1 is returned to the parent process, no child process is created, and *errno* is set to indicate the error.

getdents - read directory entries and put in a file system independent format

SYNOPSIS

#include <sys/dirent.h>
int getdents (fildes, buf, nbyte)
int fildes;
char *buf;
unsigned nbyte;

DESCRIPTION

The *fildes* argument is a file descriptor obtained from an open(2) or dup(2) system call.

The *getdents* system call attempts to read *nbyte* bytes from the directory associated with *fildes* and to format them as file system independent directory entries in the buffer pointed to by *buf*. Since the file system independent directory entries are of variable length, in most cases the actual number of bytes returned will be strictly less than *nbyte*.

The file system independent directory entry is specified by the *dirent* structure. For a description of this see *dirent*(4).

On devices capable of seeking, *getdents* starts at a position in the file given by the file pointer associated with *fildes*. Upon return from *getdents*, the file pointer is incremented to point to the next directory entry.

This system call was developed in order to implement the *readdir*(3X) routine [for a description see *directory*(3X)], and should not be used for other purposes.

The getdents system call will fail if one or more of the following are true:

- [EBADF] Fildes is not a valid file descriptor open for reading.
- [EFAULT] Buf points outside the allocated address space.
- [EINVAL] *nbyte* is not large enough for one directory entry.
- [ENOENT] The current file pointer for the directory is not located at a valid entry.
- [ENOLINK] *Fildes* points to a remote machine and the link to that machine is no longer active.
- [ENOTDIR] *Fildes* is not a directory.
- [EIO] An I/O error occurred while accessing the file system.

SEE ALSO

directory(3X), dirent(4).

DIAGNOSTICS

Upon successful completion a non-negative integer is returned, indicating the number of bytes actually read. A value of 0 indicates the end of the directory has been reached. If the system call failed, a -1 is returned, and *errno* is set to indicate the error.

GETMSG(2)

NAME

getmsg – get next message off a stream

SYNOPSIS

#include <stropts.h>

```
int getmsg(fd, ctlptr, dataptr, flags)
int fd;
struct strbuf *ctlptr;
struct strbuf *dataptr;
int *flags;
```

DESCRIPTION

The *getmsg* system call retrieves the contents of a message [see *intro*(2)] located at the *stream head* read queue from a STREAMS file, and places the contents into user-specified buffer(s). The message must contain either a data part, a control part or both. The data and control parts of the message are placed into separate buffers, as described below. The semantics of each part is defined by the STREAMS module that generated the message.

The *fd* argument specifies a file descriptor referencing an open *stream*. *Ctlptr* and *dataptr* each point to a *strbuf* structure which contains the following members:

int maxlen;	/* maximum buffer length */
int len;	/* length of data */
char *buf;	/* ptr to buffer */

where *buf* points to a buffer in which the data or control information is to be placed, and *maxlen* indicates the maximum number of bytes this buffer can hold. On return, *len* contains the number of bytes of data or control information actually received, or is 0 if there is a zero-length control or data part, or is -1 if no data or control information is present in the message. *Flags* may be set to the values 0 or RS_HIPRI and is used as described below.

The *ctlptr* argument is used to hold the control part from the message and *dataptr* is used to hold the data part from the message. If *ctlptr* (or *dataptr*) is NULL or the *maxlen* field is -1, the control (or data) part of the message is not processed and is left on the *stream head* read queue, and *len* is set to -1. If the *maxlen* field is set to 0 and there is a zero-length control (or data) part, that zero-length part is removed from the read queue and *len* is set to 0. If the *maxlen* field is set to 0 and there are more than zero bytes of control (or data) information, that information is left on the read queue and *len* is set to 0. If the *maxlen* field in *ctlptr* or *dataptr* is less than, respectively, the control or data part of the message is left on the *stream head* read queue and a non-zero return value is provided, as described below under *DIAGNOS-TICS*. If information is retrieved from a *priority* message, *flags* is set to RS_HIPRI on return.

By default, *getmsg* processes the first priority or non-priority message available on the *stream head* read queue. However, a user may choose to retrieve only priority messages by setting *flags* to RS_HIPRI. In this case, *getmsg* will only process the next message if it is a priority message.

If O_NDELAY has not been set, *getmsg* blocks until a message, of the type(s) specified by *flags* (priority or either), is available on the *stream head* read queue. If O_NDELAY has been set and a message of the specified type(s) is not present on the read queue, *getmsg* fails and sets *errno* to EAGAIN.

If a hangup occurs on the *stream* from which messages are to be retrieved, *getmsg* will continue to operate normally, as described above, until the *stream head* read queue is empty. Thereafter, it will return 0 in the *len* fields of *ctlptr* and *dataptr*.

The *getmsg* system call fails if one or more of the following are true:

[EAGAIN]	The O_NDELAY flag is set, and no messages are available.
[EBADF]	Fd is not a valid file descriptor open for reading.
[EBADMSG]	Queued message to be read is not valid for getmsg.
[EFAULT]	<i>Ctlptr, dataptr,</i> or <i>flags</i> points to a location outside the allocated address space.
[EINTR]	A signal was caught during the getmsg system call.
[EINVAL]	An illegal value was specified in <i>flags</i> , or the <i>stream</i> referenced by <i>fd</i> is linked under a multiplexer.
[ENOSTR]	A stream is not associated with fd.

A *getmsg* can also fail if a STREAMS error message had been received at the *stream head* before the call to *getmsg*. The error returned is the value contained in the STREAMS error message.

SEE ALSO

intro(2), read(2), poll(2), putmsg(2), write(2). STREAMS Primer STREAMS Programmer's Guide

DIAGNOSTICS

Upon successful completion, a non-negative value is returned. A value of 0 indicates that a full message was read successfully. A return value of MORECTL indicates that more control information is waiting for retrieval. A return value of MOREDATA indicates that more data is waiting for retrieval. A return value of MORECTLIMOREDATA indicates that both types of information remain. Subsequent *getmsg* calls will retrieve the remainder of the message.

GETPID(2)

NAME

getpid, getpgrp, getppid – get process, process group, and parent process IDs SYNOPSIS

int getpid ()

int getpgrp ()

int getppid ()

DESCRIPTION

The *getpid* system call returns the process ID of the calling process.

The *getpgrp* system call returns the process group ID of the calling process.

The getppid system call returns the parent process ID of the calling process.

٩

SEE ALSO

exec(2), fork(2), intro(2), setpgrp(2), signal(2).

getuid, get
euid, get
gid, getegid-get real user, effective user, real group, and effective group
 $\ensuremath{\mathsf{IDs}}$

SYNOPSIS

unsigned short getuid () unsigned short geteuid () unsigned short getgid () unsigned short getegid ()

DESCRIPTION

The *getuid* system call returns the real user ID of the calling process.

The geteuid system call returns the effective user ID of the calling process.

The *getgid* system call returns the real group ID of the calling process.

The getegid system call returns the effective group ID of the calling process.

SEE ALSO

intro(2), setuid(2).

IOCTL(2)

NAME

ioctl – control device

SYNOPSIS

int ioctl (fildes, request, arg) int fildes, request;

DESCRIPTION

The *ioctl* system call performs a variety of control functions on devices and STREAMS. For non-STREAMS files, the functions performed by this call are *device-specific* control functions. The arguments *request* and *arg* are passed to the file designated by *fildes* and are interpreted by the device driver. This control is infrequently used on non-STREAMS devices, with the basic input/output functions performed through the *read*(2) and *write*(2) system calls.

For STREAMS files, specific functions are performed by the *ioctl* call as described in *streamio*(7).

Fildes is an open file descriptor that refers to a device. *Request* selects the control function to be performed and will depend on the device being addressed. *Arg* represents additional information that is needed by this specific device to perform the requested function. The data type of *arg* depends upon the particular control request, but it is either an integer or a pointer to a device-specific data structure.

In addition to device-specific and STREAMS functions, generic functions are provided by more than one device driver, for example, the general terminal interface [see *termio*(7)].

The *ioctl* system call will fail for any type of file if one or more of the following are true:

- [EBADF] *Fildes* is not a valid open file descriptor.
- [ENOTTY] *Fildes* is not associated with a device driver that accepts control functions.
- [EINTR] A signal was caught during the *ioctl* system call.

The *ioctl* system call will also fail if the device driver detects an error. In this case, the error is passed through *ioctl* without change to the caller. A particular driver might not have all of the following error cases. Other requests to device drivers will fail if one or more of the following are true:

- [EFAULT] *Request* requires a data transfer to or from a buffer pointed to by *arg*, but some part of the buffer is outside the process's allocated space.
- [EINVAL] *Request* or *arg* is not valid for this device.
- [EIO] Some physical I/O error has occurred.
- [ENXIO] The *request* and *arg* are valid for this device driver, but the service requested cannot be performed on this particular subdevice.

[ENOLINK] *Fildes* is on a remote machine and the link to that machine is no longer active.

STREAMS errors are described in *streamio*(7).

SEE ALSO

streamio(7), termio(7) in the System Administrator's Reference Manual.

DIAGNOSTICS

Upon successful completion, the value returned depends upon the device control function, but must be a non-negative integer. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

kill – send a signal to a process or a group of processes

SYNOPSIS

#include <signal.h>

int kill (pid, sig) int pid, sig;

DESCRIPTION

The *kill* system call sends a signal to a process or a group of processes. The process or group of processes to which the signal is to be sent is specified by *pid*. The signal that is to be sent is specified by *sig* and is either one from the list given in *signal*(2), or 0. If *sig* is 0 (the null signal), error checking is performed but no signal is actually sent. This can be used to check the validity of *pid*.

The real or effective user ID of the sending process must match the real or effective user ID of the receiving process, unless the effective user ID of the sending process is super-user.

The processes with a process ID of 0 and a process ID of 1 are special processes [see *intro*(2)] and will be referred to below as *proc0* and *proc1*, respectively.

If *pid* is greater than zero, *sig* will be sent to the process whose process ID is equal to *pid*. *Pid* may equal 1.

If *pid* is 0, *sig* will be sent to all processes excluding *proc0* and *proc1* whose process group ID is equal to the process group ID of the sender.

If *pid* is -1 and the effective user ID of the sender is not super-user, *sig* will be sent to all processes excluding *proc0* and *proc1* whose real user ID is equal to the effective user ID of the sender.

If *pid* is -1 and the effective user ID of the sender is super-user, *sig* will be sent to all processes excluding *proc0* and *proc1*.

If *pid* is negative but not -1, *sig* will be sent to all processes whose process group ID is equal to the absolute value of *pid*.

The *kill* system call will fail and no signal will be sent if one or more of the following are true:

- [EINVAL] Sig is not a valid signal number.
- [EINVAL] Sig is SIGKILL and pid is 1 (proc1).
- [ESRCH] No process can be found corresponding to that specified by *pid*.
- [EPERM] The user ID of the sending process is not super-user, and its real or effective user ID does not match the real or effective user ID of the receiving process.

SEE ALSO

getpid(2), setpgrp(2), signal(2), sigset(2). kill(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

link – link to a file

SYNOPSIS

int link (path1, path2) char *path1, *path2;

DESCRIPTION

The *path1* argument points to a path name naming an existing file. The *path2* argument points to a path name naming the new directory entry to be created. The *link* system call creates a new link (directory entry) for the existing file.

The *link* system call will fail and no link will be created if one or more of the following are true:

[ENOTDIR] A component of either path prefix is not a directory.

- [ENOENT] A component of either path prefix does not exist.
- [EACCES] A component of either path prefix denies search permission.
- [ENOENT] The file named by *path1* does not exist.
- [EEXIST] The link named by *path2* exists.
- [EPERM] The file named by *path1* is a directory and the effective user ID is not super-user.
- [EXDEV] The link named by *path2* and the file named by *path1* are on different logical devices (file systems).
- [ENOENT] *Path2* points to a null path name.
- [EACCES] The requested link requires writing in a directory with a mode that denies write permission.
- [EROFS] The requested link requires writing in a directory on a read-only file system.
- [EFAULT] *Path* points outside the allocated address space of the process.
- [EMLINK] The maximum number of links to a file would be exceeded.
- [EINTR] A signal was caught during the *link* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

[ENOSPC] The directory containing the link cannot be extended.

SEE ALSO

unlink(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

LSEEK(2)

NAME

lseek – move read/write file pointer

SYNOPSIS

#include <unistd.h>

long lseek (fildes, offset, whence) int fildes; long offset; int whence;

DESCRIPTION

The *fildes* argument is a file descriptor returned from a *creat*, *open*, *dup*, or *fcntl* system call. The *lseek* system call sets the file pointer associated with *fildes* as follows:

If *whence* is 0, the pointer is set to *offset* bytes.

If whence is 1, the pointer is set to its current location plus offset.

If whence is 2, the pointer is set to the size of the file plus offset.

Symbolic constants for *whence* are defined in the *<unistd.h>* header file:

Name	Description
SEEK_SET	Set file-pointer equal to offset bytes.
SEEK_CUR	Set file-pointer to current location plus offset.
SEEK_END	Set file-pointer to EOF plus offset.

Upon successful completion, the resulting pointer location, as measured in bytes from the beginning of the file, is returned. Note that if *fildes* is a remote file descriptor and *offset* is negative, *lseek* will return the file pointer even if it is negative.

lseek will fail and the file pointer will remain unchanged if one or more of the following are true:

[EBADF] *Fildes* is not an open file descriptor.

[ESPIPE] *Fildes* is associated with a pipe or fifo.

[EINVAL and SIGSYS signal]

Whence is not 0, 1, or 2.

[EINVAL] *Fildes* is not a remote file descriptor, and the resulting file pointer would be negative.

Some devices are incapable of seeking. The value of the file pointer associated with such a device is undefined.

SEE ALSO

creat(2), dup(2), fcntl(2), open(2).

DIAGNOSTICS

Upon successful completion, a non-negative integer indicating the file pointer value is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

MKDIR(2)

NAME

mkdir - make a directory

SYNOPSIS

#include <sys/types.h>
#include <sys/stat.h>

int mkdir (path, mode) char *path; int mode;

DESCRIPTION

The routine *mkdir* creates a new directory with the name *path*. The argument *mode* specifies the initial mode of the new directory. The protection bits of the argument *mode* are modified by the process' file mode creation mask [see umask(2)]. The value of the argument *mode* should be the logical OR of the values of the desired permissions:

Name	Description
S_IREAD	Read by owner.
S_IWRITE	Write by owner.
S_IEXEC	Execute (search) by owner.
S_IRGRP	Read by group.
S_IWGRP	Write by group.
S_IXGRP	Execute (search) by group.
S_IROTH	Read by others (i.e., anyone else).
S_IWOTH	Write by others.
	Even wether (and such) have a the such

S_IXOTH Execute (search) by others.

The directory's owner ID is set to the process's effective user ID. The directory's group ID is set to the process's effective group ID. The newly created directory is empty with the possible exception of entries for "." and "..". *mkdir* will fail and no directory will be created if one or more of the following are true:

- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] A component of the path prefix does not exist.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

MKDIR(2)

[EACCES]	Either a component of the path prefix denies search permis- sion, or write permission is denied on the parent directory of the directory to be created.
[ENOENT]	The path is longer than the maximum allowed.
[EEXIST]	The named file already exists.
[EROFS]	The path prefix resides on a read-only file system.
[EFAULT]	<i>Path</i> points outside the allocated address space of the process.
[EMLINK]	The maximum number of links to the parent directory would be exceeded.
[EIO]	An I/O error has occurred while accessing the file system.

DIAGNOSTICS Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

MKNOD(2)

NAME

mknod - make a directory, or a special or ordinary file, or a FIFO

SYNOPSIS

#include <sys/types.h>
#include <sys/stat.h>

int mknod (path, mode, dev) char *path; int mode, dev;

DESCRIPTION

The *mknod* system call creates a new file named by the path name pointed to by *path*. The mode of the new file is initialized from *mode*. Where the value of *mode* is interpreted as follows:

0170000 file type; one of the following:

0010000 fifo special 0020000 character special 0040000 directory 0060000 block special 0100000 or 0000000 ordinary file

0004000 set user ID on execution

00020#0 set group ID on execution if # is 7, 5, 3, or 1

enable mandatory file/record locking if # is 6, 4, 2, or 0

0001000 save text image after execution

0000777 access permissions; constructed from the following:

0000400 read by owner 0000200 write by owner 0000100 execute (search on directory) by owner 0000070 read, write, execute (search) by group 0000007 read, write, execute (search) by others

Symbolic constants defining the value of the argument *mode* are in the *<sys/stat.h>* header file and should be used to construct *mode*. The value of the argument *mode* should be the logical OR of the values of the desired permissions:

Name	Description
S_IFMT	file type; one of the following:
S_IFIFO	FIFO-special
S_IFCHR	character-special
S_IFDIR	directory node
SIFBLK	block-special

MKNOD(2)

S_IFREG	ordinary-file
S_ISUID	set user-ID on execution
S_ISGID	set group-ID on execution
S_ISVTX	(reserved)
S_ENFMT	record-locking enforced
S_IRUSR	read by owner
S_IWUSR	write by owner
S_IXUSR	execute (search) by owner
S_IRGRP	read by group
S_IWGRP	write by group
S_IXGRP	execute (search) by group
S_IROTH	read by others (i.e., anyone else)
S_IWOTH	write by others
S_IXOTH	execute (search) by others

The owner ID of the file is set to the effective user ID of the process. The group ID of the file is set to the effective group ID of the process.

Values of *mode* other than those above are undefined and should not be used. The low-order 9 bits of *mode* are modified by the process's file mode creation mask: all bits set in the process's file mode creation mask are cleared [see *umask*(2)]. If *mode* indicates a block or character special file, *dev* is a configuration-dependent specification of a character or block I/O device. If *mode* does not indicate a block special or character special device, *dev* is ignored.

The *mknod* routine may be invoked only by the super-user for file types other than FIFO special.

The *mknod* routine will fail and the new file will not be created if one or more of the following are true:

- [EPERM] The effective user ID of the process is not super-user.
- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] A component of the path prefix does not exist.
- [EROFS] The directory in which the file is to be created is located on a read-only file system.

[EEXIST]	The named file exists.
[EFAULT]	Path points outside the allocated address space of the process.
[ENOSPC]	No space is available.
[EINTR]	A signal was caught during the <i>mknod</i> system call.
[ENOLINK]	<i>Path</i> points to a remote machine and the link to that machine is no longer active.
[EMULTIHOP]	Components of <i>path</i> require hopping to multiple remote machines.

SEE ALSO

chmod(2), exec(2), umask(2), fs(4). mkdir(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

WARNING

If **mknod** is used to create a device in a remote directory (Remote File Sharing), the major and minor device numbers are interpreted by the server.

mount – mount a file system

SYNOPSIS

#include <sys/mount.h>

int mount (spec, dir, mflag, fstyp) char *spec, *dir; int mflag, fstyp;

DESCRIPTION

The *mount* system call requests that a removable file system contained on the block special file identified by *spec* be mounted on the directory identified by *dir*. *Spec* and *dir* are pointers to path names. *Fstyp* is the file system type number. The *sysfs*(2) system call can be used to determine the file system type number. Note that if the MS_FSS flag bit of *mflag* is off, the file system type will default to the root file system type. Only if the bit is on will *fstyp* be used to indicate the file system type.

Upon successful completion, references to the file *dir* will refer to the root directory on the mounted file system.

The low-order bit of *mflag* is used to control write permission on the mounted file system; if **1**, writing is forbidden, otherwise writing is permitted according to individual file accessibility.

The *mount* system call may be invoked only by the super-user. It is intended for use only by the mount(1M) utility.

The *mount* system call will fail if one or more of the following are true:

[EPERM]	The effective user ID is not super-user.
[ENOENT]	Any of the named files does not exist.
[ENOTDIR]	A component of a path prefix is not a directory.
[EREMOTE]	Spec is remote and cannot be mounted.
[ENOLINK]	<i>Path</i> points to a remote machine and the link to that machine is no longer active.
[EMULTIHOP]	Components of <i>path</i> require hopping to multiple remote machines.
[ENOTBLK]	Spec is not a block special device.
[ENXIO]	The device associated with spec does not exist.
[ENOTDIR]	Dir is not a directory.
[EFAULT]	<i>Spec</i> or <i>dir</i> points outside the allocated address space of the process.
[EBUSY]	<i>Dir</i> is currently mounted on, is someone's current working directory, or is otherwise busy.
[EBUSY]	The device associated with <i>spec</i> is currently mounted.
[EBUSY]	There are no more mount table entries.

[EROFS]	Spec is write-protected and <i>mflag</i> requests write permission.
[ENOSPC]	The file system state in the super-block is not FsOKAY and <i>mflag</i> requests write permission.
[EINVAL]	The super-block has an invalid magic number, or the <i>fstyp</i> is invalid, or <i>mflag</i> is not valid.

SEE ALSO

sysfs(2), umount(2), fs(4). mount(1M) in the System Administrator's Reference Manual.

DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

MSGCTL(2)

NAME

msgctl - message control operations

SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/msg.h>

int msgctl (msqid, cmd, buf)
int msqid, cmd;
struct msqid_ds *buf;

DESCRIPTION

The *msgctl* system call provides a variety of message control operations as specified by *cmd*. The following *cmds* are available:

- **IPC_STAT** Place the current value of each member of the data structure associated with *msqid* into the structure pointed to by *buf*. The contents of this structure are defined in *intro*(2). {READ}
- **IPC_SET** Set the value of the following members of the data structure associated with *msqid* to the corresponding value found in the structure pointed to by *buf*:

msg_perm.uid msg_perm.gid msg_perm.mode /* only low 9 bits */ msg_qbytes

This *cmd* can only be executed by a process that has an effective user ID equal to either that of super user, or to the value of **msg_perm.cuid** or **msg_perm.uid** in the data structure associated with *msqid*. Only super user can raise the value of **msg_qbytes**.

IPC_RMID Remove the message queue identifier specified by *msqid* from the system and destroy the message queue and data structure associated with it. This *cmd* can only be executed by a process that has an effective user ID equal to either that of super user, or to the value of **msg_perm.cuid** or **msg_perm.uid** in the data structure associated with *msgid*.

The *msgctl* system call will fail if one or more of the following are true:

- [EINVAL] The *msqid* argument is not a valid message queue identifier.
- [EINVAL] The *cmd* argument is not a valid command.
- [EACCES] The *cmd* argument is equal to **IPC_STAT** and {READ} operation permission is denied to the calling process [see *intro*(2)].
- [EPERM] The *cmd* argument is equal to **IPC_RMID** or **IPC_SET**. The effective user ID of the calling process is not equal to that of super user, or to the value of **msg_perm.cuid** or **msg_perm.uid** in the data structure associated with *msgid*.

[EPERM]	The <i>cmd</i> argument is equal to IPC_SET , an attempt is being
	made to increase to the value of msg_qbytes, and the
	effective user ID of the calling process is not equal to that
	of super-user.

[EFAULT] The *buf* argument points to an illegal address.

SEE ALSO

intro(2), msgget(2), msgop(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

MSGGET(2)

NAME

msgget – get message queue

SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/msg.h>

```
int msgget (key, msgflg)
key_t key;
int msgflg;
```

DESCRIPTION

The *msgget* system call returns the message queue identifier associated with *key*.

A message queue identifier and associated message queue and data structure [see *intro*(2)] are created for *key* if one of the following is true:

The key argument is equal to IPC_PRIVATE.

The *key* argument does not already have a message queue identifier associated with it, and (*msgflg* & **IPC_CREAT**) is "true".

Upon creation, the data structure associated with the new message queue identifier is initialized as follows:

Msg_perm.cuid, **msg_perm.uid**, **msg_perm.cgid**, and **msg_perm.gid** are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of **msg_perm.mode** are set equal to the low-order 9 bits of *msgflg*.

Msg_qnum, msg_lspid, msg_lrpid, msg_stime, and msg_rtime are set equal to 0.

Msg_ctime is set equal to the current time.

Msg_qbytes is set equal to the system limit.

The *msgget* system call will fail if one or more of the following are true:

- [EACCES] A message queue identifier exists for *key*, but operation permission [see *intro*(2)] as specified by the low-order 9 bits of *msgflg* would not be granted.
- [ENOENT] A message queue identifier does not exist for *key* and (*msgflg* & IPC_CREAT) is "false".
- [ENOSPC] A message queue identifier is to be created but the systemimposed limit on the maximum number of allowed message queue identifiers system wide would be exceeded.
- [EEXIST] A message queue identifier exists for key but ((msgflg & IPC_CREAT) & (msgflg & IPC_EXCL)) is "true".

SEE ALSO

intro(2), msgctl(2), msgop(2).

MSGGET(2)

DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a message queue identifier, is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

MSGOP(2)

NAME

msgop: msgsnd, msgrcv – message operations

SYNOPSIS

```
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int msgsnd (msqid, msgp, msgsz, msgflg)
int msqid;
struct msgbuf *msgp;
int msgsz, msgflg;
int msgrcv (msqid, msgp, msgsz, msgtyp, msgflg)
int msqid;
struct msgbuf *msgp;
int msgsz;
long msgtyp;
int msgflg;
```

DESCRIPTION

The *msgsnd* system call is used to send a message to the queue associated with the message queue identifier specified by *msqid*. {WRITE} *Msgp* points to a structure containing the message. This structure is composed of the following members:

long	mtype;	/* message type */
char	mtext[];	/* message text */

The *mtype* integer is positive and can be used by the receiving process for message selection (see *msgrcv* below). The array *mtext* is any text of length *msgsz* bytes. The *msgsz* argument can range from 0 to a system-imposed maximum.

Msgflg specifies the action to be taken if one or more of the following are true:

The number of bytes already on the queue is equal to **msg_qbytes** [see *intro*(2)].

The total number of messages on all queues system-wide is equal to the system-imposed limit.

These actions are as follows:

If (*msgflg* & IPC_NOWAIT) is "true", the message will not be sent and the calling process will return immediately.

If (*msgflg* & **IPC_NOWAIT**) is "false", the calling process will suspend execution until one of the following occurs:

The condition responsible for the suspension no longer exists, in which case the message is sent.

The *msqid* argument is removed from the system [see msgctl(2)]. When this occurs, *errno* is set equal to EIDRM, and a value of -1 is returned.

MSGOP(2)

The calling process receives a signal that is to be caught. In this case the message is not sent and the calling process resumes execution in the manner prescribed in signal(2).

Msgsnd will fail and no message will be sent if one or more of the following are true:

- [EINVAL] *Msqid* is not a valid message queue identifier.
- [EACCES] Operation permission is denied to the calling process [see *intro*(2)].
- [EINVAL] *Mtype* is less than 1.
- [EAGAIN] The message cannot be sent for one of the reasons cited above and (*msgflg* & **IPC__NOWAIT**) is "true".
- [EINVAL] Msgsz is less than zero or greater than the system-imposed limit.

[EFAULT] *Msgp* points to an illegal address.

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid* [see intro (2)].

Msg_qnum is incremented by 1.

Msg_lspid is set equal to the process ID of the calling process.

Msg__stime is set equal to the current time.

Msgrcv reads a message from the queue associated with the message queue identifier specified by *msqid* and places it in the structure pointed to by *msgp*. {READ} This structure is composed of the following members:

long	mtype;	/* message type */
char	mtext[];	/* message text */

Mtype is the received message's type as specified by the sending process. *Mtext* is the text of the message. *Msgsz* specifies the size in bytes of *mtext*. The received message is truncated to *msgsz* bytes if it is larger than *msgsz* and (*msgflg* & **MSG_NOERROR**) is "true". The truncated part of the message is lost and no indication of the truncation is given to the calling process.

Msgtyp specifies the type of message requested as follows:

If *msgtyp* is equal to 0, the first message on the queue is received.

If *msgtyp* is greater than 0, the first message of type *msgtyp* is received.

If *msgtyp* is less than 0, the first message of the lowest type that is less than or equal to the absolute value of *msgtyp* is received.

Msgflg specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

If (*msgflg* & **IPC_NOWAIT**) is "true", the calling process will return immediately with a return value of -1 and *errno* set to ENOMSG.

If (*msgflg* & **IPC_NOWAIT**) is "false", the calling process will suspend execution until one of the following occurs:

A message of the desired type is placed on the queue.

Msqid is removed from the system. When this occurs, *errno* is set equal to EIDRM, and a value of -1 is returned.

The calling process receives a signal that is to be caught. In this case a message is not received and the calling process resumes execution in the manner prescribed in *signal*(2).

Msgrcv will fail and no message will be received if one or more of the following are true:

- [EINVAL] *Msqid* is not a valid message queue identifier.
- [EACCES] Operation permission is denied to the calling process.
- [EINVAL] Msgsz is less than 0.
- [E2BIG] Mtext is greater than *msgsz* and (*msgflg* & MSG_NOERROR) is "false".
- [ENOMSG] The queue does not contain a message of the desired type and (*msgtyp* & **IPC_NOWAIT**) is "true".
- [EFAULT] *Msgp* points to an illegal address.

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid* [see intro (2)].

Msg_qnum is decremented by 1.

Msg_lrpid is set equal to the process ID of the calling process.

Msg_rtime is set equal to the current time.

SEE ALSO

intro(2), msgctl(2), msgget(2), signal(2).

DIAGNOSTICS

If *msgsnd* or *msgrcv* return due to the receipt of a signal, a value of -1 is returned to the calling process and *errno* is set to EINTR. If they return due to removal of *msqid* from the system, a value of -1 is returned and *errno* is set to EIDRM.

Upon successful completion, the return value is as follows:

Msgsnd returns a value of 0.

Msgrcv returns a value equal to the number of bytes actually placed into *mtext*.

Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

nice - change priority of a process

SYNOPSIS

int nice (incr) int incr;

DESCRIPTION

The *nice* system call adds the value of *incr* to the nice value of the calling process. A process's *nice value* is a non-negative number for which a more positive value results in lower CPU priority.

A maximum nice value of 39 and a minimum nice value of 0 are imposed by the system. (The default nice value is 20.) Requests for values above or below these limits result in the nice value being set to the corresponding limit.

[EPERM]

The *nice* system call will fail and not change the nice value if *incr* is negative or greater than 39, and the effective user ID of the calling process is not super-user.

SEE ALSO

exec(2). nice(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, *nice* returns the new nice value minus 20. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

OPEN(2)

NAME

open – open for reading or writing

SYNOPSIS

#include <fcntl.h>
int open (path, oflag [, mode])
char *path;
int oflag, mode;

DESCRIPTION

Path points to a path name naming a file. The *open* system call opens a file descriptor for the named file and sets the file status flags according to the value of *oflag*. For non-STREAMS [see *intro*(2)] files, *oflag* values are constructed by OR-ing flags from the following list (only one of the first three flags below may be used):

- **O_RDONLY** Open for reading only.
- **O_WRONLY** Open for writing only.
- **O_RDWR** Open for reading and writing.
- **O_NDELAY** This flag may affect subsequent reads and writes [see *read*(2) and *write*(2)].

When opening a FIFO with O_RDONLY or O_WRONLY set:

If O_NDELAY is set:

An *open* for reading-only will return without delay. An *open* for writing-only will return an error if no process currently has the file open for reading.

If O_NDELAY is clear:

An *open* for reading-only will block until a process opens the file for writing. An *open* for writing-only will block until a process opens the file for reading.

When opening a file associated with a communication line:

If O_NDELAY is set:

The open will return without waiting for carrier.

If O_NDELAY is clear:

The open will block until carrier is present.

- **O_APPEND** If set, the file pointer will be set to the end of the file prior to each write.
- **O_SYNC** When opening a regular file, this flag affects subsequent writes. If set, each *write*(2) will wait for both the file data and file status to be physically updated.

O_CREAT If the file exists, this flag has no effect. Otherwise, the owner ID of the file is set to the effective user ID of the process; the group ID of the file is set to the effective group ID of the process; and the low-order 12 bits of the file mode are set to the value of *mode*, modified as follows [see *creat*(2)]:

All bits set in the file mode creation mask of the process are cleared [see *umask*(2)].

The "save text image after execution bit" of the mode is cleared [see *chmod*(2)].

- **O_TRUNC** If the file exists, its length is truncated to 0 and the mode and owner are unchanged.
- **O_EXCL** If O_EXCL and O_CREAT are set, *open* will fail if the file exists.

When opening a STREAMS file, oflag may be constructed from O_NDELAY or-ed with either O_RDONLY, O_WRONLY or O_RDWR. Other flag values are not applicable to STREAMS devices and have no effect on them. The value of O_NDELAY affects the operation of STREAMS drivers and certain system calls [see *read*(2), *getmsg*(2), *putmsg*(2), and *write*(2)]. For drivers, the implementation of O_NDELAY is device-specific. Each STREAMS device driver may treat this option differently.

Certain flag values can be set following *open* as described in *fcntl*(2).

The file pointer used to mark the current position within the file is set to the beginning of the file.

The new file descriptor is set to remain open across *exec* system calls [see *fcntl*(2)].

The named file is opened unless one or more of the following are true:

- [EACCES] A component of the path prefix denies search permission.
- [EACCES] oflag permission is denied for the named file.
- [EAGAIN] The file exists, mandatory file/record locking is set, and there are outstanding record locks on the file [see *chmod* (2)].
- [EEXIST] O_CREAT and O_EXCL are set, and the named file exists.
- [EFAULT] *Path* points outside the allocated address space of the process.
- [EINTR] A signal was caught during the *open* system call.
- [EIO] A hangup or error occurred during a STREAMS open.
- [EISDIR] The named file is a directory and *oflag* is write or read/write.
- [EMFILE] NOFILES file descriptors are currently open.

[EMULTIHOP] Components of *path* require hopping to multiple remote machines.

٠

[ENFILE]	The system file table is full.
[ENOENT]	O_CREAT is not set and the named file does not exist.
[ENOLINK]	<i>Path</i> points to a remote machine, and the link to that machine is no longer active.
[ENOMEM]	The system is unable to allocate a send descriptor.
[ENOSPC]	O_CREAT and O_EXCL are set, and the file system is out of inodes.
[ENOSR]	Unable to allocate a stream.
[ENOTDIR]	A component of the path prefix is not a directory.
[ENXIO]	The named file is a character special or block special file, and the device associated with this special file does not exist.
[ENXIO]	O_NDELAY is set, the named file is a FIFO, O_WRONLY is set, and no process has the file open for reading.
[ENXIO]	A STREAMS module or driver open routine failed.
[EROFS]	The named file resides on a read-only file system and <i>oflag</i> is write or read/write.
[ETXTBSY]	The file is a pure procedure (shared text) file that is being executed and <i>oflag</i> is write or read/write.

SEE ALSO

chmod(2), close(2), creat(2), dup(2), fcntl(2), intro(2), lseek(2), read(2), getmsg(2), putmsg(2), umask(2), write(2).

DIAGNOSTICS

Upon successful completion, the file descriptor is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

pause - suspend process until signal

SYNOPSIS

pause ()

DESCRIPTION

The *pause* system call suspends the calling process until it receives a signal. The signal must be one that is not currently set to be ignored by the calling process.

If the signal causes termination of the calling process, *pause* will not return.

If the signal is *caught* by the calling process, and control is returned from the signal-catching function [see *signal*(2)], the calling process resumes execution from the point of suspension; with a return value of -1 from *pause* and *errno* set to EINTR.

SEE ALSO

alarm(2), kill(2), signal(2), sigpause(2), wait(2).

pipe – create an interprocess channel

SYNOPSIS

int pipe (fildes)
int fildes[2];

DESCRIPTION

The *pipe* system call creates an I/O mechanism called a pipe and returns two file descriptors, *fildes*[0] and *fildes*[1]. *Fildes*[0] is opened for reading and *fildes*[1] is opened for writing.

Up to 5120 bytes of data are buffered by the pipe before the writing process is blocked. A read-only file descriptor *fildes*[0] accesses the data written to *fildes*[1] on a first-in-first-out (FIFO) basis.

The *pipe* system call will fail if:

[EMFILE]	NOFILES file descriptors are currently open.
[ENFILE]	The system file table is full.

SEE ALSO

read(2), write(2). sh(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

PLOCK(2)

NAME

plock - lock process, text, or data in memory

SYNOPSIS

#include <sys/lock.h>

int plock (op) int op;

DESCRIPTION

The *plock* system call allows the calling process to lock its text segment (text lock), its data segment (data lock), or both its text and data segments (process lock) into memory. Locked segments are immune to all routine swapping. *plock* also allows these segments to be unlocked. The effective user ID of the calling process must be super-user to use this call. *Op* specifies the following:

PROCLOCK -	lock text and data segments into memory (process lock)
TXTLOCK -	lock text segment into memory (text lock)
DATLOCK -	lock data segment into memory (data lock)
UNLOCK -	remove locks

The *plock* system call will fail and not perform the requested operation if one or more of the following are true:

- [EPERM] The effective user ID of the calling process is not super-user.
 [EINVAL] Op is equal to PROCLOCK and a process lock, a text lock, or a data lock already exists on the calling process.
 [EINVAL] Op is equal to TXTLOCK and a text lock or a process lock already exists on the calling process.
- [EINVAL] *Op* is equal to **DATLOCK** and a data lock or a process lock already exists on the calling process.
- [EINVAL] *Op* is equal to UNLOCK and no type of lock exists on the calling process.
- [EAGAIN] Not enough memory.

SEE ALSO

exec(2), exit(2), fork(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned to the calling process. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

POLL(2)

NAME

poll – STREAMS input/output multiplexing

SYNOPSIS

#include <stropts.h>
#include <poll.h>
int poll(fds, nfds, timeout)
struct pollfd fds[];
unsigned long nfds;
int timeout;

DESCRIPTION

The *poll* system call provides users with a mechanism for multiplexing input/output over a set of file descriptors that reference open *streams* [see *intro*(2)]. The *poll* system call identifies those *streams* on which a user can send or receive messages, or on which certain events have occurred. A user can receive messages using *read*(2) or *getmsg*(2) and can send messages using *write*(2) and *putmsg*(2). Certain *ioctl*(2) calls, such as LRECVFD and LSENDFD [see *streamio*(7)], can also be used to receive and send messages.

Fds specifies the file descriptors to be examined and the events of interest for each file descriptor. It is a pointer to an array with one element for each open file descriptor of interest. The array's elements are *pollfd* structures which contain the following members:

int fd;	/* file descriptor */
short events;	/* requested events */
short revents;	/* returned events */

where *fd* specifies an open file descriptor and *events* and *revents* are bitmasks constructed by or-ing any combination of the following event flags:

- POLLIN A non-priority or file descriptor passing message (see L_RECVFD) is present on the *stream head* read queue. This flag is set even if the message is of zero length. In *revents*, this flag is mutually exclusive with POLLPRI.
- POLLPRI A priority message is present on the *stream head* read queue. This flag is set even if the message is of zero length. In *revents*, this flag is mutually exclusive with POLLIN.
- POLLOUT The first downstream write queue in the *stream* is not full. Priority control messages can be sent (see *putmsg*) at any time.
- POLLERR An error message has arrived at the *stream head*. This flag is only valid in the *revents* bitmask; it is not used in the *events* field.
- POLLHUP A hangup has occurred on the *stream*. This event and POLL-OUT are mutually exclusive; a *stream* can never be writable if a hangup has occurred. However, this event and POLLIN or POLLPRI are not mutually exclusive. This flag is only valid in the *revents* bitmask; it is not used in the *events* field.

POLLNVAL The specified *fd* value does not belong to an open *stream*. This flag is only valid in the *revents* field; it is not used in the *events* field.

For each element of the array pointed to by *fds*, *poll* examines the given file descriptor for the event(s) specified in *events*. The number of file descriptors to be examined is specified by *nfds*. If *nfds* exceeds NOFILES, the system limit of open files [see *ulimit*(2)], *poll* will fail.

If the value fd is less than zero, *events* is ignored and *revents* is set to 0 in that entry on return from *poll*.

The results of the *poll* query are stored in the *revents* field in the *pollfd* structure. Bits are set in the *revents* bitmask to indicate which of the requested events are true. If none are true, none of the specified bits is set in *revents* when the *poll* call returns. The event flags POLLHUP, POLLERR and POLLNVAL are always set in *revents* if the conditions they indicate are true; this occurs even though these flags were not present in *events*.

If none of the defined events have occurred on any selected file descriptor, *poll* waits at least *timeout* msec for an event to occur on any of the selected file descriptors. On a computer where millisecond timing accuracy is not available, *timeout* is rounded up to the nearest legal value available on that system. If the value *timeout* is 0, *poll* returns immediately. If the value of *timeout* is -1, *poll* blocks until a requested event occurs or until the call is interrupted. The *poll* system call is not affected by the O_NDELAY flag.

The *poll* system call fails if one or more of the following are true:

- [EAGAIN] Allocation of internal data structures failed but request should be attempted again.
- [EFAULT] Some argument points outside the allocated address space.
- [EINTR] A signal was caught during the *poll* system call.
- [EINVAL] The argument *nfds* is less than zero, or *nfds* is greater than NOFILES.

SEE ALSO

intro(2), read(2), getmsg(2), putmsg(2), write(2). streamio(7) in the System Administrator's Reference Manual. STREAMS Primer. STREAMS Programmer's Guide.

DIAGNOSTICS

Upon successful completion, a non-negative value is returned. A positive value indicates the total number of file descriptors that has been selected (i.e., file descriptors for which the *revents* field is non-zero). A value of 0 indicates that the call timed out and no file descriptors have been selected. Upon failure, a value of -1 is returned, and *errno* is set to indicate the error.

profil – execution time profile

SYNOPSIS

void profil (buff, bufsiz, offset, scale) void (* offset)(); char *buff; int bufsiz, scale;

DESCRIPTION

Buff points to an area of core whose length (in bytes) is given by *bufsiz*. After this call, the user's program counter (pc) is examined each clock tick. Then the value of *offset* is subtracted from it, and the remainder multiplied by *scale*. If the resulting number corresponds to an entry inside *buff*, that entry is incremented. An entry is defined as a series of bytes with length *sizeof(short)*.

The scale is interpreted as an unsigned, fixed-point fraction with binary point at the left: 0177777 (octal) gives a 1-1 mapping of pc's to entries in *buff*; 077777 (octal) maps each pair of instruction entries together. 02(octal) maps all instructions onto the beginning of *buff* (producing a non-interrupting core clock).

Profiling is turned off by giving a *scale* of 0 or 1. It is rendered ineffective by giving a *bufsiz* of 0. Profiling is turned off when an *exec* is executed, but remains on in child and parent both after a *fork*. Profiling will be turned off if an update in *buff* would cause a memory fault.

SEE ALSO

prof(1), times(2), monitor(3C).

DIAGNOSTICS

Not defined.

WARNING

On the 80286 computer, the type of offset is: void (*offset)(); .

ptrace – process trace

SYNOPSIS

int ptrace (request, pid, addr, data); int request, pid, data;

DESCRIPTION

The *ptrace* system call provides a means by which a parent process may control the execution of a child process. Its primary use is for the implementation of breakpoint debugging [see sdb(1)]. The child process behaves normally until it encounters a signal [see signal(2) for the list], at which time it enters a stopped state and its parent is notified via wait(2). When the child is in the stopped state, its parent can examine and modify its "core image" using *ptrace*. Also, the parent can cause the child either to terminate or continue, with the possibility of ignoring the signal that caused it to stop. The data type of the argument *addr* depends upon the particular request given to *ptrace*.

The *request* argument determines the precise action to be taken by *ptrace* and is one of the following:

0 This request must be issued by the child process if it is to be traced by its parent. It turns on the child's trace flag that stipulates that the child should be left in a stopped state upon receipt of a signal rather than the state specified by *func* [see *signal*(2)]. The *pid*, *addr*, and *data* arguments are ignored, and a return value is not defined for this request. Peculiar results will ensue if the parent does not expect to trace the child.

The remainder of the requests can only be used by the parent process. For each, *pid* is the process ID of the child. The child must be in a stopped state before these requests are made.

- With these requests, the word at location *addr* in the address space of the child is returned to the parent process. If I and D space are separated, request 1 returns a word from I space, and request 2 returns a word from D space. If I and D space are not separated, either request 1 or request 2 may be used with equal results. The *data* argument is ignored.
- 3 With this request, the word at location *addr* in the child's USER area in the system's address space (see $\langle sys/user.h \rangle$) is returned to the parent process. The *data* argument is ignored. This request will fail if *addr* is outside the USER area, in which case a value of -1 is returned to the parent process and the parent's *errno* is set to EIO.
- **4**, **5** With these requests, the value given by the *data* argument is written into the address space of the child at location *addr*. If I and D space are separated, request **4** writes a word into I space, and request **5** writes a word into D space. If I and D space are not separated, either request **4** or request **5** may be used with equal results. Upon successful completion, the

value written into the address space of the child is returned to the parent. These two requests will fail if *addr* is a location in a pure procedure space and another process is executing in that space. Upon failure a value of -1 is returned to the parent process and the parent's *errno* is set to EIO.

6 With this request, a few entries in the child's USER area can be written. *Data* gives the value that is to be written and *addr* is the location of the entry. The few entries that can be written are all registers.

On the 80386, the *ptrace* system call can be used to modify the debug registers.

The 80386 debug registers are used to specify an address to monitor in a user process. Any access to this location by the user process will deliver a **SIGTRAP** [see *signal*(2)] to the user process and possibly restart the parent process.

The 80386 debug registers can be accessed by using the 3 or 6 options of the *ptrace* system call to read or write a traced-process's u-area. The file **<sys/debugreg.h**> should be included in the parent process that wants to control the debug registers. This header file defines bit masks that describe the debug-registers in the u_debugreg[] array in the u-area.

The debug registers numbered u.u_debugreg[DR_FIRSTADDR] (%dr0) to u.u_debugreg[DR_LASTADDR] (%dr3) contain process addresses which will be monitored according to the instructions provided in u.u_debugreg[DR_CONTROL] (%dr7). Only the DR_LOCAL_ENABLE_MASK and the various read/write and length bits in u.u_debugreg[DR_CONTROL] can be set. Setting DR_LOCAL_SLOWDOWN to slow down processing is also highly recommended. The setting of all other bits is undefined and should be set to zero to ensure compatibility with future Intel processors.

In the process being debugged, these registers are automatically loaded before entering user-mode (privilege level 3) and cleared before entering the system for any reason. In System V Release 3.0, if the location specified by a debug-register is accessed during a system call, core-dump, or interrupt service, no trap will ensue.

- 7 This request causes the child to resume execution. If the *data* argument is 0, all pending signals including the one that caused the child to stop are canceled before it resumes execution. If the *data* argument is a valid signal number, the child resumes execution as if it had incurred that signal, and any other pending signals are canceled. The *addr* argument must be equal to 1 for this request. Upon successful completion, the value of *data* is returned to the parent. This request will fail if *data* is not 0 or a valid signal number, in which case a value of –1 is returned to the parent process and the parent's *errno* is set to EIO.
- 8 This request causes the child to terminate with the same consequences as *exit*(2).
- **9** This request sets the trace bit in the Processor Status Word of the child and then executes the same steps as listed above for request **7**. The trace bit causes an interrupt upon completion of one machine instruction. This effectively allows single stepping of the child.

To forestall possible fraud, *ptrace* inhibits the set-user-id facility on subsequent *exec*(2) calls. If a traced process calls *exec*, it will stop before executing the first instruction of the new image showing signal **SIGTRAP**.

General Errors

The *ptrace* system call will in general fail if the child process is running under *i286emul*(1) or one or more of the following are true:

[EIC	$R\epsilon$	equest is	s an il	legal 1	number.

[ESRCH] *Pid* identifies a child that does not exist or has not executed a *ptrace* with request **0**.

putmsg - send a message on a stream

SYNOPSIS

#include <stropts.h>
int putmsg (fd, ctlptr, dataptr, flags)
int fd;
struct strbuf *ctlptr;
struct strbuf *dataptr;
int flags;

DESCRIPTION

The *putmsg* system call creates a message [see *intro*(2)] from user specified buffer(s) and sends the message to a STREAMS file. The message may contain either a data part, a control part or both. The data and control parts to be sent are distinguished by placement in separate buffers, as described below. The semantics of each part is defined by the STREAMS module that receives the message.

fd specifies a file descriptor referencing an open *stream*. *ctlptr* and *dataptr* each point to a *strbuf* structure which contains the following members:

int maxlen;	/* not used */
int len;	/* length of data */
char *buf;	/* ptr to buffer */

ctlptr points to the structure describing the control part, if any, to be included in the message. The *buf* field in the *strbuf* structure points to the buffer where the control information resides, and the *len* field indicates the number of bytes to be sent. The *maxlen* field is not used in *putmsg* [see *getmsg*(2)]. In a similar manner, *dataptr* specifies the data, if any, to be included in the message. *flags* may be set to the values 0 or RS_HIPRI and is used as described below.

To send the data part of a message, *dataptr* must be non-NULL and the *len* field of *dataptr* must have a value of 0 or greater. To send the control part of a message, the corresponding values must be set for *ctlptr*. No data (control) part will be sent if either *dataptr* (*ctlptr*) is NULL or the *len* field of *dataptr* (*ctlptr*) is set to -1.

If a control part is specified, and *flags* is set to RS_HIPRI, a *priority* message is sent. If *flags* is set to 0, a non-priority message is sent. If no control part is specified, and *flags* is set to RS_HIPRI, *putmsg* fails and sets *errno* to EIN-VAL. If no control part and no data part are specified, and *flags* is set to 0, no message is sent, and 0 is returned.

For non-priority messages, *putmsg* will block if the *stream* write queue is full due to internal flow control conditions. For priority messages, *putmsg* does not block on this condition. For non-priority messages, *putmsg* does not block when the write queue is full and O_NDELAY is set. Instead, it fails and sets *errno* to EAGAIN.

PUTMSG(2)

The *putmsg* system call also blocks, unless prevented by lack of internal resources, waiting for the availability of message blocks in the *stream*, regardless of priority or whether O_NDELAY has been specified. No partial message is sent.

The *putmsg* system call fails if one or more of the following are true:

- [EAGAIN] A non-priority message was specified, the O_NDELAY flag is set and the *stream* write queue is full due to internal flow control conditions.
- [EAGAIN] Buffers could not be allocated for the message that was to be created.
- [EBADF] *fd* is not a valid file descriptor open for writing.
- [EFAULT] *ctlptr* or *dataptr* points outside the allocated address space.
- [EINTR] A signal was caught during the *putmsg* system call.
- [EINVAL] An undefined value was specified in *flags*, or *flags* is set to RS_HIPRI and no control part was supplied.
- [EINVAL] The *stream* referenced by *fd* is linked below a multiplexer.
- [ENOSTR] A stream is not associated with fd.
- [ENXIO] A hangup condition was generated downstream for the specified *stream*.
- [ERANGE] The size of the data part of the message does not fall within the range specified by the maximum and minimum packet sizes of the topmost *stream* module. This value is also returned if the control part of the message is larger than the maximum configured size of the control part of a message, or if the data part of a message is larger than the maximum configured size of the data part of a message.

A *putmsg* also fails if a STREAMS error message had been processed by the *stream* head before the call to *putmsg*. The error returned is the value contained in the STREAMS error message.

SEE ALSO

intro(2), read(2), getmsg(2), poll(2), write(2). STREAMS Primer. STREAMS Programmer's Guide.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

read - read from file

SYNOPSIS

int read (fildes, buf, nbyte) int fildes; char *buf; unsigned nbyte;

DESCRIPTION

Fildes is a file descriptor obtained from a creat(2), open(2), dup(2), fcntl(2), or pipe(2) system call.

The *read* system call attempts to read *nbyte* bytes from the file associated with *fildes* into the buffer pointed to by *buf*.

On devices capable of seeking, the *read* starts at a position in the file given by the file pointer associated with *fildes*. Upon return from *read*, the file pointer is incremented by the number of bytes actually read.

Devices that are incapable of seeking always read from the current position. The value of a file pointer associated with such a file is undefined.

Upon successful completion, *read* returns the number of bytes actually read and placed in the buffer; this number may be less than *nbyte* if the file is associated with a communication line [see *ioctl*(2) and *termio*(7)], or if the number of bytes left in the file is less than *nbyte* bytes. A value of 0 is returned when an end-of-file has been reached.

A *read* from a STREAMS [see *intro*(2)] file can operate in three different modes: "byte-stream" mode, "message-nondiscard" mode, and "message-discard" mode. The default is byte-stream mode. This can be changed using the L_SRDOPT *ioctl* request [see *streamio*(7)], and can be tested with the L_GRDOPT *ioctl*. In byte-stream mode, *read* will retrieve data from the *stream* until it has retrieved *nbyte* bytes, or until there is no more data to be retrieved. Byte-stream mode ignores message boundaries.

In STREAMS message-nondiscard mode, *read* retrieves data until it has read *nbyte* bytes, or until it reaches a message boundary. If the *read* does not retrieve all the data in a message, the remaining data are replaced on the *stream*, and can be retrieved by the next *read* or *getmsg*(2) call. Message-discard mode also retrieves data until it has retrieved *nbyte* bytes, or it reaches a message boundary. However, unread data remaining in a message after the *read* returns are discarded, and are not available for a subsequent *read* or *getmsg*.

When attempting to read from a regular file with mandatory file/record locking set [see *chmod*(2)], and there is a blocking (i.e., owned by another process) write lock on the segment of the file to be read:

If O_NDELAY is set, the read will return a -1 and set errno to EAGAIN.

If O_NDELAY is clear, the read will sleep until the blocking record lock is removed.

When attempting to read from an empty pipe (or FIFO):

If O_NDELAY is set, the read will return a 0.

If O_NDELAY is clear, the read will block until data is written to the file or the file is no longer open for writing.

When attempting to read a file associated with a tty that has no data currently available:

If O_NDELAY is set, the read will return a 0.

If O_NDELAY is clear, the read will block until data becomes available.

When attempting to read a file associated with a *stream* that has no data currently available:

If O_NDELAY is set, the read will return a -1 and set errno to EAGAIN.

If O_NDELAY is clear, the read will block until data becomes available.

When reading from a STREAMS file, handling of zero-byte messages is determined by the current read mode setting. In byte-stream mode, *read* accepts data until it has read *nbyte* bytes, or until there is no more data to read, or until a zero-byte message block is encountered. The *read* system call then returns the number of bytes read, and places the zero-byte message back on the *stream* to be retrieved by the next *read* or *getmsg*. In the two other modes, a zero-byte message returns a value of 0 and the message is removed from the *stream*. When a zero-byte message is read as the first message on a *stream*, a value of 0 is returned regardless of the read mode.

A *read* from a STREAMS file can only process data messages. It cannot process any type of protocol message and will fail if a protocol message is encountered at the *stream head*.

The *read* system call will fail if one or more of the following are true:

- [EAGAIN] Mandatory file/record locking was set, O_NDELAY was set, and there was a blocking record lock.
- [EAGAIN] Total amount of system memory available when reading via raw IO is temporarily insufficient.
- [EAGAIN] No message waiting to be read on a *stream* and O_NDELAY flag set.
- [EBADF] Fildes is not a valid file descriptor open for reading.
- [EBADMSG] Message waiting to be read on a *stream* is not a data message.
- [EDEADLK] The read was going to go to sleep and cause a deadlock situation to occur.
- [EFAULT] Buf points outside the allocated address space.
- [EINTR] A signal was caught during the *read* system call.

[EIO]	A physical I/0 error has occurred.
[ENXIO]	The device associated with the file-descriptor is a block-special or character-special file, and the value of the file-pointer is out of range.
[EINVAL]	Attempted to read from a <i>stream</i> linked to a multiplexer.
[ENOLCK]	The system record lock table was full, so the read could not go to sleep until the blocking record lock was removed.
[ENOLINK]	<i>Fildes</i> is on a remote machine and the link to that machine is no longer active.

A *read* from a STREAMS file will also fail if an error message is received at the *stream head*. In this case, *errno* is set to the value returned in the error message. If a hangup occurs on the *stream* being read, *read* will continue to operate normally until the *stream head* read queue is empty. Thereafter, it will return 0.

SEE ALSO

creat(2), dup(2), fcntl(2), ioctl(2),intro(2), open(2), pipe(2), getmsg(2). streamio(7), termio(7) in the System Administrator's Reference Manual.

DIAGNOSTICS

Upon successful completion a non-negative integer is returned indicating the number of bytes actually read. Otherwise, a -1 is returned, and *errno* is set to indicate the error.

RMDIR(2)

RMDIR(2)

NAME

rmdir - remove a directory

SYNOPSIS

int rmdir (path) char *path;

DESCRIPTION

The *rmdir* system call removes the directory named by the path name pointed to by *path*. The directory must not have any entries other than "." and "..".

The named directory is removed unless one or more of the following are true:

- [EINVAL] The current directory may not be removed.
- [EINVAL] The "." entry of a directory may not be removed.
- [EEXIST] The directory contains entries other than those for "." and "..".
- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] The named directory does not exist.
- [EACCES] Search permission is denied for a component of the path prefix.
- [EACCES] Write permission is denied on the directory containing the directory to be removed.
- [EBUSY] The directory to be removed is the mount point for a mounted file system.
- [EROFS] The directory entry to be removed is part of a read-only file system.
- [EFAULT] *Path* points outside the process's allocated address space.
- [EIO] An I/O error occurred while accessing the file system.
- [ENOLINK] *Path* points to a remote machine, and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

semctl – semaphore control operations

SYNOPSIS

```
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>
int semctl (semid, semnum, cmd, arg)
int semid, cmd;
int semnum;
union semun {
    int val;
    struct semid_ds *buf;
    ushort *array;
```

} arg;

DESCRIPTION

The *semctl* system call provides a variety of semaphore control operations as specified by *cmd*.

The following *cmds* are executed with respect to the semaphore specified by *semid* and *semnum*:

GETVAL	Return the value of semval [see <i>intro</i> (2)]. {READ}
SETVAL	Set the value of semval to <i>arg.val</i> . {ALTER} When this cmd is successfully executed, the semadj value corresponding to the specified semaphore in all processes is cleared.
GETPID	Return the value of sempid. {READ}
GETNCNT	Return the value of semncnt. {READ}

GETZCNT Return the value of semzcnt. {READ}

The following *cmds* return and set, respectively, every semval in the set of semaphores.

- GETALL Place semvals into array pointed to by *arg.array*. {READ}
- **SETALL** Set semvals according to the array pointed to by *arg.array*. {ALTER} When this cmd is successfully executed the semadj values corresponding to each specified semaphore in all processes are cleared.

The following *cmds* are also available:

- **IPC_STAT** Place the current value of each member of the data structure associated with *semid* into the structure pointed to by *arg.buf*. The contents of this structure are defined in *intro*(2). {READ}
- IPC_SET Set the value of the following members of the data structure associated with *semid* to the corresponding value found in the structure pointed to by *arg.buf*: **sem_perm.uid**

sem_perm.gid sem_perm.mode /* only low 9 bits */

This cmd can only be executed by a process that has an effective user ID equal to either that of super-user, or to the value of sem_perm.cuid or sem_perm.uid in the data structure associated with semid.

IPC_RMID Remove the semaphore identifier specified by semid from the system and destroy the set of semaphores and data structure associated with it. This cmd can only be executed by a process that has an effective user ID equal to either that of super-user, or to the value of sem_perm.cuid or sem_perm.uid in the data structure associated with semid.

The *semctl* system call fails if one or more of the following are true:

- [EINVAL] Semid is not a valid semaphore identifier.
- Semnum is less than zero or greater than [EINVAL] sem_nsems.
- *Cmd* is not a valid command. [EINVAL]
- [EACCES] Operation permission is denied to the calling process [see intro(2)].
- Cmd is SETVAL or SETALL and the value to which [ERANGE] semval is to be set is greater than the system imposed maximum.
- Cmd is equal to IPC_RMID or IPC_SET and the [EPERM] effective user ID of the calling process is not equal to that of super-user or to the value of sem_perm.cuid or sem_perm.uid in the data structure associated with semid.
- Arg.buf points to an illegal address. [EFAULT]

SEE ALSO

intro(2), semget(2), semop(2).

DIAGNOSTICS

Upon successful completion, the value returned depends on *cmd* as follows:

GETVAL	The value of semval.
GETPID	The value of sempid.
GETNCNT	The value of semncnt.
GETZCNT	The value of semzcnt.
All others	A value of 0.
) therwise a value of -1^{-1}	is returned and <i>errno</i> is set to indicate the err

Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

SEMGET(2)

NAME

semget – get set of semaphores

SYNOPSIS

```
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>
int semget (key, nsems, semflg)
key_t key;
int nsems, semflg;
```

DESCRIPTION

The *semget* system call returns the semaphore identifier associated with *key*.

A semaphore identifier and associated data structure and set containing *nsems* semaphores [see *intro*(2)] are created for *key* if one of the following is true:

Key is equal to **IPC_PRIVATE**.

Key does not already have a semaphore identifier associated with it, and (*semflg* & **IPC_CREAT**) is "true".

Upon creation, the data structure associated with the new semaphore identifier is initialized as follows:

Sem_perm.cuid, **sem_perm.uid**, **sem_perm.cgid**, and **sem_perm.gid** are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of **sem_perm.mode** are set equal to the low-order 9 bits of *semflg*.

Sem__nsems is set equal to the value of *nsems*.

Sem_otime is set equal to 0 and **sem_ctime** is set equal to the current time.

The data structure associated with each semaphore in the set is not initialized. The function *semctl* with the command *setval* or *setall* can be used to initialize each semaphore.

The *semget* system call fails if one or more of the following are true:

- [EINVAL] *Nsems* is either less than or equal to zero or greater than the system-imposed limit.
- [EACCES] A semaphore identifier exists for *key*, but operation permission [see *intro*(2)] as specified by the low-order 9 bits of *semflg* would not be granted.
- [EINVAL] A semaphore identifier exists for *key*, but the number of semaphores in the set associated with it is less than *nsems*, and *nsems* is not equal to zero.
- [ENOENT] A semaphore identifier does not exist for *key*, and (*semflg* & **IPC_CREAT**) is "false".

[ENOSPC]	A semaphore identifier is to be created, but the system- imposed limit on the maximum number of allowed sema- phore identifiers system wide would be exceeded.
[ENOSPC]	A semaphore identifier is to be created, but the system- imposed limit on the maximum number of allowed sema- phores system wide would be exceeded.
[EEXIST]	A semaphore identifier exists for <i>key</i> , but ((<i>semflg</i> & IPC_CREAT) and (<i>semflg</i> & IPC_EXCL)) are "true".

SEE ALSO

intro(2), semctl(2), semop(2).

DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a semaphore identifier, is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

SEMOP(2)

NAME

semop - semaphore operations

SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>

int semop (semid, sops, nsops)
int semid;
struct sembuf **sops;
unsigned nsops;

DESCRIPTION

The *semop* system call is used to automatically perform an array of semaphore operations on the set of semaphores associated with the semaphore identifier specified by *semid*. *Sops* is a pointer to the array of semaphoreoperation structures. *Nsops* is the number of such structures in the array. The contents of each structure includes the following members:

short	sem_num;	/* semaphore number */
short	sem_op;	/* semaphore operation */
short	semflg;	/* operation flags */

Each semaphore operation specified by *sem_op* is performed on the corresponding semaphore specified by *semid* and *sem_num*.

Sem_op specifies one of three semaphore operations as follows:

If *sem_op* is a negative integer, one of the following will occur: {ALTER}

If semval [see *intro*(2)] is greater than or equal to the absolute value of *sem_op*, the absolute value of *sem_op* is subtracted from semval. Also, if (*sem_flg & SEM_UNDO*) is "true", the absolute value of *sem_op* is added to the calling process's semadj value [see *exit*(2)] for the specified semaphore.

If semval is less than the absolute value of *sem_op* and (*sem_flg* & **IPC_NOWAIT**) is "true", *semop* will return immediately.

If semval is less than the absolute value of *sem_op* and (*sem_flg* & **IPC_NOWAIT**) is "false", *semop* will increment the semncnt associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occur.

Semval becomes greater than or equal to the absolute value of *sem_op*. When this occurs, the value of semncnt associated with the specified semaphore is decremented, the absolute value of *sem_op* is subtracted from semval and, if (*sem_flg & SEM_UNDO*) is "true", the absolute value of *sem_op* is added to the calling process's semadj value for the specified semaphore.

The semid for which the calling process is awaiting action is removed from the system [see *semctl*(2)]. When this occurs, *errno* is set equal to EIDRM, and a value of -1 is returned.

The calling process receives a signal that is to be caught. When this occurs, the value of semnent associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in *signal*(2).

If *sem_op* is a positive integer, the value of *sem_op* is added to semval and, if (*sem_flg* & **SEM_UNDO**) is "true", the value of *sem_op* is subtracted from the calling process's semadj value for the specified semaphore. {ALTER}

If *sem_op* is zero, one of the following will occur: {READ}

If semval is zero, *semop* will return immediately.

If semval is not equal to zero and (*sem_flg* & **IPC_NOWAIT**) is "true", *semop* will return immediately.

If semval is not equal to zero and (*sem_flg* & **IPC_NOWAIT**) is "false", *semop* will increment the semzcnt associated with the specified semaphore and suspend execution of the calling process until one of the following occurs:

Semval becomes zero, at which time the value of semzcnt associated with the specified semaphore is decremented.

The semid for which the calling process is awaiting action is removed from the system. When this occurs, *errno* is set equal to EIDRM, and a value of -1 is returned.

The calling process receives a signal that is to be caught. When this occurs, the value of semzcnt associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in *signal*(2).

The *semop* system call will fail if one or more of the following are true for any of the semaphore operations specified by *sops*:

- [EINVAL] Semid is not a valid semaphore identifier.
- [EFBIG] Sem_num is less than zero or greater than or equal to the number of semaphores in the set associated with *semid*.
- [E2BIG] *Nsops* is greater than the system-imposed maximum.
- [EACCES] Operation permission is denied to the calling process [see *intro*(2)].
- [EAGAIN] The operation would result in suspension of the calling process but (*sem_flg* & **IPC_NOWAIT**) is "true".

[ENOSPC]	The limit on the number of individual processes requesting an SEM_UNDO would be exceeded.
[EINVAL]	The number of individual semaphores for which the calling process requests a SEM_UNDO would exceed the limit.
[ERANGE]	An operation would cause a semval to overflow the system-imposed limit.
[ERANGE]	An operation would cause a semadj value to overflow the system-imposed limit.
[EFAULT]	Sops points to an illegal address.

Upon successful completion, the value of sempid for each semaphore specified in the array pointed to by *sops* is set equal to the process ID of the calling process.

SEE ALSO

exec(2), exit(2), fork(2), intro(2), semctl(2), semget(2).

DIAGNOSTICS

If *semop* returns due to the receipt of a signal, a value of -1 is returned to the calling process and *errno* is set to EINTR. If it returns due to the removal of a *semid* from the system, a value of -1 is returned and *errno* is set to EIDRM.

Upon successful completion, a value of zero is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

setpgrp - set process group ID

SYNOPSIS

int setpgrp ()

DESCRIPTION

The *setpgrp* system call sets the process group ID of the calling process to the process ID of the calling process and returns the new process group ID.

SEE ALSO

exec(2), fork(2), getpid(2), intro(2), kill(2), signal(2).

DIAGNOSTICS

The setpgrp system call returns the value of the new process group ID.

setuid, setgid - set user and group IDs

SYNOPSIS

int setuid (uid) int uid; int setgid (gid) int gid;

DESCRIPTION

The *setuid* (*setgid*) system call is used to set the real user (group) ID and effective user (group) ID of the calling process.

If the effective user ID of the calling process is super-user, the real user (group) ID and effective user (group) ID are set to *uid* (*gid*).

If the effective user ID of the calling process is not super-user, but its real user (group) ID is equal to *uid* (*gid*), the effective user (group) ID is set to *uid* (*gid*).

If the effective user ID of the calling process is not super-user, but the saved set-user (group) ID from *exec*(2) is equal to *uid* (*gid*), the effective user (group) ID is set to *uid* (*gid*).

The *setuid* (*setgid*) system call will fail if the real user (group) ID of the calling process is not equal to *uid* (*gid*) and its effective user ID is not superuser. [EPERM]

The *uid* (gid) is out of range. [EINVAL]

SEE ALSO

getuid(2), intro(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

SHMCTL(2)

NAME

shmctl – shared memory control operations

SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/shm.h>

int shmctl (shmid, cmd, buf)
int shmid, cmd;
struct shmid_ds *buf;

DESCRIPTION

The *shmctl* system call provides a variety of shared memory control operations as specified by *cmd*. The following *cmds* are available:

IPC_STAT Place the current value of each member of the data structure associated with *shmid* into the structure pointed to by *buf*. The contents of this structure are defined in *intro*(2). {READ}

IPC_SET Set the value of the following members of the data structure associated with *shmid* to the corresponding value found in the structure pointed to by *buf*:

shm_perm.uid shm_perm.gid shm_perm.mode /* only low 9 bits */

This *cmd* can only be executed by a process that has an effective user ID equal to that of super-user, or to the value of **shm_perm.cuid** or **shm_perm.uid** in the data structure associated with *shmid*.

- **IPC_RMID** Remove the shared memory identifier specified by *shmid* from the system and destroy the shared memory segment and data structure associated with it. This *cmd* can only be executed by a process that has an effective user ID equal to that of super-user, or to the value of **shm_perm.cuid** or **shm_perm.uid** in the data structure associated with *shmid*.
- **SHM_LOCK** Lock the shared memory segment specified by *shmid* in memory. This *cmd* can only be executed by a process that has an effective user ID equal to super-user.

SHM_UNLOCK

Unlock the shared memory segment specified by *shmid*. This *cmd* can only be executed by a process that has an effective user ID equal to super-user.

The *shmctl* system call will fail if one or more of the following are true:

- [EINVAL] Shmid is not a valid shared memory identifier.
- [EINVAL] *Cmd* is not a valid command.
- [EACCES] *Cmd* is equal to **IPC_STAT** and {READ} operation permission is denied to the calling process [see *intro*(2)].

- [EPERM] *Cmd* is equal to **IPC_RMID** or **IPC_SET**, and the effective user ID of the calling process is not equal to that of super-user or to the value of **shm_perm.cuid** or **shm_perm.uid** in the data structure associated with *shmid*.
- [EPERM] *Cmd* is equal to SHM_LOCK or SHM_UNLOCK, and the effective user ID of the calling process is not equal to that of superuser.
- [EFAULT] Buf points to an illegal address.
- [ENOMEM] *Cmd* is equal to **SHM_LOCK**, and there is not enough memory.

SEE ALSO

shmget(2), shmop(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

NOTES

The user must explicitly remove shared memory segments after the last reference to them has been removed.

shmget - get shared memory segment identifier

SYNOPSIS

#include <sys/types.h> #include <sys/ipc.h> #include <sys/shm.h>

```
int shmget (key, size, shmflg)
key_t key;
int size, shmflg;
```

DESCRIPTION

The *shmget* system call returns the shared memory identifier associated with *key*.

A shared memory identifier and associated data structure and shared memory segment of at least *size* bytes [see *intro*(2)] are created for *key* if one of the following is true:

Key is equal to IPC_PRIVATE.

Key does not already have a shared memory identifier associated with it, and (*shmflg* & IPC_CREAT) is "true".

Upon creation, the data structure associated with the new shared memory identifier is initialized as follows:

Shm_perm.cuid, shm_perm.uid, shm_perm.cgid, and shm_perm.gid are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of **shm_perm.mode** are set equal to the loworder 9 bits of *shmflg*. **Shm_segsz** is set equal to the value of *size*.

Shm_lpid, **shm_nattch**, **shm_atime**, and **shm_dtime** are set equal to 0.

Shm__ctime is set equal to the current time.

The *shmget* system call will fail if one or more of the following are true:

- [EINVAL] Size is less than the system-imposed minimum or greater than the system-imposed maximum.
- [EACCES] A shared memory identifier exists for *key*, but operation permission [see *intro*(2)] as specified by the low-order 9 bits of *shmflg* would not be granted.
- [EINVAL] A shared memory identifier exists for *key*, but the size of the segment associated with it is less than *size*, and *size* is not equal to zero.
- [ENOENT] A shared memory identifier does not exist for *key*, and (*shmflg* & IPC_CREAT) is "false".

[ENOSPC] A shared memory identifier is to be created, but the system-imposed limit on the maximum number of allowed shared memory identifiers system wide would be exceeded.

[ENOMEM]	A shared memory identifier and associated shared memory segment are to be created, but the amount of available memory is not sufficient to fill the request.
[EEXIST]	A shared memory identifier exists for <i>key</i> but ((<i>shmflg</i> & IPC_CREAT) and (<i>shmflg</i> & IPC_EXCL)) are "true".

SEE ALSO

intro(2), shmctl(2), shmop(2).

DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a shared memory identifier is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

NOTES

The user must explicitly remove shared memory segments after the last reference to them has been removed.

SHMOP(2)

NAME

shmop: shmat, shmdt - shared memory operations

SYNOPSIS

#include <sys/types.h> #include <sys/ipc.h> #include <sys/shm.h>

```
char *shmat (shmid, shmaddr, shmflg)
int shmid;
char *shmaddr;
int shmflg;
```

int shmdt (shmaddr) char *shmaddr;

DESCRIPTION

The *shmat* system call attaches the shared memory segment associated with the shared memory identifier specified by *shmid* to the data segment of the calling process. The segment is attached at the address specified by one of the following criteria:

If *shmaddr* is equal to zero, the segment is attached at the first available address as selected by the system.

If *shmaddr* is not equal to zero and (*shmflg* & SHM_RND) is "true", the segment is attached at the address given by (*shmaddr* - (*shmaddr* modulus SHMLBA)).

If *shmaddr* is not equal to zero and (*shmflg* & SHM_RND) is "false", the segment is attached at the address given by *shmaddr*.

Shmdt detaches from the calling process's data segment the shared memory segment located at the address specified by *shmaddr*.

The segment is attached for reading if (*shmflg* & **SHM_RDONLY**) is "true" {READ}, otherwise it is attached for reading and writing {READ/WRITE}.

Shmat will fail and not attach the shared memory segment if one or more of the following are true:

- [EINVAL] Shmid is not a valid shared memory identifier.
- [EACCES] Operation permission is denied to the calling process [see *intro*(2)].
- [ENOMEM] The available data space is not large enough to accommodate the shared memory segment.
- [EINVAL] Shmaddr is not equal to zero, and the value of (shmaddr (shmaddr modulus SHMLBA)) is an illegal address.
- [EINVAL] Shmaddr is not equal to zero, (shmflg & SHM_RND) is "false", and the value of shmaddr is an illegal address.
- [EMFILE] The number of shared memory segments attached to the calling process would exceed the system-imposed limit.

[EINVAL] Shmdt will fail and not detach the shared memory segment if shmaddr is not the data segment start address of a shared memory segment.

SEE ALSO

exec(2), exit(2), fork(2), intro(2), shmctl(2), shmget(2).

DIAGNOSTICS

Upon successful completion, the return value is as follows:

Shmat returns the data segment start address of the attached shared memory segment.

Shmdt returns a value of 0.

Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

NOTES

The user must explicitly remove shared memory segments after the last reference to them has been removed.

SIGNAL(2)

NAME

signal - specify what to do upon receipt of a signal

SYNOPSIS

#include <signal.h>

void (*signal (sig, func))()
int sig;
void (*func)();

DESCRIPTION

The *signal* system call allows the calling process to choose one of three ways in which it is possible to handle the receipt of a specific signal. *Sig* specifies the signal and *func* specifies the choice.

Sig can be assigned any one of the following except SIGKILL:

SIGHUP	01	hangup
SIGINT	02	interrupt
SIGQUIT	$03^{[1]}$	quit
SIGILL	$04^{[1]}$	illegal instruction (not reset when caught)
SIGTRAP	$05^{[1]}$	trace trap (not reset when caught)
SIGIOT	$06^{[1]}$	IOT instruction
SIGABRT	06	used by abort, replaces SIG10T
SIGEMT	$07^{[1]}$	EMT instruction
SIGFPE	$08^{[1]}$	floating point exception
SIGKILL	09	kill (cannot be caught or ignored)
SIGBUS	$10^{[1]}$	bus error
SIGSEGV	$11^{[1]}$	segmentation violation
SIGSYS	$12^{[1]}$	bad argument to system call
SIGPIPE	13	write on a pipe with no one to read it
SIGALRM	14	alarm clock
SIGTERM	15	software termination signal
SIGUSR1	16	user-defined signal 1
SIGUSR2	17	user-defined signal 2
SIGCLD	$18^{[2]}$	death of a child
SIGPWR	19 ^[2]	power fail
SIGPOLL	22 ^[3]	selectable event pending

Func is assigned one of three values: **SIG_DFL**, **SIG_IGN**, or a *function address*. **SIG_DFL**, and **SIG_IGN**, are defined in the include file *signal.h*. Each is a macro that expands to a constant expression of type pointer to function returning *void*, and has a unique value that matches no declarable function.

The actions prescribed by the values of *func* are as follows:

SIG_DFL —terminate process upon receipt of a signal

Upon receipt of the signal sig, the receiving process is to be terminated with all of the consequences outlined in exit(2). See NOTE [1] below.

SIG_IGN —ignore signal

The signal *sig* is to be ignored.

Note: the signal SIGKILL cannot be ignored.

function address —catch signal

Upon receipt of the signal *sig*, the receiving process is to execute the signal-catching function pointed to by *func*. The signal number *sig* will be passed as the only argument to the signalcatching function. Additional arguments are passed to the signal-catching function for hardware-generated signals. Before entering the signal-catching function, the value of *func* for the caught signal will be set to SIG_DFL unless the signal is SIGILL, SIGTRAP, or SIGPWR.

Upon return from the signal-catching function, the receiving process will resume execution at the point it was interrupted.

When a signal that is to be caught occurs during a read(2), a write(2), an open(2), or an ioctl(2) system call on a slow device (like a terminal; but not a file), during a pause(2) system call, or during a wait(2) system call that does not return immediately due to the existence of a previously stopped or zombie process, the signal catching function will be executed. Then the interrupted system call may return a -1 to the calling process with *errno* set to EINTR.

The *signal* system call will not catch an invalid function argument, *func*, and results are undefined when an attempt is made to execute the function at the bad address.

Note: The signal **SIGKILL** cannot be caught.

A call to *signal* cancels a pending signal *sig* except for a pending SIGKILL signal.

The *signal* system call will fail if *sig* is an illegal signal number, including **SIGKILL**. [EINVAL]

NOTES

[1] If SIG_DFL is assigned for these signals, in addition to the process being terminated, a "core image" will be constructed in the current working directory of the process, if the following conditions are met:

The effective user ID and the real user ID of the receiving process are equal.

An ordinary file named **core** exists and is writable or can be created. If the file must be created, it will have the following properties:

• a mode of 0666 modified by the file creation mask [see *umask*(2)]

• a file owner ID that is the same as the effective user ID of the receiving process

• a file group ID that is the same as the effective group ID of the receiving process.

[2] For the signals SIGCLD and SIGPWR, *func* is assigned one of three values: SIG_DFL, SIG_IGN, or a *function address*. The actions prescribed by these values are:

SIG_DFL —ignore signal The signal is to be ignored.

SIG_IGN — ignore signal

The signal is to be ignored. Also, if *sig* is **SIGCLD**, the calling process's child processes will not create zombie processes when they terminate [see *exit*(2)].

function address —catch signal

If the signal is **SIGPWR**, the action to be taken is the same as that described above for *func* equal to *function address*. The same is true if the signal is **SIGCLD** with one exception: while the process is executing the signal-catching function, any received **SIGCLD** signals will be ignored. (This is the default action.)

In addition, **SIGCLD** affects the *wait* and *exit* system calls as follows:

- *wait* If the *func* value of **SIGCLD** is set to **SIG_IGN** and a *wait* is executed, the *wait* will block until all of the calling process's child processes terminate; it will then return a value of -1 with *errno* set to ECHILD.
- *exit* If in the exiting process's parent process the *func* value of **SIGCLD** is set to **SIG_IGN**, the exiting process will not create a zombie process.

When processing a pipeline, the shell makes the last process in the pipeline the parent of the proceeding processes. A process that may be piped into in this manner (and thus become the parent of other processes) should take care not to set **SIGCLD** to be caught.

[3] SIGPOLL is issued when a file descriptor corresponding to a STREAMS [see *intro*(2)] file has a "selectable" event pending. A process must specifically request that this signal be sent using the L_SETSIG *ioctl* call. Otherwise, the process will never receive SIGPOLL.

SEE ALSO

intro(2), kill(2), pause(2), ptrace(2), wait(2), setjmp(3C), sigset(2). kill(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, *signal* returns the previous value of *func* for the specified signal *sig*. Otherwise, a value of SIG_ERR is returned and *errno* is set to indicate the error. SIG_ERR is defined in the include file *signal.h*.

SIGSET(2)

NAME

sigset, sighold, sigrelse, sigignore, sigpause - signal management

SYNOPSIS

#include <signal.h>
void (*sigset (sig, func))()
int sig;
void (*func)();
int sighold (sig)
int sig;
int sigrelse (sig)
int sig;
int sigignore (sig)
int sig;
int sigpause (sig)
int sig;

DESCRIPTION

These functions provide signal management for application processes. The *sigset* system call specifies the system signal action to be taken upon receipt of signal *sig*. This action is either calling a process signal-catching handler *func* or performing a system-defined action.

Sig can be assigned any one of the following values except SIGKILL. Machine-or implementation-dependent signals are not included (see *NOTES* below). Each value of *sig* is a macro, defined in *<signal.h>*, that expands to an integer constant expression.

SIGHUP	hangup
SIGINT	interrupt
SIGQUIT*	quit
SIGILL*	illegal instruction (not held when caught)
SIGTRAP*	trace trap (not held when caught)
SIGABRT*	abort
SIGFPE*	floating point exception
SIGKILL	kill (cannot be caught or ignored)
SIGSYS*	bad argument to system call
SIGPIPE	write on a pipe with no one to read it
SIGALRM	alarm clock
SIGTERM	software termination signal
SIGUSR1	user-defined signal 1
SIGUSR2	user-defined signal 2
SIGCLD	death of a child (see WARNING below)
SIGPWR	power fail (see WARNING below)
SIGPOLL	selectable event pending (see NOTES below)

See below under SIG_DFL regarding asterisks (*) in the above list.

The following values for the system-defined actions of *func* are also defined in $\langle signal.h \rangle$. Each is a macro that expands to a constant expression of type pointer to function returning *void* and has a unique value that matches no declarable function.

SIG_DFL —default system action

Upon receipt of the signal sig, the receiving process is to be terminated with all of the consequences outlined in exit(2). In addition a "core image" will be made in the current working directory of the receiving process if sig is one for which an asterisk appears in the above list *and* the following conditions are met:

The effective user ID and the real user ID of the receiving process are equal.

An ordinary file named *core* exists and is writable or can be created. If the file must be created, it will have the following properties:

a mode of 0666 modified by the file creation mask [see *umask*(2)]

a file owner ID that is the same as the effective user ID of the receiving process

a file group ID that is the same as the effective group ID of the receiving process.

SIG_IGN —ignore signal

Any pending signal *sig* is discarded and the system signal action is set to ignore future occurrences of this signal type.

SIG_HOLD — hold signal

The signal *sig* is to be held upon receipt. Any pending signal of this type remains held. Only one signal of each type is held.

Otherwise, *func* must be a pointer to a function, the signal-catching handler, that is to be called when signal *sig* occurs. In this case, *sigset* specifies that the process will call this function upon receipt of signal *sig*. Any pending signal of this type is released. This handler address is retained across calls to the other signal management functions listed here.

When a signal occurs, the signal number *sig* will be passed as the only argument to the signal-catching handler. Before calling the signal-catching handler, the system signal action will be set to SIG_HOLD. During normal return from the signal-catching handler, the system signal action is restored to *func* and any held signal of this type released. If a non-local goto (*longjmp*) is taken, then *sigrelse* must be called to restore the system signal action and release any held signal of this type.

In general, upon return from the signal-catching handler, the receiving process will resume execution at the point it was interrupted. However, when a signal is caught during a read(2), a write(2), an open(2), or an ioctl(2) system call during a *sigpause* system call, or during a *wait*(2) system call that does not return immediately due to the existence of a previously stopped or

zombie process, the signal-catching handler will be executed. Then the interrupted system call may return a -1 to the calling process with *errno* set to EINTR.

Sighold and sigrelse are used to establish critical regions of code. Sighold is analogous to raising the priority level and deferring or holding a signal until the priority is lowered by sigrelse. Sigrelse restores the system signal action to that specified previously by sigset.

Sigignore sets the action for signal *sig* to SIG_IGN (see above).

Sigpause suspends the calling process until it receives a signal, the same as *pause*(2). However, if the signal *sig* had been received and held, it is released and the system signal action taken. This system call is useful for testing variables that are changed on the occurrence of a signal. The correct usage is to use *sighold* to block the signal first, then test the variables. If they have not changed, then call *sigpause* to wait for the signal. *sigset* will fail if one or more of the following are true:

[EINVAL] Sig is an illegal signal number (including SIGKILL) or the default handling of sig cannot be changed.

[EINTR] A signal was caught during the system call *sigpause*.

DIAGNOSTICS

Upon successful completion, *sigset* returns the previous value of the system signal action for the specified signal *sig*. Otherwise, a value of SIG_ERR is returned and *errno* is set to indicate the error. SIG_ERR is defined in *<signal.h>*.

For the other functions, upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SEE ALSO

kill(2), pause(2), signal(2), wait(2), setjmp(3C).

WARNING

Two signals that behave differently than the signals described above exist in this release of the system:

SIGCLDdeath of a child (reset when caught)SIGPWRpower fail (not reset when caught)

For these signals, *func* is assigned one of three values: SIG_DFL, SIG_IGN, or a *function address*. The actions prescribed by these values are as follows:

SIG_DFL - ignore signal

The signal is to be ignored.

SIG_IGN - ignore signal

The signal is to be ignored. Also, if *sig* is **SIGCLD**, the calling process's child processes will not create zombie processes when they terminate [see exit(2)].

function address - catch signal

If the signal is **SIGPWR**, the action to be taken is the same as that described above for *func* equal to *function address*. The same is

true if the signal is **SIGCLD** with one exception: while the process is executing the signal-catching function, any received **SIGCLD** signals will be ignored. (This is the default action.)

The **SIGCLD** affects two other system calls [*wait*(2), and *exit*(2)] in the following ways:

- *wait* If the *func* value of **SIGCLD** is set to SIG_IGN and a *wait* is executed, the *wait* will block until all of the calling process's child processes terminate; it will then return a value of -1 with *errno* set to ECHILD.
- *exit* If in the exiting process's parent process the *func* value of **SIGCLD** is set to SIG_IGN, the exiting process will not create a zombie process.

When processing a pipeline, the shell makes the last process in the pipeline the parent of the proceeding processes. A process that may be piped into in this manner (and thus become the parent of other processes) should take care not to set **SIGCLD** to be caught.

NOTES

SIGPOLL is issued when a file descriptor corresponding to a STREAMS [see *intro*(2)] file has a "selectable" event pending. A process must specifically request that this signal be sent using the L_SETSIG *ioctl*(2) call [see *streamio*(7)]. Otherwise, the process will never receive **SIGPOLL**.

For portability, applications should use only the symbolic names of signals rather than their values and use only the set of signals defined here. The action for the signal **SIGKILL** cannot be changed from the default system action.

Specific implementations may have other implementation-defined signals. Also, additional implementation-defined arguments may be passed to the signal-catching handler for hardware-generated signals. For certain hardware-generated signals, it may not be possible to resume execution at the point of interruption.

The signal type **SIGSEGV** is reserved for the condition that occurs on an invalid access to a data object. If an implementation can detect this condition, this signal type should be used.

The other signal management functions, *signal*(2) and *pause*(2), should not be used in conjunction with these routines for a particular signal type.

STAT(2)

NAME

stat, fstat – get file status

SYNOPSIS

#include <sys/types.h>
#include <sys/stat.h>

int stat (path, buf) char *path; struct stat *buf;

int fstat (fildes, buf) int fildes; struct stat *buf;

DESCRIPTION

Path points to a path name naming a file. Read, write, or execute permission of the named file is not required, but all directories listed in the path name leading to the file must be searchable. The *stat* system call obtains information about the named file.

Note that in a Remote File Sharing environment, the information returned by *stat* depends upon the user/group mapping set-up between the local and remote computers. [See *idload*(1M)].

Fstat obtains information about an open file known by the file descriptor *fildes*, obtained from a successful *open*, *creat*, *dup*, *fcntl*, or *pipe* system call.

Buf is a pointer to a *stat* structure into which information is placed concerning the file.

The contents of the structure pointed to by *buf* include the following members:

ushort	st_mode;	/* File mode [see <i>mknod</i> (2)] */
ino_t	st_ino;	/* Inode number */
dev_t	st_dev;	/* ID of device containing */
		/* a directory entry for this file */
dev_t	st_rdev;	/* ID of device */
		/* This entry is defined only for */
		/* character special or block special files */
short	st_nlink;	/* Number of links */
ushort	st_uid;	/* User ID of the file's owner */
ushort	st_gid;	/* Group ID of the file's group */
offt	st_size;	/* File size in bytes */
timet	st_atime;	/* Time of last access */
time_t	st;	/* Time of last data modification */
time_t	st_ctime;	/* Time of last file status change */
		/* Times measured in seconds since */
		/* 00:00:00 GMT, Jan. 1, 1970 */

st_mode The mode of the file as described in the *mknod*(2) system call.

st_ino This field uniquely identifies the file in a given file system. The pair st_ino and st_dev uniquely identifies regular files.

st_dev	This field uniquely identifies the file system that contains the
	file. Its value may be used as input to the ustat(2) system call to
	determine more information about this file system. No other
	meaning is associated with this value.

- **st_rdev** This field should be used only by administrative commands. It is valid only for block special or character special files and only has meaning on the system where the file was configured.
- st_nlink This field should be used only by administrative commands.
- **st_uid** The user ID of the file's owner.
- **st_gid** The group ID of the file's group.
- **st_size** For regular files, this is the address of the end of the file. For pipes or fifos, this is the count of the data currently in the file. For block special or character special, this is not defined.
- **st_atime** Time when file data was last accessed. Changed by the following system calls: *creat*(2), *mknod*(2), *pipe*(2), *utime*(2), and *read*(2).
- st_mtime Time when data was last modified. Changed by the following system calls: creat(2), mknod(2), pipe(2), utime(2), and write(2).
- st_ctime Time when file status was last changed. Changed by the following system calls: chmod(2), chown(2), creat(2), link(2), mknod(2), pipe(2), unlink(2), utime(2), and write(2).

The stat system call will fail if one or more of the following are true:

- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] The named file does not exist.
- [EACCES] Search permission is denied for a component of the path prefix.
- [EFAULT] Buf or path points to an invalid address.
- [EINTR] A signal was caught during the *stat* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

Fstat will fail if one or more of the following are true:

- [EBADF] Fildes is not a valid open file descriptor.
- [EFAULT] Buf points to an invalid address.
- [ENOLINK] *Fildes* points to a remote machine and the link to that machine is no longer active.

SEE ALSO

chmod(2), chown(2), creat(2), link(2), mknod(2), pipe(2), read(2), time(2), unlink(2), utime(2), write(2).

DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

statfs, fstatfs - get file system information

SYNOPSIS

#include <sys/types.h>
#include <sys/statfs.h>
int statfs (path, buf, len, fstyp)
char *path;
struct statfs *buf;

int len, fstyp; int fstatfs (fildes, buf, len, fstyp) int fildes; struct statfs *buf; int len, fstyp;

DESCRIPTION

The *statfs* system call returns a "generic superblock" describing a file system. It can be used to acquire information about mounted as well as unmounted file systems, and usage is slightly different in the two cases. In all cases, *buf* is a pointer to a structure (described below) which will be filled by the system call, and *len* is the number of bytes of information which the system should return in the structure. *Len* must be no greater than **sizeof (struct statfs)** and ordinarily it will contain exactly that value; if it holds a smaller value, the system will fill the structure with that number of bytes. (This allows future versions of the system to grow the structure without invalidating older binary programs.)

If the file system of interest is currently mounted, *path* should name a file which resides on that file system. In this case the file system type is known to the operating system and the *fstyp* argument must be zero. For an unmounted file system *path* must name the block special file containing it and *fstyp* must contain the (non-zero) file system type. In both cases read, write, or execute permission of the named file is not required, but all directories listed in the path name leading to the file must be searchable.

The *statfs* structure pointed to by *buf* includes the following members:

short	f_fstyp;	/* File system type */
short	f_bsize;	/* Block size */
short	f_frsize;	/* Fragment size */
long	fblocks;	/* Total number of blocks */
long	f_bfree;	/* Count of free blocks */
long	ffiles;	/* Total number of file nodes */
long	f_ffree;	/* Count of free file nodes */
char	f_fname[6];	/* Volume name */
char	f_fpack[6];	/* Pack name */

The *fstatfs* system call is similar, except that the file named by *path* in *statfs* is instead identified by an open file descriptor *filedes* obtained from a successful *open*(2), *creat*(2), *dup*(2), *fcntl*(2), or *pipe*(2) system call.

The *statfs* system call obsoletes *ustat(2)* and should be used in preference to it in new programs.

STATFS(2)

The *statfs* and *fstatfs* system calls will fail if one or more of the following are true:

- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] The named file does not exist.
- [EACCES] Search permission is denied for a component of the path prefix.
- [EFAULT] Buf or path points to an invalid address.
- [EBADF] Fildes is not a valid open file descriptor.
- [EINVAL] *Fstyp* is an invalid file system type; *path* is not a block special file and *fstyp* is nonzero; *len* is negative or is greater than **sizeof (struct statfs)**.
- [ENOLINK] *Path* points to a remote machine, and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

SEE ALSO

chmod(2), chown(2), creat(2), link(2), mknod(2), pipe(2), read(2), time(2), unlink(2), utime(2), write(2), fs(4).

STIME(2)

NAME

stime - set time

SYNOPSIS

int stime (tp)
long *tp;

DESCRIPTION

The *stime* system call sets the system's idea of the time and date. Tp points to the value of time as measured in seconds from 00:00:00 GMT January 1, 1970.

[EPERM] *stime* will fail if the effective user ID of the calling process is not super-user.

SEE ALSO

time(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

sync - update super block

SYNOPSIS

void sync ()

DESCRIPTION

The *sync* system call causes all information in memory that should be on disk to be written out. This includes modified super blocks, modified inodes, and delayed block I/O.

It should be used by programs which examine a file system, for example fsck, df, etc. It is mandatory before a re-boot.

The writing, although scheduled, is not necessarily complete upon return from *sync*.

SYSFS(2)

SYSFS(2)

NAME

sysfs - get file system type information

SYNOPSIS

```
#include <sys/fstyp.h>
#include <sys/fsid.h>
```

int sysfs (opcode, fsname) int opcode; char *fsname;

```
int sysfs (opcode, fs_index, buf)
int opcode;
int fs_index;
char *buf;
```

int sysfs (opcode) int opcode;

DESCRIPTION

The *sysfs* system call returns information about the file system types configured in the system. The number of arguments accepted by *sysfs* varies and depends on the *opcode*. The currently recognized *opcodes* and their functions are described below:

GETFSIND	translates <i>fsname</i> , a null-terminated file-system identifier, into a file-system type index.	
GETFSTYP	translates fs_index , a file-system type index, into a null-terminated file-system identifier and writes it into the buffer pointed to by <i>buf</i> ; this buffer must be at least of size FSTYPSZ as defined in <sys fstyp.h="">.</sys>	
GETNFSTYP	returns the total number of file system types con- figured in the system.	
The sysfs system call will fail if one or more of the following are true:		
[EINVAL]	<i>Fsname</i> points to an invalid file-system identifier; <i>fs_index</i> is zero, or invalid; <i>opcode</i> is invalid.	
[EFAULT]	Buf or fsname point to an invalid user address.	

DIAGNOSTICS

Upon successful completion, *sysfs* returns the file-system type index if the *opcode* is **GETFSIND**, a value of 0 if the *opcode* is **GETFSTYP**, or the number of file system types configured if the *opcode* is **GETNFSTYP**. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

SYSI86(2)

NAME

sysi86 - machine-specific functions

SYNOPSIS

#include <sys/sysi86.h>

int sysi86(cmd, arg)
int cmd;
char *arg;
int sysi86(cmd, arg);
int cmd;
int arg;
int sysi86(cmd, arg);
int cmd;
long arg;
long sysi86(cmd, arg);
int cmd;

DESCRIPTION

The *sysi86* system call implements machine-specific functions. The *cmd* argument determines the function to be performed. The types of the arguments expected depend on the function.

Command RTODC (80286 only)

When *cmd* is RTODC, the expected argument is the address of a *struct bcd_tm*:

struct bcd_tm {

unsigned char unit_sec, ten_sec, unit_min, ten_min, unit_hr, ten_hr, unit_day, ten_day, unit_mon, ten_mon, unit_yr, ten_yr, 11yr;

};

This function reads the hardware time of day clock and returns the data in the structure referenced by the argument. This command is available only to the *super-user*.

Command SI86FPHW

This command expects the address of an integer as its argument. After successful return from the system call, the integer specifies how floating-point computation is supported.

The low-order byte of the integer contains the value of "fpkind", a variable that specifies whether an 80287 or 80387 floating-point coprocessor is present, emulated in software, or not supported. The values are defined in the header file sys/fp.h.

FPNO	no fp chip, no emulator (no fp support)
FP_SW	no fp chip, using software emulator
FP_HW	chip present bit
FP287	80287 chip present
FP387	80387 chip present

(80386 only) The second byte of the integer contains the value of *weitek_kind*, a variable that specifies whether a Weitek floating-point coprocessor is present, emulated or not supported. The values are defined in the header file *sys/weitek.h*.

WEITEKNO	no chip support
WEITEK_HW	chip present
WEITEK_SW	emulator present

Command SETNAME

This command, which is only available to the *super-user* expects an argument of type *char* * which points to a NULL terminated string of at most 7 characters. The command will change the running system's *sysname* and *nodename* [see *uname*(2)] to this string.

Command STIME

When *cmd* is STIME, an argument of type long is expected. This function sets the system time and date. The argument contains the time as measured in seconds from 00:00:00 GMT January 1, 1970. Note that this command is only available to the super-user.

Command SI86DSCR

This command sets a segment or gate descriptor in the kernel. The following descriptor types are accepted:

- executable and data segments in the LDT at DPL 3
- a call gate in the GDT at DPL 3 that points to a segment in the LDT $% \mathcal{D}$

The argument is a pointer to a request structure that contains the values to be placed in the descriptor. The request structure is declared in the sys/sysi86.h header file.

Command SI86MEM

This command returns the size of available memory in bytes.

Command SI86SWPI

Note: This *cmd* is available only with System V Releases 2.1 and 3.0 software.

When *cmd* is SI86SWPI, individual swapping areas may be added, deleted or the current areas determined. The address of an appropriately primed swap buffer is passed as the only argument. (Refer to *sys/swap.h* header file for details of loading the buffer.)

The format of the swap buffer is:

struct swapint {

char	si_cmd;	/* command: list, add, delete */
char	*si_buf;	/* swap file path pointer */
long	si_swplo;	/* start block */
long	sinblks;	/* swap size */
long	si_blksiz;	/* The blocksize (in bytes) of the
Ū		swap file */

};

SYSI86(2)

Note that the add and delete options of the command may only be exercised by the super-user.

Typically, a swap area is added by a single call to *sysi86*. First, the swap buffer is primed with appropriate entries for the structure members. Then *sysi86* is invoked.

```
#include <sys/sysi86.h>
#include <sys/swap.h>
```

struct swapint swapbuf; /*swap into buffer ptr*/

sysi86(SI86SWPI, &swapbuf);

If this command succeeds, it returns 0 to the calling process. This command fails, returning -1, if one or more of the following is true:

- [EFAULT] Swapbuf.si_buf points to an invalid address
- [ENOTBLK] Swap area specified is not a block special device
- [EEXIST] Swap area specified has already been added
- [ENOSPC] Too many swap areas in use (if adding)
- [ENOMEM] Tried to delete last remaining swap area
- [EINVAL] Bad arguments

[ENOMEM] No place to put swapped pages when deleting a swap area

SEE ALSO

uname(2)

swap(1M) in the System Administrator's Reference Manual.

DIAGNOSTICS

Upon successful completion, the value of zero is returned; otherwise, -1 is returned, and *errno* is set to indicate the error. When the *cmd* is invalid, *errno* is set to EINVAL.

time - get time

SYNOPSIS

#include <sys/types.h>

time_t time (tloc) long *tloc;

DESCRIPTION

The *time* system call returns the value of time in seconds since 00:00:00 Greenwich Mean Time (GMT), January 1, 1970.

If *tloc* is non-zero, the return value is also stored in the location to which *tloc* points.

SEE ALSO

stime(2).

WARNING

The *time* system call fails and its actions are undefined if *tloc* points to an illegal address.

DIAGNOSTICS

Upon successful completion, *time* returns the value of time. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

TIMES(2)

NAME

times – get process and child process times

SYNOPSIS

#include <sys/types.h>
#include <sys/times.h>

long times (buffer) struct tms *buffer;

DESCRIPTION

The *times* system call fills the structure pointed to by *buffer* with timeaccounting information. The following are the contents of this structure:

struct tms {

time_t tms_utime; time_t tms_stime; time_t tms_cutime; time_t tms_cstime;

};

This information comes from the calling process and each of its terminated child processes for which it has executed a *wait*. All times are reported in clock ticks per second. Clock ticks are a system-dependent parameter. The specific value for an implementation is defined by the variable HZ, found in the include file param.h.

Tms_utime is the CPU time used while executing instructions in the user space of the calling process.

Tms_stime is the CPU time used by the system on behalf of the calling process.

Tms_cutime is the sum of the *tms_utimes* and *tms_cutimes* of the child processes.

Tms_cstime is the sum of the *tms_stimes* and *tms_cstimes* of the child processes.

[EFAULT] The times system call will fail if buffer points to an illegal address.

SEE ALSO

exec(2), fork(2), time(2), wait(2).

DIAGNOSTICS

Upon successful completion, *times* returns the elapsed real time, in clock ticks per second, from an arbitrary point in the past (e.g., system start-up time). This point does not change from one invocation of *times* to another. If *times* fails, a -1 is returned and *errno* is set to indicate the error. On a 80286 computer, clock ticks occur 60 times per second. On a 80386 computer, clock ticks occur 100 times per second.

uadmin - administrative control

SYNOPSIS

#include <sys/uadmin.h>

int uadmin (cmd, fcn, mdep) int cmd, fcn, mdep;

DESCRIPTION

The *uadmin* system call provides control for basic administrative functions. This system call is tightly coupled to the system administrative procedures and is not intended for general use. The argument *mdep* is provided for machine-dependent use and is not defined here.

As specified by *cmd*, the following commands are available:

- A_SHUTDOWN The system is shutdown. All user processes are killed, the buffer cache is flushed, and the root file system is unmounted. The action to be taken after the system has been shut down is specified by *fcn*. The functions are generic; the hardware capabilities vary on specific machines.
 - AD_HALT Halt the processor and turn off the power.
 - AD_BOOT Reboot the system, using /unix.
 - AD_IBOOT Interactive reboot; user is prompted for system name.
- A_REBOOT The system stops immediately without any further processing. The action to be taken next is specified by *fcn* as above.
- A_REMOUNT The root file system is mounted again after having been fixed. This should be used only during the startup process.

The *uadmin* system call fails if any of the following are true:

[EPERM] The effective user ID is not super-user.

DIAGNOSTICS

Upon successful completion, the value returned depends on *cmd* as follows:

ASHUTDOWN	Never returns.
AREBOOT	Never returns.
A_REMOUNT	0

Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

ULIMIT(2)

NAME

ulimit - get and set user limits

SYNOPSIS

long ulimit (cmd, newlimit) int cmd; long newlimit;

DESCRIPTION

This function provides for control over process limits. The *cmd* values available are:

- **1.** Get the regular file size limit of the process. The limit is in units of 512-byte blocks and is inherited by child processes. Files of any size can be read.
- 2. Set the regular file size limit of the process to the value of *newlimit*. Any process may decrease this limit, but only a process with an effective user ID of super-user may increase the limit. The *ulimit* system call fails and the limit is unchanged if a process with an effective user ID other than super-user attempts to increase its regular file size limit. [EPERM]
- **3.** Get the maximum possible break value [see *brk*(2)].

For the 80286 computer:

in small model, the address returned is the maximum break value; in large model, the address returned is the last address of the next segment.

4. Return configured value of NOFILES, the value for the maximum number of open files per process.

SEE ALSO

brk(2), write(2).

WARNING

The *ulimit* system call is effective in limiting the growth of regular files. Pipes are currently limited to 5,120 bytes.

DIAGNOSTICS

Upon successful completion, a non-negative value is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

UMASK(2)

NAME

umask - set and get file creation mask

SYNOPSIS

int umask (cmask) int cmask;

DESCRIPTION

The *umask* system call sets the process's file mode creation mask to *cmask* and returns the previous value of the mask. Only the low-order 9 bits of *cmask* and the file mode creation mask are used.

SEE ALSO

chmod(2), creat(2), mknod(2), open(2). mkdir(1), sh(1) in the User's Reference Manual.

DIAGNOSTICS

The previous value of the file mode creation mask is returned.

UMOUNT(2)

NAME

umount - unmount a file system

SYNOPSIS

int umount (file) char *file;

DESCRIPTION

The *umount* system call requests that a previously mounted file system contained on the block special device or directory identified by *file* be unmounted. *File* is a pointer to a path name. After unmounting the file system, the directory upon which the file system was mounted reverts to its ordinary interpretation.

The *umount* system call may be invoked only by the super-user.

The *umount* system call will fail if one or more of the following are true:

[EPERM]	The process's effective user ID is not super-user.
[EINVAL]	File does not exist.
[ENOTBLK]	File is not a block special device.
[EINVAL]	File is not mounted.
[EBUSY]	A file on <i>file</i> is busy.
[EFAULT]	File points to an illegal address.
[EREMOTE]	File is remote.
[ENOLINK]	<i>File</i> is on a remote machine, and the link to that machine is no longer active.
[EMULTIHOP]	Components of the path pointed to by <i>file</i> require hopping to multiple remote machines.
[ENOTDIR]	A component of the path-prefix is not a directory.
[ENOENT]	The named file does not exist.
LSO	

SEE ALSO

mount(2).

DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

uname - get name of current UNIX system

SYNOPSIS

#include <sys/utsname.h>

int uname (name) struct utsname *name;

DESCRIPTION

The *uname* system call stores information identifying the current UNIX system in the structure pointed to by *name*.

The *uname* system call uses the structure defined in **<sys/utsname.h>** whose members are:

char sysname[9]; char nodename[9]; char release[9]; char version[9]; char machine[9];

The *uname* system call returns a null-terminated character string naming the current UNIX system in the character array *sysname*. Similarly, *nodename* contains the name that the system is known by on a communications network. *Release* and *version* further identify the operating system. *Machine* contains a standard name that identifies the hardware that the UNIX system is running on.

[EFAULT] uname will fail if name points to an invalid address.

SEE ALSO

uname(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a non-negative value is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

UNLINK(2)

NAME

unlink – remove directory entry

SYNOPSIS

int unlink (path) char *path;

DESCRIPTION

The *unlink* system call removes the directory entry named by the path name pointed to by *path*.

The named file is unlinked unless one or more of the following are true:

[ENOTDIR]	A component of the path prefix is not a directory.
[ENOENT]	The named file does not exist.
[EACCES]	Search permission is denied for a component of the path prefix.

- [EACCES] Write permission is denied on the directory containing the link to be removed.
- [EPERM] The named file is a directory and the effective user ID of the process is not super-user.
- [EBUSY] The entry to be unlinked is the mount point for a mounted file system.
- [ETXTBSY] The entry to be unlinked is the last link to a pure procedure (shared text) file that is being executed.
- [EROFS] The directory entry to be unlinked is part of a read-only file system.
- [EFAULT] *Path* points outside the process's allocated address space.
- [EINTR] A signal was caught during the *unlink* system call.
- [ENOLINK] *Path* points to a remote machine and the link to that machine is no longer active.
- [EMULTIHOP] Components of *path* require hopping to multiple remote machines.

When all links to a file have been removed and no process has the file open, the space occupied by the file is freed and the file ceases to exist. If one or more processes have the file open when the last link is removed, the removal is postponed until all references to the file have been closed.

SEE ALSO

close(2), link(2), open(2).

rm(1) in the User's Reference Manual.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

USTAT(2)

NAME

ustat - get file system statistics

SYNOPSIS

```
#include <sys/types.h>
#include <ustat.h>
```

int ustat (dev, buf) dev_t dev; struct ustat *buf;

DESCRIPTION

The *ustat* system call returns information about a mounted file system. *Dev* is a device number identifying a device containing a mounted file system. *Buf* is a pointer to a *ustat* structure that includes the following elements:

daddr_t f_tfree;		/* Total free blocks */
inot	f_tinode;	/* Number of free inodes */
char	f_fname[6];	/* Filsys name */
char	f_fpack[6];	/* Filsys pack name */

The last two fields, *f_name* and *f_fpack* may not have significant information on all systems, and, in that case, will contain the null character.

The ustat system call will fail if one or more of the following are true:

[EINVAL]	<i>Dev</i> is not the device number of a device containing a mounted file system.		
[EFAULT]	<i>Buf</i> points outside the process's allocated address space.		

[EINTR] A signal was caught during a *ustat* system call.

- [ENOLINK] *Dev* is on a remote machine and the link to that machine is no longer active.
- [ECOMM] *Dev* is on a remote machine and the link to that machine is no longer active.

SEE ALSO

stat(2), fs(4).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

UTIME(2)

NAME

utime - set file access and modification times

SYNOPSIS

#include <sys/types.h>
int utime (path, times)
char *path;
struct utimbuf *times;

DESCRIPTION

Path points to a path name naming a file. The *utime* system call sets the access and modification times of the named file.

If *times* is NULL, the access and modification times of the file are set to the current time. A process must be the owner of the file or have write permission to use *utime* in this manner.

If *times* is not NULL, *times* is interpreted as a pointer to a *utimbuf* structure and the access and modification times are set to the values contained in the designated structure. Only the owner of the file or the super-user may use *utime* this way.

The times in the following structure are measured in seconds since 00:00:00 Greenwich Mean Time (GMT), Jan. 1, 1970.

struct	utimbuf	{	
	time_t	actime;	/* access time */
	timet	modtime;	/* modification time */
};			

The *utime* system call will fail if one or more of the following are true:

[ENOENT] The named fi	ile does not exist.
-----------------------	---------------------

- [ENOTDIR] A component of the path prefix is not a directory.
- [EACCES] Search permission is denied by a component of the path prefix.
- [EPERM] The effective user ID is not super-user and not the owner of the file, and *times* is not NULL.
- [EACCES] The effective user ID is not super-user and not the owner of the file, and *times* is NULL and write access is denied.
- [EROFS] The file system containing the file is mounted read-only.
- [EFAULT] Times is not NULL and points outside the process's allocated address space.
- [EFAULT] *Path* points outside the process's allocated address space.
- [EINTR] A signal was caught during the *utime* system call.
- [ENOLINK] *Path* points to a remote machine, and the link to that machine is no longer active.

[EMULTIHOP] Components of *path* require hopping to multiple remote machines.

SEE ALSO

stat(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

wait - wait for child process to stop or terminate

SYNOPSIS

int wait (stat_loc)
int *stat_loc;
int wait ((int *) 0)

DESCRIPTION

The *wait* system call suspends the calling process until one of the immediate children terminates or until a child that is being traced stops, because it has hit a break point. The *wait* system call will return prematurely if a signal is received and if a child process stopped or terminated prior to the call on *wait*; return is immediate.

If *stat_loc* is non-zero, 16 bits of information called status are stored in the low order 16 bits of the location pointed to by *stat_loc*. *Status* can be used to differentiate between stopped and terminated child processes and if the child process terminated, status identifies the cause of termination and passes useful information to the parent. This is accomplished in the following manner:

If the child process stopped, the high order 8 bits of status will contain the number of the signal that caused the process to stop, and the low order 8 bits will be set equal to 0177.

If the child process terminated due to an *exit* call, the low order 8 bits of status will be zero, and the high order 8 bits will contain the low order 8 bits of the argument that the child process passed to *exit* [see *exit*(2)].

If the child process terminated due to a signal, the high order 8 bits of status will be zero, and the low order 8 bits will contain the number of the signal that caused the termination. In addition, if the low order seventh bit (i.e., bit 200) is set, a "core image" will have been produced [see *signal*(2)].

If a parent process terminates without waiting for its child processes to terminate, the parent process ID of each child process is set to 1. This means the initialization process inherits the child processes [see *intro*(2)].

The *wait* system call will fail and return immediately if one or more of the following are true:

[ECHILD] The calling process has no existing unwaited-for child processes.

SEE ALSO

exec(2), exit(2), fork(2), intro(2), pause(2), ptrace(2), signal(2).

WARNING

The *wait* system call fails and its actions are undefined if *stat_loc* points to an invalid address.

See WARNING in signal(2).

DIAGNOSTICS

If wait returns due to the receipt of a signal, a value of -1 is returned to the calling process, and *errno* is set to EINTR. If wait returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

WRITE(2)

NAME

write – write on a file

SYNOPSIS

int write (fildes, buf, nbyte) int fildes; char *buf; unsigned nbyte;

DESCRIPTION

fildes is a file descriptor obtained from a creat(2), open(2), dup(2), fcntl(2), or pipe(2) system call.

The *write* system call attempts to write *nbyte* bytes from the buffer pointed to by *buf* to the file associated with the *fildes*.

On devices capable of seeking, the actual writing of data proceeds from the position in the file indicated by the file pointer. Upon return from *write*, the file pointer is incremented by the number of bytes actually written.

On devices incapable of seeking, writing always takes place starting at the current position. The value of a file pointer associated with such a device is undefined.

If the O_APPEND flag of the file status flags is set, the file pointer will be set to the end of the file prior to each write.

For regular files, if the O_SYNC flag of the file status flags is set, the write will not return until both the file data and file status have been physically updated. This function is for special applications that require extra reliability at the cost of performance. For block special files, if O_SYNC is set, the write will not return until the data has been physically updated.

A write to a regular file will be blocked if mandatory file/record locking is set [see *chmod*(2)], and there is a record lock owned by another process on the segment of the file to be written. If O_NDELAY is not set, the write will sleep until the blocking record lock is removed.

For STREAMS [see *intro*(2)] files, the operation of *write* is determined by the values of the minimum and maximum *nbyte* range ("packet size") accepted by the *stream*. These values are contained in the topmost *stream* module. Unless the user pushes [see LPUSH in *streamio*(7)] the topmost module, these values cannot be set or tested from user level. If *nbyte* falls within the packet size range, *nbyte* bytes will be written. If *nbyte* does not fall within the range and the minimum packet size value is zero, *write* will break the buffer into maximum packet size segments prior to sending the data downstream (the last segment may contain less than the maximum packet size). If *nbyte* does not fall within the range and the minimum value is non-zero, *write* will fail with *errno* set to ERANGE. Writing a zero-length buffer (*nbyte* is zero) sends zero bytes with zero returned.

For STREAMS files, if O_NDELAY is not set and the *stream* cannot accept data (the *stream* write queue is full due to internal flow control conditions), *write* will block until data can be accepted. O_NDELAY will prevent a process from blocking due to flow control conditions. If O_NDELAY is set and the *stream* cannot accept data, *write* will fail. If O_NDELAY is set and part

of the buffer has been written when a condition in which the *stream* cannot accept additional data occurs, *write* will terminate and return the number of bytes written.

The *write* system call will fail and the file pointer will remain unchanged if one or more of the following are true:

- [EAGAIN] Mandatory file/record locking was set, O_NDELAY was set, and there was a blocking record lock.
- [EAGAIN] Total amount of system memory available when reading via raw IO is temporarily insufficient.
- [EAGAIN] Attempt to write to a *stream* that cannot accept data with the O_NDELAY flag set.
- [EBADF] *fildes* is not a valid file descriptor open for writing.
- [EDEADLK] The write was going to go to sleep and cause a deadlock situation to occur.
- [EFAULT] *buf* points outside the process's allocated address space.
- [EFBIG] An attempt was made to write a file that exceeds the process's file size limit or the maximum file size [see *ulimit*(2)].
- [EINTR] A signal was caught during the *write* system call.
- [EINVAL] Attempt to write to a *stream* linked below a multiplexer.
- [ENOLCK] The system record lock table was full, so the write could not go to sleep until the blocking record lock was removed.
- [ENOLINK] *fildes* is on a remote machine and the link to that machine is no longer active.
- [ENOSPC] During a *write* to an ordinary file, there is no free space left on the device.
- [ENXIO] A hangup occurred on the *stream* being written to.

[EPIPE and SIGPIPE signal]

An attempt is made to write to a pipe that is not open for reading by any process.

- [ERANGE] Attempt to write to a *stream* with *nbyte* outside specified minimum and maximum write range, and the minimum value is non-zero.
- [EIO] A physical I/O error has occurred.

If a *write* requests that more bytes be written than there is room for (e.g., the *ulimit* [see *ulimit*(2)] or the physical end of a medium), only as many bytes as there is room for will be written. For example, suppose there is space for 20 bytes more in a file before reaching a limit. A write of 512-bytes will return 20. The next write of a non-zero number of bytes will give a failure return (except as noted below).

If the file being written is a pipe (or FIFO) and the O_NDELAY flag of the file flag word is set, then write to a full pipe (or FIFO) will return a count of 0.

Otherwise (O_NDELAY clear), writes to a full pipe (or FIFO) will block until space becomes available.

A write to a STREAMS file can fail if an error message has been received at the stream head. In this case, *errno* is set to the value included in the error message.

SEE ALSO

creat(2), dup(2), fcntl(2), intro(2), lseek(2), open(2), pipe(2), ulimit(2).

DIAGNOSTICS

Upon successful completion the number of bytes actually written is returned. Otherwise, -1 is returned, and *errno* is set to indicate the error.

intro – introduction to functions and libraries

DESCRIPTION

This section describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume. Certain major collections are identified by a letter after the section number:

- (3C) These functions, together with those of Section 2 and those marked (3S), constitute the Standard C Library *libc*, which is automatically loaded by the C compiler, cc(1). (For this reason the (3C) and (3S) sections together comprise one section of this manual.) The link editor ld(1) searches this library under the **-lc** option. A "shared library" version of *libc* can be searched using the **-lc_s** option, resulting in smaller *a.outs*. Declarations for some of these functions may be obtained from **#include** files indicated on the appropriate pages.
- (3S) These functions constitute the "standard I/O package" [see *stdio*(3S)]. These functions are in the library *libc*, already mentioned. Declarations for these functions may be obtained from the **#include** file **<stdio.h>**.
- (3M) These functions constitute the Math Library, *libm*. They are automatically loaded as needed by the FORTRAN compiler f77(1). They are not automatically loaded by the C compiler, cc(1); however, the link editor searches this library under the **-lm** option. Declarations for these functions may be obtained from the **#include** file **<math.h**>. Several generally useful mathematical constants are also defined there [see *math*(5)].
- (3N) This contains sets of functions constituting the Network Services library. These sets provide protocol independent interfaces to networking services based on the service definitions of the OSI (Open Systems Interconnection) reference model. Application developers access the function sets that provide services at a particular level.

The function sets contained in the library are:

TRANSPORT INTERFACE (TI)—provide the services of the OSI Transport Layer. These services provide reliable end-to-end data transmission using the services of an underlying network. Applications written using the TI functions are independent of the underlying protocols. Declarations for these functions may be obtained from the **#include** file <**tiuser.h**>. The link editor ld(1) searches this library under the -**Insl_s** option.

- (3X) Various specialized libraries. The files in which these libraries are found are given on the appropriate pages.
- (3F) These functions constitute the FORTRAN intrinsic function library, *libF77*. These functions are automatically available to the FORTRAN programmer and require no special invocation of the compiler.

DEFINITIONS

A *character* is any bit pattern able to fit into a byte on the machine. The *null character* is a character with value 0, represented in the C language as

'\0'. A character array is a sequence of characters. A null-terminated character array is a sequence of characters, the last of which is the null character. A string is a designation for a null-terminated character array. The null string is a character array containing only the null character. A NULL pointer is the value that is obtained by casting **0** into a pointer. The C language guarantees that this value will not match that of any legitimate pointer, so many functions that return pointers return it to indicate an error. NULL is defined as **0** in **<stdio.h**>; the user can include an appropriate definition if not using **<stdio.h**>.

Many groups of FORTRAN intrinsic functions have *generic* function names that do not require explicit or implicit type declaration. The type of the function will be determined by the type of its argument(s). For example, the generic function *max* will return an integer value if given integer arguments (*max0*), a real value if given real arguments (*amax1*), or a double-precision value if given double-precision arguments (*dmax1*).

Netbuf In the Network Services library, *netbuf* is a structure used in various Transport Interface (TI) functions to send and receive data and information. It contains the following members:

unsigned int maxlen; unsigned int len; char *buf;

Buf points to a user input and/or output buffer. *Len* generally specifies the number of bytes contained in the buffer. If the structure is used for both input and output, the function will replace the user value of *len* on return.

Maxlen generally has significance only when *buf* is used to receive output from the TI function. In this case, it specifies the physical size of the buffer, the maximum value of *len* that can be set by the function. If *maxlen* is not large enough to hold the returned information, an TBUFOVFLW error will generally result. However, certain functions may return part of the data and not generate an error.

FILES

LIBDIR usually /lib LIBDIR/libc.a LIBDIR/<model>/libc.a (80286 only) LIBDIR/libc_s.a LIBDIR/<model>/libc_s.a (80286 only) LIBDIR/libm.a LIBDIR/ib77.a /shlib/libc_s /shlib/librge/libc_s (80286 only) /shlib/large/libnsl_s (3N) /shlib/large/libnsl_s (3N) (80286 only) /usr/lib/libnsl_s.a (3N) /usr/lib/large/libnsl_s.a (3N) (80286 only) Where model is either small or large.

INTRO(3)

SEE ALSO

ar(1), cc(1), ld(1), lint(1), nm(1), intro(2), stdio(3S), math(5). f77(1) in the FORTRAN Programming Language Manual.

DIAGNOSTICS

Functions in the C and Math Libraries (3C and 3M) may return the conventional values **0** or \pm **HUGE** (the largest-magnitude single-precision floatingpoint numbers; **HUGE** is defined in the *<math.h>* header file) when the function is undefined for the given arguments or when the value is not representable. In these cases, the external variable *errno* [see *intro*(2)] is set to the value EDOM or ERANGE.

WARNING

Many of the functions in the libraries call and/or refer to other functions and external variables described in this section and in Section 2 (*System Calls*). If a program inadvertently defines a function or external variable with the same name, the presumed library version of the function or external variable may not be loaded. The *lint*(1) program checker reports name conflicts of this kind as "multiple declarations" of the names in question. Definitions for Sections 2, 3C, and 3S are checked automatically. Other definitions can be included by using the -1 option. (For example, -1m includes definitions for Section 3M, the Math Library.) Use of *lint* is highly recommended.

On the 80286 computer, size is an unsigned int.

A64L(3C)

NAME

a64l, l64a - convert between long integer and base-64 ASCII string

SYNOPSIS

long a641 (s) char *s; char *l64a (l) long l;

DESCRIPTION

These functions are used to maintain numbers stored in *base-64* ASCII characters. This is a notation by which long integers can be represented by up to six characters; each character represents a "digit" in a radix-64 notation.

The characters used to represent "digits" are . for 0, / for 1, 0 through 9 for 2-11, **A** through **Z** for 12-37, and **a** through **z** for 38-63.

The *a641* function takes a pointer to a null-terminated base-64 representation and returns a corresponding **long** value. If the string pointed to by s contains more than six characters, *a641* will use the first six.

The *a641* function scans the character string from left to right, decoding each character as a 6-bit Radix 64 number.

The l64a function takes a **long** argument and returns a pointer to the corresponding base-64 representation. If the argument is 0, l64a returns a pointer to a null string.

CAVEAT

The value returned by *l64a* is a pointer into a static buffer, the contents of which are overwritten by each call.

abort - generate an IOT fault

SYNOPSIS

int abort ()

DESCRIPTION

The *abort* function does the work of *exit*(2), but instead of just exiting, *abort* causes **SIGABRT** to be sent to the calling process. If **SIGABRT** is neither caught nor ignored, all *stdio*(3S) streams are flushed prior to the signal being sent, and a core dump results.

The *abort* function returns the value of the *kill*(2) system call.

SEE ALSO

sdb(1), exit(2), kill(2), signal(2).

DIAGNOSTICS

If **SIGABRT** is neither caught nor ignored, and the current directory is writable, a core dump is produced and the message "abort – core dumped" is written by the shell.

ABS(3C)

NAME

abs – return integer absolute value

SYNOPSIS

int abs (i) int i;

DESCRIPTION

The *abs* function returns the absolute value of its integer operand.

SEE ALSO

floor(3M).

CAVEAT

In two's-complement representation, the absolute value of the negative integer with largest magnitude is undefined. Some implementations trap this error, but others simply ignore it.

bsearch - binary search a sorted table

SYNOPSIS

#include <search.h>

char *bsearch ((char *) key, (char *) base, nel, sizeof (*key), compar) unsigned nel; int (*compar)();

DESCRIPTION

The *bsearch* function is a binary search routine generalized from Knuth (6.2.1) Algorithm B. It returns a pointer into a table indicating where a datum may be found. The table must be previously sorted in increasing order according to a provided comparison function. *Key* points to a datum instance to be sought in the table. *Base* points to the element at the base of the table. *Nel* is the number of elements in the table. *Compar* is the name of the comparison function, which is called with two arguments that point to the elements being compared. The function must return an integer less than, equal to, or greater than zero as accordingly the first argument is to be considered less than, equal to, or greater than the second.

EXAMPLE

The example below searches a table containing pointers to nodes consisting of a string and its length. The table is ordered alphabetically on the string in the node pointed to by each entry.

This code fragment reads in strings and either finds the corresponding node and prints out the string and its length, or prints an error message.

```
#include <stdio.h>
#include <search.h>
#define TABSIZE
                      1000
struct node {
                              /* these are stored in the table */
       char *string;
       int length;
};
struct node table[TABSIZE]; /* table to be searched */
{
       struct node *node_ptr, node;
       int node_compare(); /* routine to compare 2 nodes */
       char str_space[20]; /* space to read string into */
       node.string = str_space;
       while (scanf("%s", node.string) != EOF) 
               node_ptr = (struct node *)bsearch((char *)(&node),
```

```
(char *)table, TABSIZE,
                          sizeof(struct node), node_compare);
               if (node_ptr != NULL) {
                       (void)printf("string = %20s, length = %d n",
                               node_ptr->string, node_ptr->length);
               } else {
                       (void)printf("not found: %s\n", node.string);
               }
       }
}
/*
       This routine compares two nodes based on an
       alphabetical ordering of the string field.
*/
int
node_compare(node1, node2)
char *node1, *node2;
ł
       return (strcmp(
                       ((struct node *)node1)->string,
                       ((struct node *)node2)->string));
}
```

NOTES

The pointers to the key and the element at the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. Although *bsearch* is declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

SEE ALSO

hsearch(3C), lsearch(3C), qsort(3C), tsearch(3C).

DIAGNOSTICS

A NULL pointer is returned if the key cannot be found in the table.

clock - report CPU time used

SYNOPSIS

long clock ()

DESCRIPTION

The *clock* function returns the amount of CPU time (in microseconds) used since the first call to *clock*. The time reported is the sum of the user and system times of the calling process and its terminated child processes for which it has executed *wait*(2), *pclose*(3S), or *system*(3S).

The resolution of the clock is 16.6667 milliseconds on 80286 computers. The resolution of the clock is 10 milliseconds on 80386 computers.

SEE ALSO

times(2), wait(2), popen(3S), system(3S).

BUGS

The value returned by *clock* is defined in microseconds for compatibility with systems that have CPU clocks with much higher resolution. Because of this, the value returned will wrap around after accumulating only 2147 seconds of CPU time (about 36 minutes).

CONV(3C)

NAME

conv: toupper, tolower, _toupper, _tolower, toascii - translate characters

SYNOPSIS

```
#include <ctype.h>
int toupper (c)
int c;
int tolower (c)
int c;
int _toupper (c)
int c;
int _tolower (c)
int c;
int toascii (c)
int c;
```

DESCRIPTION

The *toupper* and *tolower* functions have as domain the range of getc(3S): the integers from -1 through 255. If the argument of *toupper* represents a lower case letter, the result is the corresponding upper case letter. If the argument of *tolower* represents an upper case letter, the result is the corresponding lower case letter. All other arguments in the domain are returned unchanged.

The macros *_toupper* and *_tolower*, are macros that accomplish the same thing as *toupper* and *tolower* but have restricted domains and are faster. *_toupper* requires a lower case letter as its argument; its result is the corresponding upper case letter. The macro *_tolower* requires an upper case letter as its argument; its result is the corresponding lower case letter. Arguments outside the domain cause undefined results.

Toascii yields its argument with all bits turned off that are not part of a standard ASCII character; it is intended for compatibility with other systems.

SEE ALSO

ctype(3C), getc(3S).

CRYPT(3C)

NAME

crypt, setkey, encrypt - generate hashing encryption

SYNOPSIS

char *crypt (key, salt) char *key, *salt; void setkey (key) char *key; void encrypt (block, ignored) char *block; int ignored;

DESCRIPTION

The *crypt* function is the password encryption function. It is based on a one-way hashing encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search.

Key is a user's typed password. *Salt* is a two-character string chosen from the set [**a-zA-Z0-9.**/]; this string is used to perturb the hashing algorithm in one of 4096 different ways, after which the password is used as the key to encrypt repeatedly a constant string. The returned value points to the encrypted password. The first two characters are the salt itself.

The *setkey* and *encrypt* entries provide (rather primitive) access to the actual hashing algorithm. The argument of *setkey* is a character array of length 64 containing only the characters with numerical value 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is set into the machine. This is the key that will be used with the hashing algorithm to encrypt the string *block* with the function *encrypt*.

The argument to the *encrypt* entry is a character array of length 64 containing only the characters with numerical value 0 and 1. The argument array is modified in place to a similar array representing the bits of the argument after having been subjected to the hashing algorithm using the key set by *setkey*. *Ignored* is unused by *encrypt* but it must be present.

SEE ALSO

getpass(3C), passwd(4). login(1), passwd(1) in the User's Reference Manual.

CAVEAT

The return value points to static data that are overwritten by each call.

ctermid – generate file name for terminal

SYNOPSIS

#include <stdio.h>
char *ctermid (s)
char *s;

DESCRIPTION

The *ctermid* function generates the path name of the controlling terminal for the current process and stores it in a string.

If *s* is a NULL pointer, the string is stored in an internal static area, the contents of which are overwritten at the next call to *ctermid*, and the address of which is returned. Otherwise, *s* is assumed to point to a character array of at least **L_ctermid** elements; the path name is placed in this array, and the value of *s* is returned. The constant **L_ctermid** is defined in the *<stdio.h>* header file.

NOTES

The difference between *ctermid* and *ttyname*(3C) is that *ttyname* must be handed a file descriptor and returns the actual name of the terminal associated with that file descriptor, while *ctermid* returns a string (/dev/tty) that will refer to the terminal if used as a file name. Thus *ttyname* is useful only if the process already has at least one file open to a terminal.

SEE ALSO

ttyname(3C).

ctime, localtime, gmtime, asctime, tzset - convert date and time to string

SYNOPSIS

#include <sys/types.h>
#include <time.h>

char *ctime (clock) time_t *clock;

struct tm *localtime (clock)
time_t *clock;

struct tm *gmtime (clock)
time_t *clock;

char *asctime (tm) struct tm *tm;

extern long timezone;

extern int daylight;

extern char *tzname[2];

void tzset ()

DESCRIPTION

The *ctime* function converts a long integer, pointed to by *clock*, representing the time in seconds since 00:00:00 Greenwich Mean Time (GMT), January 1, 1970, and returns a pointer to a 26-character string in the following form. All the fields have constant width.

Sun Sep 16 01:03:52 1985\n\0

Localtime and gmtime return pointers to "tm" structures, described below. Localtime corrects for the time zone and possible Daylight Saving Time; gmtime converts directly to GMT, which is the time the UNIX system uses.

Asctime converts a "tm" structure to a 26-character string, as shown in the above example, and returns a pointer to the string.

Declarations of all the functions and externals, and the "tm" structure, are in the <time.h> header file. The structure declaration is:

```
struct tm {
```

};

```
int tm_sec;
                 /* seconds (0 - 59) */
                 /* minutes (0 - 59) */
int tm_min;
                 /* hours (0 - 23) */
int tm_hour;
                 /* day of month (1 - 31) */
int tm_mday;
                 /* month of year (0 - 11) */
int tm_mon;
                /* year - 1900 */
int tm_year;
                 /* day of week (Sunday = 0) */
int tm_wday;
int tm_yday;
                 /* day of year (0 - 365) */
int tm_isdst:
```

Tm_isdst is non-zero if Daylight Saving Time is in effect.

The external **long** variable *timezone* contains the difference, in seconds, between GMT and local standard time (in EST, *timezone* is 5*60*60); the external variable *daylight* is non-zero if and only if the standard U.S.A. Daylight Saving Time conversion should be applied. The program knows about the peculiarities of this conversion in 1974 and 1975; if necessary, a table for these years can be extended.

If an environment variable named TZ is present, *asctime* uses the contents of the variable to override the default time zone. The value of TZ must be a three-letter time zone name, followed by a number representing the difference between local time and Greenwich Mean Time in hours, followed by an optional three-letter name for a daylight time zone. For example, the setting for New Jersey would be EST5EDT. The effects of setting TZ are thus to change the values of the external variables *timezone* and *daylight*; in addition, the time zone names contained in the external variable

char *tzname[2] = { "EST", "EDT" };

are set from the environment variable TZ. The function *tzset* sets these external variables from TZ; *tzset* is called by *asctime* and may also be called explicitly by the user.

Note that in most installations, TZ is set by default when the user logs on, to a value in the local /etc/profile file [see *profile*(4)].

SEE ALSO

time(2), getenv(3C), profile(4), environ(5).

CAVEAT

The return values point to static data whose content is overwritten by each call.

ctype: isalpha, isupper, islower, isdigit, isxdigit, isalnum, isspace, ispunct, isprint, isgraph, iscntrl, isascii – classify characters

SYNOPSIS

#include <ctype.h>

int isalpha (c) int c;

. . .

DESCRIPTION

These macros classify character-coded integer values by table lookup. Each is a predicate returning nonzero for true, zero for false. *Isascii* is defined on all integer values; the rest are defined only where *isascii* is true and on the single non-ASCII value **EOF** [-1; see *stdio*(3S)].

isalpha	c is a letter.
isupper	c is an uppercase letter.
islower	c is a lowercase letter.
isdigit	<i>c</i> is a digit [0-9].
isxdigit	c is a hexadecimal digit [0-9], [A-F], or [a-f].
isalnum	c is an alphanumeric (letter or digit).
isspace	<i>c</i> is a space, tab, carriage return, newline, vertical tab, or form-feed.
ispunct	<i>c</i> is a punctuation character (neither control nor alphanumeric).
isprint	c is a printing character, code 040 (space) through 0176 (tilde).
isgraph	c is a printing character, like <i>isprint</i> except false for space.
iscntrl	c is a delete character (0177) or an ordinary control character (less than 040).
isascii	c is an ASCII character, code less than 0200.
50	

SEE ALSO

stdio(3S), ascii(5).

DIAGNOSTICS

If the argument to any of these macros is not in the domain of the function, the result is undefined.

cuserid - get character login name of the user

SYNOPSIS

#include <stdio.h>

char *cuserid (s) char *s;

DESCRIPTION

The *cuserid* function generates a character-string representation of the login name that the owner of the current process is logged in under. If *s* is a NULL pointer, this representation is generated in an internal static area, the address of which is returned. Otherwise, *s* is assumed to point to an array of at least **L_cuserid** characters; the representation is left in this array. The constant **L_cuserid** is defined in the **<stdio.h**> header file.

DIAGNOSTICS

If the login name cannot be found, *cuserid* returns a NULL pointer; if s is not a NULL pointer, a null character ($\langle 0 \rangle$) will be placed at s[0].

SEE ALSO

getlogin(3C), getpwent(3C).

dial - establish an out-going terminal line connection

SYNOPSIS

#include <dial.h> int dial (call) CALL call; void undial (fd) int fd;

DESCRIPTION

The *dial* function returns a file-descriptor for a terminal line open for read/write. The argument to *dial* is a CALL structure (defined in the <*dial.h*> header file).

When finished with the terminal line, the calling program must invoke *undial* to release the semaphore that has been set during the allocation of the terminal device.

The definition of CALL in the *<dial.h>* header file is:

typedef struct {

struct termio *attr;		<pre>/* pointer to termio attribute struct */</pre>	
int	baud;	/* transmission data rate */	
int	speed;	/* 212A modem: low=300, high=1200 */	
char	*Îine;	/* device name for out-going line */	
char	<pre>*telno;</pre>	/* pointer to tel-no digits string */	
int	modem;	/* specify modem control for direct lines */	
char	*device;	/*Will hold the name of the device used	
		to make a connection */	
int	dev_len;	/* The length of the device used to make	
		connection */	

} CALL;

The CALL element *speed* is intended only for use with an outgoing dialed call, in which case its value should be either 300 or 1200 to identify the 113A modem, or the high- or low-speed setting on the 212A modem. Note that the 113A modem or the low-speed setting of the 212A modem will transmit at any rate between 0 and 300 bits per second. However, the high-speed setting of the 212A modem transmits and receives at 1200 bits per second only. The CALL element *baud* is for the desired transmission baud rate. For example, one might set *baud* to 110 and *speed* to 300 (or 1200). However, if **speed** set to 1200 **baud** must be set to high (1200).

If the desired terminal line is a direct line, a string pointer to its devicename should be placed in the *line* element in the CALL structure. Legal values for such terminal device names are kept in the *Devices* file. In this case, the value of the *baud* element need not be specified as it will be determined from the *Devices* file. The *telno* element is for a pointer to a character string representing the telephone number to be dialed. The termination symbol will be supplied by the *dial* function and should not be included in the *telno* string passed to *dial* in the CALL structure.

The CALL element *modem* is used to specify modem control for direct lines. This element should be non-zero if modem control is required. The CALL element *attr* is a pointer to a *termio* structure, as defined in the *termio.h* header file. A NULL value for this pointer element may be passed to the *dial* function, but if such a structure is included, the elements specified in it will be set for the outgoing terminal line before the connection is established. This is often important for certain attributes such as parity and baud-rate.

The CALL element *device* is used to hold the device name (cul..) that establishes the connection.

The CALL element *dev_len* is the length of the device name that is copied into the array device.

FILES

/usr/lib/uucp/Devices /usr/spool/locks/LCK..tty-device

SEE ALSO

alarm(2), read(2), write(2). termio(7) in the System Administrator's Reference Manual. uucp(1C) in the User's Reference Manual.

DIAGNOSTICS

On failure, a negative value indicating the reason for the failure will be returned. Mnemonics for the negative indices listed here are defined in the $\langle dial.h \rangle$ header file.

INTRPT	-1	/* interrupt occurred */
D_HUNG	-2	/* dialer hung (no return from write) */
NO_ANS	-3	/* no answer within 10 seconds */
ILLBD	-4	/* illegal baud-rate */
A_PROB	-5	/* acu problem (open() failure) */
L_PROB	-6	/* line problem (open() failure) */
NO_Ldv	-7	/* can't open LDEVS file */
DV_NT_A	-8	/* requested device not available */
DV_NT_K	-9	/* requested device not known */
NOBDA	-10	/* no device available at requested baud */
NO_BD_K	-11	/* no device known at requested baud */

WARNINGS

The *dial* (3C) library function is not compatible with Basic Networking Utilities on UNIX System V Release 2.0.

Including the **<dial.h**> header file automatically includes the **<termio.h**> header file.

The above routine uses **<stdio.h**>, which causes it to increase the size of programs not otherwise using standard I/O, more than might be expected.

BUGS

An *alarm*(2) system call for 3600 seconds is made (and caught) within the *dial* module for the purpose of "touching" the *LCK*.. file and constitutes the device allocation semaphore for the terminal device. Otherwise, uucp(1C) may simply delete the *LCK*.. entry on its 90-minute clean-up rounds. The alarm may go off while the user program is in a *read*(2) or *write*(2) system call, causing an apparent error return. If the user program expects to be around for an hour or more, error returns from *reads* should be checked for (errno==EINTR), and the *read* possibly reissued.

drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers

SYNOPSIS

double drand48 ()

double erand48 (xsubi) unsigned short xsubi[3];

long lrand48 ()

long nrand48 (xsubi)
unsigned short xsubi[3];

long mrand48 ()

long jrand48 (xsubi) unsigned short xsubi[3];

void srand48 (seedval) long seedval;

unsigned short *seed48 (seed16v) unsigned short seed16v[3];

void lcong48 (param)
unsigned short param[7];

DESCRIPTION

This family of functions generates pseudo-random numbers using the wellknown linear congruential algorithm and 48-bit integer arithmetic.

Functions *drand48* and *erand48* return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0].

Functions *lrand48* and *nrand48* return non-negative long integers uniformly distributed over the interval $[0, 2^{31})$.

Functions *mrand48* and *jrand48* return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31})$.

Functions *srand48*, *seed48*, and *lcong48* are initialization entry points, one of which should be invoked before either *drand48*, *lrand48*, or *mrand48* is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if *drand48*, *lrand48*, or *mrand48* is called without a prior call to an initialization entry point.) Functions *erand48*, *nrand48*, and *jrand48* do not require an initialization entry point to be called first.

All the routines work by generating a sequence of 48-bit integer values, X_i , according to the linear congruential formula

$$X_{n+1} = (aX_n + c)_{\text{mod }m} \qquad n \ge 0.$$

The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless *lcong48* has been invoked, the multiplier value *a* and the addend value *c* are given by

$$a = 5DEECE66D_{16} = 273673163155_8$$

 $c = B_{16} = 13_8.$

The value returned by any of the functions *drand48*, *erand48*, *lrand48*, *nrand48*, *mrand48*, or *jrand48* is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions *drand48*, *lrand48*, and *mrand48* store the last 48-bit X_i generated in an internal buffer, and must be initialized prior to being invoked. The functions *erand48*, *nrand48*, and *jrand48* require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions *erand48*, *nrand48*, and *jrand48* allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers; i.e., the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function *srand48* sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function *seed48* sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer used only by *seed48*, and a pointer to this buffer is the value returned by *seed48*. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize via *seed48* when the program is restarted.

The initialization function *lcong48* allows the user to specify the initial X_i , the multiplier value *a*, and the addend value *c*. Argument array elements *param*[0-2] specify X_i , *param*[3-5] specify the multiplier *a*, and *param*[6] specifies the 16-bit addend *c*. After *lcong48* has been called, a subsequent call to either *srand48* or *seed48* will restore the "standard" multiplier and addend values, *a* and *c*, specified on the previous page.

NOTES

The source code for the portable version can be used on computers which do not have floating-point arithmetic. In such a situation, functions *drand48* and *erand48* are replaced by the two new functions below.

long irand48 (m) unsigned short m;

long krand48 (xsubi, m) unsigned short xsubi[3], m;

Functions *irand48* and *krand48* return non-negative long integers uniformly distributed over the interval [0, m-1].

SEE ALSO

rand(3C).

dup2 - duplicate an open file descriptor

SYNOPSIS

int dup2 (fildes, fildes2) int fildes, fildes2;

DESCRIPTION

The *fildes* argument is a file descriptor referring to an open file, and *fildes2* is a non-negative integer less than NOFILES. *dup2* causes *fildes2* to refer to the same file as *fildes.* If *fildes2* already referred to an open file, it is closed first.

The *dup2* function will fail if one or more of the following are true:

[EBADF] Fildes is not a valid open file descriptor.

[EMFILE] NOFILES file descriptors are currently open.

SEE ALSO

creat(2), close(2), exec(2), fcntl(2), open(2), pipe(2), lockf(3C).

DIAGNOSTICS

Upon successful completion a non-negative integer, namely the file descriptor, is returned. Otherwise, a value of -1 is returned, and *errno* is set to indicate the error.

ECVT(3C)

NAME

ecvt, fcvt, gcvt - convert floating-point number to string

SYNOPSIS

char *ecvt (value, ndigit, decpt, sign) double value; int ndigit, *decpt, *sign;

char *fcvt (value, ndigit, decpt, sign) double value; int ndigit, *decpt, *sign;

char *gcvt (value, ndigit, buf) double value; int ndigit; char *buf;

DESCRIPTION

The *ecvt* function converts *value* to a null-terminated string of *ndigit* digits and returns a pointer thereto. The high-order digit is non-zero, unless the value is zero. The low-order digit is rounded. The position of the decimal point relative to the beginning of the string is stored indirectly through *decpt* (negative means to the left of the returned digits). The decimal point is not included in the returned string. If the sign of the result is negative, the word pointed to by *sign* is non-zero, otherwise it is zero.

Fcvt is identical to *ecvt*, except that the correct digit has been rounded for printf "%f" (FORTRAN F-format) output of the number of digits specified by *ndigit*.

Gcvt converts the *value* to a null-terminated string in the array pointed to by *buf* and returns *buf*. It attempts to produce *ndigit* significant digits in FORTRAN F-format if possible, otherwise E-format, ready for printing. A minus sign, if there is one, or a decimal point will be included as part of the returned string. Trailing zeros are suppressed.

SEE ALSO

printf(3S).

BUGS

The values returned by *ecvt* and *fcvt* point to a single static data array whose content is overwritten by each call.

END(3C)

NAME

end, etext, edata - last locations in program

SYNOPSIS

extern end; extern etext; extern edata;

DESCRIPTION

These names refer neither to routines nor to locations with interesting contents. The address of *etext* is the first address above the program text, *edata* above the initialized data region, and *end* above the uninitialized data region.

When execution begins, the program break (the first location beyond the data) coincides with *end*, but the program break may be reset by the routines of brk(2), *malloc*(3C), standard input/output [*stdio*(3S)], the profile (**-p**) option of *cc*(1), and so on. Thus, the current value of the program break should be determined by **sbrk ((char *)0)** [see brk(2)].

SEE ALSO

cc(1), brk(2), malloc(3C), stdio(3S).

fclose, fflush - close or flush a stream

SYNOPSIS

#include <stdio.h>

int fclose (stream) FILE *stream;

int fflush (stream) FILE *stream;

DESCRIPTION

The *fclose* function causes any buffered data for the named *stream* to be written out, and the *stream* to be closed.

The *fclose* function is performed automatically for all open files upon calling *exit*(2).

Fflush causes any buffered data for the named *stream* to be written to that file. The *stream* remains open.

SEE ALSO

close(2), exit(2), fopen(3S), setbuf(3S), stdio(3S).

DIAGNOSTICS

These functions return 0 for success and **EOF** if any error (such as trying to write to a file that has not been opened for writing) was detected.

FERROR(3S)

NAME

ferror, feof, clearerr, fileno - stream status inquiries

SYNOPSIS

#include <stdio.h>
int ferror (stream)
FILE *stream;

int feof (stream) FILE *stream;

void clearerr (stream) FILE *stream; int fileno (stream)

FILE *stream:

DESCRIPTION

The *ferror* function returns non-zero when an I/O error has previously occurred reading from or writing to the named *stream*, otherwise zero.

Feof returns non-zero when EOF has previously been detected reading the named input *stream*, otherwise zero.

Clearerr resets the error indicator and EOF indicator to zero on the named *stream*.

Fileno returns the integer file descriptor associated with the named stream; see open(2).

NOTES

All these functions are implemented as macros; they cannot be declared or redeclared.

SEE ALSO

open(2), fopen(3S), stdio(3S).

fopen, freopen, fdopen - open a stream

SYNOPSIS

#include <stdio.h>

FILE *fopen (filename, type) char *filename, *type; FILE *freopen (filename, type, stream) char *filename, *type; FILE *stream; FILE *fdopen (fildes, type) int fildes; char *type;

DESCRIPTION

The *fopen* function opens the file named by *filename* and associates a *stream* with it. The *fopen* function returns a pointer to the FILE structure associated with the *stream*.

Filename points to a character string that contains the name of the file to be opened.

Type is a character string having one of the following values:

- "r" open for reading
- "w" truncate or create for writing
- "a" append; open for writing at end of file, or create for writing
- "r+" open for update (reading and writing)
- "w+" truncate or create for update
- "a+" append; open or create for update at end-of-file

Freopen substitutes the named file in place of the open *stream*. The original *stream* is closed, regardless of whether the open ultimately succeeds. *Freopen* returns a pointer to the FILE structure associated with *stream*.

Freopen is typically used to attach the preopened *streams* associated with **stdin**, **stdout**, and **stderr** to other files.

Fdopen associates a *stream* with a file descriptor. File descriptors are obtained from *open*, *dup*, *creat*, or *pipe*(2), which open files but do not return pointers to a FILE structure *stream*. Streams are necessary input for many of the Section 3S library routines. The *type* of *stream* must agree with the mode of the open file.

When a file is opened for update, both input and output may be done on the resulting *stream*. However, output may not be directly followed by input without an intervening *fseek* or *rewind*, and input may not be directly followed by output without an intervening *fseek*, *rewind*, or an input operation which encounters end-of-file. When a file is opened for append (i.e., when *type* is "a" or "a+"), it is impossible to overwrite information already in the file. The *fseek* function may be used to reposition the file pointer to any position in the file, but when output is written to the file, the current file pointer is disregarded. All output is written at the end of the file and causes the file pointer to be repositioned at the end of the output. If two separate processes open the same file for append, each process may write freely to the file without fear of destroying output being written by the other. The output from the two processes will be intermixed in the file in the order in which it is written.

When the file cannot be opened, the function *fopen* or the function *freopen* will fail and will set *errno* to:

- [ENOTDIR] If a component of the path prefix in path is not a directory.
- [ENOENT] If the named file does not exist, or a component of the path name should exist but does not.
- [EACCES] If a component of the path prefix denies search permission, or type permission is denied for the named file.
- [EISDIR] If the named file is a directory, and type is write or read/write.
- [EROFS] If the named file resides on a read-only file system, and type is write or read/write.
- [ETXTBSY] If the file is a pure procedure (shared text) file that is being executed, and type is write or read/write.
- [EINTR] If a signal was caught during the open operation.

SEE ALSO

creat(2), dup(2), open(2), pipe(2), fclose(3S), fseek(3S), stdio(3S).

DIAGNOSTICS

fopen, fdopen, and freopen return a NULL pointer on failure.

fpgetround, fpsetround, fpgetmask, fpsetmask, fpgetsticky, fpsetsticky – IEEE floating point environment control

SYNOPSIS

#include <ieeefp.h>

typedef enum {

FP_RN=0, /* round to nearest */ FP_RM, /* round to minus */ FP_RP, /* round to plus */ FP_RZ, /* round to zero (truncate) */ } fp_rnd;

fp_rnd fpgetround();

fp_rnd fpsetround(rnd_dir)
fp_rnd rnd_dir;

#define fp_ex	cept	int
#define FP_X_INV	0x01	/* invalid operation exception*/
#define FP_X_OFL	0x08	/* overflow exception*/
#define FPXUFL	0x10	/* underflow exception*/
#define FP_X_DZ	0x04	/* divide-by-zero exception*/
#define FP_X_IMP	0x20	/* imprecise (loss of precision)*/
#define FP_X_DNML	0x02	/* denormalization exception */

fp_except fpgetmask();

fp_except fpsetmask(mask);
fp_except mask;

fp_except fpgetsticky();

fp_except fpsetsticky(sticky);
fp_except sticky;

DESCRIPTION

There are six floating point exceptions: divide-by-zero, overflow, underflow, imprecise (inexact) result, denormalization, and invalid operation. When a floating point exception occurs, the corresponding sticky bit is set (1), and if the mask bit is enabled (1), the trap takes place. These routines let the user change the behavior on occurrence of any of these exceptions, as well as change the rounding mode for floating point operations.

fpgetround() returns the current rounding mode.

fpsetround() sets the rounding mode and returns the previous rounding mode.

fpgetmask() returns the current exception masks.

fpsetmask() sets the exception masks and returns the previous setting.

fpgetsticky() returns the current exception sticky flags.

fpsetsticky() sets (clears) the exception sticky flags and returns the previous setting.

The default environment on the Intel 80386 processor family is:

Rounding mode set to nearest(FP_RN), Divide-by-zero, Floating point overflow, and Invalid operation traps enabled.

SEE ALSO

isnan(3C).

WARNINGS

fpsetsticky() modifies all sticky flags. fpsetmask() changes all mask bits.

Both C and F77 require truncation (round to zero) for floating point to integral conversions. The current rounding mode has no effect on these conversions.

CAVEATS

One must clear the sticky bit to recover from the trap and to proceed. If the sticky bit is not cleared before the next floating point instruction is executed, a wrong exception type may be signaled.

For the same reason, when calling *fpsetmask()* the user should make sure that the sticky bit corresponding to the exception being enabled is cleared.

fread, fwrite – binary input/output

SYNOPSIS

#include <stdio.h>
#include <sys/types.h>
int fread (ptr, size, nitems, stream)
char *ptr;
int nitems;
size_t size;
FILE *stream;
int fwrite (ptr, size, nitems, stream)
char *ptr;

char *ptr; int nitems; size_t size; FILE *stream;

DESCRIPTION

The *fread* function copies, into an array pointed to by *ptr*, *nitems* items of data from the named input *stream*, where an item of data is a sequence of bytes (not necessarily terminated by a null byte) of length *size*. *fread* stops appending bytes if an end-of-file or error condition is encountered while reading *stream*, or if *nitems* items have been read. *fread* leaves the file pointer in *stream*, if defined, pointing to the byte following the last byte read if there is one. *fread* does not change the contents of *stream*.

fwrite appends at most *nitems* items of data from the array pointed to by *ptr* to the named output *stream*. *fwrite* stops appending when it has appended *nitems* items of data or if an error condition is encountered on *stream*. *fwrite* does not change the contents of the array pointed to by *ptr*.

The argument *size* is typically *sizeof(*ptr)* where the pseudo-function *sizeof* specifies the length of an item pointed to by *ptr*. If *ptr* points to a data type other than *char*, it should be cast into a pointer to *char*.

SEE ALSO

read(2), write(2), fopen(3S), getc(3S), gets(3S), printf(3S), putc(3S), puts(3S), scanf(3S), stdio(3S).

DIAGNOSTICS

The *fread* and *fwrite* functions return the number of items read or written. If *nitems* is non-positive, no characters are read or written, and 0 is returned by both *fread* and *fwrite*.

WARNING

On the 80286 computer, the number of bytes transferred is the product of *size* and *nitems*, modulo 65536.

FREXP(3C)

NAME

frexp, ldexp, modf - manipulate parts of floating-point numbers

SYNOPSIS

double frexp (value, eptr) double value; int *eptr; double ldexp (value, exp) double value; int exp; double modf (value, iptr) double value, *iptr;

DESCRIPTION

Every non-zero number can be written uniquely as $x * 2^n$, where the "mantissa" (fraction) x is in the range $0.5 \le |x| < 1.0$, and the "exponent" *n* is an integer. *frexp* returns the mantissa of a double *value* and stores the exponent indirectly in the location pointed to by *eptr*. If *value* is zero, both results returned by *frexp* are zero.

Ldexp returns the quantity value $* 2^{exp}$.

Modf returns the signed fractional part of *value* and stores the integral part indirectly in the location pointed to by *iptr*.

DIAGNOSTICS

If *ldexp* would cause overflow, \pm HUGE (defined in <math.h>) is returned (according to the sign of *value*), and *errno* is set to ERANGE.

If *ldexp* would cause underflow, zero is returned and *errno* is set to **ERANGE**.

FSEEK(3S)

NAME

fseek, rewind, ftell - reposition a file pointer in a stream

SYNOPSIS

#include <stdio.h> int fseek (stream, offset, ptrname) FILE *stream; long offset; int ptrname; void rewind (stream) FILE *stream;

long ftell (stream) FILE *stream;

DESCRIPTION

The *fseek* function sets the position of the next input or output operation on the stream. The new position is at the signed distance offset bytes from the beginning, from the current position, or from the end of the file, according as *ptrname* has the value 0, 1, or 2, which is defined in the $\langle unistd.h \rangle$ header file as follows:

Name	Description
SEEK_SET	Set position equal to offset bytes.
SEEK_CUR	Set position to current location plus offset.
SEEK_END	Set position to EOF plus offset.

Rewind(stream) is equivalent to fseek(stream, 0L, 0), except that no value is returned.

fseek and rewind undo any effects of ungetc(3S).

After *fseek* or *rewind*, the next operation on a file opened for update may be either input or output.

Ftell returns the offset of the current byte relative to the beginning of the file associated with the named stream.

SEE ALSO

lseek(2), fopen(3S), popen(3S), stdio(3S), ungetc(3S).

DIAGNOSTICS

The *fseek* function returns non-zero for improper seeks, otherwise zero. An improper seek can be, for example, an *fseek* done on a file that has not been opened via *fopen*; in particular, *fseek* may not be used on a terminal or on a file opened via popen(3S).

WARNING

Although on the UNIX system an offset returned by *ftell* is measured in bytes, and it is permissible to seek to positions relative to that offset, portability to non-UNIX systems requires that an offset be used by *fseek* directly. Arithmetic may not meaningfully be performed on such an offset, which is not necessarily measured in bytes.

ftw - walk a file tree

SYNOPSIS

#include <ftw.h>
int ftw (path, fn, depth)
char *path;
int (*fn) ();
int depth;

DESCRIPTION

The *ftw* function recursively descends the directory hierarchy rooted in *path*. For each object in the hierarchy, *ftw* calls *fn*, passing it a pointer to a null-terminated character string containing the name of the object, a pointer to a **stat** structure [see *stat*(2)] containing information about the object, and an integer. Possible values of the integer, defined in the <ftw.h> header file, are FTW_F for a file, FTW_D for a directory, FTW_DNR for a directory that cannot be read, and FTW_NS for an object for which *stat* could not successfully be executed. If the integer is FTW_DNR, descendants of that directory will not be processed. If the integer is FTW_NS, the **stat** structure will contain garbage. An example of an object that would cause FTW_NS to be passed to *fn* would be a file in a directory with read but without execute (search) permission.

The *ftw* function visits a directory before visiting any of its descendants.

The tree traversal continues until the tree is exhausted, an invocation of fn returns a nonzero value, or some error is detected within ftw (such as an I/O error). If the tree is exhausted, ftw returns zero. If fn returns a nonzero value, ftw stops its tree traversal and returns whatever value was returned by fn. If ftw detects an error, it returns -1 and sets the error type in *errno*.

The *ftw* function uses one file descriptor for each level in the tree. The *depth* argument limits the number of file descriptors so used. If *depth* is zero or negative, the effect is the same as if it were 1. *Depth* must not be greater than the number of file descriptors currently available for use. *ftw* will run more quickly if *depth* is at least as large as the number of levels in the tree.

SEE ALSO

stat(2), malloc(3C).

BUGS

Because *ftw* is recursive, it is possible for it to terminate with a memory fault when applied to very deep file structures.

CAVEAT

The *ftw* function uses *malloc*(3C) to allocate dynamic storage during its operation. If *ftw* is forcibly terminated, such as by *longjmp* being executed by *fn* or an interrupt routine, *ftw* will not have a chance to free that storage, so it will remain permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred, and arrange to have *fn* return a nonzero value at its next invocation.

getc, getchar, fgetc, getw – get character or word from a stream

SYNOPSIS

#include <stdio.h>

int getc (stream) FILE *stream;

int getchar ()

int fgetc (stream) FILE *stream;

int getw (stream) FILE *stream;

DESCRIPTION

The getc function returns the next character (i.e., byte) from the named input *stream*, as an integer. It also moves the file pointer, if defined, ahead one character in *stream*. getchar is defined as getc(stdin). getc and getchar are macros.

The *fgetc* function behaves like *getc*, but is a function rather than a macro. *Fgetc* runs more slowly than *getc*, but it takes less space per invocation and its name can be passed as an argument to a function.

The *getw* function returns the next word (i.e., integer) from the named input *stream. Getw* increments the associated file pointer, if defined, to point to the next word. The size of a word is the size of an integer and varies from machine to machine. *Getw* assumes no special alignment in the file.

SEE ALSO

fclose(3S), ferror(3S), fopen(3S), fread(3S), gets(3S), putc(3S), scanf(3S), stdio(3S).

DIAGNOSTICS

These functions return the constant EOF at end-of-file or upon an error. Because EOF is a valid integer, *ferror*(3S) should be used to detect *getw* errors.

WARNING

If the integer value returned by *getc*, *getchar*, or *fgetc* is stored into a character variable and then compared against the integer constant EOF, the comparison may never succeed, because sign-extension of a character on widening to integer is machine-dependent.

CAVEATS

Because it is implemented as a macro, *getc* evaluates a *stream* argument more than once. In particular, getc(*f++) does not work sensibly. *Fgetc* should be used instead.

Because of possible differences in word length and byte ordering, files written using *putw* are machine-dependent, and may not be read using *getw* on a different processor.

SEE ALSO

getlogin(3C), getpwent(3C), group(4).

DIAGNOSTICS

A NULL pointer is returned on EOF or error.

WARNING

The above routines use <stdio.h>, which causes them to increase the size of programs, not otherwise using standard I/O, more than might be expected.

CAVEAT

All information is contained in a static area, so it must be copied if it is to be saved.

GETCWD(3C)

NAME

getcwd - get path name of current working directory

SYNOPSIS

char *getcwd (buf, size) char *buf; int size:

DESCRIPTION

The *getcwd* function returns a pointer to the current directory path name. The value of *size* must be at least two greater than the length of the path name to be returned.

If *buf* is a NULL pointer, *getcwd* will obtain *size* bytes of space using *malloc*(3C). In this case, the pointer returned by *getcwd* may be used as the argument in a subsequent call to *free*.

The function is implemented by using popen(3S) to pipe the output of the pwd(1) command into the specified string space.

EXAMPLE

void exit(), perror(); .

.
if ((cwd = getcwd((char *)NULL, 64)) == NULL) {
 perror("pwd");
 exit(2);
}
printf("%s\n", cwd);

SEE ALSO

malloc(3C), popen(3S). pwd(1) in the User's Reference Manual.

DIAGNOSTICS

Returns **NULL** with *errno* set if *size* is not large enough, or if an error occurs in a lower-level function.

[EINVAL] If size is zero.

[ERANGE] If size is not large enough to hold the path name.

GETENV(3C)

NAME

getenv - return value for environment name

SYNOPSIS

char *getenv (name)
char *name;

DESCRIPTION

The *getenv* function searches the environment list [see *environ*(5)] for a string of the form name = value and returns a pointer to the *value* in the current environment if such a string is present, otherwise a NULL pointer.

SEE ALSO

exec(2), putenv(3C), environ(5).

getgrent, getgrgid, getgrnam, setgrent, endgrent, fgetgrent - get group file entry

SYNOPSIS

#include <grp.h>

```
struct group *getgrent ( )
```

```
struct group *getgrgid (gid)
int gid;
struct group *getgrnam (name)
char *name;
void setgrent ( )
void endgrent ( )
```

struct group *fgetgrent (f) FILE *f;

DESCRIPTION

The *getgrent*, *getgrgid*, and *getgrnam* functions each return pointers to an object with the following structure containing the broken-out fields of a line in the **/etc/group** file. Each line contains a "group" structure, defined in the $\langle grp.h \rangle$ header file.

```
struct group {
    char *gr_name; /* the name of the group */
    char *gr_passwd; /* the encrypted group password */
    int gr_gid; /* the numerical group ID */
    char **gr_mem; /* vector of pointers to member names */
};
```

The *getgrent* function when first called returns a pointer to the first group structure in the file; thereafter, it returns a pointer to the next group structure in the file; so, successive calls may be used to search the entire file. *Getgrgid* searches from the beginning of the file until a numerical group id matching *gid* is found and returns a pointer to the particular structure in which it was found. *Getgrnam* searches from the beginning of the file until a group name matching *name* is found and returns a pointer to the particular structure in which it was found. If an end-of-file or an error is encountered on reading, these functions return a NULL pointer.

A call to *setgrent* has the effect of rewinding the group file to allow repeated searches. *Endgrent* may be called to close the group file when processing is complete.

Fgetgrent returns a pointer to the next group structure in the stream *f*, which matches the format of **/etc/group**.

FILES

/etc/group

getlogin – get login name

SYNOPSIS

char *getlogin ();

DESCRIPTION

The *getlogin* function returns a pointer to the login name as found in **/etc/utmp**. It may be used in conjunction with *getpwnam* to locate the correct password file entry when the same user ID is shared by several login names.

If *getlogin* is called within a process that is not attached to a terminal, it returns a **NULL** pointer. The correct procedure for determining the login name is to call *cuserid*, or to call *getlogin* and if it fails, to call *getpwuid*.

FILES

/etc/utmp

SEE ALSO

cuserid(3S), getgrent(3C), getpwent(3C), utmp(4).

DIAGNOSTICS

Returns the NULL pointer if name is not found.

CAVEAT

The return values point to static data whose content is overwritten by each call.

GETOPT(3C)

NAME

getopt – get option letter from argument vector

SYNOPSIS

int getopt (argc, argv, optstring)
int argc;
char **argv, *opstring;
extern char *optarg;

extern int optind, opterr;

DESCRIPTION

The *getopt* function returns the next option letter in *argv* that matches a letter in *optstring*. It supports all the rules of the command syntax standard [see *intro*(1)]. So all new commands will adhere to the command syntax standard, they should use *getopts*(1) or *getopt*(3C) to parse positional parameters and check for options that are legal for that command.

optstring must contain the option letters the command using *getopt* will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

optarg is set to point to the start of the option-argument on return from *getopt*.

getopt places in **optind** the argv index of the next argument to be processed. **optind** is external and is initialized to 1 before the first call to getopt.

When all options have been processed (i.e., up to the first non-option argument), *getopt* returns -1. The special option "--" may be used to delimit the end of the options; when it is encountered, -1 will be returned, and "--" will be skipped.

The following rules comprise the System V standard for command-line syntax:

- **RULE 1** Command names must be between two and nine characters.
- **RULE 2** Command names must include lowercase letters and digits only.
- **RULE 3** Option names must be a single character in length.
- **RULE 4** All options must be delimited by the character.
- RULE 5 Options with no arguments may be grouped behind one delimiter.
- **RULE 6** The first option-argument following an option must be preceded by white space.
- **RULE 7** Option arguments cannot be optional.
- **RULE 8** Groups of option arguments following an option must be separated by commas or separated by white space and quoted.

- RULE 9 All options must precede operands on the command line.
- **RULE 10** The characters -- may be used to delimit the end of the options.
- **RULE 11** The order of options relative to one another should not matter.
- **RULE 12** The order of operands may matter and position-related interpretations should be determined on a command-specific basis.
- **RULE 13** The character preceded and followed by white space should be used only to mean standard input.

The function *getopt* is the command-line parser that will enforce the rules of this command syntax standard.

DIAGNOSTICS

getopt prints an error message on standard error and returns a question mark (?) when it encounters an option letter not included in *optstring* or no option-argument after an option that expects one. This error message may be disabled by setting **opterr** to 0.

EXAMPLE

The following code fragment shows how one might process the arguments for a command that can take the mutually exclusive options \mathbf{a} and \mathbf{b} , and the option \mathbf{o} , which requires an option-argument:

```
main (argc, argv)
int argc;
char **argv;
ł
     int c;
     extern char *optarg;
     extern int optind;
     while ((c = getopt(argc, argv, "abo:")) != -1)
          switch (c) {
          case 'a':
                if (bflg)
                     errflg++;
                else
                     aflg++;
                break;
          case 'b':
                if (aflg)
                     errflg++;
                else
                     bproc( );
                break;
          case 'o':
                ofile = optarg;
```

```
break;
case '?':
errflg++;
}
if (errflg) {
(void)fprintf(stderr, "usage: . . . ");
exit (2);
}
for ( ; optind < argc; optind++) {
if (access(argv[optind], 4)) {
...
```

WARNING

}

Although the following command syntax rule [see intro(1)] relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the **EXAMPLE** section above, **a** and **b** are options, and the option **o** requires an option-argument:

cmd -aboxxx file (Rule 5 violation: options with
 option-arguments must not be grouped with other options)
cmd -ab -oxxx file (Rule 6 violation: there must be
 white space after an option that takes an option-argument)

SEE ALSO

getopts(1), intro(1) in the User's Reference Manual.

WARNING

Although the following command syntax rule [see intro(1)] relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the EXAMPLE section above, **a** and **b** are options, and the option **o** requires an option-argument:

\mathtt{cmd}	-aboxxx file	(Rule 5 violation: options with
		option-arguments must not be
		grouped with other options)
\mathtt{cmd}	-ab -oxxx file	(Rule 6 violation: there must be
		white space after an option that
		takes an option-argument)

Changing the value of the variable **optind** or calling *getopt* with different values of *argv* may lead to unexpected results.

getpass - read a password

SYNOPSIS

char *getpass (prompt) char *prompt;

DESCRIPTION

The *getpass* function reads up to a new-line or EOF from the file /dev/tty after prompting on the standard error output with the null-terminated string *prompt* and disabling echoing. A pointer is returned to a null-terminated string of at most 8 characters. If /dev/tty cannot be opened, a NULL pointer is returned. An interrupt will terminate input and send an interrupt signal to the calling program before returning.

FILES

/dev/tty

WARNING

The above routine uses **<stdio.h**>, which causes it to increase the size of programs not otherwise using standard I/O more than might be expected.

CAVEAT

The return value points to static data whose content is overwritten by each call.

getpw - get name from UID

SYNOPSIS

int getpw (uid, buf) int uid; char *buf:

DESCRIPTION

The *getpw* function searches the password file for a user id number that equals *uid*, copies the line of the password file in which *uid* was found into the array pointed to by *buf*, and returns 0. *getpw* returns non-zero if *uid* cannot be found.

This routine is included only for compatibility with prior systems and should not be used; see *getpwent*(3C) for routines to use instead.

FILES

/etc/passwd

SEE ALSO

getpwent(3C), passwd(4).

DIAGNOSTICS

The *getpw* function returns non-zero on error.

WARNING

The above routine uses **<stdio.h**>, which causes it to increase, more than might be expected, the size of programs not otherwise using standard I/O.

getpwent, getpwuid, getpwnam, setpwent, endpwent, fgetpwent - get password file entry

SYNOPSIS

#include <pwd.h>
struct passwd *getpwent ()
struct passwd *getpwuid (uid)
int uid;
struct passwd *getpwnam (name)
char *name;
void setpwent ()
void endpwent ()
struct passwd *fgetpwent (f)
FILE *f;

DESCRIPTION

The *getpwent*, *getpwuid*, and *getpwnam* functions each returns a pointer to an object with the following structure containing the broken-out fields of a line in the **/etc/passwd** file. Each line in the file contains a "passwd" structure, declared in the < pwd.h > header file:

struct passwd { char *pw_name; char *pw_passwd; int pw_uid; pw_gid; int char *pw_age; char *pw_comment; char *pw_gecos; char *pw_dir; *pw__shell; char

};

This structure is declared in < pwd.h > so it is not necessary to redeclare it.

The fields have meanings described in passwd(4).

The *getpwent* function when first called, returns a pointer to the first passwd structure in the file; thereafter, it returns a pointer to the next passwd structure in the file; so successive calls can be used to search the entire file. *Getpwuid* searches from the beginning of the file until a numerical user id matching *uid* is found and returns a pointer to the particular structure in which it was found. *Getpwnam* searches from the beginning of the file until a login name matching *name* is found, and returns a pointer to the particular structure in which it was found. If an end-of-file or an error is encountered on reading, these functions return a NULL pointer.

A call to *setpwent* has the effect of rewinding the password file to allow repeated searches. *Endpwent* may be called to close the password file when processing is complete.

Fgetpwent returns a pointer to the next passwd structure in the stream f, which matches the format of **/etc/passwd**.

FILES

/etc/passwd

SEE ALSO

getlogin(3C), getgrent(3C), passwd(4).

DIAGNOSTICS

A NULL pointer is returned on EOF or error.

WARNING

The above routines use \langle **stdio.h** \rangle , which causes them to increase the size of programs, not otherwise using standard I/O, more than might be expected.

CAVEAT

All information is contained in a static area, so it must be copied if it is to be saved.

gets, fgets - get a string from a stream

SYNOPSIS

#include <stdio.h>
char *gets (s)
char *s;
char *fgets (s, n, stream)
char *s;
int n;
FILE *stream;

DESCRIPTION

The *gets* function reads characters from the standard input stream, *stdin*, into the array pointed to by *s*, until a new-line character is read or an end-of-file condition is encountered. The new-line character is discarded and the string is terminated with a null character.

The *fgets* function reads characters from the *stream* into the array pointed to by s, until n-1 characters are read, or a new-line character is read and transferred to s, or an end-of-file condition is encountered. The string is then terminated with a null character.

SEE ALSO

ferror(3S), fopen(3S), fread(3S), getc(3S), scanf(3S), stdio(3S).

DIAGNOSTICS

If end-of-file is encountered and no characters have been read, no characters are transferred to s and a NULL pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a NULL pointer is returned. Otherwise s is returned.

getut: getutent, getutid, getutline, pututline, setutent, endutent, utmpname – access utmp file entry

SYNOPSIS

#include <utmp.h>

struct utmp *getutent ()

struct utmp *getutid (id)

struct utmp *id;

struct utmp *getutline (line)
struct utmp *line;

void pututline (utmp)
struct utmp *utmp;

void setutent ()

void endutent ()

void utmpname (file) char *file;

.....

DESCRIPTION

The *getutent*, *getutid*, and *getutline* functions each return a pointer to a structure of the following type:

		0.71.	
struct	utmp {		
	char	ut_user[8];	/* User login name */
	char	ut_id[4];	<pre>/* /etc/inittab id (usually line #) */</pre>
	char	ut_line[12];	/* device name (console, lnxx) */
	short	ut_pid;	/* process id */
	short	ut_type;	/* type of entry */
	struct	exit_status {	
	short	e_termination;	/* Process termination status */
	short	eexit;	/* Process exit status */
	} ut_exit;		/* The exit status of a process
	-		* marked as DEAD_PROCESS. */
	timet	ut_time;	/* time entry was made */
};			

The *getutent* function reads in the next entry from a *utmp*-like file. If the file is not already open, it opens it. If it reaches the end of the file, it fails.

The *getutid* function searches forward from the current point in the *utmp* file until it finds an entry with a *ut_type* matching *id->ut_type* if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME or NEW_TIME. If the type specified in *id* is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS or DEAD_PROCESS, then *getutid* will return a pointer to the first entry whose type is one of these four and whose *ut_id* field matches *id->ut_id*. If the end of file is reached without a match, it fails.

The *getutline* function searches forward from the current point in the *utmp* file until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS, which also has a *ut_line* string matching the *line->ut_line* string. If the end of file is reached without a match, it fails.

Pututline writes out the supplied *utmp* structure into the *utmp* file. It uses *getutid* to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of *pututline* will have searched for the proper entry using one of the *getut* routines. If so, *pututline* will not search. If *pututline* does not find a matching slot for the new entry, it will add a new entry to the end of the file.

Setutent resets the input stream to the beginning of the file. This should be done before each search for a new entry if it is desired that the entire file be examined.

Endutent closes the currently open file.

Utmpname allows the user to change the name of the file examined, from **/etc/utmp** to any other file. It is most often expected that this other file will be **/etc/wtmp**. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. *Utmpname* does not open the file. It just closes the old file if it is currently open and saves the new file name.

FILES

/etc/utmp /etc/wtmp

SEE ALSO

ttyslot(3C), utmp(4).

DIAGNOSTICS

A NULL pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

NOTES

The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. Each call to either *getutid* or *getutline* sees the routine examine the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use *getutline* to search for multiple occurrences, it would be necessary to zero out the static after each success, or *getutline* would just return the same pointer over and over again. There is one exception to the rule about removing the structure before further reads are done. The implicit read done by *pututline* (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the *getutent*, *getutid*, or *getutline* routines, if the user has just modified those contents and passed the pointer back to *pututline*.

These routines use buffered standard I/O for input, but *pututline* uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the *utmp* and *wtmp* files.

hsearch, hcreate, hdestroy - manage hash search tables

SYNOPSIS

#include <search.h>

ENTRY *hsearch (item, action) ENTRY item; ACTION action;

int hcreate (nel) unsigned nel;

void hdestroy ()

DESCRIPTION

The *hsearch* function is a hash-table search routine generalized from Knuth (6.4) Algorithm D. It returns a pointer into a hash table indicating the location at which an entry can be found. *Item* is a structure of type ENTRY (defined in the *<search.h>* header file) containing two pointers: *item.key* points to the comparison key, and *item.data* points to any other data to be associated with that key. (Pointers to types other than character should be cast to pointer-to-character.) *Action* is a member of an enumeration type ACTION indicating the disposition of the entry if it cannot be found in the table. **ENTER** indicates that the item should be inserted in the table at an appropriate point. **FIND** indicates that no entry should be made. Unsuccessful resolution is indicated by the return of a NULL pointer.

Hcreate allocates sufficient space for the table and must be called before *hsearch* is used. *Nel* is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.

Hdestroy destroys the search table and may be followed by another call to *hcreate*.

NOTES

The *hsearch* function uses *open addressing* with a *multiplicative* hash function. However, its source code has many other options available which the user may select by compiling the *hsearch* source with the following symbols defined to the preprocessor:

- **DIV** Use the *remainder modulo table size* as the hash function instead of the multiplicative algorithm.
- USCR Use a User-Supplied Comparison Routine for ascertaining table membership. The routine should be named *hcompar* and should behave in a mannner similar to *strcmp* [see *string*(3C)].
- **CHAINED** Use a linked list to resolve collisions. If this option is selected, the following other options become available.
 - **START** Place new entries at the beginning of the linked list (default is at the end).

SORTUP Keep the linked list sorted by key in ascending order.

SORTDOWN Keep the linked list sorted by key in descending order.

Additionally, there are preprocessor flags for obtaining debugging printout (-DDEBUG) and for including a test driver in the calling routine (-DDRIVER). The source code should be consulted for further details.

EXAMPLE

The following example will read in strings followed by two numbers and store them in a hash table, discarding duplicates. It will then read in strings and find the matching entry in the hash table and print it out.

```
#include <stdio.h>
#include <search.h>
struct info {
                      /* this is the info stored in the table */
       int age, room; /* other than the key. */
};
#define NUM_EMPL
                             /* # of elements in search table */
                       5000
main()
ł
       /* space to store strings */
       char string_space[NUM_EMPL*20];
       /* space to store employee info */
       struct info info_space[NUM_EMPL];
       /* next avail space in string_space */
       char *str_ptr = string_space;
       /* next avail space in info_space */
       struct info *info_ptr = info_space;
       ENTRY item, *found_item, *hsearch();
       /* name to look for in table */
       char name_to_find[30];
       int i = 0:
       /* create table */
       (void) hcreate(NUM_EMPL);
       while (scanf("%s%d%d", str_ptr, &info_ptr->age,
              info_ptr->room != EOF && i++ < NUM_EMPL) {
               /* put info in structure, and structure in item */
               item.key = str_ptr;
               item.data = (char *)info_ptr;
               str_ptr += strlen(str_ptr) + 1;
               info_ptr++;
               /* put item into table */
               (void) hsearch(item, ENTER);
       }
       /* access table */
```

SEE ALSO

```
bsearch(3C), lsearch(3C), malloc(3C), malloc(3X), string(3C), tsearch(3C).
```

DIAGNOSTICS

}

The *hsearch* function returns a NULL pointer if either the action is **FIND** and the item could not be found, or the action is **ENTER** and the table is full.

Hcreate returns zero if it cannot allocate sufficient space for the table.

WARNING

hsearch and hcreate use malloc(3C) to allocate space.

CAVEAT

Only one hash search table may be active at any given time.

ISNAN(3C)

NAME

isnan: isnand, isnanf - test for floating point NaN (Not-A-Number)

SYNOPSIS

#include <ieeefp.h>
int isnand (dsrc)
double dsrc;
int isnanf (fsrc)
float fsrc;

DESCRIPTION

The *isnand* and *isnanf* functions return true (1) if the argument dsrc or fsrc is a NaN; otherwise they return false (0).

Neither routine generates any exception, even for signaling NaNs.

isnanf() is implemented as a macro included in <ieeefp.h>.

SEE ALSO

÷,

fpgetround(3C).

L3TOL(3C)

NAME

13tol, 1tol3 - convert between 3-byte integers and long integers

SYNOPSIS

void 13tol (lp, cp, n) long *lp; char *cp; int n; void ltol3 (cp, lp, n) char *cp; long *lp; int n;

DESCRIPTION

The *l3tol* function converts a list of n three-byte integers packed into a character string pointed to by cp into a list of long integers pointed to by lp.

Ltol3 performs the reverse conversion from long integers (lp) to three-byte integers (cp).

These functions are useful for file-system maintenance where the block numbers are three bytes long.

SEE ALSO

fs(4).

CAVEAT

Because of possible differences in byte ordering, the numerical values of the long integers are machine-dependent.

lockf – record locking on files

SYNOPSIS

#include <unistd.h>

int lockf (fildes, function, size) long size; int fildes, function;

DESCRIPTION

The *lockf* command will allow sections of a file to be locked; advisory or mandatory write locks depending on the mode bits of the file [see *chmod*(2)]. Locking calls from other processes which attempt to lock the locked file section will either return an error value or be put to sleep until the resource becomes unlocked. All the locks for a process are removed when the process terminates. [See *fcntl*(2) for more information about record locking.]

Fildes is an open file descriptor. The file descriptor must have O_WRONLY or O_RDWR permission in order to establish lock with this function call.

Function is a control value which specifies the action to be taken. The permissible values for *function* are defined in **<unistd.h>** as follows:

#define	F_ULOCK	0	/* Unlock a previously locked section */
#define	F_LOCK	1	/* Lock a section for exclusive use */
#define	F_TLOCK	2	/* Test and lock a section for exclusive use */
#define	F_TEST	3	/* Test section for other processes locks */

All other values of *function* are reserved for future extensions and will result in an error return if not implemented.

F_TEST is used to detect if a lock by another process is present on the specified section. F_LOCK and F_TLOCK both lock a section of a file if the section is available. F_ULOCK removes locks from a section of the file.

Size is the number of contiguous bytes to be locked or unlocked. The resource to be locked starts at the current offset in the file and extends forward for a positive size and backward for a negative size (the preceding bytes up to but not including the current offset). If *size* is zero, the section from the current offset through the largest file offset is locked (i.e., from the current offset through the present or any future end-of-file). An area need not be allocated to the file in order to be locked as such locks may exist past the end-of-file.

The sections locked with F_LOCK or F_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent sections occur, the sections are combined into a single section. If the request requires that a new element be added to the table of active locks and this table is already full, an error is returned, and the new section is not locked.

F_LOCK and F_TLOCK requests differ only by the action taken if the resource is not available. F_LOCK will cause the calling process to sleep

until the resource is available. F_TLOCK will cause the function to return a -1 and set *errno* to [EACCES] error if the section is already locked by another process.

F_ULOCK requests may, in whole or in part, release one or more locked sections controlled by the process. When sections are not fully released, the remaining sections are still locked by the process. Releasing the center section of a locked section requires an additional element in the table of active locks. If this table is full, an [EDEADLK] error is returned, and the requested section is not released.

A potential for deadlock occurs if a process controlling a locked resource is put to sleep by accessing another process's locked resource. Thus calls to *lockf* or *fcntl* scan for a deadlock prior to sleeping on a locked resource. An error return is made if sleeping on the locked resource would cause a deadlock.

Sleeping on a resource is interrupted with any signal. The *alarm*(2) command may be used to provide a timeout facility in applications which require this facility.

The *lockf* utility will fail if one or more of the following are true:

[EBADF]

Fildes is not a valid open descriptor.

[EACCES]

Cmd is F_TLOCK or F_TEST and the section is already locked by another process.

[EDEADLK]

Cmd is F_LOCK and a deadlock would occur. Also the *cmd* is either F_LOCK, F_TLOCK, or F_ULOCK and the number of entries in the lock table would exceed the number allocated on the system.

[ECOMM]

Fildes is on a remote machine and the link to that machine is no longer active.

SEE ALSO

chmod(2), close(2), creat(2), fcntl(2), intro(2), open(2), read(2), write(2).

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

WARNINGS

Unexpected results may occur in processes that do buffering in the user address space. The process may later read/write data which is/was locked. The standard I/O package is the most common source of unexpected buffering.

Because in the future the variable *errno* will be set to EAGAIN rather than EACCES when a section of a file is already locked by another process, portable application programs should expect and test for either value.

lsearch, lfind – linear search and update

SYNOPSIS

#include <stdio.h>
#include <search.h>

char *lsearch ((char *)key, (char *)base, nelp, sizeof(*key), compar) unsigned *nelp;

int (*compar)();

char *lfind ((char *)key, (char *)base, nelp, sizeof(*key), compar)
unsigned *nelp;
int (*compar)();

DESCRIPTION

The *lsearch* function is a linear search routine generalized from Knuth (6.1) Algorithm S. It returns a pointer into a table indicating where a datum may be found. If the datum does not occur, it is added at the end of the table. **Key** points to the datum to be sought in the table. **Base** points to the first element in the table. **Nelp** points to an integer containing the current number of elements in the table. The integer is incremented if the datum is added to the table. **Compar** is the name of the comparison function which the user must supply (*strcmp*, for example). It is called with two arguments that point to the elements being compared. The function must return zero if the elements are equal and non-zero otherwise.

Lfind is the same as *lsearch* except that if the datum is not found, it is not added to the table. Instead, a NULL pointer is returned.

NOTES

The pointers to the key and the element at the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. Although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

EXAMPLE

This fragment will read in less than TABSIZE strings of length less than ELSIZE and store them in a table, eliminating duplicates.

(void) lsearch(line, (char *)tab, &nel, ELSIZE, strcmp);

SEE ALSO

bsearch(3C), hsearch(3C), string(3C), tsearch(3C).

. . .

DIAGNOSTICS

If the searched-for datum is found, both *lsearch* and *lfind* return a pointer to it. Otherwise, *lfind* returns NULL and *lsearch* returns a pointer to the newly added element.

BUGS

Undefined results can occur if there is not enough room in the table to add a new item.

MALLOC(3C)

NAME

malloc, free, realloc, calloc – main memory allocator

SYNOPSIS

char *malloc (size) unsigned size; void free (ptr) char *ptr; char *realloc (ptr, size) char *ptr; unsigned size; char *calloc (nelem, elsize)

unsigned nelem, elsize;

DESCRIPTION

The *malloc* and *free* functions provide a simple, general-purpose, memory allocation package. The *malloc* function returns a pointer to a block of at least *size* bytes suitably aligned for any use.

The argument to *free* is a pointer to a block previously allocated by *malloc*; after *free* is performed this space is made available for further allocation, but its contents are left undisturbed.

Undefined results will occur if the space assigned by *malloc* is overrun or if some random number is handed to *free*.

The *malloc* function allocates the first big enough, contiguous reach of free space found in a circular search from the last block allocated or freed, coalescing, adjacent free blocks as it searches. It calls *sbrk* [see *brk*(2)] to get more memory from the system when there is no suitable space already free.

Realloc changes the size of the block pointed to by *ptr* to *size* bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If no free block of *size* bytes is available in the storage arena, then *realloc* will ask *malloc* to enlarge the arena by *size* bytes and will then move the data to the new space.

Realloc also works if *ptr* points to a block freed since the last call of *malloc*, *realloc*, or *calloc*; thus sequences of *free*, *malloc*, and *realloc* can exploit the search strategy of *malloc* to do storage compaction.

Calloc allocates space for an array of *nelem* elements of size *elsize*. The space is initialized to zeros.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

SEE ALSO

brk(2), malloc(3X).

DIAGNOSTICS

The *malloc*, *realloc* and *calloc* functions return a NULL pointer if there is no available memory, or if the arena has been detectably corrupted by storing outside the bounds of a block. When this happens the block pointed to by *ptr* may be destroyed.

MALLOC(3C)

NOTES

Search time increases when many objects have been allocated; that is, if a program allocates but never frees, then each successive allocation takes longer. For an alternate, more flexible implementation, see malloc(3X).

memory: memccpy, memchr, memcmp, memcpy, memset - memory operations

SYNOPSIS

#include <memory.h> char *memccpy (s1, s2, c, n) char *s1, *s2; int c, n; char *memchr (s, c, n) char *s: int c, n; int memcmp (s1, s2, n) char *s1, *s2; int n; char *memcpy (s1, s2, n) char *s1, *s2; int n; char *memset (s, c, n) char *s; int c, n;

DESCRIPTION

These functions operate as efficiently as possible on memory areas (arrays of characters bounded by a count, not terminated by a null character). They do not check for the overflow of any receiving memory area.

Memccpy copies characters from memory area s2 into s1, stopping after the first occurrence of character c has been copied, or after n characters have been copied, whichever comes first. It returns a pointer to the character after the copy of c in s1, or a NULL pointer if c was not found in the first n characters of s2.

Memchr returns a pointer to the first occurrence of character c in the first n characters of memory area s, or a NULL pointer if c does not occur.

Memcmp compares its arguments, looking at the first **n** characters only, and returns an integer less than, equal to, or greater than 0, according as **s1** is lexicographically less than, equal to, or greater than **s2**.

Memcpy copies **n** characters from memory area **s2** to **s1**. It returns **s1**.

Memset sets the first **n** characters in memory area **s** to the value of character **c**. It returns **s**.

For user convenience, all these functions are declared in the optional *<memory.h>* header file.

CAVEATS

Memcmp is implemented by using the most natural character comparison on the machine. Thus the sign of the value returned when one of the characters has its high order bit set is not the same in all implementations and should not be relied upon.

Character movement is performed differently in different implementations. Thus overlapping moves may yield surprises.

mktemp - make a unique file name

SYNOPSIS

char *mktemp (template)
char *template;

DESCRIPTION

The *mktemp* function replaces the contents of the string pointed to by *template* by a unique file name, and returns the address of *template*. The string in *template* should look like a file name with six trailing Xs; *mktemp* will replace the Xs with a letter and the current process ID. The letter will be chosen so that the resulting name does not duplicate an existing file.

SEE ALSO

getpid(2), tmpfile(3S), tmpnam(3S).

DIAGNOSTIC

The *mktemp* function will assign to *template* the NULL string if it cannot create a unique name.

CAVEAT

If called more than 17,576 time in a single process, this function will start recycling previously used names.

monitor - prepare execution profile

SYNOPSIS

#include <mon.h>

void monitor (lowpc, highpc, buffer, bufsize, nfunc)
int (*lowpc)(), (*highpc)();
WORD *buffer;
int bufsize, nfunc;

DESCRIPTION

An executable program created by **cc** -**p** automatically includes calls for *monitor* with default parameters; *monitor* need not be called explicitly except to gain fine control over profiling.

The monitor function is an interface to profil(2). Lowpc and highpc are the addresses of two functions; buffer is the address of a user-supplied array of bufsize WORDs (defined in the <mon.h> header file). monitor arranges to record a histogram of periodically sampled values of the program counter, and of counts of calls of certain functions, in the buffer. The lowest address sampled is that of lowpc and the highest is just below highpc. Lowpc may not equal 0 for this use of monitor. At most nfunc, call counts can be kept; only calls of functions compiled with the profiling option $-\mathbf{p}$ of cc(1) are recorded.

For the results to be significant, especially where there are small, heavily used routines, it is suggested that the buffer be no more than a few times smaller than the range of locations sampled.

To profile the entire program, it is sufficient to use

extern etext;

monitor ((int (*)())2, &etext, buf, bufsize, nfunc);

Etext lies just above all the program text; see end(3C).

To stop execution monitoring and write the results, use

monitor ((int (*)())0, 0, 0, 0, 0);

The *prof*(1) command can then be used to examine the results.

The name of the file written by *monitor* is controlled by the environment variable PROFDIR. If PROFDIR does not exist, "mon.out" is created in the current directory. If PROFDIR exists but has no value, *monitor* does not do any profiling and creates no output file. Otherwise, the value of PROFDIR is used as the name of the directory in which to create the output file. If PROFDIR is *dirname*, then the file written is "*dirname/pid*.mon.out" where *pid* is the program's process id. (When *monitor* is called automatically by compiling via **cc** -**p**, the file created is "*dirname/pid*.progname" where *progname* is the name of the program.)

FILES

mon.out

SEE ALSO

cc(1), prof(1), profil(2), end(3C).

BUGS

The "dirname/pid.mon.out" form does not work; the "dirname/pid.progname" form (automatically called via cc -p) does work.

NLIST(3C)

NAME

nlist – get entries from name list

SYNOPSIS

#include <nlist.h>

int nlist (filename, nl)
char *filename;
struct nlist *nl;

DESCRIPTION

The *nlist* function examines the name list in the executable file whose name is pointed to by *filename*, and selectively extracts a list of values and puts them in the array of nlist structures pointed to by nl. The name list nl consists of an array of structures containing names of variables, types, and values. The list is terminated with a null name; that is, a null string is in the name position of the structure. Each variable name is looked up in the name list of the file. If the name is found, the type and value of the name are inserted in the next two fields. The type field will be set to 0 unless the file was compiled with the -g option. If the name is not found, both entries are set to 0. See *a.out*(4) for a discussion of the symbol table structure.

This function is useful for examining the system name list kept in the file /unix. In this way programs can obtain system addresses that are up to date.

NOTES

The *<nlist.h>* header file is automatically included by *<a.out.h>* for compatability. However, if the only information needed from *<a.out.h>* is for use of *nlist*, then including *<a.out.h>* is discouraged. If *<a.out.h>* is included, the line "#undef n_name" may need to follow it.

SEE ALSO

a.out(4).

DIAGNOSTICS

All value entries are set to 0 if the file cannot be read or if it does not contain a valid name list.

The *nlist* function returns -1 upon error; otherwise it returns 0.

perror, errno, sys_errlist, sys_nerr – system error messages

SYNOPSIS

void perror (s) char *s; extern int errno; extern char *sys_errlist[]; extern int sys_nerr;

DESCRIPTION

The *perror* function produces a message on the standard error output, describing the last error encountered during a call to a system or library function. The argument string *s* is printed first, then a colon and a blank, then the message and a new-line. (However, if s="" the colon is not printed.) To be of most use, the argument string should include the name of the program that incurred the error. The error number is taken from the external variable *errno*, which is set when errors occur but not cleared when non-erroneous calls are made.

To simplify variant formatting of messages, the array of message strings *sys_errlist* is provided; *errno* can be used as an index into this table to get the message string without the new-line. *Sys_nerr* is the number of messages in the table; it should be checked because new error codes may be added to the system before they are added to the table.

SEE ALSO

intro(2).

POPEN(3S)

NAME

popen, pclose – initiate pipe to/from a process

SYNOPSIS

#include <stdio.h>

FILE *popen (command, type) char *command, *type;

int pclose (stream) FILE *stream:

DESCRIPTION

The *popen* function creates a pipe between the calling program and the command to be executed. The arguments to *popen* are pointers to null-terminated strings. *Command* consists of a shell command line. *Type* is an I/O mode, either **r** for reading or **w** for writing. The value returned is a stream pointer such that one can write to the standard input of the command, if the I/O mode is **w**, by writing to the file *stream*; and one can read from the standard output of the command, if the I/O mode is **r**, by reading from the file *stream*.

A stream opened by *popen* should be closed by *pclose*, which waits for the associated process to terminate and returns the exit status of the command.

Because open files are shared, a type \mathbf{r} command may be used as an input filter and a type \mathbf{w} as an output filter.

EXAMPLE

A typical call may be:

char *cmd = "ls *.c"; FILE *ptr; if ((ptr = popen(cmd, "r")) != NULL) while (fgets(buf, n, ptr) != NULL) (void) printf("%s ",buf);

This will print in *stdout* [see *stdio* (3S)] all the file names in the current directory that have a ".c" suffix.

SEE ALSO

pipe(2), wait(2), fclose(3S), fopen(3S), stdio(3S), system(3S).

DIAGNOSTICS

The *popen* function returns a NULL pointer if files or processes cannot be created.

The *pclose* function returns -1 if *stream* is not associated with a "*popen* ed" command.

WARNING

If the original and "*popen* ed" processes concurrently read or write a common file, neither should use buffered I/O, because the buffering gets all mixed up. Problems with an output filter may be forestalled by careful buffer flushing, e.g., with *fflush* [see *fclose*(3S)].

printf, fprintf, sprintf - print formatted output

SYNOPSIS

#include <stdio.h>
int printf (format , arg ...)
char *format;
int fprintf (stream, format , arg ...)
FILE *stream;
char *format;
int sprintf (s, format [, arg]...)
char *s, *format;

DESCRIPTION

The *printf* function places output on the standard output stream *stdout*. *Fprintf* places output on the named output *stream*. *Sprintf* places "output," followed by the null character (**\0**), in consecutive bytes starting at **s*; it is the user's responsibility to ensure that enough storage is available. Each function returns the number of characters transmitted (not including the **\0** in the case of *sprintf*), or a negative value if an output error was encountered.

Each of these functions converts, formats, and prints its *args* under control of the *format*. The *format* is a character string that contains three types of objects: plain characters, which are simply copied to the output stream; escape sequences that represent non-graphic characters; and conversion specifications, each of which results in fetching of zero or more *args*. The results are undefined if there are insufficient *args* for the format. If the format is exhausted while *args* remain, the excess *args* are simply ignored.

The following escape sequences produce the associated action on display devices capable of the action:

\b	Backspace. Moves the printing position to one character before the current position, unless the current position is the start of a line.
\ f	Form feed. Moves the printing position to the initial printing position of the next logical page.
\ n	New line. Moves the printing position to the start of the next line.
\ r	Carriage return. Moves the printing position to the start of the current line.
\t	Horizontal tab. Moves the printing position to the next implementation-defined horizontal tab position on the current line.

v

Vertical tab

Moves the printing position to the start of the next implementation-defined vertical tab position.

Each conversion specification is introduced by the character %. After the %, the following appear in sequence:

Zero or more *flags*, which modify the meaning of the conversion specification.

An optional, decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag '-', described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.

A *precision* that gives the minimum number of digits to appear for the **d**, **i**, **o**, **u**, **x**, or **X** conversions, the number of digits to appear after the decimal point for the **e**, **E**, and **f** conversions, the maximum number of significant digits for the **g** and **G** conversion, or the maximum number of characters to be printed from a string in **s** conversion. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

An optional 1 (ell) specifying that a following d, i, o, u, x, or X conversion character applies to a long integer *arg*. An 1 before any other conversion character is ignored.

A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a '-' flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

The result of the conversion will be left-justified within the field.

The result of a signed conversion will always begin with a sign (+ or -).

blank If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.

#

+

This flag specifies that the value is to be converted to an "alternate form." For c, d, i, s, and u conversions, the flag has no effect. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result will have 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For **g** and **G** conversions, trailing zeroes will *not* be removed from the result (which they normally are).

The conversion characters and their meanings are:

- d,i,o,u,x,X The integer arg is converted to signed decimal (d or i), unsigned octal, (o), decimal (u), or hexadecimal notation (x or X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. The default precision is 1. The result of converting a zero value with a precision of zero is a null string.
- **f** The float or double *arg* is converted to decimal notation in the style "[-]ddd.ddd," where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, six digits are output; if the precision is explicitly 0, no decimal point appears.
- **e**,**E** The float or double *arg* is converted in the style "[-]d.ddd $\mathbf{e} \pm dd$," where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, six digits are produced; if the precision is zero, no decimal point appears. The **E** format code will produce a number with **E** instead of **e** introducing the exponent. The exponent always contains at least two digits.
- **g**,**G** The float or double *arg* is printed in style **f** or **e** (or in style **E** in the case of a **G** format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style **e** will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
- **c** The character *arg* is printed.
- **s** The *arg* is taken to be a string (character pointer) and characters from the string are printed until a null character (\setminus 0) is encountered or the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first null character are printed. A NULL value for *arg* will yield undefined results.
- % Print a %; no argument is converted.

In printing floating point types (float and double), if the exponent is 0x7FF and the mantissa is not equal to zero, then the output is

[-]NaN0xddddddd

where 0xddddddd is the hexadecimal representation of the leftmost 32 bits of the mantissa. If the mantissa is zero, the output is

 $[\pm]$ inf.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by *printf* and *fprintf* are printed as if *putc*(3S) had been called.

EXAMPLES

To print a date and time in the form "Sunday, July 3, 10:02," where weekday and month are pointers to null-terminated strings:

printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);

To print π to 5 decimal places:

printf("pi = %.5f", 4 * atan(1.0));

SEE ALSO

ecvt(3C), putc(3S), scanf(3S), stdio(3S).

putc, putchar, fputc, putw - put character or word on a stream

SYNOPSIS

```
#include <stdio.h>
int putc (c, stream)
int c;
FILE *stream;
int putchar (c)
int c;
int fputc (c, stream)
int c;
FILE *stream;
int putw (w, stream)
int w;
```

FILE *stream;

DESCRIPTION

The *putc* function writes the character c onto the output *stream* (at the position where the file pointer, if defined, is pointing). *putchar*(c) is defined as *putc*(c, *stdout*). *putc* and *putchar* are macros.

Fputc behaves like *putc*, but is a function rather than a macro. *Fputc* runs more slowly than *putc*, but it takes less space per invocation and its name can be passed as an argument to a function.

Putw writes the word (i.e., integer) w to the output stream (at the position at which the file pointer, if defined, is pointing). The size of a word is the size of an integer and varies from machine to machine. Putw neither assumes nor causes special alignment in the file.

SEE ALSO

fclose(3S), ferror(3S), fopen(3S), fread(3S), printf(3S), puts(3S), setbuf(3S), stdio(3S).

DIAGNOSTICS

On success, these functions (with the exception of *putw*) each return the value they have written. [*Putw* returns *ferror* (*stream*)]. On failure, they return the constant **EOF**. This will occur if the file *stream* is not open for writing or if the output file cannot grow. Because **EOF** is a valid integer, *ferror*(3S) should be used to detect *putw* errors.

CAVEATS

Because it is implemented as a macro, *putc* evaluates a *stream* argument more than once. In particular, **putc(c, *f++)** doesn't work sensibly. *Fputc* should be used instead.

Because of possible differences in word length and byte ordering, files written using *putw* are machine-dependent, and may not be read using *getw* on a different processor.

putenv – change or add value to environment

SYNOPSIS

int putenv (string) char *string;

DESCRIPTION

String points to a string of the form "name=value." The putenv function makes the value of the environment variable name equal to value by altering an existing variable or creating a new one. In either case, the string pointed to by string becomes part of the environment, so altering the string will change the environment. The space used by string is no longer used once a new string-defining name is passed to putenv.

SEE ALSO

exec(2), getenv(3C), malloc(3C), environ(5).

DIAGNOSTICS

The *putenv* function returns non-zero if it was unable to obtain enough space via *malloc* for an expanded environment, otherwise zero.

WARNINGS

The *putenv* function manipulates the environment pointed to by *environ*, and can be used in conjunction with *getenv*. However, *envp* (the third argument to *main*) is not changed.

This routine uses malloc(3C) to enlarge the environment.

After *putenv* is called, environmental variables are not in alphabetical order. A potential error is to call *putenv* with an automatic variable as the argument, then exit the calling function while *string* is still part of the environment.

PUTPWENT(3C)

NAME

putpwent - write password file entry

SYNOPSIS

#include <pwd.h>

int putpwent (p, f)
struct passwd *p;
FILE *f;

DESCRIPTION

The *putpwent* function is the inverse of *getpwent*(3C). Given a pointer to a passwd structure created by *getpwent* (or *getpwuid* or *getpwnam*), *putpwent* writes a line on the stream f, which matches the format of **/etc/passwd**.

SEE ALSO

getpwent(3C).

DIAGNOSTICS

The *putpwent* function returns non-zero if an error was detected during its operation, otherwise zero.

WARNING

The above routine uses **<stdio.h>**, which causes it to increase the size of programs, not otherwise using standard I/O, more than might be expected.

PUTS(3S)

NAME

puts, fputs - put a string on a stream

SYNOPSIS

#include <stdio.h>

int puts (s) char *s; int fputs (s, stream) char *s; FILE *stream;

DESCRIPTION

The *puts* function writes the null-terminated string pointed to by *s*, followed by a new-line character, to the standard output stream *stdout*.

Fputs writes the null-terminated string pointed to by s to the named output *stream*.

Neither function writes the terminating null character.

SEE ALSO

ferror(3S), fopen(3S), fread(3S), printf(3S), putc(3S), stdio(3S).

DIAGNOSTICS

Both routines return **EOF** on error. This will happen if the routines try to write on a file that has not been opened for writing.

NOTES

The *puts* function appends a new-line character while *fputs* does not.

qsort - quicker sort

SYNOPSIS

void qsort ((char *) base, nel, sizeof (*base), compar)
unsigned nel;
int (*compar)();

DESCRIPTION

The *qsort* function is an implementation of the quicker-sort algorithm. It sorts a table of data in place.

Base points to the element at the base of the table. *Nel* is the number of elements in the table. *Compar* is the name of the comparison function, which is called with two arguments that point to the elements being compared. The comparison function must return an integer less than, equal to, or greater than zero, according to whether the first argument is to be considered as less than, equal to, or greater than the second argument.

NOTES

The pointer to the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. The order in the output of two items which compare as equal is unpredictable.

SEE ALSO

bsearch(3C), lsearch(3C), string(3C). sort(1) in the User's Reference Manual.

WARNING

The total size of the table (*nel x sizeof*(**base*)) must be less than 65536 on the 80286 computer.

RAND(3C)

NAME

rand, srand - simple random-number generator

SYNOPSIS

int rand () void srand (seed) unsigned seed;

DESCRIPTION

The *rand* function uses a multiplicative congruential random-number generator with period 2^{32} that returns successive pseudo-random numbers in the range from 0 to 2^{15} -1.

The *srand* function can be called at any time to reset the random-number generator to a random starting point. The generator is initially seeded with a value of 1.

NOTES

The spectral properties of *rand* are limited. The *drand48*(3C) function provides a much better, though more elaborate, random-number generator.

The follwoing functions define the semantics of the functions *rand* and *srand*.

Specifying the semantics makes it possible to reproduce the behavior of programs that use pseudo-random sequences. This facilitates the testing of portable applications in different implementations.

SEE ALSO

drand48(3C).

scanf, fscanf, sscanf - convert formatted input

SYNOPSIS

#include <stdio.h>
int scanf (format [, pointer] ...)
char *format;
int fscanf (stream, format [, pointer] ...)
FILE *stream;
char *format;
int sscanf (s, format [, pointer] ...)
char *s, *format;

DESCRIPTION

The *scanf* function reads from the standard input stream *stdin*. *Fscanf* reads from the named input *stream*. *Sscanf* reads from the character string *s*. Each function reads characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string *format* described below, and a set of *pointer* arguments indicating where the converted input should be stored. The results are undefined in that there are insufficient *args* for the format. If the format is exhausted while *args* remain, the excess *args* are simply ignored.

The control string usually contains conversion specifications, which are used to direct interpretation of input sequences. The control string may contain:

- 1. White-space characters (blanks, tabs, new-lines, or form-feeds) which, except in two cases described below, cause input to be read up to the next non-white-space character.
- 2. An ordinary character (not %), which must match the next character of the input stream.
- Conversion specifications, consisting of the character %, an optional assignment suppressing character *, an optional numerical maximum field width, an optional l (ell) or h indicating the size of the receiving variable, and a conversion code.

A conversion specification directs the conversion of the next input field; the result is placed in the variable pointed to by the corresponding argument, unless assignment suppression was indicated by *****. The suppression of assignment provides a way of describing an input field which is to be skipped. An input field is defined as a string of non-space characters; it extends to the next inappropriate character or until the field width, if specified, is exhausted. For all descriptors except "[" and "c", white space leading an input field is ignored.

The conversion code indicates the interpretation of the input field; the corresponding pointer argument must usually be of a restricted type. For a suppressed field, no pointer argument is given. The following conversion codes are legal:

% a single % is expected in the input at this point; no assignment is done.

- **d** a decimal integer is expected; the corresponding argument should be an integer pointer.
- **u** an unsigned decimal integer is expected; the corresponding argument should be an unsigned integer pointer.
- **o** an octal integer is expected; the corresponding argument should be an integer pointer.
- **x** a hexadecimal integer is expected; the corresponding argument should be an integer pointer.
- i an integer is expected; the corresponding argument should be an integer pointer. It will store the value of the next input item interpreted according to C conventions: a leading "0" implies octal; a leading "0x" implies hexadecimal; otherwise, decimal.
- **n** stores in an integer argument the total number of characters (including white space) that have been scanned so far since the function call. No input is consumed.
- **e**,**f**,**g** a floating point number is expected; the next field is converted accordingly and stored through the corresponding argument, which should be a pointer to a *float*. The input format for floating point numbers is an optionally signed string of digits, possibly containing a decimal point, followed by an optional exponent field consisting of an E or an e, followed by an optional + or -, followed by an integer.
- **s** a character string is expected; the corresponding argument should be a character pointer pointing to an array of characters large enough to accept the string and a terminating $\backslash 0$, which will be added automatically. The input field is terminated by a white-space character.
- **c** a character is expected; the corresponding argument should be a character pointer. The normal skip over white space is suppressed in this case; to read the next non-space character, use **%1s**. If a field width is given, the corresponding argument should refer to a character array; the indicated number of characters is read.
- [indicates string data and the normal skip over leading white space is suppressed. The left bracket is followed by a set of characters, which we will call the *scanset*, and a right bracket; the input field is the maximal sequence of input characters consisting entirely of characters in the scanset. The circumflex (), when it appears as the first character in the scanset, serves as a complement operator and redefines the scanset as the set of all characters *not* contained in the remainder of the scanset string. There are some conventions used in the construction of the scanset. A range of characters may be

represented by the construct *first-last*, thus [0123456789] may be expressed [0–9]. Using this convention, *first* must be lexically less than or equal to *last*, or else the dash will stand for itself. The dash will also stand for itself whenever it is the first or the last character in the scanset. To include the right square bracket as an element of the scanset, it must appear as the first character (possibly preceded by a circumflex) of the scanset, and in this case it will not be syntactically interpreted as the closing bracket. The corresponding argument must point to a character array large enough to hold the data field and the terminating $\backslash 0$, which will be added automatically. At least one character must match for this conversion to be considered successful.

The conversion characters d, u, o, x and i may be preceded by l or h to indicate that a pointer to **long** or to **short** rather than to **int** is in the argument list. Similarly, the conversion characters e, f, and g may be preceded by l to indicate that a pointer to **double** rather than to **float** is in the argument list. The l or h modifier is ignored for other conversion characters.

The *scanf* function conversion terminates at **EOF**, at the end of the control string, or when an input character conflicts with the control string. In the latter case, the offending character is left unread in the input stream.

The *scanf* function returns the number of successfully matched and assigned input items; this number can be zero in the event of an early conflict between an input character and the control string. If the input ends before the first conflict or conversion, **EOF** is returned.

EXAMPLES

The call:

int n ; float x; char name[50]; n = scanf("%d%f%s", &i, &x, name);

with the input line:

25 54.32E-1 thompson

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain **thompson**\0. Or:

int i, j; float x; char name[50]; (void) scanf ("%i%2d%f%*d %[0-9] ", &j, &i, &x, name);

with input:

011 56789 0123 56a72

will assign 9 to *j*, 56 to *i*, 789.0 to *x*, skip 0123, and place the string $56\setminus 0$ in *name*. The next call to *getchar* [see *getc*(3S)] will return **a**. Or:

int i, j, s, e; char name[50]; (void) scanf("%i %i %n%s%n", &i, &j, &s, name, &e);

with input:

0x11 0xy johnson

will assign 17 to *i*, 0 to *j*, 6 to *s*, will place the string $xy \setminus 0$ in *name*, and will assign 8 to *e*. Thus, the length of *name* is e - s = 2. The next call to getchar [see getc(3S)] will return a blank.

SEE ALSO

getc(3S), printf(3S), stdio(3S), strtod(3C), strtol(3C).

DIAGNOSTICS

These functions return EOF on end of input and a short count for missing or illegal data items.

CAVEATS

Trailing white space (including a new-line) is left unread unless matched in the control string.

setbuf, setvbuf - assign buffering to a stream

SYNOPSIS

#include <stdio.h>
void setbuf (stream, buf)
FILE *stream;
char *buf;
int setvbuf (stream, buf, type, size)
FILE *stream;
char *buf;
int type, size;

DESCRIPTION

The *setbuf* function may be used after a stream has been opened but before it is read or written. It causes the array pointed to by *buf* to be used instead of an automatically allocated buffer. If *buf* is the NULL pointer, input/output will be completely unbuffered.

A constant **BUFSIZ**, defined in the **<stdio.h**> header file, tells how big an array is needed:

char buf[BUFSIZ];

Setvbuf may be used after a stream has been opened but before it is read or written. *Type* determines how *stream* will be buffered. Legal values for *type* (defined in stdio.h) are:

- _IOFBF causes input/output to be fully buffered.
- _IOLBF causes output to be line buffered; the buffer will be flushed when a newline is written, the buffer is full, or input is requested.
- _IONBF causes input/output to be completely unbuffered.

If *buf* is not the **NULL** pointer, the array it points to will be used for buffering, instead of an automatically allocated buffer. *Size* specifies the size of the buffer to be used. The constant **BUFSIZ** in **<stdio.h>** is suggested as a good buffer size. If input/output is unbuffered, *buf* and *size* are ignored.

By default, output to a terminal is line-buffered and all other input/output is fully buffered.

SEE ALSO

fopen(3S), getc(3S), malloc(3C), putc(3S), stdio(3S).

DIAGNOSTICS

If an illegal value for *type* or *size* is provided, *setvbuf* returns a non-zero value. Otherwise, the value returned will be zero.

NOTES

A common source of error is allocating buffer space as an "automatic" variable in a code block, and then failing to close the stream in the same block.

setjmp, longjmp – non-local goto

SYNOPSIS

#include <setjmp.h>

int setjmp (env)
jmp_buf env;

void longjmp (env, val)
jmp_buf env;
int val;

DESCRIPTION

These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.

The *setjmp* function saves its stack environment in *env* (whose type, *jmp_buf*, is defined in the *<setjmp.h>* header file) for later use by *longjmp*. It returns the value 0.

Longjmp restores the environment saved by the last call of *setjmp* with the corresponding *env* argument. After *longjmp* is completed, program execution continues as if the corresponding call of *setjmp* (which must not itself have returned in the interim) had just returned the value *val*. Longjmp cannot cause *setjmp* to return the value 0. If *longjmp* is invoked with a second argument of 0, *setjmp* will return 1. At the time of the second return from *setjmp*, all accessible data have values as of the time *longjmp* is called. However, global variables will have the expected values, i.e., those as of the time of the *longjmp* (see example).

EXAMPLE

#include <setjmp.h>

```
jmp__buf env;
int i = 0;
main ()
{
       void exit();
       if(setjmp(env) != 0) {
               (void) printf("value of i on 2nd return from setjmp: %d\n", i);
                exit(0);
       (void) printf("value of i on 1st return from setjmp: %d\n", i);
       i = 1;
       g();
        /*NOTREACHED*/
}
g()
       longjmp(env, 1);
        /*NOTREACHED*/
```

}

If the a.out resulting from this C language code is run, the output will be: value of i on 1st return from setjmp:0

value of i off 1st retailt from seginp.o

value of i on 2nd return from setjmp:1

SEE ALSO

signal(2).

WARNING

If *longjmp* is called even though *env* was never primed by a call to *setjmp*, or when the last such call was in a function which has since returned, absolute chaos is guaranteed.

BUGS

The values of the registers on the second return from *setjmp* are the register values at the time of the first call to *setjmp*, not those at the time of the *longjmp*. This means that variables in a given function may behave differently in the presence of *setjmp*, depending on whether they are register or stack variables.

sleep - suspend execution for interval

SYNOPSIS

unsigned sleep (seconds) unsigned seconds;

DESCRIPTION

The current process is suspended from execution for the number of *seconds* specified by the argument. The actual suspension time may be less than that requested for two reasons: (1) Because scheduled wakeups occur at fixed 1-second intervals, (on the second, according to an internal clock) and (2) because any caught signal will terminate the *sleep* following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount due to the scheduling of other activity in the system. The value returned by *sleep* will be the "unslept" amount (the requested time minus the time actually slept) in case the caller had an alarm set to go off earlier than the end of the requested *sleep* time, or premature arousal due to another caught signal.

The routine is implemented by setting an alarm signal and pausing until it (or some other signal) occurs. The previous state of the alarm signal is saved and restored. The calling program may have set up an alarm signal before calling *sleep*. If the *sleep* time exceeds the time till such alarm signal, the process sleeps only until the alarm signal would have occurred. The caller's alarm catch routine is executed just before the *sleep* routine returns. But if the *sleep* time is less than the time till such alarm, the prior alarm time is reset to go off at the same time it would have without the intervening *sleep*.

SEE ALSO

alarm(2), pause(2), signal(2).

ssignal, gsignal – software signals

SYNOPSIS

#include <signal.h>
int (*ssignal (sig, action))()
int sig, (*action)();
int gsignal (sig)
int sig;

DESCRIPTION

The *ssignal* and *gsignal* functions implement a software facility similar to *signal*(2). This facility is used by the Standard C Library to enable users to indicate the disposition of error conditions, and is also made available to users for their own purposes.

Software signals made available to users are associated with integers in the inclusive range 1 through 16. A call to *ssignal* associates a procedure, *action*, with the software signal *sig*; the software signal, *sig*, is raised by a call to *gsignal*. Raising a software signal causes the action established for that signal to be *taken*.

The first argument to *ssignal* is a number identifying the type of signal for which an action is to be established. The second argument defines the action; it is either the name of a (user-defined) *action function* or one of the manifest constants **SIG_DFL** (default) or **SIG_IGN** (ignore). The *ssignal* function returns the action previously established for that signal type; if no action has been established or the signal number is illegal, *ssignal* returns **SIG_DFL**.

The *gsignal* function raises the signal identified by its argument, *sig*:

If an action function has been established for *sig*, then that action is reset to **SIG_DFL** and the action function is entered with argument *sig*. *Gsignal* returns the value returned to it by the action function.

If the action for *sig* is **SIG_IGN**, *gsignal* returns the value 1 and takes no other action.

If the action for *sig* is **SIG_DFL**, *gsignal* returns the value 0 and takes no other action.

If sig has an illegal value or no action was ever specified for sig, gsignal returns the value 0 and takes no other action.

SEE ALSO

signal(2), sigset(2).

NOTES

There are some additional signals with numbers outside the range 1 through 16 which are used by the Standard C Library to indicate error conditions. Thus, some signal numbers outside the range 1 through 16 are legal, although their use may interfere with the operation of the Standard C Library.

stdio – standard buffered input/output package

SYNOPSIS

#include <stdio.h>

FILE *stdin, *stdout, *stderr;

DESCRIPTION

The functions described in the entries of sub-class 3S of this manual constitute an efficient, user-level I/O buffering scheme. The in-line macros getc(3S) and putc(3S) handle characters quickly. The macros getchar and putchar, and the higher-level routines fgetc, fgets, fprintf, fputc, fputs, fread, fscanf, fwrite, gets, getw, printf, puts, putw, and scanf all use or act as if they use getc and putc; they can be freely intermixed.

A file with associated buffering is called a *stream* and is declared to be a pointer to a defined type **FILE**. The *fopen*(3S) function creates certain descriptive data for a stream and returns a pointer to designate the stream in all further transactions. Normally, there are three open streams with constant pointers declared in the <stdio.h> header file and associated with the standard open files:

stdin	standard input file
stdout	standard output file
stderr	standard error file

A constant NULL (0) designates a nonexistent pointer.

An integer-constant EOF (-1) is returned upon end-of-file or error by most integer functions that deal with streams (see the individual descriptions for details).

An integer constant **BUFSIZ** specifies the size of the buffers used by the particular implementation.

Any program that uses this package must include the header file of pertinent macro definitions, as follows:

#include <stdio.h>

The functions and constants mentioned in the entries of sub-class 3S of this manual are declared in that header file and need no further declaration. The constants and the following "functions" are implemented as macros (redeclaration of these names is perilous): getc, getchar, putc, putchar, ferror, feof, clearerr, and fileno.

Output streams, with the exception of the standard error stream *stderr*, are by default buffered if the output refers to a file, and line-buffered if the output refers to a terminal. The standard error output stream *stderr* is by default unbuffered, but use of *freopen* [see *fopen*(3S)] will cause it to become

buffered or line-buffered. When an output stream is unbuffered, information is queued for writing on the destination file or terminal as soon as written. When it is buffered, many characters are saved up and written as a block. When it is line-buffered, each line of output is queued for writing on the destination terminal as soon as the line is completed (that is, as soon as a new-line character is written or terminal input is requested). The *setbuf*(3S) or *setvbuf*() functions in *setbuf*(3S) may be used to change the stream's buffering strategy.

SEE ALSO

open(2), close(2), lseek(2), pipe(2), read(2), write(2), ctermid(3S), cuserid(3S), fclose(3S), ferror(3S), fopen(3S), fread(3S), fseek(3S), getc(3S), gets(3S), popen(3S), printf(3S), putc(3S), puts(3S), scanf(3S), setbuf(3S), system(3S), tmpfile(3S), tmpnam(3S), ungetc(3S).

DIAGNOSTICS

Invalid *stream* pointers will usually cause grave disorder, possibly including program termination. Individual function descriptions describe the possible error conditions.

stdipc: ftok - standard interprocess communication package

SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>

key_t ftok(path, id)
char *path;
char id;

DESCRIPTION

All interprocess communication facilities require the user to supply a key to be used by the msgget(2), semget(2), and shmget(2) system calls to obtain interprocess communication identifiers. One suggested method for forming a key is to use the *ftok* subroutine described below. Another way to compose keys is to include the project ID in the most significant byte and to use the remaining portion as a sequence number. There are many other ways to form keys, but it is necessary for each system to define standards for forming them. If some standard is not adhered to, it will be possible for unrelated processes to unintentionally interfere with each other's operation. Therefore, it is strongly suggested that the most significant byte of a key in some sense refer to a project so that keys do not conflict across a given system.

Ftok returns a key based on *path* and *id* that is usable in subsequent *msgget*, *semget*, and *shmget* system calls. *Path* must be the path name of an existing file that is accessible to the process. *Id* is a character which uniquely identifies a project. Note that *ftok* will return the same key for linked files when called with the same *id*, and that it will return different keys when called with the same file name but different *ids*.

SEE ALSO

intro(2), msgget(2), semget(2), shmget(2).

DIAGNOSTICS

Ftok returns (**key_t**) -1 if *path* does not exist or if it is not accessible to the process.

WARNING

If the file whose *path* is passed to *ftok* is removed when keys still refer to the file, future calls to *ftok* with the same *path* and *id* will return an error. If the same file is recreated, then *ftok* is likely to return a different key than it did the original time it was called.

string: strcat, strdup, strncat, strcmp, strncmp, strncpy, strncpy, strlen, strchr, strrchr, strpbrk, strspn, strcspn, strtck – string operations

SYNOPSIS

#include <string.h> #include <sys/types.h> char *strcat (s1, s2) char *s1, *s2; char *strdup (s1) char *s1; char *strncat (s1, s2, n) char *s1, *s2; size_t n; int strcmp (s1, s2) char *s1, *s2; int strncmp (s1, s2, n) char *s1, *s2; size_t n; char *strcpy (s1, s2) char *s1, *s2; char *strncpy (s1, s2, n) char *s1, *s2; size_t n; int strlen (s) char *s: char *strchr (s, c) char *s; int c; char *strrchr (s, c) char *s; int c; char *strpbrk (s1, s2) char *s1, *s2; int strspn (s1, s2) char *s1, *s2; int strcspn (s1, s2) char *s1, *s2; char *strtok (s1, s2) char *s1, *s2;

DESCRIPTION

The arguments s1, s2, and s point to strings (arrays of characters terminated by a null character). The functions *strcat*, *strncat*, *strcpy*, and *strncpy* all alter s1. These functions do not check for overflow of the array pointed to by s1.

Streat appends a copy of string **s2** to the end of string **s1**.

Strdup returns a pointer to a new string which is a duplicate of the string pointed to by **s1**. The space for the new string is obtained using malloc(3C). If the new string cannot be created, null is returned.

Strncat appends at most \mathbf{n} characters. Each returns a pointer to the null-terminated result.

Strcmp compares its arguments and returns an integer less than, equal to, or greater than 0, according as **s1** is lexicographically less than, equal to, or greater than **s2**. *Strncmp* makes the same comparison but looks at most **n** characters.

Strcpy copies string s2 to s1, stopping after the null character has been copied. Strncpy copies exactly **n** characters, truncating s2 or adding null characters to s1 if necessary. The result will not be null-terminated if the length of s2 is **n** or more. Each function returns s1.

Strlen returns the number of characters in **s**, not including the terminating null character.

Strchr (*strrchr*) returns a pointer to the first (last) occurrence of character c in string s, or a NULL pointer if c does not occur in the string. The null character terminating a string is considered to be part of the string.

Strpbrk returns a pointer to the first occurrence in string **s1** of any character from string **s2**, or a NULL pointer if no character from **s2** exists in **s1**.

Strspn (*strcspn*) returns the length of the initial segment of string **s1** which consists entirely of characters from (not from) string **s2**.

Strtok considers the string **s1** to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string **s2**. The first call (with pointer **s1** specified) returns a pointer to the first character of the first token, and will have written a null character into **s1** immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument a NULL pointer) will work through the string **s1** immediately following that token. In this way subsequent calls will work through the string **s1** until no tokens remain. The separator string **s2** may be different from call to call. When no token remains in **s1**, a NULL pointer is returned.

For user convenience, all these functions are declared in the optional *<string.h>* header file.

SEE ALSO

malloc(3C), malloc(3X).

CAVEATS

Strcmp and *strncmp* are implemented by using the most natural character comparison on the machine. Thus the sign of the value returned when one of the characters has its high-order bit set not the same in all implementations and should not be relied upon.

Character movement is performed differently in different implementations. Thus overlapping moves may yield surprises. STRTOD(3C)

NAME

strtod, atof - convert string to double-precision number

SYNOPSIS

double strtod (str, ptr) char *str, **ptr; double atof (str) char *str;

DESCRIPTION

The *strtod* function returns as a double-precision floating-point number the value represented by the character string pointed to by *str*. The string is scanned up to the first unrecognized character.

The *strtod* function recognizes an optional string of "white-space" characters [as defined by *isspace* in *ctype*(3C)], then an optional sign, then a string of digits optionally containing a decimal point, then an optional \mathbf{e} or \mathbf{E} followed by an optional sign or space, followed by an integer.

If the value of ptr is not (char ******)NULL, a pointer to the character terminating the scan is returned in the location pointed to by ptr. If no number can be formed, *****ptr is set to str, and zero is returned.

Atof(str) is equivalent to strtod(str, (char **)NULL).

SEE ALSO

ctype(3C), scanf(3S), strtol(3C).

DIAGNOSTICS

If the correct value would cause overflow, \pm HUGE (as defined in **<math.h**>) is returned (according to the sign of the value), and *errno* is set to ERANGE. If the correct value would cause underflow, zero is returned and *errno* is set to ERANGE.

strtol, atol, atoi - convert string to integer

SYNOPSIS

```
long strtol (str, ptr, base)
char *str, **ptr;
int base;
long atol (str)
char *str;
int atoi (str)
char *str;
```

DESCRIPTION

The *strtol* function returns as a long integer the value represented by the character string pointed to by *str*. The string is scanned up to the first character inconsistent with the base. Leading "white-space" characters [as defined by *isspace* in ctype(3C)] are ignored.

If the value of ptr is not (char ******)NULL, a pointer to the character terminating the scan is returned in the location pointed to by ptr. If no integer can be formed, that location is set to str, and zero is returned.

If *base* is positive (and not greater than 36), it is used as the base for conversion. After an optional leading sign, leading zeros are ignored, and "0x" or "0X" is ignored if *base* is 16.

If *base* is zero, the string itself determines the base thusly: After an optional leading sign a leading zero indicates octal conversion, and a leading "0x" or "0X" hexadecimal conversion. Otherwise, decimal conversion is used.

Truncation from long to int can, of course, take place upon assignment or by an explicit cast.

Atol(str) is equivalent to strtol(str, (char **)NULL, 10).

Atoi(str) is equivalent to (int) strtol(str, (char **)NULL, 10).

SEE ALSO

ctype(3C), scanf(3S), strtod(3C).

CAVEAT

Overflow conditions are ignored.

DIAGNOSTICS

If the argument *ptr* is a null-pointer, the function *strtol* will return the value of the string *str* as a long integer.

If the argument *ptr* is not NULL, the function *strtol* will return the value of the string *str* as a long integer, and a pointer to the character terminating the scan will be returned in the location pointed to by *ptr*.

If no integer can be formed, that location is set to the argument *str* and the function *strtol* returns 0.

SWAB(3C)

NAME

swab – swap bytes

SYNOPSIS

void swab (from, to, nbytes) char *from, *to; int nbytes;

DESCRIPTION

The *swab* function copies *nbytes* bytes pointed to by *from* to the array pointed to by *to*, exchanging adjacent even and odd bytes. *Nbytes* should be even and non-negative. If *nbytes* is odd and positive *swab* uses *nbytes*-1 instead. If *nbytes* is negative, *swab* does nothing.

system - issue a shell command

SYNOPSIS

#include <stdio.h>

int system (string) char *string;

DESCRIPTION

The system function causes the string to be given to sh(1) as input, as if the string had been typed as a command at a terminal. The current process waits until the shell has completed, then returns the exit status of the shell.

FILES

/bin/sh

SEE ALSO

exec(2).

sh(1) in the User's Reference Manual.

DIAGNOSTICS

The *system* function forks to create a child process that in turn exec's /bin/sh in order to execute *string*. If the fork or exec fails, *system* returns a negative value and sets *errno*.

TMPFILE(3S)

NAME

tmpfile - create a temporary file

SYNOPSIS

#include <stdio.h>

FILE ***tmpfile** ()

DESCRIPTION

The *tmpfile* function creates a temporary file using a name generated by *tmpnam*(3S), and returns a corresponding FILE pointer. If the file cannot be opened, an error message is printed using *perror*(3C), and a NULL pointer is returned. The file will automatically be deleted when the process using it terminates. The file is opened for update ("w+").

SEE ALSO

creat(2), unlink(2), fopen(3S), mktemp(3C), perror(3C), stdio(3S), tmpnam(3S).

tmpnam, tempnam – create a name for a temporary file

SYNOPSIS

```
#include <stdio.h>
char *tmpnam (s)
char *s;
char *tempnam (dir, pfx)
char *dir, *pfx;
```

DESCRIPTION

These functions generate file names that can safely be used for a temporary file.

The *tmpnam* function always generates a file name using the path-prefix defined as **P_tmpdir** in the *<stdio.h>* header file. If *s* is NULL, *tmpnam* leaves its result in an internal static area and returns a pointer to that area. The next call to *tmpnam* will destroy the contents of the area. If *s* is not NULL, it is assumed to be the address of an array of at least **L_tmpnam** bytes, where **L_tmpnam** is a constant defined in *<stdio.h>*; *tmpnam* places its result in that array and returns *s*.

Tempnam allows the user to control the choice of a directory. The argument *dir* points to the name of the directory in which the file is to be created. If *dir* is NULL or points to a string that is not a name for an appropriate directory, the path-prefix defined as **P_tmpdir** in the *<stdio.h>* header file is used. If that directory is not accessible, */tmp* will be used as a last resort. This entire sequence can be up-staged by providing an environment variable **TMPDIR** in the user's environment, whose value is the name of the desired temporary-file directory.

Many applications prefer their temporary files to have certain favorite initial letter sequences in their names. Use the pfx argument for this. This argument may be NULL or point to a string of up to five characters to be used as the first few characters of the temporary-file name.

Tempnam uses malloc(3C) to get space for the constructed file name and returns a pointer to this area. Thus, any pointer value returned from tempnam may serve as an argument to free [see malloc(3C)]. If tempnam cannot return the expected result for any reason, i.e., malloc(3C) failed, or none of the above mentioned attempts to find an appropriate directory was successful, a NULL pointer will be returned.

NOTES

These functions generate a different file name each time they are called.

Files created using these functions and either fopen(3S) or creat(2) are temporary only in the sense that they reside in a directory intended for temporary use, and their names are unique. It is the user's responsibility to use unlink(2) to remove the file when its use is ended.

SEE ALSO

creat(2), unlink(2), fopen(3S), malloc(3C), mktemp(3C), tmpfile(3S).

CAVEATS

If called more than 17,576 times in a single process, these functions will start recycling previously used names.

Between the time a file name is created and the file is opened, it is possible for some other process to create a file with the same name. This can never happen if that other process is using these functions or *mktemp*, and the file names are chosen to render duplication by other means unlikely.

tsearch, tfind, tdelete, twalk – manage binary search trees

SYNOPSIS

#include <search.h>

char *tsearch ((char *) key, (char **) rootp, compar)
int (*compar)();

char *tfind ((char *) key, (char **) rootp, compar)
int (*compar)();

char *tdelete ((char *) key, (char **) rootp, compar)
int (*compar)();

void twalk ((char *) root, action)
void (*action)();

DESCRIPTION

The *tsearch*, *tfind*, *tdelete*, and *twalk* functions are routines for manipulating binary search trees. They are generalized from Knuth (6.2.2) Algorithms T and D. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to, or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

The *tsearch* function is used to build and access the tree. **Key** is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to *key (the value pointed to by key), a pointer to this found datum is returned. Otherwise, *key is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. **Rootp** points to a variable that points to the root of the tree. A NULL value for the variable pointed to by **rootp** denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.

Like *tsearch*, *tfind* will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, *tfind* will return a NULL pointer. The arguments for *tfind* are the same as for *tsearch*.

Tdelete deletes a node from a binary search tree. The arguments are the same as for *tsearch*. The variable pointed to by **rootp** will be changed if the deleted node was the root of the tree. *Tdelete* returns a pointer to the parent of the deleted node, or a NULL pointer if the node is not found.

Twalk traverses a binary search tree. **Root** is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) *Action* is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type *typedef enum* { *preorder, postorder, endorder, leaf* } *VISIT;* (defined in the *<search.h>* header file), depending on whether this is the first, second, or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf.

The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointerto-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

EXAMPLE

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <search.h>
#include <stdio.h>
struct node {
                       /* pointers to these are stored in the tree */
       char *string;
       int length;
};
char string_space[10000];
                              /* space to store strings */
struct node nodes[500]; /* nodes to store */
struct node *root = NULL;
                            /* this points to the root */
main()
ł
       char *strptr = string_space;
       struct node *nodeptr = nodes;
       void print_node( ), twalk( );
       int i = 0, node_compare();
       while (gets(strptr) != NULL && i++ < 500) {
               /* set node */
               nodeptr -> string = strptr;
               nodeptr->length = strlen(strptr);
               /* put node into the tree */
               (void) tsearch((char *)nodeptr, (char **) &root,
                         node_compare);
               /* adjust pointers, so we don't overwrite tree */
               strptr += nodeptr->length + 1;
               nodeptr++;
       twalk((char *)root, print_node);
}
/*
       This routine compares two nodes, based on an
       alphabetical ordering of the string field.
*/
int
node_compare(node1, node2)
char *node1, *node2;
```

```
{
       return strcmp(((struct node *)node1)->string,
       ((struct node *) node2)->string);
/*
       This routine prints out a node, the first time
       twalk encounters it.
*/
void
print_node(node, order, level)
char **node;
VISIT order;
int level;
ł
       if (order == preorder | order == leaf) {
               (void)printf("string = \%20s, length = \%d n",
                          (*((struct node **)node))->string,
                          (*((struct node **)node))->length);
       }
}
```

SEE ALSO

bsearch(3C), hsearch(3C), lsearch(3C).

DIAGNOSTICS

A NULL pointer is returned by *tsearch* if there is not enough space available to create a new node.

A NULL pointer is returned by *tfind* and *tdelete* if **rootp** is NULL on entry. If the datum is found, both *tsearch* and *tfind* return a pointer to it. If not, *tfind* returns NULL, and *tsearch* returns a pointer to the inserted item.

WARNINGS

The **root** argument to *twalk* is one level of indirection less than the **rootp** arguments to *tsearch* and *tdelete*.

There are two nomenclatures used to refer to the order in which tree nodes are visited. The *tsearch* function uses preorder, postorder, and endorder to respectively refer to visting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder, and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

CAVEAT

If the calling function alters the pointer to the root, results are unpredictable.

TTYNAME(3C)

NAME

ttyname, isatty - find name of a terminal

SYNOPSIS

char *ttyname (fildes) int fildes;

int isatty (fildes) int fildes;

DESCRIPTION

The *ttyname* function returns a pointer to a string containing the null-terminated path name of the terminal device associated with file descriptor *fildes*.

Isatty returns 1 if fildes is associated with a terminal device, 0 otherwise.

FILES

/dev/*

DIAGNOSTICS

The *ttyname* function returns a NULL pointer if *fildes* does not describe a terminal device in directory **/dev**.

CAVEAT

The return value points to static data whose content is overwritten by each call.

ttyslot - find the slot in the utmp file of the current user

SYNOPSIS

int ttyslot ()

DESCRIPTION

The *ttyslot* function returns the index of the current user's entry in the **/etc/utmp** file. This is accomplished by actually scanning the file **/etc/inittab** for the name of the terminal associated with the standard input, the standard output, or the error output (0, 1 or 2).

FILES

/etc/inittab /etc/utmp

SEE ALSO

getut(3C), ttyname(3C).

DIAGNOSTICS

A value of 0 is returned if an error was encountered while searching for the terminal name or if none of the above file descriptors is associated with a terminal device.

UNGETC(3S)

NAME

ungetc - push character back into input stream

SYNOPSIS

#include <stdio.h>

int ungetc (c, stream) int c; FILE *stream;

DESCRIPTION

The *ungetc* function inserts the character c into the buffer associated with an input *stream*. That character, c, will be returned by the next *getc*(3S) call on that *stream*. The *ungetc* function returns c, and leaves the file *stream* unchanged.

One character of pushback is guaranteed, provided something has already been read from the stream and the stream is actually buffered.

If *c* equals EOF, *ungetc* does nothing to the buffer and returns EOF.

The *fseek*(3S) function erases all memory of inserted characters.

SEE ALSO

fseek(3S), getc(3S), setbuf(3S), stdio(3S).

DIAGNOSTICS

ungetc returns EOF if it cannot insert the character.

BUGS

When *stream* is *stdin*, one character may be pushed back onto the buffer without a previous read statement.

VPRINTF(3S)

NAME

vprintf, vfprintf, vsprintf - print formatted output of a varargs argument list

SYNOPSIS

#include <stdio.h>
#include <varargs.h>
int vprintf (format, ap)
char *format;
va_list ap;
int vfprintf (stream, format, ap)
FILE *stream;
char *format;
va_list ap;
int vsprintf (s, format, ap)
char *s, *format;
va_list ap;

DESCRIPTION

The *vprintf*, *vfprintf*, and *vsprintf* functions are the same as *printf*, *fprintf*, and *sprintf* respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by *varargs*(5).

EXAMPLE

The following demonstrates the use of *vfprintf* to write an error routine.

```
#include <stdio.h>
#include <varargs.h>
       .
/*
 *
       error should be called like
        error(function_name, format, arg1, arg2...); */
*
/*VARARGS*/
void
error(va_alist)
/* Note that the function_name and format arguments cannot be
*
      separately declared because of the definition of varargs. */
va_dcl
{
       va_list args;
       char *fmt;
       va_start(args);
       /* print out name of function causing error */
       (void)fprintf(stderr, "ERROR in %s: ", va_arg(args, char *));
       fmt = va_arg(args, char *);
       /* print out remainder of message */
       (void)vfprintf(stderr, fmt, args);
       va_end(args);
```

VPRINTF(3S)

(void)abort(); }

SEE ALSO

printf(3S), varargs(5).

bessel: j0, j1, jn, y0, y1, yn - Bessel functions

SYNOPSIS

#include <math.h>
double j0 (x)
double x;
double j1 (x)
double x;
double jn (n, x)
int n;
double y0 (x)
double y0 (x)
double y1 (x)
double x;
double y1 (x)
double x;
double yn (n, x)
int n;
double x;

DESCRIPTION

J0 and j1 return Bessel functions of x of the first kind of orders 0 and 1 respectively. Jn returns the Bessel function of x of the first kind of order n.

Y0 and y1 return Bessel functions of x of the second kind of orders 0 and 1 respectively. Yn returns the Bessel function of x of the second kind of order n. The value of x must be positive.

SEE ALSO

matherr(3M).

DIAGNOSTICS

Non-positive arguments cause y0, y1, and yn to return the value -HUGE and to set *errno* to **EDOM**. In addition, a message indicating DOMAIN error is printed on the standard error output.

Arguments too large in magnitude cause j0, j1, y0, and y1 to return zero and to set *errno* to **ERANGE**. In addition, a message indicating TLOSS error is printed on the standard error output.

These error-handling procedures may be changed with the function *matherr*(3M).

ERF(3M)

NAME

erf, erfc - error function and complementary error function

SYNOPSIS

#include <math.h>
double erf (x)
double x;
double erfc (x)
double x;

DESCRIPTION

The *erf* function returns the error function of x, defined as $\frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-t^2} dt$.

erfc, which returns 1.0 - erf(x), is provided because of the extreme loss of relative accuracy if *erf(x)* is called for large x and the result subtracted from 1.0 (e.g., for x = 5, 12 places are lost).

SEE ALSO

exp(3M).

exp, log, log10, pow, sqrt - exponential, logarithm, power, square root functions

SYNOPSIS

#include <math.h>
double exp (x)
double x;
double log (x)
double x;
double log10 (x)
double x;
double pow (x, y)
double x, y;
double sqrt (x)
double x;

DESCRIPTION

The *exp* function returns e^x .

Log returns the natural logarithm of *x*. The value of *x* must be positive.

Log10 returns the logarithm base ten of x. The value of x must be positive.

Pow returns x^y . If x is zero, y must be positive. If x is negative, y must be an integer.

Sqrt returns the non-negative square root of x. The value of x may not be negative.

SEE ALSO

hypot(3M), matherr(3M), sinh(3M).

DIAGNOSTICS

The *exp* function returns **HUGE** when the correct value would overflow, or 0 when the correct value would underflow, and sets *errno* to **ERANGE**.

Log and log10 return -HUGE and set *errno* to EDOM when x is non-positive. A message indicating DOMAIN error (or SING error when x is 0) is printed on the standard error output.

Pow returns 0 and sets *errno* to **EDOM** when x is 0 and y is non-positive, or when x is negative and y is not an integer. In these cases a message indicating DOMAIN error is printed on the standard error output. When the correct value for *pow* would overflow or underflow, *pow* returns ±HUGE or 0 respectively, and sets *errno* to **ERANGE**.

Sqrt returns 0 and sets *errno* to **EDOM** when *x* is negative. A message indicating DOMAIN error is printed on the standard error output.

These error-handling procedures may be changed with the function *matherr*(3M).

FLOOR(3M)

NAME

floor, ceil, fmod, fabs - floor, ceiling, remainder, absolute value functions

SYNOPSIS

#include <math.h>
double floor (x)
double x;
double ceil (x)
double x;
double fmod (x, y)
double x, y;
double fabs (x)
double x;

DESCRIPTION

The *floor* function returns the largest integer (as a double-precision number) not greater than x.

Ceil returns the smallest integer not less than *x*.

Fmod returns the floating-point remainder of the division of x by y: zero if y is zero or if x/y would overflow; otherwise the number f with the same sign as x, such that x = iy + f for some integer i, and |f| < |y|.

Fabs returns the absolute value of x, |x|.

SEE ALSO

abs(3C).

gamma - log gamma function

SYNOPSIS

#include <math.h>
double gamma (x)
double x;
extern int signgam;

DESCRIPTION

The gamma function returns $\ln(|\Gamma(x)|)$, where $\Gamma(x)$ is defined as $\int e^{-t} t^{x-1} dt$.

The sign of $\Gamma(x)$ is returned in the external integer *signgam*. The argument x may not be a non-positive integer.

The following C program fragment might be used to calculate Γ :

if ((y = gamma(x)) > LN_MAXDOUBLE)
 error();
y = signgam * exp(y);

where LN_MAXDOUBLE is the least value that causes exp(3M) to return a range error, and is defined in the $\langle values.h \rangle$ header file.

SEE ALSO

exp(3M), matherr(3M), values(5).

DIAGNOSTICS

For non-negative integer arguments HUGE is returned, and *errno* is set to EDOM. A message indicating SING error is printed on the standard error output.

If the correct value would overflow, *gamma* returns **HUGE** and sets *errno* to **ERANGE**.

These error-handling procedures may be changed with the function *matherr*(3M).

HYPOT(3M)

NAME

hypot – Euclidean distance function

SYNOPSIS

#include <math.h>

double hypot (x, y) double x, y;

DESCRIPTION

hypot returns

```
sqrt(x * x + y * y),
```

taking precautions against unwarranted overflows.

SEE ALSO

matherr(3M).

DIAGNOSTICS

When the correct value would overflow, *hypot* returns HUGE and sets *errno* to ERANGE.

These error-handling procedures may be changed with the function *matherr*(3M).

matherr - error-handling function

SYNOPSIS

#include <math.h>

int matherr (x) struct exception *x;

DESCRIPTION

The *matherr* function is invoked by functions in the Math Library when errors are detected. Users may define their own procedures for handling errors by including a function named *matherr* in their programs. The *matherr* function must be of the form described above. When an error occurs, a pointer to the exception structure x will be passed to the user-supplied *matherr* function. This structure, which is defined in the *<math.h>* header file, is as follows:

struct exception {
 int type;
 char *name;
 double arg1, arg2, retval;
}

};

The element *type* is an integer describing the type of error that has occurred, from the following list of constants (defined in the header file):

DOMAIN	argument domain error
SING	argument singularity
OVERFLOW	overflow range error
UNDERFLOW	underflow range error
TLOSS	total loss of significance
PLOSS	partial loss of significance

The element *name* points to a string containing the name of the function that incurred the error. The variables *arg1* and *arg2* are the arguments with which the function was invoked. *Retval* is set to the default value that will be returned by the function unless the user's *matherr* sets it to a different value.

If the user's *matherr* function returns non-zero, no error message will be printed, and *errno* will not be set.

If *matherr* is not supplied by the user, the default error-handling procedures, described with the math functions involved, will be invoked upon error. These procedures are also summarized in the table below. In every case, *errno* is set to EDOM or ERANGE and the program continues.

EXAMPLE

#include <math.h>

```
int
matherr(x)
register struct exception *x;
{
    switch (x->type) {
```

}

case DOMAIN: /* change sqrt to return sqrt(-arg1), not 0 */ if (!strcmp(x->name, "sqrt")) { $x \rightarrow retval = sqrt(-x \rightarrow arg1);$ return (0); /* print message and set errno */ case SING: /* all other domain or sing errors, print message and abort */ fprintf(stderr, "domain error in %s\n", x->name); abort(); case PLOSS: /* print detailed error message */ fprintf(stderr, "loss of significance in %s(%g) = %g n", x->name, x->arg1, x->retval); return (1); /* take no other action */ } return (0); /* all other errors, execute default procedure */

ر ا	DEFAULT	ERROR	HANDLING I	PROCEDURES

ABBREVIATIONS

- As much as possible of the value is returned. Message is printed (EDOM error). *
- М
- HUGE is returned. Н
- -H -HUGE is returned.
- ±Η HUGE or -HUGE is returned.
- 0 0 is returned.

SINH(3M)

NAME

sinh, cosh, tanh – hyperbolic functions

SYNOPSIS

#include <math.h>

double sinh (x) double x; double cosh (x) double x; double tanh (x) double x;

DESCRIPTION

The *sinh*, *cosh*, and *tanh* functions return, respectively, the hyberbolic sine, cosine and tangent of their argument.

SEE ALSO

matherr(3M).

DIAGNOSTICS

The *sinh* and *cosh* functions return HUGE (and *sinh* may return -HUGE for negative x) when the correct value would overflow and set *errno* to **ERANGE**.

These error-handling procedures may be changed with the function *matherr*(3M).

TRIG(3M)

NAME

trig: sin, cos, tan, asin, acos, atan, atan2 - trigonometric functions

SYNOPSIS

#include <math.h>
double sin (x)
double cos (x)
double cos (x)
double tan (x)
double tan (x)
double asin (x)
double asin (x)
double acos (x)
double atan (x)
double atan (x)
double atan (x)
double atan (x)
double y;

DESCRIPTION

The *sin*, *cos*, and *tan* functions return respectively the sine, cosine, and tangent of their argument, *x*, measured in radians.

Asin returns the arcsine of x, in the range $[-\pi/2,\pi/2]$.

Acos returns the arccosine of x, in the range $[0,\pi]$.

Atan returns the arctangent of x, in the range $\left[-\pi/2, \pi/2\right]$.

Atan2 returns the arctangent of y/x, in the range $(-\pi,\pi]$, using the signs of both arguments to determine the quadrant of the return value.

SEE ALSO

matherr(3M).

DIAGNOSTICS

Sin, cos, and *tan* lose accuracy when their argument is far from zero. For arguments sufficiently large, these functions return zero when there would otherwise be a complete loss of significance. In this case a message indicating TLOSS error is printed on the standard error output. For less extreme arguments causing partial loss of significance, a PLOSS error is generated but no message is printed. In both cases, *errno* is set to **ERANGE**.

If the magnitude of the argument of *asin* or *acos* is greater than one, or if both arguments of *atan2* are zero, zero is returned and *errno* is set to EDOM. In addition, a message indicating DOMAIN error is printed on the standard error output.

These error-handling procedures may be changed with the function *matherr*(3M).

t_accept - accept a connect request

SYNOPSIS

#include <tiuser.h>

int t_accept(fd, resfd, call)
int fd;
int resfd;
struct t_call *call;

DESCRIPTION

This function is issued by a transport user to accept a connect request. *Fd* identifies the local transport endpoint where the connect indication arrived, *resfd* specifies the local transport endpoint where the connection is to be established, and *call* contains information required by the transport provider to complete the connection. *Call* points to a *t*_*call* structure which contains the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;

Netbuf is described in *intro*(3). In *call, addr* is the address of the caller, *opt* indicates any protocol-specific parameters associated with the connection, *udata* points to any user data to be returned to the caller, and *sequence* is the value returned by t_listen that uniquely associates the response with a previously received connect indication.

A transport user may accept a connection on either the same, or on a different, local transport endpoint than the one on which the connect indication arrived. If the same endpoint is specified (i.e., resfd=fd), the connection can be accepted unless the following condition is true: The user has received other indications on that endpoint but has not responded to them (with *t_accept* or *t_snddis*). For this condition, *t_accept* will fail and set *t_errno* to TBADF.

If a different transport endpoint is specified (*resfd*!=*fd*), the endpoint must be bound to a protocol address and must be in the T_IDLE state [see $t_getstate(3N)$] before the t_accept is issued.

For both types of endpoints, *t_accept* will fail and set *t_errno* to TLOOK if there are indications (e.g., a connect or disconnect) waiting to be received on that endpoint.

The values of parameters specified by *opt* and the syntax of those values are protocol-specific. The *udata* argument enables the called transport user to send user data to the caller and the amount of user data must not exceed the limits supported by the transport provider as returned by t_open or $t_getinfo$. If the *len* [see *netbuf* in *intro*(3)] field of *udata* is zero, no data will be sent to the caller.

T_ACCEPT(3N)

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a tran-
	sport endpoint, or the user is illegally accepting a con- nection on the same transport endpoint on which the connect indication arrived.
	connect multation arrived.

- [TOUTSTATE] The function was issued in the wrong sequence on the transport endpoint referenced by *fd*, or the transport endpoint referred to by *resfd* is not in the T_IDLE state.
- [TACCES] The user does not have permission to accept a connection on the responding transport endpoint or use the specified options.
- [TBADOPT] The specified options were in an incorrect format or contained illegal information.
- [TBADDATA] The amount of user data specified was not within the bounds allowed by the transport provider.
- [TBADSEQ] An invalid sequence number was specified.
- [TLOOK] An asynchronous event has occurred on the transport endpoint referenced by *fd* and requires immediate attention.
- [TNOTSUPPORT] This function is not supported by the underlying transport provider.
- [TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_connect(3N), t_getstate(3N), t_listen(3N), t_open(3N), t_rcvconnect(3N).

Network Programmer's Guide.

DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned, and *t_errno* is set to indicate the error.

T_ALLOC(3N)

NAME

t_alloc - allocate a library structure

SYNOPSIS

#include <tiuser.h>

char *t_alloc(fd, struct_type, fields)
int fd;
int struct_type;
int fields;

DESCRIPTION

The *t_alloc* function dynamically allocates memory for the various transport function argument structures as specified below. This function will allocate memory for the specified structure, and will also allocate memory for buffers referenced by the structure.

The structure to allocate is specified by *struct_type*, and can be one of the following:

TBIND	struct t_bind
T_CALL	struct t_call
T_OPTMGMT	struct t_optmgmt
T_DIS	struct t_discon
T_UNITDATA	struct t_unitdata
T_UDERROR	struct t_uderr
T_INFO	struct t_info

where each of these structures may subsequently be used as an argument to one or more transport functions.

Each of the above structures, except T_INFO, contains at least one field of type *struct netbuf*. *Netbuf* is described in *intro*(3). For each field of this type, the user may specify that the buffer for that field should be allocated as well. The *fields* argument specifies this option, where the argument is the bitwise-OR of any of the following:

- T_ADDR The *addr* field of the *t_bind*, *t_call*, *t_unitdata*, or *t_uderr* structures.
- T_OPT The opt field of the t_optmgmt, t_call, t_unitdata, or t_uderr structures.

T_UDATA The *udata* field of the *t_call*, *t_discon*, or *t_unitdata* structures.

T_ALL All relevant fields of the given structure.

For each field specified in *fields*, t_alloc will allocate memory for the buffer associated with the field, and initialize the *buf* pointer and *maxlen* [see *net-buf* in *intro*(3) for description of *buf* and *maxlen*] field accordingly. The length of the buffer allocated will be based on the same size information that is returned to the user on t_open and $t_getinfo$. Thus, *fd* must refer to the transport endpoint through which the newly allocated structure will be passed, so that the appropriate size information can be accessed. If the size

value associated with any specified field is -1 or -2 (see *t_open* or *t_getinfo*), *t_alloc* will be unable to determine the size of the buffer to allocate and will fail, setting *t_errno* to TSYSERR and *errno* to EINVAL. For any field not specified in *fields*, *buf* will be set to NULL and *maxlen* will be set to zero.

Use of $t_{--alloc}$ to allocate structures will help ensure the compatibility of user programs with future releases of the transport interface.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_free(3N), t_getinfo(3N), t_open(3N). Network Programmer's Guide.

DIAGNOSTICS

On successful completion, *t_alloc* returns a pointer to the newly allocated structure. On failure, NULL is returned.

t_bind - bind an address to a transport endpoint

SYNOPSIS

#include <tiuser.h>
int t_bind(fd, req, ret)
int fd;
struct t_bind *req;
struct t_bind *ret;

DESCRIPTION

This function associates a protocol address with the transport endpoint specified by fd and activates that transport endpoint. In connection mode, the transport provider may begin accepting or requesting connections on the transport endpoint. In connectionless mode, the transport user may send or receive data units through the transport endpoint.

The *req* and *ret* arguments point to a *t_bind* structure containing the following members:

struct netbuf addr; unsigned qlen;

Netbuf is described in *intro*(3). The *addr* field of the *t_bind* structure specifies a protocol address and the *qlen* field is used to indicate the maximum number of outstanding connect indications.

Req is used to request that an address, represented by the *netbuf* structure, be bound to the given transport endpoint. *Len* [see *netbuf* in *intro*(3); also for *buf* and *maxlen*] specifies the number of bytes in the address and *buf* points to the address buffer. *Maxlen* has no meaning for the *req* argument. On return, *ret* contains the address that the transport provider actually bound to the transport endpoint; this may be different from the address specified by the user in *req*. In *ret*, the user specifies *maxlen* which is the maximum size of the address buffer and *buf* which points to the buffer where the address is to be placed. On return, *len* specifies the number of bytes in the bound address and *buf* points to the bound address. If *maxlen* is not large enough to hold the returned address, an error will result.

If the requested address is not available, or if no address is specified in *req* (the *len* field of *addr* in *req* is zero) the transport provider will assign an appropriate address to be bound, and will return that address in the *addr* field of *ret*. The user can compare the addresses in *req* and *ret* to determine whether the transport provider bound the transport endpoint to a different address than that requested.

Req may be NULL if the user does not wish to specify an address to be bound. Here, the value of *qlen* is assumed to be zero, and the transport provider must assign an address to the transport endpoint. Similarly, *ret* may be NULL if the user does not care what address was bound by the provider and is not interested in the negotiated value of *qlen*. It is valid to set *req* and *ret* to NULL for the same call, in which case the provider chooses the address to bind to the transport endpoint and does not return that information to the user.

The *qlen* field has meaning only when initializing a connection-mode service. It specifies the number of outstanding connect indications the transport provider should support for the given transport endpoint. An outstanding connect indication is one that has been passed to the transport user by the transport provider. A value of *qlen* greater than zero is only meaningful when issued by a passive transport user that expects other users to call it. The value of *qlen* will be negotiated by the transport provider and may be changed if the transport provider cannot support the specified number of outstanding connect indications. On return, the *qlen* field in *ret* will contain the negotiated value.

This function allows more than one transport endpoint to be bound to the same protocol address (however, the transport provider must support this capability also), but it is not allowable to bind more than one protocol address to the same transport endpoint. If a user binds more than one transport endpoint to the same protocol address, only one endpoint can be used to listen for connect indications associated with that protocol address. In other words, only one *t_bind* for a given protocol address may specify a value of *glen* greater than zero. In this way, the transport provider can identify which transport endpoint should be notified of an incoming connect indication. If a user attempts to bind a protocol address to a second transport endpoint with a value of *glen* greater than zero, the transport provider will assign another address to be bound to that endpoint. If a user accepts a connection on the transport endpoint that is being used as the listening endpoint, the bound protocol address will be found to be busy for the duration of that connection. No other transport endpoints may be bound for listening while that initial listening endpoint is in the data transfer phase. This will prevent more than one transport endpoint bound to the same protocol address from accepting connect indications.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a tran- sport endpoint.
[TOUTSTATE]	The function was issued in the wrong sequence.
[TBADADDR]	The specified protocol address was in an incorrect for- mat or contained illegal information.
[TNOADDR]	The transport provider could not allocate an address.
[TACCES]	The user does not have permission to use the specified address.
[TBUFOVFLW]	The number of bytes allowed for an incoming argument is not sufficient to store the value of that argument. The provider's state will change to T_IDLE and the information to be returned in <i>ret</i> will be discarded.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_open(3N), t_optmgmt(3N), t_unbind(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_bind* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_close - close a transport endpoint

SYNOPSIS

#include <tiuser.h>

int t_close(fd)
int fd;

DESCRIPTION

The t_close function informs the transport provider that the user is finished with the transport endpoint specified by fd, and frees any local library resources associated with the endpoint. In addition, t_close closes the file associated with the transport endpoint.

The *t_close* function should be called from the T_UNBND state [see *t_getstate* (3N)]. However, this function does not check state information, so it may be called from any state to close a transport endpoint. If this occurs, the local library resources associated with the endpoint will be freed automatically. In addition, *close*(2) will be issued for that file descriptor; the close will be abortive if no other process has that file open, and will break any transport connection that may be associated with that endpoint.

On failure, *t_errno* may be set to the following:

[TBADF] The specified file descriptor does not refer to a transport endpoint.

SEE ALSO

t_getstate(3N), t_open(3N), t_unbind(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_close* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_connect - establish a connection with another transport user

SYNOPSIS

#include <tiuser.h>
int t_connect(fd, sndcall, rcvcall)
int fd;
struct t_call *sndcall;
struct t_call *rcvcall;

DESCRIPTION

This function enables a transport user to request a connection to the specified destination transport user. Fd identifies the local transport endpoint where communication will be established, while *sndcall* and *rcvcall* point to a *t_call* structure which contains the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;

Sndcall specifies information needed by the transport provider to establish a connection, and *rcvcall* specifies information that is associated with the newly established connection.

Netbuf is described in *intro*(3). In *sndcall, addr* specifies the protocol address of the destination transport user, *opt* presents any protocol-specific information that might be needed by the transport provider, *udata* points to optional user data that may be passed to the destination transport user during connection establishment, and *sequence* has no meaning for this function.

On return in *rcvcall, addr* returns the protocol address associated with the responding transport endpoint; *opt* presents any protocol-specific information associated with the connection; *udata* points to optional user data that may be returned by the destination transport user during connection establishment; and *sequence* has no meaning for this function.

The *opt* argument implies no structure on the options that may be passed to the transport provider. The transport provider is free to specify the structure of any options passed to it. These options are specific to the underlying protocol of the transport provider. The user may choose not to negotiate protocol options by setting the *len* field of *opt* to zero. In this case, the provider may use default options.

The *udata* argument enables the caller to pass user data to the destination transport user and receive user data from the destination user during connection establishment. However, the amount of user data must not exceed the limits supported by the transport provider as returned by t_open (3N) or $t_getinfo$ (3N). If the *len* [see *netbuf* in *intro*(3)] field of *udata* is zero in *sndcall*, no data will be sent to the destination transport user.

On return, the *addr*, *opt*, and *udata* fields of *rcvcall* will be updated to reflect values associated with the connection. Thus, the *maxlen* [see *netbuf* in *intro*(3)] field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *rcvcall* may be NULL, in which case no information is given to the user on return from $t_connect$.

By default, *t_connect* executes in synchronous mode, and will wait for the destination user's response before returning control to the local user. A successful return (i.e., return value of zero) indicates that the requested connection has been established. However, if O_NDELAY is set (via *t_open* or *fcntl*), *t_connect* executes in asynchronous mode. In this case, the call will not wait for the remote user's response, but will return control immediately to the local user and return -1 with *t_errno* set to TNODATA to indicate that the connection has not yet been established. In this way, the function simply initiates the connection establishment procedure by sending a connect request to the destination transport user.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a tran- sport endpoint.
[TOUTSTATE]	The function was issued in the wrong sequence.
[TNODATA]	O_NDELAY was set, so the function successfully ini- tiated the connection establishment procedure, but did not wait for a response from the remote user.
[TBADADDR]	The specified protocol address was in an incorrect for- mat or contained illegal information.
[TBADOPT]	The specified protocol options were in an incorrect for- mat or contained illegal information.
[TBADDATA]	The amount of user data specified was not within the bounds allowed by the transport provider.
[TACCES]	The user does not have permission to use the specified address or options.
[TBUFOVFLW]	The number of bytes allocated for an incoming argument is not sufficient to store the value of that argument. If executed in synchronous mode, the provider's state, as seen by the user, changes to T_DATAXFER, and the connect indication information to be returned in <i>rcvcall</i> is discarded.
[TLOOK]	An asynchronous event has occurred on this transport endpoint and requires immediate attention.
[TNOTSUPPORT]	This function is not supported by the underlying tran- sport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_accept(3N), t_getinfo(3N), t_listen(3N), t_open(3N), t_optmgmt(3N), t_rcvconnect(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_connect* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

T_ERROR(3N)

NAME

t_error - produce error message

SYNOPSIS

#include <tiuser.h>
void t_error(errmsg)
char *errmsg;
extern int t_errno;
extern char *t_errlist[];
extern int t_nerr;

DESCRIPTION

The *t_error* function produces a message on the standard error output which describes the last error encountered during a call to a transport function. The argument string *errmsg* is a user-supplied error message that gives context to the error. The *t_error* function prints the user-supplied error message followed by a colon and a standard error message for the current error defined in *t_errno*. To simplify variant formatting of messages, the array of message strings *t_errlist* is provided; *t_errno* can be used as an index in this table to get the message string without the new line. The *t_nerr* function is the largest message number provided for in the *t_errlist* table.

The *t_errno* function is only set when an error occurs and is not cleared on successful calls.

EXAMPLE

If a *t_connect* function fails on transport endpoint *fd2* because a bad address was given, the following call might follow the failure:

t_error("t_connect failed on fd2");

The diagnostic message to be printed would look like:

t_connect failed on fd2: Incorrect transport address format

where "Incorrect transport address format" identifies the specific error that occurred, and "t_connect failed on fd2" tells the user which function failed on which transport endpoint.

SEE ALSO

Network Programmer's Guide.

t_free – free a library structure

SYNOPSIS

#include <tiuser.h>

int t_free(ptr, struct_type)
char *ptr;
int struct_type;

DESCRIPTION

The *t_free* function frees memory previously allocated by *t_alloc*. This function will free memory for the specified structure and will also free memory for buffers referenced by the structure.

Ptr points to one of the six structure types described for *t_alloc*, and *struct_type* identifies the type of that structure which can be one of the following:

T_BIND	struct tbind
T_CALL	struct t_call
T_OPTMGMT	<pre>struct t_optmgmt</pre>
T_DIS	struct t_discon
T_UNITDATA	struct t_unitdata
T_UDERROR	struct t_uderr
T_INFO	struct t_info

where each of these structures is used as an argument to one or more transport functions.

The t_free function will check the *addr*, *opt*, and *udata* fields of the given structure (as appropriate) and free the buffers pointed to by the *buf* field of the *netbuf* [see *intro*(3)] structure. If *buf* is NULL, *t_free* will not attempt to free memory. After all buffers are freed, *t_free* will free the memory associated with the structure pointed to by *ptr*.

Undefined results will occur if *ptr* or any of the *buf* pointers points to a block of memory that was not previously allocated by t_alloc .

On failure, *t_errno* may be set to the following:

[TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_alloc(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_free* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_getinfo – get protocol-specific service information

SYNOPSIS

#include <tiuser.h>
int t_getinfo(fd, info)
int fd;
struct t_info *info;

DESCRIPTION

This function returns the current characteristics of the underlying transport protocol associated with file descriptor fd. The *info* structure is used to return the same information returned by *t_open*. This function enables a transport user to access this information during any phase of communication.

This argument points to a t_info structure which contains the following members:

long addr;	/* max size of the transport protocol address */	
long options;	/* max number of bytes of protocol-specific options */	
long tsdu;	/* max size of a transport service data unit (TSDU) */	
long etsdu;	/* max size of an expedited transport service data	
	unit (ETSDU) */	
long connect;	/* max amount of data allowed on connection establishment	
	functions */	
long discon;	/* max amount of data allowed on <i>t_snddis</i> and <i>t_rcvdis</i>	
	functions */	
long servtype;	/* service type supported by the transport provider */	
The values of the fields have the following meanings:		

addr	A value greater than or equal to zero indicates the maximum
	size of a transport protocol address; a value of -1 specifies
	that there is no limit on the address size; and a value of -2
	specifies that the transport provider does not provide user
	access to transport protocol addresses.

- options A value greater than or equal to zero indicates the maximum number of bytes of protocol-specific options supported by the provider; a value of -1 specifies that there is no limit on the option size; and a value of -2 specifies that the transport provider does not support user-settable options.
- tsdu A value greater than zero specifies the maximum size of a transport service data unit (TSDU); a value of zero specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a data stream with no logical boundaries preserved across a connection; a value of -1 specifies that there is no limit on the size of a TSDU; and a value of -2 specifies that the transfer of normal data is not supported by the transport provider.

T_GETINFO(3N)

etsdu

connect

A value greater than zero specifies the maximum size of an expedited transport service data unit (ETSDU); a value of zero specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of -1 specifies that there is no limit on the size of an ETSDU; and a value of -2 specifies that the transfer of expedited data is not supported by the transport provider.

A value greater than or equal to zero specifies the maximum amount of data that may be associated with connection establishment functions; a value of -1 specifies that there is no limit on the amount of data sent during connection establishment; and a value of -2 specifies that the transport provider does not allow data to be sent with connection establishment functions.

discon A value greater than or equal to zero specifies the maximum amount of data that may be associated with the *t_snddis* and *t_rcvdis* functions; a value of -1 specifies that there is no limit on the amount of data sent with these abortive release functions; and a value of -2 specifies that the transport provider does not allow data to be sent with the abortive release functions.

servtype This field specifies the service type supported by the transport provider, as described below.

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the t_alloc function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function. The value of each field may change as a result of option negotiation, and $t_getinfo$ enables a user to retrieve the current characteristics.

The *servtype* field of *info* may specify one of the following values on return:

- T_COTS The transport provider supports a connection-mode service but does not support the optional orderly release facility.
- T_COTS_ORD The transport provider supports a connection-mode service with the optional orderly release facility.
- T_CLTS The transport provider supports a connectionless-mode service. For this service type, t_open will return -2 for etsdu, connect, and discon.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TSYSERR] A system error has occurred during execution of this function.

- 2 -

SEE ALSO

t_open(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_getinfo* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_getstate - get the current state

SYNOPSIS.

#include <tiuser.h>

int t__getstate(fd)
int fd;

DESCRIPTION

The *t_getstate* function returns the current state of the provider associated with the transport endpoint specified by fd.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TSTATECHNG]	The transport provider is undergoing a state change.
(TC)/CEDDI	A system amony has accurated during execution of this

[TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

t_open(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_getstate* function returns the current state on successful completion and -1 on failure, and *t_errno* is set to indicate the error. The current state may be one of the following:

Т	UNBND	unbound

T_IDLE idle

- T_OUTCON outgoing connection pending
- T_INCON incoming connection pending
- T_DATAXFER data transfer

T_OUTREL outgoing orderly release (waiting for an orderly release indication)

T_INREL incoming orderly release (waiting for an orderly release request)

If the provider is undergoing a state transition when $t_getstate$ is called, the function will fail.

t_listen - listen for a connect request

SYNOPSIS

#include <tiuser.h>
int t_listen(fd, call)
int fd;
struct t_call *call;

DESCRIPTION

This function listens for a connect request from a calling transport user. Fd identifies the local transport endpoint where connect indications arrive, and on return, *call* contains information describing the connect indication. *Call* points to a *t_call* structure which contains the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;

Netbuf is described in *intro*(3). In *call, addr* returns the protocol address of the calling transport user; *opt* returns protocol-specific parameters associated with the connect request; *udata* returns any user data sent by the caller on the connect request; and *sequence* is a number that uniquely identifies the returned connect indication. The value of *sequence* enables the user to listen for multiple connect indications before responding to any of them.

Since this function returns values for the *addr*, *opt*, and *udata* fields of *call*, the *maxlen* [see *netbuf* in *intro*(3)] field of each must be set before issuing the t_listen to indicate the maximum size of the buffer for each.

By default, t_listen executes in synchronous mode and waits for a connect indication to arrive before returning to the user. However, if O_NDELAY is set (via t_open or fcntl), t_listen executes asynchronously, reducing to a poll for existing connect indications. If none are available, it returns -1 and sets t_errno to TNODATA.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TBUFOVFLW] The number of bytes allocated for an incoming argument is not sufficient to store the value of that argument. The provider's state, as seen by the user, changes to T_INCON, and the connect indication information to be returned in *call* is discarded.
- [TNODATA] O_NDELAY was set, but no connect indications had been queued.
- [TLOOK] An asynchronous event has occurred on this transport endpoint and requires immediate attention.

[TNOTSUPPORT]	This function is not supported by the underlying tran- sport provider.
[TSYSERR]	A system error has occurred during execution of this function.

CAVEATS

If a user issues t_listen in synchronous mode on a transport endpoint that was not bound for listening (i.e., *qlen* was zero on t_bind), the call will wait forever because no connect indications will arrive on that endpoint.

SEE ALSO

intro(3), t_accept(3N), t_bind(3N), t_connect(3N), t_open(3N), t_rcvconnect(3N).

Network Programmer's Guide.

DIAGNOSTICS

The *t_listen* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_look – look at the current event on a transport endpoint

SYNOPSIS

#include <tiuser.h>

int t_look(fd)
int fd;

DESCRIPTION

This function returns the current event on the transport endpoint specified by fd. This function enables a transport provider to notify a transport user of an asynchronous event when the user is issuing functions in synchronous mode. Certain events require immediate notification of the user and are indicated by a specific error, TLOOK, on the current or next function to be executed.

This function also enables a transport user to poll a transport endpoint periodically for asynchronous events.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

t_open(3N).

Network Programmer's Guide.

DIAGNOSTICS

Upon success, t_look returns a value that indicates which of the allowable events has occurred, or returns zero if no event exists. One of the following events is returned:

T_LISTEN	connection indication received
T_CONNECT	connect confirmation received
T_DATA	normal data received
T_EXDATA	expedited data received
T_DISCONNECT	disconnect received
T_ERROR	fatal error indication
T_UDERR	datagram error indication
T_ORDREL	orderly release indication

On failure, -1 is returned, and *t_errno* is set to indicate the error.

t_open - establish a transport endpoint

SYNOPSIS

#include <tiuser.h>

int t_open(path, oflag, info)
char *path;
int oflag;
struct t_info *info;

DESCRIPTION

The *t_open* function must be called as the first step in the initialization of a transport endpoint. This function establishes a transport endpoint by opening a UNIX system file that identifies a particular transport provider (i.e., transport protocol) and returning a file descriptor that identifies that endpoint. For example, opening the file /*dev/iso_cots* identifies an OSI connection-oriented transport layer protocol as the transport provider.

Path points to the path name of the file to open, and *oflag* identifies any open flags [as in *open*(2)]. *t_open* returns a file descriptor that will be used by all subsequent functions to identify the particular local transport endpoint.

This function also returns various default characteristics of the underlying transport protocol by setting fields in the t_info structure. This argument points to a t_info which contains the following members:

*/
:*/

The values of the fields have the following meanings:

- addr A value greater than or equal to zero indicates the maximum size of a transport protocol address; a value of -1 specifies that there is no limit on the address size; and a value of -2 specifies that the transport provider does not provide user access to transport protocol addresses.
- options A value greater than or equal to zero indicates the maximum number of bytes of protocol-specific options supported by the provider; a value of -1 specifies that there is no limit on the option size; and a value of -2 specifies that the transport provider does not support user-settable options.

- tsdu A value greater than zero specifies the maximum size of a transport service data unit (TSDU); a value of zero specifies that the transport provider does not support the concept of TSDU, although it does support the sending of a data stream with no logical boundaries preserved across a connection; a value of -1 specifies that there is no limit on the size of a TSDU; and a value of -2 specifies that the transfer of normal data is not supported by the transport provider.
- etsdu A value greater than zero specifies the maximum size of an expedited transport service data unit (ETSDU); a value of zero specifies that the transport provider does not support the concept of ETSDU, although it does support the sending of an expedited data stream with no logical boundaries preserved across a connection; a value of -1 specifies that there is no limit on the size of an ETSDU; and a value of -2 specifies that the transfer of expedited data is not supported by the transport provider.
- *connect* A value greater than or equal to zero specifies the maximum amount of data that may be associated with connection establishment functions; a value of -1 specifies that there is no limit on the amount of data sent during connection establishment; and a value of -2 specifies that the transport provider does not allow data to be sent with connection establishment functions.
- discon A value greater than or equal to zero specifies the maximum amount of data that may be associated with the *t_snddis* and *t_rcvdis* functions; a value of -1 specifies that there is no limit on the amount of data sent with these abortive release functions; and a value of -2 specifies that the transport provider does not allow data to be sent with the abortive release functions.
- *servtype* This field specifies the service type supported by the transport provider, as described below.

If a transport user is concerned with protocol independence, the above sizes may be accessed to determine how large the buffers must be to hold each piece of information. Alternatively, the t_alloc function may be used to allocate these buffers. An error will result if a transport user exceeds the allowed data size on any function.

The *servtype* field of *info* may specify one of the following values on return:

- T_COTS The transport provider supports a connection-mode service but does not support the optional orderly release facility.
- T_COTS_ORD The transport provider supports a connection-mode service with the optional orderly release facility.
- T_CLTS The transport provider supports a connectionless-mode service. For this service type, *t_open* will return -2 for *etsdu*, *connect*, and *discon*.

- 2 -

T_OPEN(3N)

A single transport endpoint may support only one of the above services at one time.

If *info* is set to ULL by the transport user, no protocol information is returned by t_open .

On failure, *t_errno* may be set to the following:

[TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

open(2). Network Programmer's Guide.

DIAGNOSTICS

The *t_open* function returns a valid file descriptor on success and -1 on failure, and *t_errno* is set to indicate the error.

t_optmgmt – manage options for a transport endpoint

SYNOPSIS

#include <tiuser.h>
int t_optmgmt(fd, req, ret)
int fd;
struct t_optmgmt *req;
struct t_optmgmt *ret;

DESCRIPTION

The *t_optmgmt* function enables a transport user to retrieve, verify, or negotiate protocol options with the transport provider. *Fd* identifies a bound transport endpoint.

The *req* and *ret* arguments point to a *t_optmgmt* structure containing the following members:

struct netbuf opt; long flags;

The *opt* field identifies protocol options, and the *flags* field is used to specify the action to take with those options.

The options are represented by a *netbuf* [see *intro*(3); also for *len*, *buf*, and *maxlen*] structure in a manner similar to the address in *t_bind*. *Req* is used to request a specific action of the provider and to send options to the provider. Len specifies the number of bytes in the options, *buf* points to the options buffer, and *maxlen* has no meaning for the *req* argument. The transport provider may return options and flag values to the user through *ret*. For *ret*, *maxlen* specifies the maximum size of the options buffer and *buf* points to the buffer where the options are to be placed. On return, *len* specifies the number of bytes of options returned. *Maxlen* has no meaning for the *req* argument, but must be set in the *ret* argument to specify the maximum number of bytes the options buffer can hold. The actual structure and content of the options is imposed by the transport provider.

The *flags* field of *reg* can specify one of the following actions:

- T_NEGOTIATE This action enables the user to negotiate the values of the options specified in *req* with the transport provider. The provider will evaluate the requested options and negotiate the values, returning the negotiated values through *ret*.
- T_CHECK This action enables the user to verify whether the options specified in *req* are supported by the transport provider. On return, the *flags* field of *ret* will have either T_SUCCESS or T_FAILURE set to indicate to the user whether the options are supported. These flags are only meaningful for the T_CHECK request.

T_DEFAULT This action enables a user to retrieve the default options supported by the transport provider into the *opt* field of *ret*. In *req*, the *len* field of *opt* must be zero, and the *buf* field may be NULL.

If issued as part of the connectionless-mode service, $t_optmgmt$ may block due to flow control constraints. The function will not complete until the transport provider has processed all previously sent data units.

On failure, *t_errno* may be set to one of the following:

function.

[TBADF]	The specified file descriptor does not refer to a tran- sport endpoint.
[TOUTSTATE]	The function was issued in the wrong sequence.
[TACCES]	The user does not have permission to negotiate the specified options.
[TBADOPT]	The specified protocol options were in an incorrect format or contained illegal information.
[TBADFLAG]	An invalid flag was specified.
[TBUFOVFLW]	The number of bytes allowed for an incoming argument is not sufficient to store the value of that argument. The information to be returned in <i>ret</i> will be discarded.
[TSYSERR]	A system error has occurred during execution of this

SEE ALSO

intro(3), t_getinfo(3N), t_open(3N). Network Programmer's Guide.

DIAGNOSTICS

The $t_optmgmt$ function returns 0 on success and -1 on failure, and t_errno is set to indicate the error.

t_rcv - receive data or expedited data sent over a connection

SYNOPSIS

int t_rcv(fd, buf, nbytes, flags)
int fd;
char *buf;
unsigned nbytes;
int *flags;

DESCRIPTION

This function receives either normal or expedited data. Fd identifies the local transport endpoint through which data will arrive; *buf* points to a receive buffer where user data will be placed; and *nbytes* specifies the size of the receive buffer. *Flags* may be set on return from t_rcv and specifies optional flags as described below.

By default, *t_rcv* operates in synchronous mode and will wait for data to arrive if none is currently available. However, if O_NDELAY is set (via *t_open* or *fcntl*), *t_rcv* will execute in asynchronous mode and will fail if no data is available. (See TNODATA below.)

On return from the call, if T_MORE is set in *flags*, this indicates that there is more data and the current transport service data unit (TSDU) or expedited transport service data unit (ETSDU) must be received in multiple t_rcv calls. Each t_rcv with the T_MORE flag set indicates that another t_rcv must follow immediately to get more data for the current TSDU. The end of the TSDU is identified by the return of a t_rcv call with the T_MORE flag not set. If the transport provider does not support the concept of a TSDU as indicated in the *info* argument on return from t_open or $t_getinfo$, the T_MORE flag is not meaningful and should be ignored.

On return, the data returned is expedited data if T_EXPEDITED is set in *flags*. If the number of bytes of expedited data exceeds *nbytes*, t_rcv will set T_EXPEDITED and T_MORE on return from the initial call. Subsequent calls to retrieve the remaining ETSDU will not have T_EXPEDITED set on return. The end of the ETSDU is identified by the return of a t_rcv call with the T_MORE flag not set.

If expedited data arrives after part of a TSDU has been retrieved, receipt of the remainder of the TSDU will be suspended until the ETSDU has been processed. Only after the full ETSDU has been retrieved (T_MORE not set) will the remainder of the TSDU be available to the user.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TNODATA] O_NDELAY was set, but no data is currently available from the transport provider.
- [TLOOK] An asynchronous event has occurred on this transport endpoint and requires immediate attention.

[TNOTSUPPORT]	This function is not supported by the underlying tran- sport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

t_open(3N), t_snd(3N). Network Programmer's Guide.

DIAGNOSTICS

On successful completion, t_rcv returns the number of bytes received, and it returns -1 on failure, and t_errno is set to indicate the error.

t_rcvconnect - receive the confirmation from a connect request

SYNOPSIS

#include <tiuser.h>
int t_rcvconnect(fd, call)
int fd;
struct t_call *call;

DESCRIPTION

This function enables a calling transport user to determine the status of a previously sent connect request and is used in conjunction with $t_connect$ to establish a connection in asynchronous mode. The connection will be established on successful completion of this function.

Fd identifies the local transport endpoint where communication will be established, and *call* contains information associated with the newly established connection. *Call* points to a *t_call* structure which contains the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;

Netbuf is described in *intro*(3). In *call*, *addr* returns the protocol address associated with the responding transport endpoint, *opt* presents any protocol-specific information associated with the connection, *udata* points to optional user data that may be returned by the destination transport user during connection establishment, and *sequence* has no meaning for this function.

The *maxlen* [see *netbuf* in *intro*(3)] field of each argument must be set before issuing this function to indicate the maximum size of the buffer for each. However, *call* may be NULL, in which case no information is given to the user on return from $t_rcvconnect$. By default, $t_rcvconnect$ executes in synchronous mode and waits for the connection to be established before returning. On return, the *addr*, *opt*, and *udata* fields reflect values associated with the connection.

If O_NDELAY is set (via *t_open* or *fcntl*), *t_rcvconnect* executes in asynchronous mode and reduces to a poll for existing connect confirmations. If none are available, *t_rcvconnect* fails and returns immediately without waiting for the connection to be established. (See TNODATA below.) *t_rcvconnect* must be re-issued at a later time to complete the connection establishment phase and retrieve the information returned in *call*.

On failure, *t_errno* may be set to one of the following:

[TBADF] The specified file descriptor does not refer to a transport endpoint.

[TBUFOVFLW] The number of bytes allocated for an incoming argument is not sufficient to store the value of that argument and the connect information to be returned in *call* will be discarded. The provider's state, as seen by the user, will be changed to DATAXFER.

- [TNODATA] O_NDELAY was set, but a connect confirmation has not yet arrived.
- [TLOOK] An asynchronous event has occurred on this transport connection and requires immediate attention.
- [TNOTSUPPORT] This function is not supported by the underlying transport provider.
- [TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_accept(3N), t_bind(3N), t_connect(3N), t_listen(3N), t_open(3N).

Network Programmer's Guide.

DIAGNOSTICS

 $t_rcvconnect$ returns 0 on success and -1 on failure, and t_errno is set to indicate the error.

t_rcvdis - retrieve information from disconnect

SYNOPSIS

#include <tiuser.h>
t_rcvdis(fd, discon)
int fd;
struct t_discon *discon;

DESCRIPTION

This function is used to identify the cause of a disconnect, and to retrieve any user data sent with the disconnect. Fd identifies the local transport endpoint where the connection existed, and *discon* points to a t_discon structure containing the following members:

struct netbuf udata; int reason; int sequence;

Netbuf is described in *intro*(3). Reason specifies the reason for the disconnect through a protocol-dependent reason code, *udata* identifies any user data that was sent with the disconnect, and *sequence* may identify an outstanding connect indication with which the disconnect is associated. Sequence is only meaningful when t_rcvdis is issued by a passive transport user who has executed one or more t_listen functions and is processing the resulting connect indications. If a disconnect indication occurs, *sequence* can be used to identify which of the outstanding connect indications is associated with the disconnect.

If a user does not care if there is incoming data and does not need to know the value of *reason* or *sequence*, *discon* may be NULL and any user data associated with the disconnect will be discarded. However, if a user has retrieved more than one outstanding connect indication (via t_listen) and *discon* is NULL, the user will be unable to identify with which connect indication the disconnect is associated.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a tran-	
	sport endpoint.	

- [TNODIS] No disconnect indication currently exists on the specified transport endpoint.
- [TBUFOVFLW] The number of bytes allocated for incoming data is not sufficient to store the data. The provider's state, as seen by the user, will change to T_IDLE, and the disconnect indication information to be returned in *discon* will be discarded.
- [TNOTSUPPORT] This function is not supported by the underlying transport provider.
- [TSYSERR] A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_connect(3N), t_listen(3N), t_open(3N), t_snddis(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_rcvdis* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_rcvrel - acknowledge receipt of an orderly release indication

SYNOPSIS

#include <tiuser.h>

t_rcvrel(fd) int fd;

DESCRIPTION

This function is used to acknowledge receipt of an orderly release indication. *Fd* identifies the local transport endpoint where the connection exists. After receipt of this indication, the user may not attempt to receive more data because such an attempt will block forever. However, the user may continue to send data over the connection if *t_sndrel* has not been issued by the user.

This function is an optional service of the transport provider, and is only supported if the transport provider returned service type T_COTS_ORD on t_open or $t_getinfo$.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a tran- sport endpoint.
[TNOREL]	No orderly release indication currently exists on the specified transport endpoint.
[TLOOK]	An asynchronous event has occurred on this transport endpoint and requires immediate attention.
[TNOTSUPPORT]	This function is not supported by the underlying tran- sport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

t_open(3N), t_sndrel(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_rcvrel* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_rcvudata - receive a data unit

SYNOPSIS

#include <tiuser.h>

int t_rcvudata(fd, unitdata, flags)
int fd;
struct t_unitdata *unitdata;
int *flags;

DESCRIPTION

This function is used in connectionless mode to receive a data unit from another transport user. Fd identifies the local transport endpoint through which data will be received, *unitdata* holds information associated with the received data unit, and *flags* is set on return to indicate that the complete data unit was not received. *Unitdata* points to a *t_unitdata* structure containing the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata;

The *maxlen* [see *netbufin intro*(3)] field of *addr*, *opt*, and *udata* must be set before issuing this function to indicate the maximum size of the buffer for each.

On return from this call, *addr* specifies the protocol address of the sending user, *opt* identifies protocol-specific options that were associated with this data unit, and *udata* specifies the user data that was received.

By default, *t_rcvudata* operates in synchronous mode and will wait for a data unit to arrive if none is currently available. However, if O_NDELAY is set (via *t_open* or *fcntl*), *t_rcvudata* will execute in asynchronous mode and will fail if no data units are available.

If the buffer defined in the *udata* field of *unitdata* is not large enough to hold the current data unit, the buffer will be filled and T_MORE will be set in *flags* on return to indicate that another $t_rcvudata$ should be issued to retrieve the rest of the data unit. Subsequent $t_rcvudata$ call(s) will return zero for the length of the address and options until the full data unit has been received.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TNODATA]	O_NDELAY was set, but no data units are currently available from the transport provider.
[TBUFOVFLW]	The number of bytes allocated for the incoming pro- tocol address or options is not sufficient to store the information. The unit data information to be returned

in unitdata will be discarded.

T_RCVUDATA(3N)	(Networking Support Utilities)	T_RCVUDATA(3N)

intro(3), t_rcvuderr(3N), t_sndudata(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_rcvudata* function returns 0 on successful completion and -1 on failure, and *t_errno* is set to indicate the error.

T_RCVUDERR(3N)

NAME

t_rcvuderr – receive a unit data error indication

SYNOPSIS

#include <tiuser.h>
int t_rcvuderr(fd, uderr)
int fd;
struct t_uderr *uderr;

DESCRIPTION

This function is used in connectionless mode to receive information concerning an error on a previously sent data unit, and should only be issued following a unit data error indication. It informs the transport user that a data unit with a specific destination address and protocol options produced an error. *Fd* identifies the local transport endpoint through which the error report will be received, and *uderr* points to a *t_uderr* structure containing the following members:

> struct netbuf addr; struct netbuf opt; long error;

Netbuf is described in *intro*(3). The *maxlen* [see *netbuf* in *intro*(3)] field of *addr* and *opt* must be set before issuing this function to indicate the maximum size of the buffer for each.

On return from this call, the *addr* structure specifies the destination protocol address of the erroneous data unit; the *opt* structure identifies protocol-specific options that were associated with the data unit; and *error* specifies a protocol-dependent error code.

If the user does not care to identify the data unit that produced an error, *uderr* may be set to NULL and $t_rcvuderr$ will simply clear the error indication without reporting any information to the user.

On failure, *t_errno* may be set to one of the following:

- [TBADF] The specified file descriptor does not refer to a transport endpoint.
- [TNOUDERR] No unit data error indication currently exists on the specified transport endpoint.
- [TBUFOVFLW] The number of bytes allocated for the incoming protocol address or options is not sufficient to store the information. The unit data error information to be returned in *uderr* will be discarded.
- [TNOTSUPPORT] This function is not supported by the underlying transport provider.
- [TSYSERR] A system error has occurred during execution of this function.

.

SEE ALSO

intro(3), t_rcvudata(3N), t_sndudata(3N). Network Programmer's Guide.

DIAGNOSTICS

The $t_rcvuderr$ function returns 0 on successful completion and -1 on failure, and *t_errno* is set to indicate the error.

t_snd - send data or expedited data over a connection

SYNOPSIS

#include <tiuser.h>
int t_snd(fd, buf, nbytes, flags)
int fd;
char *buf;
unsigned nbytes;
int flags;

DESCRIPTION

This function is used to send either normal or expedited data. *Fd* identifies the local transport endpoint over which data should be sent, *buf* points to the user data, *nbytes* specifies the number of bytes of user data to be sent, and *flags* specifies any optional flags described below.

By default, *t_snd* operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if O_NDELAY is set (via *t_open* or *fcntl*), *t_snd* will execute in asynchronous mode and will fail immediately if there are flow control restrictions.

On successful completion, *t_snd* returns the number of bytes accepted by the transport provider. Normally this will equal the number of bytes specified in *nbytes*. However, if O_NDELAY is set, it is possible that only part of the data will be accepted by the transport provider. In this case, *t_snd* will set T_MORE for the data that was sent (see below) and will return a value less than *nbytes*. If *nbytes* is zero, no data will be passed to the provider, and *t_snd* will return zero.

If T_EXPEDITED is set in *flags*, the data will be sent as expedited data and will be subject to the interpretations of the transport provider.

If T_MORE is set in *flags* or set as described above, an indication is sent to the transport provider that the transport service data unit (TSDU) (or expedited transport service data unit - ETSDU) is being sent through multiple *t_snd* calls. Each *t_snd* with the T_MORE flag set indicates that another *t_snd* will follow with more data for the current TSDU. The end of the TSDU (or ETSDU) is identified by a *t_snd* call with the T_MORE flag not set. Use of T_MORE enables a user to break up large logical data units without losing the boundaries of those units at the other end of the connection. The flag implies nothing about how the data is packaged for transfer below the transport interface. If the transport provider does not support the concept of a TSDU as indicated in the *info* argument on return from *t_open* or *t_getinfo*, the T_MORE flag is not meaningful and should be ignored.

The size of each TSDU or ETSDU must not exceed the limits of the transport provider as returned by *t_open* or *t_getinfo*. Failure to comply will result in protocol error EPROTO. (See TSYSERR below.)

If t_snd is issued from the T_IDLE state, the provider may silently discard the data. If t_snd is issued from any state other than T_DATAXFER or T_IDLE, the provider will generate an EPROTO error.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TFLOW]	O_NDELAY was set, but the flow control mechanism prevented the transport provider from accepting data at this time.
[TNOTSUPPORT]	This function is not supported by the underlying transport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

t_open(3N), t_rcv(3N). Network Programmer's Guide.

DIAGNOSTICS

On successful completion, t_snd returns the number of bytes accepted by the transport provider. It returns -1 on failure, and t_errno is set to indicate the error.

t_snddis - send user-initiated disconnect request

SYNOPSIS

#include <tiuser.h>
int t_snddis(fd, call)
int fd;
struct t_call *call;

DESCRIPTION

This function is used to initiate an abortive release on an already established connection or to reject a connect request. *Fd* identifies the local transport endpoint of the connection, and *call* specifies information associated with the abortive release. *Call* points to a t_call structure which contains the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata; int sequence;

Netbuf is described in *intro*(3). The values in *call* have different semantics, depending on the context of the call to t_snddis . When rejecting a connect request, *call* must be non-NULL and contain a valid value of *sequence* to uniquely identify the rejected connect indication to the transport provider. The *addr* and *opt* fields of *call* are ignored. In all other cases, *call* need only be used when data is being sent with the disconnect request. The *addr*, *opt*, and *sequence* fields of the t_call structure are ignored. If the user does not wish to send data to the remote user, the value of *call* may be NULL.

Udata specifies the user data to be sent to the remote user. The amount of user data must not exceed the limits supported by the transport provider as returned by t_open or $t_getinfo$. If the *len* field of *udata* is zero, no data will be sent to the remote user.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TOUTSTATE]	The function was issued in the wrong sequence. The transport provider's outgoing queue may be flushed, so data may be lost.
[TBADDATA]	The amount of user data specified was not within the bounds allowed by the transport provider. The trans- port provider's outgoing queue will be flushed, so data may be lost.
[TBADSEQ]	An invalid sequence number was specified, or a NULL call structure was specified when rejecting a connect request. The transport provider's outgoing queue will be flushed, so data may be lost.

intro(3), t_connect(3N), t_getinfo(3N), t_listen(3N), t_open(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_snddis* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_sndrel - initiate an orderly release

SYNOPSIS

#include <tiuser.h>

int t_sndrel(fd)
int fd;

DESCRIPTION

This function is used to initiate an orderly release of a transport connection and indicates to the transport provider that the transport user has no more data to send. *Fd* identifies the local transport endpoint where the connection exists. After issuing t_sndrel , the user may not send any more data over the connection. However, a user may continue to receive data if an orderly release indication has been received.

This function is an optional service of the transport provider and is only supported if the transport provider returned service type T_COTS_ORD on t_open or $t_getinfo$.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TFLOW]	O_NDELAY was set, but the flow control mechanism prevented the transport provider from accepting the function at this time.
[TNOTSUPPORT]	This function is not supported by the underlying transport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

t_open(3N), t_rcvrel(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_sndrel* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

t_sndudata – send a data unit

SYNOPSIS

#include <tiuser.h>
int t_sndudata(fd, unitdata)
int fd;
struct t_unitdata *unitdata;

DESCRIPTION

This function is used in connectionless mode to send a data unit to another transport user. *Fd* identifies the local transport endpoint through which data will be sent, and *unitdata* points to a $t_unitdata$ structure containing the following members:

struct netbuf addr; struct netbuf opt; struct netbuf udata;

Netbuf is described in *intro*(3). In *unitdata*, *addr* specifies the protocol address of the destination user, *opt* identifies protocol-specific options that the user wants associated with this request, and *udata* specifies the user data to be sent. The user may choose not to specify what protocol options are associated with the transfer by setting the *len* field of *opt* to zero. In this case, the provider may use default options.

If the *len* field of *udata* is zero, no data unit will be passed to the transport provider; *t_sndudata* will not send zero-length data units.

By default, *t_sndudata* operates in synchronous mode and may wait if flow control restrictions prevent the data from being accepted by the local transport provider at the time the call is made. However, if O_NDELAY is set (via *t_open* or *fcntl*), *t_sndudata* will execute in asynchronous mode and will fail under such conditions.

If *t_sndudata* is issued from an invalid state, or if the amount of data specified in *udata* exceeds the TSDU size as returned by *t_open* or *t_getinfo*, the provider will generate an EPROTO protocol error. (See TSYSERR below.)

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TFLOW]	O_NDELAY was set, but the flow control mechanism prevented the transport provider from accepting data at this time.
[TNOTSUPPORT]	This function is not supported by the underlying transport provider.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

intro(3), t_rcvudata(3N), t_rcvuderr(3N). Network Programmer's Guide.

DIAGNOSTICS

The *t_sndudata* function returns 0 on successful completion and -1 on failure, and *t_errno* is set to indicate the error.

t_sync – synchronize transport library

SYNOPSIS

#include <tiuser.h>

int t_sync(fd)
int fd;

DESCRIPTION

For the transport endpoint specified by fd, t_sync synchronizes the data structures managed by the transport library with information from the underlying transport provider. In doing so, it can convert a raw file descriptor [obtained via *open*(2), *dup*(2), or as a result of a *fork*(2) and *exec*(2)] to an initialized transport endpoint, assuming that file descriptor referenced a transport provider. This function also allows two cooperating processes to synchronize their interaction with a transport provider.

For example, if a process *forks* a new process and issues an *exec*, the new process must issue a t_sync to build the private library data structure associated with a transport endpoint and to synchronize the data structure with the relevant provider information.

It is important to remember that the transport provider treats all users of a transport endpoint as a single user. If multiple processes are using the same endpoint, they should coordinate their activities so as not to violate the state of the provider. t_sync returns the current state of the provider to the user, thereby enabling the user to verify the state before taking further action. This coordination is only valid among cooperating processes; it is possible that a process or an incoming event could change the provider's state *after* a t_sync is issued.

If the provider is undergoing a state transition when t_sync is called, the function will fail.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor is a valid open file descrip- tor but does not refer to a transport endpoint.
[TSTATECHNG]	The transport provider is undergoing a state change.
[TSYSERR]	A system error has occurred during execution of this function.

SEE ALSO

dup(2), exec(2), fork(2), open(2). Network Programmer's Guide.

DIAGNOSTICS

The *t_sync* function returns the state of the transport provider on successful completion and -1 on failure, and *t_errno* is set to indicate the error. The state returned may be one of the following:

T_UNBND	unbound
T_IDLE	idle

- 1 -

T_SYNC(3N))
------------	---

T_OUTCON	outgoing connection pending
T_INCON	incoming connection pending
T_DATAXFER	data transfer
T_OUTREL	outgoing orderly release (waiting for an orderly release indication)
T_INREL	incoming orderly release (waiting for an orderly release request).

T_UNBIND(3N)

NAME

t_unbind - disable a transport endpoint

SYNOPSIS

#include <tiuser.h>

int t_unbind(fd)
int fd;

DESCRIPTION

The *t_unbind* function disables the transport endpoint specified by fd, which was previously bound by *t_bind* (3N). On completion of this call, no further data or events destined for this transport endpoint will be accepted by the transport provider.

On failure, *t_errno* may be set to one of the following:

[TBADF]	The specified file descriptor does not refer to a transport endpoint.
[TOUTSTATE]	The function was issued in the wrong sequence.
[TLOOK]	An asynchronous event has occurred on this transport end- point.
[TSYSERR]	A system error has occurred during execution of this func- tion.

SEE ALSO

t_bind(3N).

Network Programmer's Guide.

DIAGNOSTICS

The *t_unbind* function returns 0 on success and -1 on failure, and *t_errno* is set to indicate the error.

assert - verify program assertion

SYNOPSIS

#include <assert.h>

assert (expression) int expression;

DESCRIPTION

This macro is useful for putting diagnostics into programs. When it is executed, if *expression* is false (zero), *assert* prints

"Assertion failed: expression, file xyz, line nnn"

on the standard error output and aborts. In the error message, xyz is the name of the source file and nnn the source line number of the *assert* statement.

Compiling with the preprocessor option **-DNDEBUG** [see *cpp*(1)], or with the preprocessor control statement **"#define** NDEBUG" ahead of the **"#include** <assert.h>" statement, will stop assertions from being compiled into the program.

SEE ALSO

cpp(1), abort(3C).

CAVEAT

Since *assert* is implemented as a macro, the *expression* may not contain any string literals.

crypt - password and file encryption functions SYNOPSIS cc [flag ...] file ... -lcrypt char *crypt (key, salt) char *key, *salt; void setkey (key) char *key; void encrypt (block, flag) char *block; int flag; char *des_crypt (key, salt) char *key, *salt; void des_setkey (key) char *key; void des_encrypt (block, flag) char *block; int flag; int run_setkey (p, key) int p[2]; char *key; int run_crypt (offset, buffer, count, p) long offset; char *buffer; unsigned int count; int p[2]; int crypt_close(p) int p[2];

DESCRIPTION

des_crypt is the password encryption function. It is based on a one-way hashing encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search.

Key is a user's typed password. Salt is a two-character string chosen from the set [a-zA-Z0-9./]; this string is used to perturb the hashing algorithm in one of 4096 different ways, after which the password is used as the key to encrypt repeatedly a constant string. The returned value points to the encrypted password. The first two characters are the salt itself.

The des_setkey and des_encrypt entries provide (rather primitive) access to the actual hashing algorithm. The argument of des_setkey is a character array of length 64 containing only the characters with numerical value 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is set into the machine. This is the key that will be used with the hashing algorithm to encrypt the string *block* with the function *des_encrypt*.

The argument to the *des_encrypt* entry is a character array of length 64 containing only the characters with numerical value 0 and 1. The argument array is modified in place to a similar array representing the bits of the argument after having been subjected to the hashing algorithm using the key set by *des_setkey*. If *edflag* is zero, the argument is encrypted; if nonzero, it is decrypted.

Note that decryption is not provided in the international version of crypt(3X). The international version is part of the *C* Programming Language Utilities, and the domestic version is part of the Security Administration Utilities. If decryption is attempted with the international version of $des_encrypt$, an error message is printed.

Crypt, setkey, and *encrypt* are front-end routines that invoke *des_crypt, des_setkey*, and *des_encrypt* respectively.

The routines run_setkey and run_crypt are designed for use by applications that need cryptographic capabilities [such as ed(1) and vi(1)] that must be compatible with the crypt(1) user-level utility. Run_setkey establishes a two-way pipe connection with crypt(1), using key as the password argument. Run_crypt takes a block of characters and transforms the cleartext or ciphertext into their ciphertext or cleartext using crypt(1). Offset is the relative byte position from the beginning of the file that the block of text provided in block is coming from. Count is the number of characters in block, and connection is an array containing indices to a table of input and output file streams. When encryption is finished, $crypt_close$ is used to terminate the connection with crypt(1).

Run_setkey returns -1 if a connection with crypt(1) cannot be established. This will occur on international versions of UNIX where crypt(1) is not available. If a null key is passed to run_setkey , 0 is returned. Otherwise, 1 is returned. *Run_crypt* returns -1 if it cannot write output or read input from the pipe attached to crypt. Otherwise it returns 0.

DIAGNOSTICS

In the international version of crypt(3X), a flag argument of 1 to $des_encrypt$ is not accepted, and an error message is printed.

SEE ALSO

getpass(3C), passwd(4).

crypt(1), login(1), passwd(1) in the User's Reference Manual.

CAVEAT

The return value in *crypt* points to static data that are overwritten by each call.

curses - terminal screen handling and optimization package

SYNOPSIS

The curses manual page is organized as follows:

In SYNOPSIS

- compiling information
- summary of parameters used by curses routines
- alphabetical list of curses routines, showing their parameters
- In DESCRIPTION:
 - An overview of how curses routines should be used
- In ROUTINES, descriptions of *curses* routines are grouped under the appropriate topics:
 - Overall Screen Manipulation
 - Window and Pad Manipulation
 - Output
 - Input
 - Output Options Setting
 - Input Options Setting
 - Environment Queries
 - Soft Labels
 - Low-Level Curses Access
 - Terminfo-Level Manipulations
 - Termcap Emulation
 - Miscellaneous
 - Use of curscr

Then come sections on:

- ATTRIBUTES
- FUNCTION CALLS
- LINE GRAPHICS

cc [flag ...] file ... -lcurses [library ...]

The parameters in the following list are not global variables, but rather this is a summary of the parameters used by the *curses* library routines. All routines return the **int** values **ERR** or **OK** unless otherwise noted. Routines that return pointers always return **NULL** on error. (**ERR**, **OK**, and **NULL** are all defined in **<curses.h**>.) Routines that return integers are not listed in the parameter list below.

DESCRIPTION

The *curses* routines give the user a terminal-independent method of updating screens with reasonable optimization.

In order to initialize the routines, the routine **initscr()** or **newterm()** must be called before any of the other routines that deal with windows and screens are used. (Three exceptions are noted where they apply.) The routine **endwin()** must be called before exiting. To get character-at-a-time input without echoing, (most interactive, screen- oriented programs want this) after calling **initscr()** you should call **"cbreak()**; **noecho()**;" Most programs would additionally call **"nonl()**; **intrflush (stdscr, FALSE)**; **keypad(stdscr, TRUE)**;".

Before a *curses* program is run, a terminal's tab stops should be set and its initialization strings, if defined, must be output. This can be done by executing the **tput init** command after the shell environment variable **TERM** has been exported. For further details, see *profile*(4), *tput*(1), and the "Tabs and Initialization" subsection of *terminfo*(4).

The *curses* library contains routines that manipulate data structures called *windows* that can be thought of as two-dimensional arrays of characters representing all or part of a terminal screen. A default window called **stdscr** is supplied, which is the size of the terminal screen. Others may be created with **newwin()**. Windows are referred to by variables declared as **WIN-DOW** *; the type **WINDOW** is defined in <**curses.h**> to be a C structure. These data structures are manipulated with routines described below, among which the most basic are **move()** and **addch()**. (More general versions of these routines are included with names beginning with **w**, allowing you to specify a window. The routines not beginning with **w** usually affect **stdscr**.) Then **refresh()** is called, telling the routines to make the user's terminal screen look like **stdscr**. The characters in a window are actually of type **chtype**, so that other information about the character may also be stored with each character.

Special windows called *pads* may also be manipulated. These are windows which are not constrained to the size of the screen and whose contents need not be displayed completely. See the description of **newpad()** under "Window and Pad Manipulation" for more information.

In addition to drawing characters on the screen, video attributes may be included which cause the characters to show up in modes such as underlined or in reverse video on terminals that support such display enhancements. Line drawing characters may be specified to be output. On input, *curses* is also able to translate arrow and function keys that transmit escape sequences into single values. The video attributes, line-drawing characters, and input values use names, defined in <**curses.h**>, such as **A_REVERSE**, **ACS_HLINE**, and **KEY_LEFT**.

The *curses* function also defines the **WINDOW** * variable, **curscr**, which is used only for certain low-level operations like clearing and redrawing a garbaged screen. **curscr** can be used in only a few routines. If the window argument to **clearok()** is **curscr**, the next call to **wrefresh()** with any window will cause the screen to be cleared and repainted from scratch. If the window argument to **wrefresh()** is **curscr**, the screen is immediately cleared and repainted from scratch. This is how most programs would implement a "repaint-screen" function. More information on using **curscr** is provided where its use is appropriate.

The environment variables **LINES** and **COLUMNS** may be set to override **terminfo**'s idea of how large a screen is. These may be used in an AT&T Teletype 5620 layer, for example, where the size of a screen is changeable.

If the environment variable **TERMINFO** is defined, any program using *curses* will check for a local terminal definition before checking in the standard place. For example, if the environment variable **TERM** is set to **att4425**, then the compiled terminal definition is found in */usr/lib/terminfo/a/att4425*. (The **a** is copied from the first letter of **att4425** to avoid creation of huge directories.) However, if **TERMINFO** is set to *\$HOME/myterms, curses* will first check *\$HOME/myterms/a/att4425*, and, if that fails, will then check */usr/lib/terminfo/a/att4425*. This is useful for developing experimental definitions or when write permission on */usr/lib/terminfo/* is not available.

The integer variables LINES and COLS are defined in <curses.h> and will be filled in by initscr() with the size of the screen. (For more information, see the subsection "Terminfo-Level Manipulations".) The constants TRUE and FALSE have the values 1 and 0, respectively. The constants ERR and OK are returned by routines to indicate whether the routine successfully completed. These constants are also defined in <curses.h>.

ROUTINES

Many of the following routines have two or more versions. The routines prefixed with \mathbf{w} require a *window* argument. The routines prefixed with \mathbf{p} require a *pad* argument. Those without a prefix generally use **stdscr**.

The routines prefixed with **mv** require y and x coordinates to move to before performing the appropriate action. The **mv()** routines imply a call to **move()** before the call to the other routine. The window argument is always specified before the coordinates; y always refers to the row (of the window), and x always refers to the column. The upper left corner is always (0,0), not (1,1). The routines prefixed with **mvw** take both a *window* argument and y and x coordinates.

In each case, *win* is the window affected and *pad* is the pad affected. (**win** and **pad** are always of type **WINDOW** *.) Option-setting routines require a Boolean flag *bf* with the value **TRUE** or **FALSE**. (*bf* is always of type **bool**.) The types **WINDOW**, **bool**, and **chtype** are defined in **<curses.h**>. See the SYNOPSIS for a summary of what types all variables are.

All routines return either the integer **ERR** or the integer **OK**, unless otherwise noted. Routines that return pointers always return **NULL** on error.

Overall Screen Manipulation

WINDOW *initscr() The first routine called should almost always be initscr(). [The exceptions are slk_init(), filter(), and ripoffline().] This will determine the terminal type and initialize all curses data structures. initscr() also arranges that the first call to refresh() will clear the screen. If errors occur, initscr() will write an appropriate error message to standard error and exit; otherwise, a pointer to stdscr is returned. If the program wants an indication of error conditions, **newterm()** should be used instead of **initscr()**. **initscr()** should only be called once per application.

endwin() A program should always call endwin() before exiting or escaping from *curses* mode temporarily, to do a shell escape or *system*(3S) call, for example. This routine will restore *tty*(7) modes, move the cursor to the lower left corner of the screen and reset the terminal into the proper non-visual mode. To resume after a temporary escape, call wrefresh() or doupdate().

isendwin() Returns **TRUE** if **endwin()** has been called without any subsequent calls to **wrefresh()**.

SCREEN *newterm(type, outfd, infd)

A program that outputs to more than one terminal must use **newterm()** for each terminal instead of initscr(). A program that wants an indication of error conditions, so that it may continue to run in a lineoriented mode if the terminal cannot support a screen-oriented program, must also use this routine. **newterm()** should be called once for each terminal. It returns a variable of type SCREEN* that should be saved as a reference to that terminal. The arguments are the *type* of the terminal to be used in place of the environment variable TERM; outfd, a stdio(3S) file pointer for output to the terminal; and *infd*, another file pointer for input from the terminal. When it is done running, the program must also call endwin() for each terminal being used. If newterm() is called more than once for the same terminal, the first terminal referred to must be the last one for which endwin() is called.

SCREEN *set_term(new)

This routine is used to switch between different terminals. The screen reference *new* becomes the new current terminal. A pointer to the screen of the previous terminal is returned by the routine. This is the only routine which manipulates **SCREEN** pointers; all other routines affect only the current terminal.

Window and Pad Manipulation

refresh()

wrefresh (win)

These routines [or prefresh(), pnoutrefresh(), wnoutrefresh(), or doupdate()] must be called to write output to the terminal, as most other routines merely manipulate data structures. wrefresh() copies the named window to the physical terminal screen, taking into account what is already there in order to minimize the amount of information that's sent to the terminal (called optimization). refresh() does the same thing, except it uses stdscr as a default window. Unless **leaveok()** has been enabled, the physical cursor of the terminal is left at the location of the window's cursor. The number of characters output to the terminal is returned.

Note that **refresh()** is a macro.

wnoutrefresh(win)
doupdate()
These two routines allow multiple updates to the
physical terminal screen with more efficiency than
wrefresh() alone. How this is accomplished is
described in the next paragraph.

The *curses* function keeps two data structures representing the terminal screen: a physical terminal screen, describing what is actually on the screen, and a virtual terminal screen, describing what the programmer wants to have on the screen. wrefresh() works by first calling wnoutrefresh(), which copies the named window to the virtual screen, and then by calling **doupdate()**, which compares the virtual screen to the physical screen and does the actual update. If the programmer wishes to output several windows at once, a series of calls to wrefresh() will result in alternating calls to **wnoutrefresh()** and **doupdate()**, causing several bursts of output to the screen. By first calling wnoutrefresh() for each window, it is then possible to call **doupdate()** once, resulting in only one burst of output, with probably fewer total characters transmitted and certainly less processor time used.

WINDOW ***newwin**(nlines, ncols, begin_y, begin_x)

Create and return a pointer to a new window with the given number of lines (or rows), *nlines*, and columns, *ncols*. The upper left corner of the window is at line *begin_y*, column *begin_x*. If either *nlines* or *ncols* is **0**, they will be set to the value of **lines**-*begin_y* and **cols**-*begin_x*. A new full-screen window is created by calling **newwin(0,0,0,0)**.

mvwin(win, y, x) Move the window so that the upper left corner will be at position (y, x). If the move would cause the window to be off the screen, it is an error and the window is not moved.

WINDOW ***subwin**(orig, nlines, ncols, begin_y, begin_x)

Create and return a pointer to a new window with the given number of lines (or rows), *nlines*, and columns, *ncols*. The window is at position (*begin_y*, *begin_x*) on the screen. (This position is relative to the screen, and not to the window *orig*.) The window is made in the middle of the window *orig*, so that

CURSES(3X)

changes made to one window will affect both windows. When using this routine, often it will be necessary to call **touchwin()** or **touchline()** on *orig* before calling **wrefresh()**.

delwin(win) Delete the named window, freeing up all memory associated with it. In the case of overlapping windows, subwindows should be deleted before the main window.

WINDOW ***newpad**(nlines, ncols)

Create and return a pointer to a new pad data structure with the given number of lines (or rows), *nlines*, and columns, *ncols*. A pad is a window that is not restricted by the screen size and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (e.g., from scrolling or echoing of input) do not occur. It is not legal to call **wrefresh()** with a pad as an argument; the routines **prefresh()** or **pnoutrefresh()** should be called instead. Note that these routines require additional parameters to specify the part of the pad to be displayed and the location on the screen to be used for display.

WINDOW ***subpad**(orig, nlines, ncols, begin_y, begin_x)

Create and return a pointer to a subwindow within a pad with the given number of lines (or rows), *nlines*, and columns, *ncols*. Unlike **subwin**(), which uses screen coordinates, the window is at position (*begin_y*, *begin_x*) on the pad. The window is made in the middle of the window *orig*, so that changes made to one window will affect both windows. When using this routine, often it will be necessary to call **touchwin()** or **touchline()** on *orig* before calling **prefresh()**.

prefresh(pad, pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol)

pnoutrefresh(pad, pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol) These routines are analogous to wrefresh() and wnoutrefresh() except that pads, instead of windows, are involved. The additional parameters are needed to indicate what part of the pad and screen are involved. pminrow and pmincol specify the upper left corner, in the pad, of the rectangle to be displayed. sminrow, smincol, smaxrow, and smaxcol specify the edges, on the screen, of the rectangle to be displayed in. The lower right corner in the pad of the rectangle to be displayed is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

Output

These routines are used to "draw" text on windows.

addch(ch)

waddch(win, ch) mvaddch(y, x, ch) mvwaddch(win, y, x, ch)

The character ch is put into the window at the current cursor position of the window and the position of the window cursor is advanced. Its function is similar to that of *putchar* [see *putc*(3S)]. At the right margin, an automatic new-line is performed. At the bottom of the scrolling region, if **scrollok**() is enabled, the scrolling region will be scrolled up one line.

If *ch* is a tab, new-line, or backspace, the cursor will be moved appropriately within the window. A newline also does a **clrtoeol()** before moving. Tabs are considered to be at every eighth column. If *ch* is another control character, it will be drawn in the \hat{X} notation. [Calling **winch()** after adding a control character will not return the control character, but instead will return the representation of the control character.]

Video attributes can be combined with a character by or-ing them into the parameter. This will result in these attributes also being set. [The intent here is that text, including attributes, can be copied from one place to another using **inch()** and **addch()**.] See **standout()**, below.

Note that *ch* is actually of type **chtype**, not a character.

Note that **addch()**, **mvaddch()**, and **mvwaddch()**, are macros.

echochar(ch)
wechochar(win, ch)

pechochar(pad, ch)

These routines are functionally equivalent to a call to **addch**(ch) followed by a call to **refresh**(), a call to **waddch**(win, ch) followed by a call to **wrefresh**(win), or a call to **waddch**(pad, ch) followed by a call to **prefresh**(pad). The knowledge that only a single character is being output is taken into consideration and, for non-control characters, a considerable performance gain can be seen by using these routines

instead of their equivalents. In the case of **pecho-char()**, the last location of the pad on the screen is reused for the arguments to **prefresh()**.

Note that *ch* is actually of type **chtype**, not a character.

Note that echochar() is a macro.

addstr(str) waddstr(win, str) mvwaddstr(win, y, x, str) mvaddstr(y, x, str) The

 x, str) These routines write all the characters of the nullterminated character string *str* on the given window. This is equivalent to calling **waddch()** once for each character in the string.

Note that **addstr()**, **mvaddstr()**, and **mvwaddstr()** are macros.

attroff(attrs) wattroff(win, attrs) attron(attrs) wattron(win, attrs) attrset(attrs) wattrset(win, attrs) standend() wstandend(win) standout() wstandout(win)

These routines manipulate the current attributes of the named window. These attributes can be any combination of A_STANDOUT, A_REVERSE, A_BOLD, A_DIM, A_BLINK, A_UNDERLINE, and A_ALTCHARSET. These constants are defined in <curses.h> and can be combined with the C logical OR (1) operator.

The current attributes of a window are applied to all characters that are written into the window with **waddch()**. Attributes are a property of the character, and move with the character through any scrolling and insert/delete line/character operations. To the extent possible on the particular terminal, they will be displayed as the graphic rendition of the characters put on the screen.

attrset(attrs) sets the current attributes of the given window to attrs. attroff(attrs) turns off the named attributes without turning on or off any other attributes. attron(attrs) turns on the named attributes without affecting any others. standout() is the same as attron(A_STANDOUT). standend() is the same as attrset (0), that is, it turns off all attributes.

CURSES(3X)	(Terminal Information Utilities)	CURSES(3X)
	Note that <i>attrs</i> is actually of type cht acter. Note that attroff (), attron (), attrse	
	and standout() are macros.	t(), standenu(),
beep() flash()	These routines are used to signal th beep() will sound the audible alarm if possible, and if not, will flash th bell), if that is possible. flash() will and if that is not possible, will sound nal. If neither signal is possible, noth Nearly all terminals have an audible beep) but only some can flash the screen	on the terminal, e screen (visible flash the screen, the audible sig- ning will happen. e signal (bell or

clrtoeol() wclrtoeol(win)	The current line to the right of the curerased.	rsor, inclusive, is
	Note that clrtoeol() is a macro.	

CURSES(3X)

delay_output (ms)	Insert an <i>ms</i> millisecond pause in the output. It is not recommended that this routine be used extensively, because padding characters are used rather than a processor pause.
delch() wdelch(win) mvdelch(y, x)	
mvwdelcĥ (win, y, x)	The character under the cursor in the window is deleted. All characters to the right on the same line are moved to the left one position and the last character on the line is filled with a blank. The cursor position does not change [after moving to (y, x) , if specified]. (This does not imply use of the hardware "delete-character" feature.)
	Note that delch() , mvdelch() , and mvwdelch() are macros.
deleteln() wdeleteln(win)	The line under the cursor in the window is deleted. All lines below the current line are moved up one line. The bottom line of the window is cleared. The cursor position does not change. (This does not imply use of the hardware "delete-line" feature.)
	Note that deleteln() is a macro.
getyx (win, y, x)	The cursor position of the window is placed in the two integer variables y and x . This is implemented as a macro, so no "&" is necessary before the variables.
getbegyx(win, y, x) getmaxyx(win, y, x)	Like getyx() , these routines store the current beginning coordinates and size of the specified window.
	Note that getbegyx() and getmaxyx() are macros.
insch (ch) winsch (win, ch) mvwinsch (win, y, x,	ch)
mvinsch (y, x, ch)	The character <i>ch</i> is inserted before the character under the cursor. All characters to the right are moved one space to the right, possibly losing the rightmost char- acter of the line. The cursor position does not change (after moving to $[y, x)$, if specified]. (This does not imply use of the hardware "insert-character" feature.)
	Note that <i>ch</i> is actually of type chtype , not a character.
	Note that insch() , mvinsch() , and mvwinsch() are macros.

insertln()
winsertln(win)
A blank line is inserted above the current line and the
bottom line is lost. (This does not imply use of the
hardware "insert-line" feature.)
Note that insertln() is a macro.

move(y, x)

wmove(win, y, x)The cursor associated with the window is moved to
line (row) y, column x. This does not move the phy-
sical cursor of the terminal until refresh() is called.
The position specified is relative to the upper left
corner of the window, which is (0, 0).

Note that **move()** is a macro.

overlay(srcwin, dstwin)

overwrite(srcwin, dstwin)

These routines overlay *srcwin* on top of *dstwin*; that is, all text in *srcwin* is copied into *dstwin*. *scrwin* and *dstwin* need not be the same size; only text where the two windows overlap is copied. The difference is that **overlay()** is non-destructive (blanks are not copied), while **overwrite()** is destructive.

copywin(srcwin, dstwin, sminrow, smincol, dminrow, dmincol, dmaxrow,

dmaxcol, overlay) This routine provides a finer grain of control over the
 overlay() and overwrite() routines. Like in the
 prefresh() routine, a rectangle is specified in the des tination window, (dminrow, dmincol) and (dmaxrow,
 dmaxcol), and the upper-left-corner coordinates of the
 source window, (sminrow, smincol). If the argument
 overlay is true, then copying is non-destructive, as in
 overlay().

printw(fmt [, arg...])

wprintw(win, fmt [, arg...])

mvprintw(y, x, fmt [, arg...])

mvwprintw(win, y, x, fmt [, arg...])

These routines are analogous to **printf**(3S). The string which would be output by **printf**(3S) is instead output using **waddstr**() on the given window.

vwprintw(win, fmt, varglist)

This routine corresponds to vfprintf(3S). It performs a **wprintw()** using a variable argument list. The third argument is a va_list , a pointer to a list of arguments, as defined in <**varargs.h**>. See the vprintf(3S) and varargs(5) manual pages for a detailed description on how to use variable argument lists.

scroll(win) The window is scrolled up one line. This involves moving the lines in the window data structure. As an optimization, if the window is stdscr and the scrolling

region is the entire window, the physical screen will be scrolled at the same time.

touchwin(win) touchline(win, start, count)

Throw away all optimization information about which parts of the window have been touched, by pretending that the entire window has been drawn on. This is sometimes necessary when using overlapping windows, since a change to one window will affect the other window, but the records of which lines have been changed in the other window will not reflect the change. **touchline()** only pretends that *count* lines have been changed, beginning with line *start*.

Input

getch() wgetch(win) mvgetch(y, x) mvwgetch(win, y, x)

mvwgetch(win, y, x) A character is read from the terminal associated with the window. In NODELAY mode, if there is no input waiting, the value ERR is returned. In DELAY mode, the program will hang until the system passes text through to the program. Depending on the setting of cbreak(), this will be after one character (CBREAK mode), or after the first new-line (NOCBREAK mode). In HALF-DELAY mode, the program will hang until a character is typed or the specified timeout has been reached. Unless noecho() has been set, the character will also be echoed into the designated window. No refresh() will occur between the move() and the getch() done within the routines mvgetch() and mvwgetch().

> When using getch(), wgetch(), mvgetch(), or mvwgetch(), do not set both NOCBREAK mode [nocbreak()] and ECHO mode [echo()] at the same time. Depending on the state of the *tty*(7) driver when each character is typed, the program may produce undesirable results.

> If **keypad**(win, **TRUE**) has been called, and a function key is pressed, the token for that function key will be returned instead of the raw characters. [See **keypad**() under "Input Options Setting."] Possible function keys are defined in **<curses.h**> with integers beginning with **0401**, whose names begin with KEY_... If a character is received that could be the beginning of a function key (such as escape), *curses* will set a timer. If the remainder of the sequence is not received within the designated time, the character will be passed through, otherwise the function key value will

be returned. For this reason, on many terminals, there will be a delay after a user presses the escape key before the escape is returned to the program. [Use by a programmer of the escape key for a single character routine is discouraged. Also see **notimeout()** below.]

Note that getch(), mvgetch(), and mvwgetch() are macros.

getstr(str) wgetstr(win, str) mvgetstr(v, x, str) mvwgetstr(win, y, x, str) A series of calls to getch() is made, until a new-line, carriage return, or enter key is received. The resulting value is placed in the area pointed at by the character pointer str. The user's erase and kill characters are interpreted. As in mvgetch(), no refresh() is done between the **move()** and **getstr()** within the routines mvgetstr() and mvwgetstr(). Note that getstr(), mvgetstr(), and mvwgetstr() are macros. flushinp() Throws away any typeahead that has been typed by the user and has not yet been read by the program. Place *c* back onto the input queue to be returned by **ungetch**(c) the next call to wgetch(). inch() winch(win) mvinch(y, x)mvwinch(win, y, x) The character, of type chtype, at the current position in the named window is returned. If any attributes are set for that position, their values will be OR'ed into the value returned. The predefined constants A_CHARTEXT and A_ATTRIBUTES, defined in <curses.h>, can be used with the C logical AND (&) operator to extract the character or attributes alone. Note inch(), winch(), mvinch(), that and mvwinch() are macros. scanw(fmt [, arg . . .]) wscanw(win, fmt [, arg...]) **mvscanw**(y, x, fmt [, arg...]) **mvwscanw**(win, y, x, fmt [, arg...]) These routines correspond to scanf(3S), as do their arguments and return values. wgetstr() is called on the window, and the resulting line is used as input for the scan.

vwscanw(win, fmt, ap)

This routine is similar to **vwprintw**() above in that performs a **wscanw**() using a variable argument list. The third argument is a *va_list*, a pointer to a list of arguments, as defined in **<varargs.h**>. See the *vprintf*(3S) and *varargs*(5) manual pages for a detailed description on how to use variable argument lists.

Output Options Setting

These routines set options within *curses* that deal with output. All options are initially FALSE, unless otherwise stated. It is not necessary to turn these options off before calling **endwin()**.

- **clearok**(win, bf) If enabled (*bf* is **TRUE**), the next call to **wrefresh**() with this window will clear the screen completely and redraw the entire screen from scratch. This is useful when the contents of the screen are uncertain, or in some cases for a more pleasing visual effect.
- idlok(win, bf) If enabled (bf is TRUE), curses will consider using the hardware "insert/delete-line" feature of terminals so equipped. If disabled (bf is FALSE), curses will very seldom use this feature. (The "insert/delete-character" feature is always considered.) This option should be enabled only if your application needs "insert/delete-line", for example, for a screen editor. It is disabled by default because "insert/delete-line" tends to be visually annoying when used in applications where it isn't really needed. If "insert/delete-line" cannot be used, curses will redraw the changed portions of all lines.
- leaveok(win, bf) Normally, the hardware cursor is left at the location of the window cursor being refreshed. This option allows the cursor to be left wherever the update happens to leave it. It is useful for applications where the cursor is not used, since it reduces the need for cursor motions. If possible, the cursor is made invisible when this option is enabled.

setscrreg(top, bot)
wsetscrreg(win, top, bot)

These routines allow the user to set a software scrolling region in a window. *top* and *bot* are the line numbers of the top and bottom margin of the scrolling region. (Line 0 is the top line of the window.) If this option and **scrollok()** are enabled, an attempt to move off the bottom margin line will cause all lines in the scrolling region to scroll up one line. (Note that this has nothing to do with use of a physical scrolling region capability in the terminal, like that in the DEC VT100. Only the text of the window is scrolled; if

CURSES(3X)	(Terminal Information Utilities)	CURSES(3X)
idlok () is enabled and the terminal has either ling region or "insert/delete-line" capability, th probably be used by the output routines.)		apability, they will
	Note that setscrreg() and wsetscrre	g () are macros.
scrollok (win, bf)	This option controls what happens of a window is moved off the edge scrolling region, either from a new- line, or typing the last character of disabled (<i>bf</i> is FALSE), the cursor is line at the location where the offend entered. If enabled (<i>bf</i> is TRUE), w on the window, and then the phy window are scrolled up one line. [to get the physical scrolling effect of is also necessary to call idlok ().]	of the window or line on the bottom of the last line. If left on the bottom ding character was refresh() is called sical terminal and Note that in order
nl() nonl()	These routines control whether new into carriage return and linefeed whether return is translated into n	on output, and

into carriage return and linefeed on output, and whether return is translated into new-line on input. Initially, the translations do occur. By disabling these translations using **nonl()**, *curses* is able to make better use of the linefeed capability, resulting in faster cursor motion.

Input Options Setting

These routines set options within *curses* that deal with input. The options involve using *ioctl*(2) and therefore interact with *curses* routines. It is not necessary to turn these options off before calling **endwin**().

For more information on these options, see Chapter 10 of the *Programmer's Guide*.

cbreak()
nocbreak()

These two routines put the terminal into and out of CBREAK mode, respectively. In CBREAK mode, characters typed by the user are immediately available to the program and erase/kill character processing is not performed. When in NOCBREAK mode, the tty driver will buffer characters typed until a new-line or carriage return is typed. Interrupt and flow-control characters are unaffected by this mode [see *termio*(7)]. Initially the terminal may or may not be in CBREAK mode, as it is inherited, therefore, a program should call **cbreak()** or **nocbreak()** explicitly. Most interactive programs using *curses* will set CBREAK mode.

Note that **cbreak()** overrides **raw()**. See **getch()** under "Input" for a discussion of how these routines interact with **echo()** and **noecho()**.

CURSES(3X)

- echo() noecho() These routines control whether characters typed by the user are echoed by getch() as they are typed. Echoing by the tty driver is always disabled, but initially getch() is in ECHO mode, so characters typed are echoed. Authors of most interactive programs prefer to do their own echoing in a controlled area of the screen, or not to echo at all, so they disable echoing by calling noecho(). See getch() under "Input" for a discussion of how these routines interact with cbreak() and nocbreak().
- halfdelay(tenths) Half-delay mode is similar to CBREAK mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, ERR will be returned if nothing has been typed. *tenths* must be a number between 1 and 255. Use **nocbreak(**) to leave half-delay mode.
- intrflush(win, bf) If this option is enabled, when an interrupt key is pressed on the keyboard (interrupt, break, quit) all output in the tty driver queue will be flushed, giving the effect of faster response to the interrupt, but causing *curses* to have the wrong idea of what is on the screen. Disabling the option prevents the flush. The default for the option is inherited from the tty driver settings. The window argument is ignored.
- keypad(win, bf) This option enables the keypad of the user's terminal. If enabled, the user can press a function key (such as an arrow key) and wgetch() will return a single value representing the function key, as in KEY_LEFT. If disabled, *curses* will not treat function keys specially and the program would have to interpret the escape sequences itself. If the keypad in the terminal can be turned on (made to transmit) and off (made to work locally), turning on this option will cause the terminal keypad to be turned on when wgetch() is called.
- meta(win, bf) If enabled, characters returned by wgetch() are transmitted with all 8 bits, instead of with the highest bit stripped. In order for meta() to work correctly, the km (has_meta_key) capability has to be specified in the terminal's terminfo(4) entry.
- nodelay(win, bf) This option causes wgetch() to be a non-blocking call. If no input is ready, wgetch() will return ERR. If disabled, wgetch() will hang until a key is pressed.
- notimeout(win, bf) While interpreting an input escape sequence, wgetch() will set a timer while waiting for the next character. If notimeout(win, TRUE) is called, then wgetch() will not set a timer. The purpose of the

raw()

Environment Queries

timeout is to differentiate between sequences received from a function key and those typed by a user.

noraw() The terminal is placed into or out of raw mode. RAW mode is similar to CBREAK mode, in that characters typed are immediately passed through to the user program. The differences are that in RAW mode, the interrupt, quit, suspend, and flow control characters are passed through uninterpreted, instead of generating a signal. RAW mode also causes 8-bit input and output. The behavior of the BREAK key depends on other bits in the *tty*(7) driver that are not set by *curses*.

typeahead(fildes)
curses does ''line-breakout optimization'' by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update will be postponed until refresh() or doupdate() is called again. This allows faster response to commands typed in advance. Normally, the file descriptor for the input FILE pointer passed to newterm(), or stdin in the case that initscr() was used, will be used to do this typeahead checking. The typeahead() routine specifies that the file descriptor fildes is to be used to check for typeahead instead. If fildes is -1, then no typeahead checking will be done.

Note that *fildes* is a file descriptor, not a **<stdio.h>** FILE pointer.

baudrate() Returns the output speed of the terminal. The number returned is in bits per second, for example, 9600, and is an integer.

char erasechar() The user's current erase character is returned.

has_ic() True if the terminal has insert- and delete-character capabilities.

- has_il() True if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This might be used to check to see if it would be appropriate to turn on physical scrolling using scrollok().
- **char killchar()** The user's current line-kill character is returned.

char *longname() This routine returns a pointer to a static area containing a verbose description of the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to initscr() or newterm(). The area is overwritten by each call to **newterm()** and is not restored by **set_term()**, so the value should be saved between calls to **newterm()** if **longname()** is going to be used with multiple terminals.

Soft Labels

If desired, *curses* will manipulate the set of soft function-key labels that exist on many terminals. For those terminals that do not have soft labels, if you want to simulate them, *curses* will take over the bottom line of **stdscr**, reducing the size of **stdscr** and the variable **LINES**. *curses* standardizes on 8 labels of 8 characters each.

slk_init(labfmt) In order to use soft labels, this routine must be called before initscr() or newterm() is called. If initscr() winds up using a line from stdscr to emulate the soft labels, then labfmt determines how the labels are arranged on the screen. Setting labfmt to 0 indicates that the labels are to be arranged in a 3-2-3 arrangement; 1 asks for a 4-4 arrangement.

slk__set(labnum, label, labfmt)

labnum is the label number, from 1 to 8. *label* is the string to be put on the label, up to 8 characters in length. A NULL string or a NULL pointer will put up a blank label. *labfmt* is one of 0, 1 or 2, to indicate whether the label is to be left-justified, centered, or right-justified within the label.

slk_refresh()

slk_noutrefresh() These routines correspond to the routines wrefresh()
and wnoutrefresh(). Most applications would use
slk_noutrefresh() because a wrefresh() will most
likely soon follow.

char *slk_label(labnum)

The current label for label number *labnum*, with leading and trailing blanks stripped, is returned.

slk_clear() The soft labels are cleared from the screen.

- slk_restore() The soft labels are restored to the screen after a
 slk_clear().
- slk_touch() All of the soft labels are forced to be output the next time a slk_noutrefresh() is performed.

Low-Level curses Access

The following routines give low-level access to various *curses* functionality. These routines typically would be used inside of library routines.

def_prog_mode() def_shell_mode() Save the current terminal mod curses) or "shell" (not in curs

) Save the current terminal modes as the "program" (in curses) or "shell" (not in curses) state for use by the reset_prog_mode() and reset_shell_mode() routines. This is done automatically by initscr().

nal modes. **savetty()** saves the current state of the terminal in a buffer and **resetty()** restores the state to what it was at the last call to **savetty()**.

getsyx(y, x) The current coordinates of the virtual screen cursor are returned in y and x. Like getyx(), the variables y and x do not take an "&" before them. If leaveok() is currently TRUE, then -1,-1 will be returned. If lines may have been removed from the top of the screen using ripoffline() and the values are to be used beyond just passing them on to setsyx(), the value y+stdscr->_yoffset should be used for those other uses.

Note that **getsyx()** is a macro.

- setsyx(y, x) The virtual screen cursor is set to y, x. If y and x are both -1, then leaveok() will be set. The two routines getsyx() and setsyx() are designed to be used by a library routine which manipulates curses windows but does not want to mess up the current position of the program's cursor. The library routine would call getsyx() at the beginning, do its manipulation of its own windows, do a wnoutrefresh() on its windows, call setsyx(), and then call doupdate().
- ripoffline(line, init) This routine provides access to the same facility that slk_init() uses to reduce the size of the screen. ripoffline() must be called before initscr() or **newterm()** is called. If *line* is positive, a line will be removed from the top of stdscr; if negative, a line will be removed from the bottom. When this is done inside initscr(), the routine init() is called with two arguments: a window pointer to the 1-line window that has been allocated and an integer with the number of columns in the window. Inside this initialization routine, the integer variables LINES and COLS (defined in <curses.h>) are not guaranteed to be accurate and wrefresh() or doupdate() must not be called. It is allowable to call wnoutrefresh() during the initialization routine.

ripoffline() can be called up to five times before calling **initscr()** or **newterm()**.

scr_dump(filename) The current contents of the virtual screen are written to the file *filename*.

scr_restore(filename)

The virtual screen is set to the contents of *filename*, which must have been written using **scr_dump()**. The next call to **doupdate()** will restore the screen to what it looked like in the dump file.

scr_init(filename) The contents of filename are read in and used to initialize the curses data structures about what the terminal currently has on its screen. If the data is determined to be valid, curses will base its next update of the screen on this information rather than clearing the screen and starting from scratch. scr_init() would be used after initscr() or a system(3S) call to share the screen with another process which has done a scr_dump() after its endwin() call. The data will be declared invalid if the time-stamp of the tty is old or the terminfo(4) capability nrrmc is true.

- **curs_set**(visibility) The cursor is set to invisible, normal, or very visible for *visibility* equal to 0, 1, or 2.
- **draino**(ms) Wait until the output has drained enough that it will only take *ms* more milliseconds to drain completely.

garbagedlines(win, begline, numlines)

This routine indicates to *curses* that a screen line is garbaged and should be thrown away before having anything written over the top of it. It could be used for programs such as editors which want a command to redraw just a single line. Such a command could be used in cases where there is a noisy communications line and redrawing the entire screen would be subject to even more communication noise. Just redrawing the single line gives some semblance of hope that it would show up unblemished. The current location of the window is used to determine which lines are to be redrawn.

napms(ms)

Sleep for *ms* milliseconds.

Terminfo-Level Manipulations

These low-level routines must be called by programs that need to deal directly with the *terminfo*(4) data base to handle certain terminal capabilities, such as programming function keys. For all other functionality, *curses* routines are more suitable and their use is recommended.

Initially, **setupterm()** should be called. [Note that **setupterm()** is automatically called by **initscr()** and **newterm()**.] This will define the set of terminal-dependent variables defined in the *terminfo*(4) data base. The *terminfo*(4) variables **lines** and **columns** [see *terminfo*(4)] are initialized by **setupterm()** as follows: if the environment variables LINES and COLUMNS

exist, their values are used. If the above environment variables do not exist and the program is running in a layer [see *layers*(1)], the size of the current layer is used. Otherwise, the values for **lines** and **columns** specified in the *terminfo*(4) data base are used.

The header files **<curses.h>** and **<term.h>** should be included, in this order, to get the definitions for these strings, numbers, and flags. Parameterized strings should be passed through **tparm()** to instantiate them. All *terminfo*(4) strings [including the output of **tparm()**] should be printed with **tputs()** or **putp()**. Before exiting, **reset_shell_mode()** should be called to restore the tty modes. Programs which use cursor addressing should output **enter_ca_mode** upon startup and should output **exit_ca_mode** before exiting [see *terminfo*(4)]. (Programs desiring shell escapes should call **reset_shell_mode()** and output **exit_ca_mode** before the shell is called and should output **enter_ca_mode** and call **reset_prog_mode()** after returning from the shell. Note that this is different from the *curses* routines [see **endwin()**].

setupterm(term, fildes, errret)

Reads in the *terminfo*(4) data base, initializing the *terminfo*(4) structures, but does not set up the output virtualization structures used by *curses*. The terminal type is in the character string *term*; if *term* is NULL, the environment variable TERM will be used. All output is to the file descriptor *fildes*. If *errret* is not NULL, then **setupterm()** will return OK or ERR and store a status value in the integer pointed to by *errret*. A status of 1 in *errret* is normal, 0 means that the terminal could not be found, and -1 means that the *terminfo*(4) data base could not be found. If *errret* is NULL, **setupterm()** will print an error message upon finding an error and exit. Thus, the simplest call is **setupterm [(char *)0, 1, (int *)0]**, which uses all the defaults.

The *terminfo*(4) Boolean, numeric and string variables are stored in a structure of type **TERMINAL**. After **setupterm()** returns successfully, the variable **cur_term** (of type **TERMINAL ***) is initialized with all of the information that the *terminfo*(4) Boolean, numeric and string variables refer to. The pointer may be saved before calling **setupterm()** again. Further calls to **setupterm()** will allocate new space rather than reuse the space pointed to by **cur_term**.

set_curterm(nterm) nterm is of type TERMINAL *. set_curterm() sets the
variable cur_term to nterm, and makes all of the terminfo(4) Boolean, numeric and string variables use the
values from nterm.

del_curterm(oterm) oterm is of type **TERMINAL ***. **del_curterm**() frees the space pointed to by oterm and makes it available for further use. If oterm is the same as cur_term, then references to any of the terminfo(4) Boolean, numeric and string variables thereafter may refer to invalid memory locations until another setupterm() has been called.

restartterm(term, fildes, errret)

Like **setupterm()** after a memory restore.

char *tparm(str, $p_1, p_2, ..., p_9$) Instantiate the string *str* with parms p. A pointer is returned to the result of str with the parameters applied.

tputs(str, count, putc)

Apply padding to the string str and output it. str must be a terminfo(4) string variable or the return value from tparm(), tgetstr(), tigetstr() or tgoto(). *count* is the number of lines affected, or **1** if not applicable. *putc()* is a *putchar(3S)*-like routine to which the characters are passed, one at a time.

putp(str) A routine that calls **tputs** [*str*, **1**, **putchar**()].

vidputs(attrs, putc) Output a string that puts the terminal in the video attribute mode attrs, which is any combination of the attributes listed below. The characters are passed to the *putchar*(3S)-like routine *putc*().

vidattr(attrs) Like vidputs(), except that it outputs through putchar(3S).

mvcur(oldrow, oldcol, newrow, newcol)

Low-level cursor motion.

The following routines return the value of the capability corresponding to the *terminfo*(4) *capname* passed to them, such as **xenl**.

tigetflag(capname)	The value -1 is returned if <i>capname</i> is not a Boolean capability.
tigetnum (capname)	The value -2 is returned if <i>capname</i> is not a numeric capability.
tigetstr(capname)	The value (char *) -1 is returned if <i>capname</i> is not a string capability.

char *boolnames[], *boolcodes[], *boolfnames[] char *numnames[], *numcodes[], *numfnames[]

char *strnames[], *strcodes[], *strfnames[]

These null-terminated arrays contain the capnames, the termcap codes, and the full C names, for each of the *terminfo*(4) variables.

Termcap Emulation These routines are included as a conversion aid for programs that use the <i>termcap</i> library. Their parameters are the same and the routines are emulated using the <i>terminfo</i> (4) data base.			
tgetent (bp, name)	Look up <i>termcap</i> entry for <i>name</i> . The emulation ignores the buffer pointer <i>bp</i> .		
tgetflag (codename)	Get the Boolean entry for codename.		
tgetnum(codes)	Get numeric entry for codename.		
char *tgetstr (codena	me, area) Return the string entry for <i>codename</i> . If <i>area</i> is not NULL , then also store it in the buffer pointed to by <i>area</i> and advance <i>area</i> . tputs () should be used to output the returned string.		
char *tgoto (cap, col,	row)		
	Instantiate the parameters into the given capability. The output from this routine is to be passed to tputs ().		
tputs (str, affcnt, putc	tputs (str, affcnt, putc) See tputs() above, under "Terminfo-Level Manipula- tions".		
Miscellaneous			
traceoff()			
traceon()	Turn off and on debugging trace output when using the debug version of the <i>curses</i> library, <i>/usr/lib/libdcurses.a</i> . This facility is available only to customers with a source license.		
unctrl(c)	This macro expands to a character string which is a printable representation of the character c . Control characters are displayed in the X notation. Printing characters are displayed as is.		
	unctrl() is a macro, defined in <unctrl.h< b="">>, which is automatically included by <curses.h< b="">>.</curses.h<></unctrl.h<>		
<pre>char *keyname(c)</pre>	A character string corresponding to the key <i>c</i> is returned.		
filter()	This routine is one of the few that is to be called before initscr() or newterm() is called. It arranges things so that <i>curses</i> thinks that there is a 1-line screen. <i>curses</i> will not use any terminal capabilities that assume that they know what line on the screen the cursor is on.		

Use of curscr

The special window **curscr** can be used in only a few routines. If the window argument to **clearok()** is **curscr**, the next call to **wrefresh()** with any window will cause the screen to be cleared and repainted from scratch. If the window argument to **wrefresh()** is **curscr**, the screen is immediately cleared and repainted from scratch. (This is how most programs would implement a "repaint-screen" routine.) The source window argument to **overlay()**, **overwrite()**, and **copywin()** may be **curscr**, in which case the current contents of the virtual terminal screen will be accessed.

Obsolete Calls

Various routines are provided to maintain compatibility in programs written for older versions of the curses library. These routines are all emulated as indicated below.

crmode()	Replaced by cbreak() .
fixterm()	Replaced by reset_prog_mode().
gettmode()	A no-op.
nocrmode()	Replaced by nocbreak() .
resetterm()	Replaced by reset_shell_mode().
saveterm()	Replaced by def_prog_mode() .
setterm()	Replaced by setupterm().

ATTRIBUTES

The following video attributes, defined in <curses.h>, can be passed to the routines attron(), attroff(), and attrset(), or OR'ed with the characters passed to addch().

A_STANDOUT	Terminal's best highlighting mode
A_UNDERLINE	Underlining
A_REVERSE	Reverse video
A_BLINK	Blinking
A_DIM	Half bright
A_BOLD	Extra bright or bold
A_ALTCHARSET	Alternate character set
A_CHARTEXT	Bit-mask to extract character [described under winch()]
A_ATTRIBUTES	Bit-mask to extract attributes [described under winch()]

FUNCTION-KEYS

A_NORMAL

The following function keys, defined in $\langle curses.h \rangle$, might be returned by **getch()** if **keypad()** has been enabled. Note that not all of these may be supported on a particular terminal if the terminal does not transmit a unique code when the key is pressed or the definition for the key is not present in the *terminfo*(4) data base.

Bit mask to reset all attributes off

(for example: attrset (A_NORMAL)

Name	Value	Key name
KEY_BREAK KEY_DOWN KEY_UP KEY_LEFT	0401 0402 0403 0404	break key (unreliable) The four arrow keys

KEY_UNDO	0630	undo key
		-

LINE GRAPHICS

The following variables may be used to add line-drawing characters to the screen with **waddch()**. When defined for the terminal, the variable will have the **A_ALTCHARSET** bit turned on. Otherwise, the default character listed below will be stored in the variable. The names were chosen to be consistent with the DEC VT100 nomenclature.

Ν	ame

Default Glyph Description

ACS_ULCORNER	+	upper left corner
ACS_LLCORNER	+	lower left corner
ACS_URCORNER	+	upper right corner
ACS_LRCORNER	+	lower right corner
ACS_RTEE	+	right tee (-)
ACS_LTEE	+	left tee (
ACS_BTEE	+	bottom tee (\perp)
ACS_TTEE	+	top tee (†)
ACS_HLINE	-	horizontal line
ACS_VLINE	l I	vertical line
ACS_PLUS	+	plus
ACS_S1	-	scan line 1
ACS_S9		scan line 9
ACS_DIAMOND	+	diamond
ACS_CKBOARD	:	checker board (stipple)
ACS_DEGREE	,	degree symbol
ACS_PLMINUS	#	plus/minus
ACS_BULLET	0	bullet
ACS_LARROW	<	arrow pointing left
ACS_RARROW	>	arrow pointing right
ACS_DARROW	v	arrow pointing down
ACS_UARROW	^	arrow pointing up
ACS_BOARD	#	board of squares
ACS_LANTERN	#	lantern symbol
ACS_BLOCK	#	solid square block

RETURN VALUES

All routines return the integer **OK** upon successful completion and the integer **ERR** upon failure, unless otherwise noted in the preceding routine descriptions.

All macros return the value of their **w** version, except **setscrreg()**, **wsetscrreg()**, **getsyx()**, **getbegy()**, **getmaxyx()**. For these macros, no useful value is returned.

Routines that return pointers always return (type *) NULL on error.

BUGS

Currently typeahead checking is done using a nodelay read followed by an **ungetch()** of any character that may have been read. Typeahead checking is done only if **wgetch()** has been called at least once. This will be changed when proper kernel support is available. Programs which use a mixture of their own input routines with *curses* input routines may wish to call **typeahead(-1)** to turn off typeahead checking.

The argument to **napms()** is currently rounded up to the nearest second.

draino (ms) only works for ms equal to 0.

WARNINGS

To use the new *curses* features, use the Release 3.0 version of *curses* on UNIX System Release 3.0. All programs that ran with System V Release 2

curses will run with System V Release 3.0. You may link applications with object files based on the Release 2 *curses/terminfo* with the Release 3.0 *libcurses.a* library. You may link applications with object files based on the Release 3.0 *curses/terminfo* with the Release 2 *libcurses.a* library, so long as the application does not use the new features in the Release 3.0 *curses/terminfo*.

The plotting library plot(3X) and the curses library curses(3X) both use the names **erase()** and **move()**. The *curses* versions are macros. If you need both libraries, put the plot(3X) code in a different source file than the curses(3X) code, and/or **#undef move()** and **erase()** in the plot(3X) code.

Between the time a call to **initscr()** and **endwin()** has been issued, use only the routines in the *curses* library to generate output. Using system calls or the "standard I/O package" [see *stdio*(3S)] for output during that time can cause unpredictable results.

directory: opendir, readdir, telldir, seekdir, rewinddir, closedir – directory operations

SYNOPSIS

#include <sys/types.h>
#include <dirent.h>
DIR *opendir (filename)

char *filename; struct dirent *readdir (dirp) DIR *dirp; long telldir (dirp) DIR *dirp; void seekdir (dirp, loc) DIR *dirp; long loc; void rewinddir (dirp) DIR *dirp; void closedir(dirp) DIR *dirp;

DESCRIPTION

Opendir opens the directory named by filename and associates a directory stream with it. Opendir returns a pointer to be used to identify the directory stream in subsequent operations. The pointer NULL is returned if filename cannot be accessed or is not a directory, or if it cannot malloc(3X) enough memory to hold a DIR structure or a buffer for the directory entries.

Readdir returns a pointer to the next active directory entry. No inactive entries are returned. It returns NULL upon reaching the end of the directory or upon detecting an invalid location in the directory.

Telldir returns the current location associated with the named directory stream.

Seekdir sets the position of the next readdir operation on the directory stream. The new position reverts to the one associated with the directory stream when the telldir operation from which loc was obtained was performed. Values returned by telldir are good only if the directory has not changed due to compaction or expansion. This is not a problem with System V, but it may be with some file system types.

Rewinddir resets the position of the named *directory stream* to the beginning of the directory.

Closedir closes the named directory stream and frees the DIR structure.

The following errors can occur as a result of these operations.

opendir:	
[ENOTDIR]	A component of <i>filename</i> is not a directory.
[EACCES]	A component of <i>filename</i> denies search permission.
[EMFILE]	The maximum number of file descriptors are currently open.
[EFAULT]	Filename points outside the allocated address space.
readdir:	
[ENOENT]	The current file pointer for the directory is not located at a valid entry.
[EBADF]	The file descriptor determined by the DIR stream is no longer valid. This results if the DIR stream has been closed.

telldir, seekdir, and closedir:

[EBADF] The file descriptor determined by the DIR stream is no longer valid. This results if the DIR stream has been closed.

EXAMPLE

Sample code which searches a directory for entry name:

SEE ALSO

getdents(2), dirent(4).

WARNINGS

Rewinddir is implemented as a macro, so its function address cannot be taken.

ldahread - read the archive header of a member of an archive file

SYNOPSIS

#include <stdio.h>
#include <ar.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldahread (ldptr, arhead) LDFILE *ldptr; ARCHDR *arhead;

DESCRIPTION

If **TYPE**(*ldptr*) is the archive file magic number, *ldahread* reads the archive header of the common object file currently associated with *ldptr* into the area of memory beginning at *arhead*.

ldahread returns **SUCCESS** or **FAILURE**. *ldahread* will fail if **TYPE**(*ldptr*) does not represent an archive file, or if it cannot read the archive header.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldfcn(4), ar(4).

ldclose, ldaclose - close a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldclose (ldptr) LDFILE *ldptr;

int ldaclose (ldptr) LDFILE *ldptr;

DESCRIPTION

The ldopen(3X) and ldclose functions are designed to provide uniform access to both simple object files and object files that are members of archive files. Thus an archive of common object files can be processed as if it were a series of simple common object files.

If **TYPE**(*ldptr*) does not represent an archive file, *ldclose* will close the file and free the memory allocated to the **LDFILE** structure associated with *ldptr*. If **TYPE**(*ldptr*) is the magic number of an archive file, and if there are any more files in the archive, *ldclose* will reinitialize **OFFSET**(*ldptr*) to the file address of the next archive member and return **FAILURE**. The **LDFILE** structure is prepared for a subsequent *ldopen*(3X). In all other cases, *ldclose* returns **SUCCESS**.

Ldaclose closes the file and frees the memory allocated to the LDFILE structure associated with *ldptr* regardless of the value of TYPE(*ldptr*). *Ldaclose* always returns SUCCESS. The function is often used in conjunction with *ldaopen*.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

fclose(3S), ldopen(3X), ldfcn(4).

ldfhread - read the file header of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldfhread (ldptr, filehead) LDFILE *ldptr; FILHDR *filehead;

DESCRIPTION

The *ldfhread* function reads the file header of the common object file currently associated with *ldptr* into the area of memory beginning at *file-head*.

ldfhread returns **SUCCESS** or **FAILURE**. *ldfhread* will fail if it cannot read the file header.

In most cases the use of *ldfhread* can be avoided by using the macro **HEADER**(*ldptr*) defined in **ldfcn.h** [see ldfcn (4)]. The information in any field, *fieldname*, of the file header may be accessed using **HEADER**(*ldptr*).*fieldname*.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldfcn(4).

ldgetname - retrieve symbol name for common object file symbol table entry

SYNOPSIS

#include <stdio.h> #include <filehdr.h> #include <syms.h> #include <ldfcn.h>

char *ldgetname (ldptr, symbol) LDFILE *ldptr; SYMENT *symbol;

DESCRIPTION

The *ldgetname* function returns a pointer to the name associated with **symbol** as a string. The string is contained in a static buffer local to *ldgetname* that is overwritten by each call to *ldgetname*, and therefore must be copied by the caller if the name is to be saved.

The *ldgetname* function can be used to retrieve names from object files without any backward compatibility problems. The *ldgetname* function will return NULL (defined in **stdio.h**) for an object file if the name cannot be retrieved. This situation can occur:

- if the "string table" cannot be found,
- if not enough memory can be allocated for the string table,
- if the string table appears not to be a string table (for example, if an auxiliary entry is handed to *ldgetname* that looks like a reference to a name in a nonexistent string table), or
- if the name's offset into the string table is past the end of the string table.

Typically, *ldgetname* will be called immediately after a successful call to *ldtbread* to retrieve the name associated with the symbol table entry filled by *ldtbread*.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldlread, ldlinit, ldlitem – manipulate line number entries of a common object file function

SYNOPSIS

#include <stdio.h> #include <filehdr.h> #include <linenum.h> #include <ldfcn.h>

int ldlread(ldptr, fcnindx, linenum, linent) LDFILE *ldptr; long fcnindx; unsigned short linenum; LINENO *linent;

int ldlinit(ldptr, fcnindx) LDFILE *ldptr; long fcnindx;

int ldlitem(ldptr, linenum, linent) LDFILE *ldptr; unsigned short linenum; LINENO *linent;

DESCRIPTION

The *ldlread* function searches the line number entries of the common object file currently associated with *ldptr*. The *ldlread* function begins its search with the line number entry for the beginning of a function and confines its search to the line numbers associated with a single function. The function is identified by *fcnindx*, the index of its entry in the object file symbol table. The *ldlread* function reads the entry with the smallest line number equal to or greater than *linenum* into the memory beginning at *linent*.

The *ldlinit* and *ldlitem* functions together perform exactly the same function as *ldlread*. After an initial call to *ldlread* or *ldlinit*, *ldlitem* may be used to retrieve a series of line number entries associated with a single function. *Ldlinit* simply locates the line number entries for the function identified by *fcnindx*. *Ldlitem* finds and reads the entry with the smallest line number equal to or greater than *linenum* into the memory beginning at *linent*.

The *ldlread*, *ldlinit*, and *ldlitem* functions each return either SUCCESS or FAILURE. *ldlread* will fail if there are no line number entries in the object file, if *fcnindx* does not index a function entry in the symbol table, or if it finds no line number equal to or greater than *linenum*. *Ldlinit* will fail if there are no line number entries in the object file or if *fcnindx* does not index a function entry in the symbol table. *Ldlitem* will fail if this no line number equal to or greater than *linenum*.

The programs must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldlseek, ldnlseek – seek to line number entries of a section of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldlseek (ldptr, sectindx) LDFILE *ldptr; unsigned short sectindx;

int ldnlseek (ldptr, sectname) LDFILE *ldptr; char *sectname;

DESCRIPTION

The *ldlseek* function seeks to the line number entries of the section specified by *sectindx* of the common object file currently associated with *ldptr*.

The *ldnlseek* function seeks to the line number entries of the section specified by *sectname*.

The *ldlseek* and *ldnlseek* functions return SUCCESS or FAILURE. *ldlseek* will fail if *sectindx* is greater than the number of sections in the object file; *ldnlseek* will fail if there is no section name corresponding with **sectname*. Either function will fail if the specified section has no line number entries or if it cannot seek to the specified line number entries.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

ldohseek - seek to the optional file header of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>
int ldohseek (ldptr)

LDFILE *ldptr;

DESCRIPTION

The *ldohseek* function seeks to the optional file header of the common object file currently associated with *ldptr*.

The *ldohseek* function returns **SUCCESS** or **FAILURE**. *ldohseek* will fail if the object file has no optional header or if it cannot seek to the optional header.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldfhread(3X), ldfcn(4).

ldopen, ldaopen - open a common object file for reading

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

LDFILE *ldopen (filename, ldptr) char *filename; LDFILE *ldptr;

LDFILE *ldaopen (filename, oldptr) char *filename; LDFILE *oldptr;

DESCRIPTION

The *ldopen* and *ldclose*(3X) functions are designed to provide uniform access to both simple object files and object files that are members of archive files. Thus an archive of common object files can be processed as if it were a series of simple common object files.

If *ldptr* has the value NULL, then *ldopen* will open *filename* and allocate and initialize the LDFILE structure, and return a pointer to the structure to the calling program.

If *ldptr* is valid and if **TYPE**(*ldptr*) is the archive magic number, *ldopen* will reinitialize the **LDFILE** structure for the next archive member of *filename*.

The *ldopen* and *ldclose*(3X) functions are designed to work in concert. *Ldclose* will return **FAILURE** only when **TYPE**(*ldptr*) is the archive magic number and there is another file in the archive to be processed. Only then should *ldopen* be called with the current value of *ldptr*. In all other cases, in particular whenever a new *filename* is opened, *ldopen* should be called with a **NULL** *ldptr* argument.

The following is a prototype for the use of *ldopen* and *ldclose*(3X).

```
/* for each filename to be processed */
ldptr = NULL;
do
{
    if ( (ldptr = ldopen(filename, ldptr)) != NULL )
        {
            /* check magic number */
            /* process the file */
    }
```

```
} while (ldclose(ldptr) == FAILURE );
```

If the value of *oldptr* is not NULL, *ldaopen* will open *filename* anew and allocate and initialize a new LDFILE structure, copying the TYPE, OFFSET, and HEADER fields from *oldptr*. *Ldaopen* returns a pointer to the new LDFILE structure. This new pointer is independent of the old pointer, *oldptr*. The two pointers may be used concurrently to read separate parts of the object file. For example, one pointer may be used to step sequentially through the

relocation information, while the other is used to read indexed symbol table entries.

Both *ldopen* and *ldaopen* open *filename* for reading. Both functions return NULL if *filename* cannot be opened, or if memory for the LDFILE structure cannot be allocated. A successful open does not insure that the given file is a common object file or an archived object file.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

fopen(3S), ldclose(3X), ldfcn(4).

ldrseek, ldnrseek - seek to relocation entries of a section of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldrseek (ldptr, sectindx) LDFILE *ldptr; unsigned short sectindx;

int ldnrseek (ldptr, sectname) LDFILE *ldptr; char *sectname;

DESCRIPTION

The *ldrseek* function seeks to the relocation entries of the section specified by *sectindx* of the common object file currently associated with *ldptr*.

The *ldnrseek* function seeks to the relocation entries of the section specified by *sectname*.

The *ldrseek* and *ldnrseek* functions return SUCCESS or FAILURE. *ldrseek* will fail if *sectindx* is greater than the number of sections in the object file; *ldnrseek* will fail if there is no section name corresponding with *sectname*. Either function will fail if the specified section has no relocation entries or if it cannot seek to the specified relocation entries.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

ldshread, ldnshread – read an indexed/named section header of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <scnhdr.h>
#include <ldfcn.h>

int ldshread (ldptr, sectindx, secthead) LDFILE *ldptr; unsigned short sectindx; SCNHDR *secthead;

int ldnshread (ldptr, sectname, secthead) LDFILE *ldptr; char *sectname; SCNHDR *secthead;

DESCRIPTION

The *ldshread* function reads the section header specified by *sectindx* of the common object file currently associated with *ldptr* into the area of memory beginning at *secthead*.

The *ldnshread* function reads the section header specified by *sectname* into the area of memory beginning at *secthead*.

The *ldshread* and *ldnshread* functions return **SUCCESS** or **FAILURE**. *ldshread* will fail if *sectindx* is greater than the number of sections in the object file; *ldnshread* will fail if there is no section name corresponding with *sectname*. Either function will fail if it cannot read the specified section header.

Note that the first section header has an index of one.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldfcn(4).

ldsseek, ldnsseek – seek to an indexed/named section of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldsseek (ldptr, sectindx) LDFILE *ldptr; unsigned short sectindx;

int ldnsseek (ldptr, sectname) LDFILE *ldptr; char *sectname;

DESCRIPTION

The *ldsseek* function seeks to the section specified by *sectindx* of the common object file currently associated with *ldptr*.

The *ldnsseek* function seeks to the section specified by *sectname*.

The *ldsseek* and *ldnsseek* functions return **SUCCESS** or **FAILURE**. *ldsseek* will fail if *sectindx* is greater than the number of sections in the object file; *ldnsseek* will fail if there is no section name corresponding with *sectname*. Either function will fail if there is no section data for the specified section or if it cannot seek to the specified section.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

ldtbindex – compute the index of a symbol table entry of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>

long ldtbindex (ldptr) LDFILE *ldptr;

DESCRIPTION

The *ldtbindex* function returns the (**long**) index of the symbol table entry at the current position of the common object file associated with *ldptr*.

The index returned by *ldtbindex* may be used in subsequent calls to *ldtbread*(3X). However, since *ldtbindex* returns the index of the symbol table entry that begins at the current position of the object file, if *ldtbindex* is called immediately after a particular symbol table entry has been read, it will return the index of the next entry.

The *ldtbindex* function will fail if there are no symbols in the object file, or if the object file is not positioned at the beginning of a symbol table entry.

Note that the first symbol in the symbol table has an index of zero.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldtbread(3X), ldtbseek(3X), ldfcn(4).

LDTBREAD(3X)

NAME

ldtbread - read an indexed symbol table entry of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>

int ldtbread (ldptr, symindex, symbol) LDFILE *ldptr; long symindex; SYMENT *symbol;

DESCRIPTION

The *ldtbread* function reads the symbol table entry specified by *symindex* of the common object file currently associated with *ldptr* into the area of memory beginning at **symbol**.

The *ldtbread* function returns **SUCCESS** or **FAILURE**. *ldtbread* will fail if *symindex* is greater than or equal to the number of symbols in the object file, or if it cannot read the specified symbol table entry.

Note that the first symbol in the symbol table has an index of zero.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

ldclose(3X), ldopen(3X), ldtbseek(3X), ldgetname(3X), ldfcn(4).

(Specialized Libraries)

NAME

ldtbseek - seek to the symbol table of a common object file

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>
int ldtbseek (ldptr)
LDFILE *ldptr;

DESCRIPTION

The *ldtbseek* function seeks to the symbol table of the common object file currently associated with *ldptr*.

The *ldtbseek* function returns **SUCCESS** or **FAILURE**. *ldtbseek* will fail if the symbol table has been stripped from the object file, or if it cannot seek to the symbol table.

The program must be loaded with the object file access routine library **libld.a**.

LIBWINDOWS(3X)

NAME

libwindows – windowing terminal function library

SYNOPSIS

```
cc [flag ...] file ... -lwindows [library ...]
```

int cntlfd, fd

int chan

int origin_x, origin_y, corner_x, corner_y *command

cntlfd = openagent ()

chan = New (cntlfd, origin_x, origin_y, corner_x, corner_y)

chan = Newlayer (cntlfd, origin_x, origin_y, corner_x, corner_y)

fd = openchan (chan)

Runlayer (chan, command)

Current (cntlfd, chan)

Delete (cntlfd, chan)

Top (cntlfd, chan)

Bottom (cntlfd, chan)

Move (cntlfd, chan, origin_x, origin_y)

Reshape (cntlfd, chan, origin_x, origin_y, corner_x, corner_y)

Exit (cntlfd)

DESCRIPTION

This library of routines enables a program running on a host UNIX system to perform windowing terminal functions [see layers(1)].

The **openagent()** routine opens the control channel of the xt(7) channel group to which the calling process belongs. Upon successful completion, openagent() returns a file descriptor, cntlfd, that can be passed to any of the other *libwindows* routines except **openchan()** and **Runlayer()**. [cntlfd can also be passed to *close*(2).] Otherwise, the value -1 is returned.

The **New()** routine creates a new layer with a separate shell. The *origin_x*, origin_y, corner_x, and corner_y arguments are the coordinates of the layer rectangle. If all the coordinate arguments are 0, the user must define the layer's rectangle interactively. The layer appears on top of any overlapping layers. The layer is not made current (i.e., the keyboard is not attached to the new layer). Upon successful completion, New() returns the xt(7) channel number associated with the layer. Otherwise, the value -1 is returned.

The Newlayer() routine creates a new layer without executing a separate shell. Otherwise it is identical to **New()**, described above.

The **openchan()** routine opens the channel argument *chan* which is obtained from the New() or Newlayer() routine. Upon successful completion, openchan() returns a file descriptor that can be used as input to *write*(2) or *close*(2). Otherwise, the value -1 is returned.

The **Runlayer()** routine runs the specified *command* in the layer associated with the channel argument *chan*. Any processes currently attached to this layer will be killed, and the new process will have the environment of the *layers*(1) process.

The **Current()** routine makes the layer associated with the channel argument *chan* current (i.e., attached to the keyboard).

The **Delete()** routine deletes the layer associated with the channel argument *chan* and kills all host processes associated with the layer.

The **Top**() routine makes the layer associated with the channel argument *chan* appear on top of all overlapping layers.

The **Bottom()** routine puts the layer associated with the channel argument *chan* under all overlapping layers.

The **Move()** routine moves the layer associated with the channel argument *chan* from its current screen location to a new screen location at the origin point (*origin_x, origin_y*). The size and contents of the layer are maintained.

The **Reshape**() routine reshapes the layer associated with the channel argument *chan*. The arguments *origin_x*, *origin_y*, *corner_x*, and *corner_y* are the new coordinates of the layer rectangle. If all the coordinate arguments are 0, the user is allowed to define the layer's rectangle interactively.

The **Exit()** routine causes the **layers(1)** program to exit, killing all processes associated with it.

RETURN VALUE

Upon successful completion, Runlayer(), Current(), Delete(), Top(), Bottom(), Move(), Reshape(), and Exit() return a 0, while openagent(), New(), Newlayer(), and openchan() return values as described above under each routine. If an error occurs, -1 is returned.

FILES

/usr/lib/libwindows.a windowing terminal function library

NOTE

The values of layer rectangle coordinates are dependent on the type of terminal. This dependency affects the routines that pass layer rectangle coordinates: **Move()**, **New()**, **Newlayer()**, and **Reshape()**. Some terminals will expect these numbers to be passed as character positions (bytes); others will expect the information to be in pixels (bits).

For example, for the AT&T Teletype 5620 DMD terminal, **New()**, **Newlayer()**, and **Reshape()** take minimum values of 8 (pixels) for *origin_x* and *origin_y* and maximum values of 792 (pixels) for *corner_x* and 1016 (pixels) for *corner_y*. In addition, the minimum layer size is 28 by 28 pixels and the maximum layer size is 784 by 1008 pixels.

close(2), jagent(5), write(2). layers(1) in the User's Reference Manual. xt(7) in the System Administrator's Reference Manual.

logname - return login name of user

SYNOPSIS

char *logname()

DESCRIPTION

The *logname* function returns a pointer to the null-terminated login name; it extracts the **LOGNAME** environment variable from the user's environment.

This routine is kept in /lib/libPW.a.

FILES

/etc/profile

SEE ALSO

getenv(3C), profile(4), environ(5). env(1), login(1) in the User's Reference Manual.

CAVEATS

The return values point to static data whose content is overwritten by each call.

This method of determining a login name is subject to forgery.

malloc, free, realloc, calloc, mallopt, mallinfo - fast main memory allocator

SYNOPSIS

#include <malloc.h>

char *malloc (size) unsigned size; void free (ptr) char *ptr; char *realloc (ptr, size) char *ptr; unsigned size;

char *calloc (nelem, elsize) unsigned nelem, elsize;

int mallopt (cmd, value) int cmd, value;

struct mallinfo mallinfo()

DESCRIPTION

The *malloc* and *free* functions provide a simple general-purpose memory allocation package, which runs considerably faster than the *malloc*(3C) package. It is found in the library "malloc" and is loaded if the option "–lmalloc" is used with cc(1) or ld(1).

The *malloc* function returns a pointer to a block of at least *size* bytes suitably aligned for any use.

The argument to *free* is a pointer to a block previously allocated by *malloc*; after *free* is performed, this space is made available for further allocation, and its contents have been destroyed. But see *mallopt* below for a way to change this behavior.

Undefined results will occur if the space assigned by *malloc* is overrun or if some random number is handed to *free*.

Realloc changes the size of the block pointed to by *ptr* to *size* bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes.

Calloc allocates space for an array of *nelem* elements of size *elsize*. The space is initialized to zeros.

Mallopt provides for control over the allocation algorithm. The available values for *cmd* are:

- M_MXFAST Set *maxfast* to *value*. The algorithm allocates all blocks below the size of *maxfast* in large groups and then doles them out very quickly. The default value for *maxfast* is 24.
- M_NLBLKS Set *numlblks* to *value*. The above mentioned "large groups" each contain *numlblks* blocks. *Numlblks* must be greater than 0. The default value for *numlblks* is 100.

M_GRAIN Set grain to value. The sizes of all blocks smaller than maxfast are considered to be rounded up to the nearest multiple of grain. Grain must be greater than 0. The default value of grain is the smallest number of bytes which will allow alignment of any data type. Value will be rounded up to a multiple of the default when grain is set.

M_KEEP Preserve data in a freed block until the next *malloc*, *realloc*, or *calloc*. This option is provided only for compatibility with the old version of *malloc* and is not recommended.

These values are defined in the *<malloc.h* > header file.

Mallopt may be called repeatedly, but may not be called after the first small block is allocated.

Mallinfo provides instrumentation describing space usage. It returns the structure:

struct mallinfo {	
int arena;	/* total space in arena */
int ordblks;	/* number of ordinary blocks */
int smblks;	/* number of small blocks */
int hblkhd;	/* space in holding block headers */
int hblks;	/* number of holding blocks */
int usmblks;	/* space in small blocks in use */
int fsmblks;	/* space in free small blocks */
int uordblks;	/* space in ordinary blocks in use */
int fordblks;	/* space in free ordinary blocks */
int keepcost;	/* space penalty if keep option */
•	/* is used */

}

This structure is defined in the *<malloc.h>* header file.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

SEE ALSO

brk(2), malloc(3C).

DIAGNOSTICS

The *malloc*, *realloc*, and *calloc* functions return a NULL pointer if there is not enough available memory. When *realloc* returns NULL, the block pointed to by *ptr* is left intact. If *mallopt* is called after any allocation or if *cmd* or *value* are invalid, non-zero is returned. Otherwise, it returns zero.

WARNINGS

This package usually uses more data space than *malloc*(3C).

The code size is also bigger than *malloc*(3C).

Note that unlike malloc(3C), this package does not preserve the contents of a block when it is freed, unless the M_KEEP option of *mallopt* is used.

Undocumented features of malloc(3C) have not been duplicated.

plot – graphics interface subroutines SYNOPSIS

```
openpl ()
erase ()
label (s)
char *s;
line (x1, y1, x2, y2)
int x1, y1, x2, y2;
circle (x, y, r)
int x, y, r;
arc (x, y, x0, y0, x1, y1)
int x, y, x0, y0, x1, y1;
move (x, y)
int x, y;
cont (x, y)
int x, y;
point (x, y)
int x, y;
linemod (s)
char *s;
space (x0, y0, x1, y1)
int x0, y0, x1, y1;
```

closep1 ()

DESCRIPTION

These subroutines generate graphic output in a relatively deviceindependent manner. *Space* must be used before any of these functions to declare the amount of space necessary [see plot(4)]. *Openpl* must be used before any of the others to open the device for writing. *Closepl* flushes the output.

Circle draws a circle of radius r with center at the point (x, y).

Arc draws an arc of a circle with center at the point (x, y) between the points (x0, y0) and (x1, y1).

String arguments to *label* and *linemod* are terminated by nulls and do not contain new-lines.

See *plot*(4) for a description of the effect of the remaining functions.

The library files listed below provide several flavors of these routines.

FILES

LIBDIR/libplot.a	produces output for <i>tplot</i> (1G) filters
LIBDIR/lib300.pa	for DASI 300

LIBDIR /lib300.a	for DASI 300s
LIBDIR/lib450.a	for DASI 450
LIBDIR/lib4014.a	for TEKTRONIX 4014

LIBDIRusually /usr/lib

SEE ALSO

plot(4).

graph(1G), stat(1G), tplot(1G) in the User's Reference Manual.

WARNINGS

In order to compile a program containing these functions in *file.c*, it is necessary to use "cc *file.c* –lplot".

In order to execute it, it is necessary to use "a.out | tplot".

The above routines use \langle **stdio.h** \rangle , which causes them to increase the size of programs, not otherwise using standard I/O more than might be expected.

regcmp, regex – compile and execute regular expression

SYNOPSIS

```
char *regcmp (string1 [, string2, ...], (char *)0)
char *string1, *string2, ...;
char *regex (re, subject[, ret0, ...])
char *re, *subject, *ret0, ...;
```

extern char *__loc1;

DESCRIPTION

The *regcmp* function compiles a regular expression (consisting of the concatenated arguments) and returns a pointer to the compiled form. The *malloc*(3C) function is used to create space for the compiled form. It is the user's responsibility to free unneeded space so allocated. A NULL return from *regcmp* indicates an incorrect argument. *regcmp*(1) has been written to generally preclude the need for this routine at execution time.

Regex executes a compiled pattern against the subject string. Additional arguments are passed to receive values back. *Regex* returns NULL on failure or a pointer to the next unmatched character on success. A global character pointer $__loc1$ points to where the match began. *regcmp* and *regex* were mostly borrowed from the editor, *ed*(1); however, the syntax and semantics have been changed slightly. The following are the valid symbols and their associated meanings.

These symbols retain their meaning in

ed(1).

By necessity, all the above defined symbols are special.

They must, therefore, be escaped with a \setminus (backslash) to be used as themselves.

EXAMPLES

Example 1:

char *cursor, *newcursor, *ptr;

newcursor = regex((ptr = regcmp("^\n", (char *)0)), cursor); free(ptr);

This example will match a leading new-line in the subject string pointed at by cursor.

Example 2:

char ret0[9];
char *newcursor, *name;

name = regcmp("($[A-Za-z][A-za-z0-9]{0,7}$)0, (char *)0);

This example will match through the string "Testing3" and will return the address of the character after the last matched character (the "4"). The string "Testing3" will be copied to the character array *ret0*.

Example 3:

#include "file.i"

sputl, sgetl - access long integer data in a machine independent fashion

SYNOPSIS

void sputl (value, buffer) long value; char *buffer; long sgetl (buffer) char *buffer;

DESCRIPTION

The *sputl* function takes the four bytes of the long integer *value* and places them in memory starting at the address pointed to by *buffer*. The ordering of the bytes is the same across all machines.

The *sgetl* function retrieves the four bytes in memory starting at the address pointed to by *buffer* and returns the long integer value in the byte ordering of the host machine.

The combination of *sputl* and *sgetl* provides a machine-independent way of storing long numeric data in a file in binary form without conversion to characters.

A program which uses these functions must be loaded with the object-file access routine library **libld.a**.

SEE ALSO

intro(4),

abort - terminate FORTRAN program

SYNOPSIS

call abort ()

DESCRIPTION

The *abort* function terminates the program which calls it, closing all open files truncated to the current position of the file pointer. The abort usually results in a core dump.

DIAGNOSTICS

When invoked, *abort* prints "FORTRAN abort routine called" on the standard error output. The shell prints the message "abort - core dumped" if a core dump results.

SEE ALSO

abort(3C). sh(1) in the User's Reference Manual.

abs, iabs, dabs, cabs, zabs - FORTRAN absolute value

SYNOPSIS

integer i1, i2 real r1, r2 double precision dp1, dp2 complex cx1, cx2 double complex dx1, dx2

r2 = abs(r1) i2 = iabs(i1) i2 = abs(i1) dp2 = dabs(dp1) dp2 = abs(dp1) cx2 = cabs(cx1) cx2 = abs(cx1)dx2 = zabs(dx1)

dx2 = abs(dx1)

DESCRIPTION

The *abs* functions are a family of absolute value functions. The *iabs* function returns the integer absolute value of its integer argument. The *dabs* function returns the double-precision absolute value of its double-precision argument. The *cabs* function returns the complex absolute value of its complex argument. The *zabs* function returns the double-complex absolute value of its double-complex absolute value of its argument. The *zabs* function returns the double-complex absolute value of its absolute value of its absolute value of its argument.

ACOS(3F)

NAME

acos, dacos - FORTRAN arccosine intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
r2 = acos(r1)
dp2 = dacos(dp1)
dp2 = acos(dp1)
```

DESCRIPTION

The *acos* function returns the real arccosine of its real argument. The *dacos* function returns the double-precision arccosine of its double-precision argument. The generic form *acos* may be used with impunity as its argument will determine the type of the returned value.

SEE ALSO

aimag, dimag - FORTRAN imaginary part of complex argument

SYNOPSIS

real r complex cxr double precision dp double complex cxd

r = aimag(cxr)

dp = dimag(cxd)

DESCRIPTION

The *aimag* function returns the imaginary part of its single-precision complex argument. The *dimag* function returns the double-precision imaginary part of its double-complex argument.

aint, dint – FORTRAN integer part intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
r2 = aint(r1)
dp2 = dint(dp1)
dp2 = aint(dp1)
```

DESCRIPTION

The *aint* function returns the truncated value of its real argument in a real. The *dint* function returns the truncated value of its double-precision argument as a double-precision value. The *aint* function may be used as a generic function name, returning either a real or double-precision value depending on the type of its argument. ASIN(3F)

NAME

asin, dasin - FORTRAN arcsine intrinsic function

SYNOPSIS

real r1, r2 double precision dp1, dp2

r2 = asin(r1)

dp2 = dasin(dp1)dp2 = asin(dp1)

DESCRIPTION

The *asin* function returns the real arcsine of its real argument. The *dasin* function returns the double-precision arcsine of its double-precision argument. The generic form *asin* may be used with impunity as it derives its type from that of its argument.

SEE ALSO

ATAN(3F)

NAME

atan, datan - FORTRAN arctangent intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
r2 = atan(r1)
dp2 = datan(dp1)
dp2 = atan(dp1)
```

DESCRIPTION

The *atan* function returns the real arctangent of its real argument. The *datan* function returns the double-precision arctangent of its double-precision argument. The generic form *atan* may be used with a double-precision argument returning a double-precision value.

SEE ALSO

atan2, datan2 - FORTRAN arctangent intrinsic function

SYNOPSIS

real r1, r2, r3 double precision dp1, dp2, dp3

r3 = atan2(r1, r2)

dp3 = datan2(dp1, dp2)dp3 = atan2(dp1, dp2)

DESCRIPTION

The *atan2* function returns the arctangent of arg1/arg2 as a real value. The *datan2* function returns the double-precision arctangent of its double-precision arguments. The generic form *atan2* may be used with impunity with double-precision arguments.

SEE ALSO

BOOL(3F)

NAME

bool: and, or, xor, not, lshift, rshift - FORTRAN Bitwise Boolean functions

SYNOPSIS

integer i, j, k real a, b, c k = and(i, j)c = or(a, b)j = xor(i, a)j = not(i)k = lshift(i, j)k = rshift(i, j)

DESCRIPTION

The generic intrinsic Boolean functions *and*, *or* and *xor* return the value of the binary operations on their arguments. *Not* is a unary operator returning the one's complement of its argument. *Lshift* and *rshift* return the value of the first argument shifted left or right, respectively, the number of times specified by the second (integer) argument.

While it is recommended that Boolean functions be used only on integer data, these functions are generic; that is, they are defined for all data types as arguments and return values. Where required, the compiler generates appropriate type conversions. However, when the functions are not used with integer data, the results are unpredictable.

BUGS

The implementation of the shift functions may cause large shift values to deliver weird results.

SEE ALSO

mil(3F).

CONJG(3F)

NAME

conjg, dconjg - FORTRAN complex conjugate intrinsic function

SYNOPSIS

complex cx1, cx2 double complex dx1, dx2

cx2 = conjg(cx1)

dx2 = dconjg(dx1)

DESCRIPTION

The *conjg* function returns the complex conjugate of its complex argument. The *dconjg* function returns the double-complex conjugate of its double-complex argument. COS(3F)

NAME

cos, dcos, ccos - FORTRAN cosine intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = cos(r1)
dp2 = dcos(dp1)
dp2 = cos(dp1)
cx2 = ccos(cx1)
cx2 = cos(cx1)
```

DESCRIPTION

The *cos* function returns the real cosine of its real argument. The *dcos* function returns the double-precision cosine of its double-precision argument. The *ccos* function returns the complex cosine of its complex argument. The generic form *cos* may be used with impunity as its returned type is determined by that of its argument.

SEE ALSO

COSH(3F)

NAME

cosh, dcosh - FORTRAN hyperbolic cosine intrinsic function

SYNOPSIS

real r1, r2
double precision dp1, dp2
r2 = cosh(r1)
dp2 = dcosh(dp1)
dp2 = cosh(dp1)

DESCRIPTION

The *cosh* function returns the real hyperbolic cosine of its real argument. The *dcosh* function returns the double-precision hyperbolic cosine of its double-precision argument. The generic form *cosh* may be used to return the hyperbolic cosine in the type of its argument.

SEE ALSO

sinh(3M).

DIM(3F)

NAME

dim, ddim, idim – positive difference intrinsic functions

SYNOPSIS

integer a1, a2, a3 a3 = idim(a1, a2)

real a1, a2, a3 a3 = dim(a1, a2)

double precision a1, a2, a3 a3 = ddim(a1, a2)

DESCRIPTION

These functions return: a1-a2 if a1 > a20 if a1 <= a2 DPROD(3F)

NAME

dprod - double precision product intrinsic function

SYNOPSIS

real a1, a2

double precision a3

a3 = dprod(a1, a2)

DESCRIPTION

The *dprod* function returns the double precision product of its real arguments.

exp, dexp, cexp - FORTRAN exponential intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = exp(r1)
dp2 = dexp(dp1)
dp2 = exp(dp1)
cx2 = cexp(cx1)
cx2 = exp(cx1)
```

DESCRIPTION

The *exp* function returns the real exponential function e^x of its real argument. The *dexp* function returns the double-precision exponential function of its double-precision argument. The *cexp* function returns the complex exponential function of its complex argument. The generic function *exp* becomes a call to *dexp* or *cexp* as required, depending on the type of its argument.

SEE ALSO

exp(3M).

ftype: int, ifix, idint, real, float, sngl, dble, cmplx, dcmplx, ichar, char – explicit FORTRAN type conversion

SYNOPSIS

r = sngl(dp)

dp = dble(i)

dp = dble(r)

dp = dble(cx)

dp = dble(dcx)

cx = cmplx(i)

cx = cmplx(i, j)

cx = cmplx(r)

cx = cmplx(r, s)

cx = cmplx(dp)

cx = cmplx(dp, dq)

cx = cmplx(dcx)

dcx = dcmplx(i)

dcx = dcmplx(i, j)

dcx = dcmplx(r)

dcx = dcmplx(r, s)

dcx = dcmplx(dp)

dcx = dcmplx(dp, dq)

dcx = dcmplx(cx)

i = ichar(ch)

ch = char(i)

DESCRIPTION

These functions perform conversion from one data type to another.

The function **int** converts to *integer* form its *real*, *double precision*, *complex*, or *double complex* argument. If the argument is *real* or *double precision*, **int**

returns the integer whose magnitude is the largest integer that does not exceed the magnitude of the argument and whose sign is the same as the sign of the argument (i.e., truncation). For complex types, the above rule is applied to the real part. **ifix** and **idint** convert only *real* and *double precision* arguments, respectively.

The function **real** converts to *real* form an *integer*, *double precision*, *complex*, or *double complex* argument. If the argument is *double precision* or *double complex*, as much precision is kept as possible. If the argument is one of the complex types, the real part is returned. **float** and **sngl** convert only *integer* and *double precision* arguments, respectively.

The function **dble** converts any *integer, real, complex,* or *double complex* argument to *double precision* form. If the argument is of a complex type, the real part is returned.

The function **cmplx** converts its *integer*, *real*, *double precision*, or *double complex* argument(s) to *complex* form.

The function **dcmplx** converts to *double complex* form its *integer*, *real*, *double precision*, or *complex* argument(s).

Either one or two arguments may be supplied to **cmplx** and **dcmplx**. If there is only one argument, it is taken as the real part of the complex type and an imaginary part of zero is supplied. If two arguments are supplied, the first is taken as the real part and the second as the imaginary part.

The function **ichar** converts from a character to an integer depending on the character's position in the collating sequence.

The function **char** returns the character in the ith position in the processor collating sequence where i is the supplied argument.

For a processor capable of representing *n* characters,

ichar(char(i)) = i for $0 \le i < n$, and

char(**ichar**(ch)) = ch for any representable character *ch*.

GETARG(3F)

NAME

getarg - return FORTRAN command-line argument

SYNOPSIS

character*N c integer i

call getarg(i, c)

DESCRIPTION

The *getarg* function returns the i-th command-line argument of the current process. Thus, if a program were invoked via

for arg1 arg2 arg3

The getarg(2, c) function would return the string "arg2" in the character variable c.

SEE ALSO

getopt(3C).

getenv - return FORTRAN environment variable

SYNOPSIS

character*N c

call getenv("VARIABLE_NAME", c)

DESCRIPTION

The *getenv* function returns the character-string value of the environment variable represented by its first argument into the character variable of its second argument. If no such environment variable exists, all blanks will be returned.

SEE ALSO

getenv(3C), environ(5).

IARGC(3F)

NAME

iargc - return the number of command line arguments

SYNOPSIS

integer i

i = iargc()

DESCRIPTION

The *iargc* function returns the number of command line arguments passed to the program. Thus, if a program were invoked via

foo arg1 arg2 arg3

iargc() would return 3.

SEE ALSO

getarg(3F).

INDEX(3F)

NAME

index - return location of FORTRAN substring

SYNOPSIS

```
character*N1 ch1
character*N2 ch2
integer i
```

i = index(ch1, ch2)

DESCRIPTION

The *index* function returns the location of substring ch^2 in string ch^1 . The value returned is the position at which substring ch^2 starts, or 0 if it is not present in string ch^1 . If N2 is greater than N1, a zero is returned.

LEN(3F)

NAME

len – return length of FORTRAN string

SYNOPSIS

character*N ch integer i

i = len(ch)

DESCRIPTION

The *len* function returns the length of string *ch*.

LOG(3F)

NAME

log, alog, dlog, clog - FORTRAN natural logarithm intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = alog(r1)
r2 = log(r1)
dp2 = dlog(dp1)
dp2 = log(dp1)
cx2 = clog(cx1)
cx2 = log(cx1)
```

DESCRIPTION

The *alog* function returns the real natural logarithm of its real argument. The *dlog* function returns the double-precision natural logarithm of its double-precision argument. The *clog* function returns the complex logarithm of its complex argument. The generic function *log* becomes a call to *alog*, *dlog*, or *clog* depending on the type of its argument.

SEE ALSO

exp(3M).

LOG10(3F)

NAME

log10, alog10, dlog10 - FORTRAN common logarithm intrinsic function

SYNOPSIS

real r1, r2
double precision dp1, dp2
r2 = alog10(r1)
r2 = log10(r1)
dp2 = dlog10(dp1)

dp2 = log10(dp1)

DESCRIPTION

The *alog10* function returns the real common logarithm of its real argument. The *dlog10* function returns the double-precision common logarithm of its double-precision argument. The generic function log10 becomes a call to *alog10* or *dlog10* depending on the type of its argument.

SEE ALSO

exp(3M).

max, max0, amax0, max1, amax1, dmax1 – FORTRAN maximum-value functions

SYNOPSIS

integer i, j, k, l real a, b, c, d double precision dp1, dp2, dp3 l = max(i, j, k)c = max(a, b)dp = max(a, b, c)k = max0(i, j)a = amax0(i, j, k)i = max1(a, b)d = amax1(a, b, c)dp3 = dmax1(dp1, dp2)

DESCRIPTION

The maximum-value functions return the largest of their arguments (of which there may be any number). *max* is the generic form which can be used for all data types and takes its return type from that of its arguments (which must all be of the same type). *max0* returns the integer form of the maximum value of its integer arguments; *amax0*, the real form of its integer arguments; *max1*, the integer form of its real arguments; *amax1*, the real form of its double-precision form of its double-precision arguments.

SEE ALSO

min(3F).

mclock - return FORTRAN time accounting

SYNOPSIS

integer i

i = mclock()

DESCRIPTION

The *mclock* function returns time accounting information about the current process and its child processes. The value returned is the sum of the current process's user time and the user and system times of all child processes.

SEE ALSO

times(2), clock(3C), system(3F).

MIL(3F)

NAME

mil: ior, iand, not, ieor, ishft, ishftc, ibits, btest, ibset, ibclr, mvbits – FOR-TRAN Military Standard functions

SYNOPSIS

integer i, k, l, m, n, len logical b

```
i = ior(m, n)
i = iand(m, n)
i = not(m)
i = ieor(m, n)
i = ishft(m, k)
i = ishftc(m, k, len)
i = ibits(m, k, len)
b = btest(n, k)
i = ibclr(n, k)
i = ibclr(n, k, len, n, l)
```

DESCRIPTION

mil is the general name for the bit field manipulation intrinsic functions and subroutines from the FORTRAN Military Standard (MIL-STD-1753). *ior, iand, not, ieor* – return the same results as *and, or, not,* and *xor* as defined in *bool*(3F).

ishft, ishftc – **m** specifies the integer to be shifted. **k** specifies the shift count. $\mathbf{k} > 0$ indicates a left shift. $\mathbf{k} = 0$ indicates no shift. $\mathbf{k} < 0$ indicates a right shift. In *ishft*, zeros are shifted in. In *ishftc*, the rightmost **len** bits are shifted circularly **k** bits. If **k** is greater than the machine word-size, *ishftc* will not shift.

Bit fields are numbered from right to left and the rightmost bit position is zero. The length of the **len** field must be greater than zero.

ibits – extract a subfield of **len** bits from **m** starting with bit position **k** and extending left for **len** bits. The result field is right justified and the remaining bits are set to zero.

btest – The kth bit of argument **n** is tested. The value of the function is .TRUE. if the bit is a 1 and .FALSE. if the bit is 0.

ibset – the result is the value of \mathbf{n} with the **k**th bit set to 1.

ibclr – the result is the value of \mathbf{n} with the **k**th bit set to 0.

mvbits – len bits are moved beginning at position \mathbf{k} of argument \mathbf{m} to position \mathbf{l} of argument \mathbf{n} .

SEE ALSO

bool(3F).

min, min0, amin0, min1, amin1, dmin1 – FORTRAN minimum-value functions

SYNOPSIS

integer i, j, k, l real a, b, c, d double precision dp1, dp2, dp3 l = min(i, j, k)c = min(a, b)dp = min(a, b, c)k = min0(i, j)a = amin0(i, j, k)i = min1(a, b)d = amin1(a, b, c)dp3 = dmin1(dp1, dp2)

DESCRIPTION

The minimum-value functions return the minimum of their arguments (of which there may be any number). *min* is the generic form which can be used for all data types and takes its return type from that of its arguments (which must all be of the same type). *min0* returns the integer form of the minimum value of its integer arguments; *amin0*, the real form of its integer arguments; *min1*, the integer form of its real arguments; *amin1*, the real form of its real arguments; and *dmin1*, the double-precision form of its double-precision arguments.

SEE ALSO

max(3F).

MOD(3F)

NAME

mod, amod, dmod - FORTRAN remaindering intrinsic functions

SYNOPSIS

```
integer i, j, k
real r1, r2, r3
double precision dp1, dp2, dp3
k = mod(i, j)
r3 = amod(r1, r2)
r3 = mod(r1, r2)
dp3 = dmod(dp1, dp2)
dp3 = mod(dp1, dp2)
```

DESCRIPTION

The *mod* function returns the integer remainder of its first argument divided by its second argument. *Amod* and *dmod* return, respectively, the real and double-precision whole number remainder of the integer division of their two arguments. The generic version *mod* will return the data type of its arguments. RAND(3F)

NAME

rand, irand, srand - random number generator

SYNOPSIS

integer iseed, i, irand double precision x, rand

call srand(iseed)

i = irand()

x = rand()

DESCRIPTION

The *irand* function generates successive pseudo-random integers in the range from 0 to 2^{**15-1} . The *rand* function generates pseudo-random numbers distributed in [0, 1.0]. The *srand* function uses its integer argument to re-initialize the seed for successive invocations of *irand* and *rand*.

SEE ALSO

rand(3C).

round: anint, dnint, nint, idnint - FORTRAN nearest integer functions

SYNOPSIS

```
integer i
real r1, r2
double precision dp1, dp2
r2 = anint(r1)
i = nint(r1)
dp2 = anint(dp1)
dp2 = dnint(dp1)
i = nint(dp1)
i = idnint(dp1)
```

DESCRIPTION

The *anint* function returns the nearest whole real number to its real argument (i.e., int(a+0.5) if $a \ge 0$, int(a-0.5) otherwise). The *dnint* function does the same for its double-precision argument. The *nint* function returns the nearest integer to its real argument. The *idnint* function is the double-precision version. The *anint* function is the generic form of *anint* and *dnint*, performing the same operation and returning the data type of its argument. The *nint* function is also the generic form of *idnint*.

SIGN(3F)

NAME

sign, isign, dsign - FORTRAN transfer-of-sign intrinsic function

SYNOPSIS

```
integer i, j, k
real r1, r2, r3
double precision dp1, dp2, dp3
k = isign(i, j)
k = sign(i, j)
r3 = sign(r1, r2)
dp3 = dsign(dp1, dp2)
dp3 = sign(dp1, dp2)
```

DESCRIPTION

The *isign* function returns the magnitude of its first argument with the sign of its second argument. The *sign* and *dsign* functions are its real and double-precision counterparts, respectively. The generic version is *sign* and will devolve to the appropriate type depending on its arguments.

signal - specify FORTRAN action on receipt of a system signal

SYNOPSIS

integer i, intfc external intfc

call signal(i, intfc)

DESCRIPTION

The argument **i** specifies the signal to be caught. *signal* allows a process to specify a function to be invoked upon receipt of a specific signal. The first argument specifies which fault or exception. The second argument specifies the function to be invoked.

NOTE: The interrupt processing function, *intfc*, does not take an argument.

SEE ALSO

kill(2), signal(2).

SIN(3F)

NAME

sin, dsin, csin - FORTRAN sine intrinsic function

SYNOPSIS

real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = sin(r1)
dp2 = dsin(dp1)

 $dp^{2} = sin(dp1)$ $cx^{2} = csin(cx1)$ $cx^{2} = sin(cx1)$

DESCRIPTION

The *sin* function returns the real sine of its real argument. The *dsin* function returns the double-precision sine of its double-precision argument. The *csin* function returns the complex sine of its complex argument. The generic *sin* function becomes *dsin* or *csin* as required by argument type.

SEE ALSO

trig(3M).

SINH(3F)

NAME

sinh, dsinh – FORTRAN hyperbolic sine intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
r2 = sinh(r1)
dp2 = dsinh(dp1)
dp2 = sinh(dp1)
```

DESCRIPTION

The *sinh* function returns the real hyperbolic sine of its real argument. The *dsinh* function returns the double-precision hyperbolic sine of its double-precision argument. The generic form *sinh* may be used to return a double-precision value when given a double-precision argument.

SEE ALSO

sinh(3M).

SQRT(3F)

NAME

sqrt, dsqrt, csqrt - FORTRAN square root intrinsic function

SYNOPSIS

real r1, r2 double precision dp1, dp2 complex cx1, cx2

r2 = sqrt(r1)

dp2 = dsqrt(dp1) dp2 = sqrt(dp1) cx2 = csqrt(cx1) cx2 = sqrt(cx1)

DESCRIPTION

The *sqrt* function returns the real square root of its real argument. The *dsqrt* function returns the double-precision square root of its double-precision argument. The *csqrt* function returns the complex square root of its complex argument. *sqrt*, the generic form, will become *dsqrt* or *csqrt* as required by its argument type.

SEE ALSO

exp(3M).

STRCMP(3F)

NAME

strcmp: lge, lgt, lle, llt - string comparison intrinsic functions

SYNOPSIS

character*N a1, a2 logical l

DESCRIPTION

These functions return .TRUE. if the inequality holds and .FALSE. otherwise.

system - issue a shell command from FORTRAN

SYNOPSIS

character*N c

call system(c)

DESCRIPTION

The *system* function causes its character argument to be given to sh(1) as input, as if the string had been typed at a terminal. The current process waits until the shell has completed.

SEE ALSO

exec(2), system(3S). sh(1) in the User's Reference Manual.

tan, dtan - FORTRAN tangent intrinsic function

SYNOPSIS

```
real r1, r2
double precision dp1, dp2
r2 = tan(r1)
dp2 = dtan(dp1)
dp2 = tan(dp1)
```

DESCRIPTION

The *tan* function returns the real tangent of its real argument. The *dtan* function returns the double-precision tangent of its double-precision argument. The generic *tan* function becomes *dtan* as required with a double-precision argument.

SEE ALSO

trig(3M).

TANH(3F)

NAME

tanh, dtanh - FORTRAN hyperbolic tangent intrinsic function

SYNOPSIS

real r1, r2
double precision dp1, dp2
r2 = tanh(r1)
dp2 = dtanh(dp1)
dp2 = tanh(dp1)

DESCRIPTION

The *tanh* function returns the real hyperbolic tangent of its real argument. The *dtanh* function returns the double-precision hyperbolic tangent of its double-precision argument. The generic form *tanh* may be used to return a double-precision value given a double-precision argument.

SEE ALSO

sinh(3M).

INTRO(4)

NAME

intro - introduction to file formats

DESCRIPTION

This section outlines the formats of various files. The C structure declarations for the file formats are given where applicable. Usually, the header files containing these structure declarations can be found in the directories /usr/include or /usr/include/sys. For inclusion in C language programs, however, the syntax **#include** <**filename.h**> or **#include** <**sys/filename.h**> should be used.

a.out - common assembler and link editor output

SYNOPSIS

#include <a.out.h>

DESCRIPTION

The file name **a.out** is the default output file name from the link editor ld(1). The link editor will make *a.out* executable if there were no errors in linking. The output file of the assembler *as* (1) also follows the common object file format of the *a.out* file although the default file name is different.

A common object file consists of a file header, a UNIX system header (if the file is link editor output), a table of section headers, relocation information, (optional) line numbers, a symbol table and a string table. The order is given below.

File header. UNIX system header. Section 1 header. Section n header. Section 1 data. ... Section n data. Section 1 relocation. ... Section n relocation. Section 1 line numbers. ... Section n line numbers. Symbol table. String table.

The last three parts of an object file (line numbers, symbol table and string table) may be missing if the program was linked with the -s option of ld(1) or if they were removed by *strip*(1). Also note that the relocation information will be absent after linking unless the -r option of ld(1) was used. The string table exists only if the symbol table contains symbols with names longer than eight characters.

The sizes of each section (contained in the header, discussed below) are in bytes.

When an **a.out** file is loaded into memory for execution, three logical segments are set up: the text segment, the data segment (initialized data followed by uninitialized, the latter actually being initialized to all 0's), and a stack. On your computer, the text segment starts at location virtual address 0.

The a.out file produced by ld(1) may have one of two magic numbers in the first field of the UNIX system header. A magic number of 0410 indicates

that the executable must be swapped through the private swapping store of the UNIX system, while the magic number 0413 causes the system to attempt to page the text directly from the a.out file.

In a 0410 executable, the text section is loaded at virtual location 0x00000000. The data section is loaded immediately following the end of the text section.

For a 0413 executable, the headers (file header, UNIX system header, and section headers) are loaded at the beginning of the text segment and the text immediately follows the headers in the user address space. The first text address will equal the sum of the sizes of the headers, and will vary depending on the number of sections in the a.out file. In an a.out file with 3 sections (.text, .data, and .bss) the first text address is at 0x000000D0. The data section starts in the next page table directory after the last one used by the text section, in the first page of that directory, with an offset into that page equal to the 1st unused memory offset in the last page of text. That is to say, given that *etext* is the address of the last byte of the text section, the 1st byte of the data section will be at 0x00400000 + (*etext* & 0xFFC00000) + ((*etext*+1) & 0xFFC00FFF).

The user address space of the 80286 consists of 4096 segments. Segment number N is located at address (N*8+7)*65536. A small model process has one text segment (segment number 10), and one segment that contains data, bss, and stack (segment 11). A large model process has one segment for the stack (segment 9), one or more segments for text (starting at segment 10), and one or more segments for data and bss (starting at the first segment after the last text segment). Segments consist of some integer multiple of 512 bytes, with a maximum of 65536 bytes per segment.

On the 80386 computer the stack begins at location 7FFFFFC and grows toward lower addresses. On the 80286 computer the stack begins at location 0x004FFFFF and grows toward lower addresses. The stack is automatically extended as required. The data segment is extended only as requested by the *brk*(2) system call.

For relocatable files the value of a word in the text or data portions that is not a reference to an undefined external symbol is exactly the value that will appear in memory when the file is executed. If a word in the text involves a reference to an undefined external symbol, there will be a relocation entry for the word, the storage class of the symbol-table entry for the symbol will be marked as an "external symbol", and the value and section number of the symbol-table entry will be undefined. When the file is processed by the link editor and the external symbol becomes defined, the value of the symbol will be added to the word in the file.

A.OUT(4)

File Header

The format of the **filehdr** header is

struct filehdr

```
unsigned short f_magic; /* magic number */

unsigned short f_nscns; /* number of sections */

long f_timdat; /* time and date stamp */

long f_symptr; /* file ptr to symtab */

long f_nsyms; /* # symtab entries */

unsigned short f_opthdr; /* sizeof(opt hdr) */

unsigned short f_flags; /* flags */
```

};

ł

UNIX System Header

The format of the UNIX system header is

typedef struct aouthdr

short	magic;	/* magic number */
short	vstamp;	/* version stamp */
long	tsize;	/* text size in bytes, padded */
long	dsize;	/* initialized data (.data) */
long	bsize;	/* uninitialized data (.bss) */
long	entry;	/* entry point */
long	text_start;	/* hase of text used for this file */
long	text_start;	/* base of text used for this file */
long	data_start;	/* base of data used for this file */

} AOUTHDR;

Section Header

The format of the section header is

struct scnhdr

{

char s_name[SYMNMLEN];/* section name */ long s_paddr; /* physical address */ long s_vaddr; /* virtual address */ long s_size; /* section size */ long /* file ptr to raw data */ s_scnptr; long s__relptr; /* file ptr to relocation */ long s_lnnoptr; /* file ptr to line numbers */ /* # reloc entries */ unsigned short s_nreloc; /* # line number entries */ unsigned short s_nlnno; long s_flags; /* flags */

};

Relocation

Object files have one relocation entry for each relocatable reference in the text or data. If relocation information is present, it will be in the following format:

```
struct reloc
{
    long r_vaddr; /* (virtual) address of reference */
    long r_symndx; /* index into symbol table */
    ushort r_type; /* relocation type */
};
```

The start of the relocation information is s_relptr from the section header. If there is no relocation information, s_relptr is 0.

Symbol Table

The format of each symbol in the symbol table is

#define SYMNMLEN #define FILNMLEN #define DIMNUM	8 14 4	
struct syment { union		/* all ways to get a symbol name */
{ char struct {	_n_name[SYM	/INMLEN];
long long }n_n;	_n_offset;	<pre>/* == 0L if in string table */ /* location in string table */</pre>
char }n;	*_n_nptr[2];	/* allows overlaying */
Íong short unsigned short char	n_scnum; n_type; n_sclass;	/* value of symbol */ /* section number */ /* type and derived type */ /* storage class */ /* number of aux entries */
#define n_name #define n_zeroes #define n_offset #define n_nptr	_nn_name nn nnn nn	_offset

Some symbols require more information than a single entry; they are followed by *auxiliary entries* that are the same size as a symbol entry. The format follows.

```
union auxent {
      struct {
                   x_tagndx;
            long
            union {
                   struct {
                            unsigned short x_lnno;
                            unsigned short x_size;
                    } x_lnsz;
                            x_fsize;
                   long
            } x_misc;
            union {
                   struct {
                                   x_lnnoptr;
                            long
                            long
                                   x_endndx;
                   } x_fcn;
                   struct {
                            unsigned short x_dimen[DIMNUM];
                   } x_ary;
            } x_fcnary;
            unsigned short x_tvndx;
      } x_sym;
      struct {
            char
                   x_fname[FILNMLEN];
      } x_file;
      struct {
            long
                      x__scnlen;
            unsigned short x_nreloc;
            unsigned short x_nlinno;
      } x__scn;
      struct {
            long
                           x_tvfill;
            unsigned short x_tvlen;
            unsigned short x_tvran[2];
      } x_tv;
};
```

Indexes of symbol table entries begin at zero. The start of the symbol table is f_symptr (from the file header) bytes from the beginning of the file. If the symbol table is stripped, f_symptr is 0. The string table (if one exists) begins at $f_symptr + (f_nsyms * SYMESZ)$ bytes from the beginning of the file.

acct - per-process accounting file format

SYNOPSIS

#include <sys/acct.h>

DESCRIPTION

Files produced as a result of calling acct(2) have records in the form defined by **<sys/acct.h**>, whose contents are:

typedef ushort comp_t; /* "floating point" */ /* 13-bit fraction, 3-bit exponent */

struct	acct		
{	ushort	ac_flag; ac_stat; ac_uid; ac_gid;	/* Accounting flag */ /* Exit status */
	dev_t time_t comp_t comp_t comp_t comp_t	ac_tty; ac_btime; ac_utime;	/* Beginning time */ /* acctng user time in clock ticks */ /* acctng system time in clock ticks */ /* acctng elapsed time in clock ticks */ /* memory usage in clicks */ /* chars trnsfrd by read/write */ /* number of block reads/writes */
}:	1		/* command name */

};

4

extern struct	acct	acctbuf;
extern struct	inode	*acctp; /* inode of accounting file */
#define AFORK #define ASU #define ACCTF	02	/* has executed fork, but no exec */ /* used super-user privileges */ /* record type: 00 = acct */

In ac_flag, the AFORK flag is turned on by each fork(2) and turned off by an exec(2). The ac_comm field is inherited from the parent process and is reset by any exec. Each time the system charges the process with a clock tick, it also adds to *ac_mem* the current process size, computed as follows:

(data size) + (text size) / (number of in-core processes using text)

The value of ac_mem / (ac_stime + ac_utime) can be viewed as an approximation to the mean process size, as modified by text-sharing.

The structure **tacct.h**, which resides with the source files of the accounting commands, represents the total accounting format used by the various accounting commands:

/*

```
* total accounting (for acct period), also for day
```

*/

struct	tacct {		
	uid_t	ta_uid;	/* userid */
	char	ta_name[8];	/* login name */
	float	ta_cpu[2];	/* cum. cpu time, p/np (mins) */
	float	ta_kcore[2];	/* cum kcore-minutes, p/np */
	float		/* cum. connect time, p/np, mins */
	float	ta_du;	/* cum. disk usage */
	long	ta_pc;	/* count of processes */
	unsigned short		/* count of login sessions */
	unsigned short		/* count of disk samples */
	unsigned short	ta_fee;	/* fee for special services */
};			

SEE ALSO

acct(2), exec(2), fork(2). acct(1M) in the System Administrator's Reference Manual. acctcom(1) in the User's Reference Manual.

BUGS

The *ac_mem* value for a short-lived command gives little information about the actual size of the command, because *ac_mem* may be incremented while a different command (e.g., the shell) is being executed by the process.

ar - common archive file format

SYNOPSIS

#include <ar.h>

DESCRIPTION

The archive command ar(1) is used to combine several files into one. Archives are used mainly as libraries to be searched by the link editor ld(1).

Each archive begins with the archive magic string.

#define	ARMAG	"! <arch>\n"</arch>	/* magic string */
#define	SARMAG	8	/* length of magic string */

Each archive which contains common object files [see a.out(4)] includes an archive symbol table. This symbol table is used by the link editor ld(1) to determine which archive members must be loaded during the link edit process. The archive symbol table (if it exists) is always the first file in the archive (but is never listed) and is automatically created and/or updated by ar.

Following the archive magic string are the archive file members. Each file member is preceded by a file member header which is of the following format:

#define ARFN	/AG "`\n"	/* header trailer string */
struct ar_hdr		/* file member header */
char ar_ char ar_ char ar_ char ar_ char ar_	date[12]; uid[6]; gid[6]; mode[8]; size[10];	/* '/' terminated file member name */ /* file member date */ /* file member user identification */ /* file member group identification */ /* file member mode (octal) */ /* file member size */ /* header trailer string */

All information in the file member headers is in printable ASCII. The numeric information contained in the headers is stored as decimal numbers (except for *ar_mode* which is in octal). Thus, if the archive contains printable files, the archive itself is printable.

The ar_name field is blank-padded and slash (/) terminated. The ar_date field is the modification date of the file at the time of its insertion into the archive. Common format archives can be moved from system to system as long as the portable archive command ar(1) is used. Conversion tools such as convert(1) exist to aid in the transportation of non-common format archives to this format.

- 1 -

Each archive file member begins on an even byte boundary; a new-line is inserted between files if necessary. Nevertheless, the size given reflects the actual size of the file exclusive of padding.

Notice there is no provision for empty areas in an archive file.

If the archive symbol table exists, the first file in the archive has a zero length name (i.e., **ar_name[0]** == '/'). The contents of this file are as follows:

- The number of symbols. Length: 4 bytes.
- The array of offsets into the archive file. Length: 4 bytes * "the number of symbols".
- The name string table. Length: ar_size (4 bytes * ("the number of symbols" + 1)).

The number of symbols and the array of offsets are managed with *sgetl* and *sputl*. The string table contains exactly as many null-terminated strings as there are elements in the offsets array. Each offset from the array is associated with the corresponding name from the string table (in order). The names in the string table are all the defined global symbols found in the common object files in the archive. Each offset is the location of the archive header for the associated symbol.

SEE ALSO

ar(1), ld(1), strip(1), sputl(3X), a.out(4).

WARNINGS

The *strip*(1) command will remove all archive symbol entries from the header. The archive symbol entries must be restored via the **ts** option of the ar(1) command before the archive can be used with the link editor ld(1).

checklist - list of file systems processed by fsck and ncheck

DESCRIPTION

The *checklist* file format resides in directory **/etc** and contains a list of, at most, 15 *special file* names. Each *special file* name is contained on a separate line and corresponds to a file system. Each file system will then be automatically processed by the fsck(1M) command.

FILES

/etc/checklist

SEE ALSO

fsck(1M), ncheck(1M) in the System Administrator's Reference Manual.

config – per-module configuration information

DESCRIPTION

Each module in a configuration tree can have a file named config associated with it [see mkunix(1M)]. This file specifies various attributes of the module. In the syntax given below, the following non-terminals are used:

<name> := alphanumeric sequence

<string> := "alphanumeric sequence"

<number> := "decimal number"

White space may be inserted anywhere, and comments begin with an asterisk and end at the end of the line. All lines are optional and may be specified in any order:

prefix = <name>

module function prefix

```
block(<number>)
```

module is a block device driver with specified major number

```
character(<number>)
```

module is a character device driver with specified major number

```
streamd(<number>)
```

module is a STREAMS driver with specified major number

streamm

module is a STREAMS module

fs(<number>, <string>, <number>)

module is a file system type; the parameters are used to fill in the kernel's fsinfo structure, and represent the fs_flags, fs_name, and fs_notify members, respectively.

```
intvec = <number> [,<number>]...
```

interrupt vector number(s) for hardware device drivers

functions = <name> [,<name>]...

list of standard interface functions supplied with the module. These may include start, init, intr (for hardware drivers), or one of the following depending on module type:

Module TypeLegal Functions

streamminfo

streamdinfo

blockopen, close, strategy, print

characteropen, close, read, write, ioctl, tty

fsinit, iput, iread, iupdat, readi,

writei, itrunc, statf, namei, mount,

umount, getinode, openi, closei,

update, statfs, access, getdents,

allocmap, freemap, readmap, setattr,

notify, fcntl, fsinfo, ioctl

Not all combinations of the above lines are legal; for example, a module cannot be both a file system and any other type of driver. Config(1M)

CONFIG(4)

performs consistency checks of this nature.

FILES

\$CONF/modules/*/config

SEE ALSO mkunix(1M), config(1M), system(4).

core – format of core image file

DESCRIPTION

The UNIX system writes out a core image of a terminated process when any of various errors occur. See *signal*(2) for the list of reasons; the most common are memory violations, illegal instructions, bus errors, and user-generated quit signals. The core image is called **core** and is written in the process's working directory (provided it can be; normal access controls apply). A process with an effective user ID different from the real user ID will not produce a core image.

The first section of the core image is a copy of the system's per-user data for the process, including the registers as they were at the time of the fault. The size of this section depends on the parameter *usize*, which is defined in **<sys/param.h>**. The remainder represents the actual contents of the user's core area when the core image was written. If the text segment is read-only and shared, or separated from data space, it is not dumped.

The format of the information in the first section is described by the *user* structure of the system, defined in **<sys/user.h**>. Not included in this file are the locations of the registers. These are outlined in **<sys/reg.h**>.

sdb(1), setuid(2), signal(2). crash(1M) in the System Administrator's Reference Manual.

- 1 -

cpio - format of cpio archive

DESCRIPTION

The *header* structure, when the -c option of cpio(1) is not used, is:

struct {

short	h_magic,
	h_dev;
ushort	h_ino,
	h_mode,
	h_uid,
	h_gid;
short	h_nlink,
	h_rdev,
	h_mtime[2],
	h_namesize,
	h_filesize[2];
char	h_name[h_namesize rounded to word];

} Hdr;

When the **-c** option is used, the *header* information is described by:

Longtime and Longfile are equivalent to $Hdr.h_mtime$ and $Hdr.h_filesize$, respectively. The contents of each file are recorded in an element of the array of varying length structures, *archive*, together with other items describing the file. Every instance of h_magic contains the constant 070707 (octal). The items h_dev through h_mtime have meanings explained in *stat*(2). The length of the null-terminated path name h_name , including the null byte, is given by $h_namesize$.

The last record of the *archive* always contains the name TRAILER!!!. Special files, directories, and the trailer are recorded with $h_{filesize}$ equal to zero.

SEE ALSO

stat(2). cpio(1), find(1) in the User's Reference Manual. DIR(4)

dir – format of directories

SYNOPSIS

#include <sys/dir.h>

DESCRIPTION

A directory behaves exactly like an ordinary file, save that no user may write into a directory. The fact that a file is a directory is indicated by a bit in the flag word of its i-node entry [see fs(4)]. The structure of a directory entry as given in the include file is:

By convention, the first two entries in each directory are for . and ... The first is an entry for the directory itself. The second is for the parent directory. The meaning of .. is modified for the root directory of the master file system; there is no parent, so .. has the same meaning as ..

SEE ALSO

fs(4).

dirent - file system independent directory entry

SYNOPSIS

#include <sys/dirent.h>
#include <sys/types.h>

DESCRIPTION

Different file system types may have different directory entries. The *dirent* structure defines a file system independent directory entry, which contains information common to directory entries in different file system types. A set of these structures is returned by the *getdents*(2) system call.

The *dirent* structure is defined below. struct dirent {

long	d_ino;
offt	d_off;
unsigned short	d_reclen;
char	d_name[1];

};

The d_ino is a number which is unique for each file in the file system. The field d_off is the offset of that directory entry in the actual file system directory. The field d_name is the beginning of the character array giving the name of the directory entry. This name is null-terminated and may have at most MAXNAMLEN characters. This results in file system independent directory entries being variable length entities. The value of d_reclen is the record length of this entry. This length is defined to be the number of bytes between the current entry and the next one, so that it will always result in the next entry being on a long boundary.

FILES

/usr/include/sys/dirent.h

SEE ALSO

getdents(2).

filehdr - file header for common object files

SYNOPSIS

#include <filehdr.h>

DESCRIPTION

Every common object file begins with a 20-byte header. The following C struct declaration is used:

struct {	filehdr		
ł	unsigned short long long long	f_nscns ; f_timdat ; f_symptr ; f_nsyms ; f_opthdr ;	/* magic number */ /* number of sections */ /* time & date stamp */ /* file ptr to symtab */ /* # symtab entries */ /* sizeof(opt hdr) */ /* flags */
};		-	

 F_{symptr} is the byte offset into the file at which the symbol table can be found. Its value can be used as the offset in fseek(3S) to position an I/O stream to the symbol table. The UNIX system optional header is 28-bytes. The valid magic numbers are given below:

#define I286SMAGIC	0512 /* 80286 computers—small model
	programs */
#define I286LMAGIC	0522 /* 80286 computers—large model
	programs */
#define I386MAGIC	0514 /* 80386 computers */
#define FBOMAGIC	0560 /* 3B2 and 3B5 computers */
#define N3BMAGIC	0550 /* 3B20 computer */
#define NTVMAGIC	0551 /* 3B20 computer */
	0570 /* VAX writable text segments */
#define VAXROMAGIC	0575 /* VAX read only sharable
	text segments */

The value in f_timdat is obtained from the time(2) system call. Flag bits currently defined are:

0000001 /* relocation entries stripped */
0000002 /* file is executable */
0000004 /* line numbers stripped */
0000010 /* local symbols stripped */
0000020 /* minimal object file */
0000040 /* update file, ogen produced */
0000100 /* file is "pre-swabbed" */
0000200 /* 16-bit DEC host */
0000400 /* 32-bit DEC host */
0001000 /* non-DEC host */
0002000 /* "patch" list in opt hdr */
010000 /* contains 80186 instructions */

- 1 -

#define F_80286	020000	/* contains 80286 instructions */
#define F_BM32ID	0160000	/* WE32000 family ID field */

#define F_BM32MAU	0040000	/* file reqs MAU to execute */
#define F_BM32RST	0010000	/* this object file contains restore
		work around [3B5/3B2 only] */

SEE ALSO

time(2), fseek(3S), a.out(4).

FS(4)

NAME

fs: file system - format of system volume

SYNOPSIS

#include <sys/filsys.h> #include <sys/types.h> #include <sys/param.h>

DESCRIPTION

Every file system storage volume has a common format for certain vital information. Every such volume is divided into a certain number of 512byte long sectors. Sector 0 is unused and is available to contain a bootstrap program or other information.

Sector 1 is the *super* block. The format of a super block is:

filsys struct

ł

1			
	ushort	s_isize;	/* size in blocks of i-list */
	daddr_t	s_fsize;	/* size in blocks of entire volume */
	short	s_nfree;	/* number of addresses in s_free */
	daddr_t	s_free[NICFREE];	/* free block list */
	short	s_ninode;	/* number of i-nodes in s_inode */
	ushort	sinode[NICINOD];	/* free i-node list */
	char	s_flock;	/* lock during free list manipulation */
	char	silock;	/* lock during i-list manipulation */
	char	sfmod;	/* super block modified flag */
	char	s_ronly;	/* mounted read-only flag */
	time_t	s_time;	/* last super block update */
	short	s_dinfo[4];	/* device information */
	daddr_t	stfree;	/* total free blocks*/
	ushort	s_tinode;	/* total free i-nodes */
	char	s_fname[6];	/* file system name */
	char	s_fpack[6];	/* file system pack name */
	long	s_fill[12];	/* ADJUST to make sizeof filsys
			be 512; for 80286, array is s_fill[14] */
	long	s_state;	/* file system state */
	long	s_magic;	/* magic number to denote new
			file system */
	long	s_type;	/* type of new file system */
};	-	•	
#define	Fsmagic	0xfd187e20	/* s_magic number */
#define	Fs1b	1	/* 512-byte block */
#define	Fs2b	2	/* 1024-byte block */
	FsOKAY	0x7c269d38	/* s_state: clean */
	FSACTIVE	0x5e72d81a	/* s_state: active */
#define		0xcb096f43	/* s_state: bad root */
#define	FsBADBLK	0xbadbc14b	/* s_state: bad block corrupted it */

S_type indicates the file system type. Currently, two types of file systems are supported: the original 512-byte logical block and the improved 1024-byte logical block. *S_magic* is used to distinguish the original 512-byte oriented file systems from the newer file systems. If this field is not equal to the magic number, *fsMAGIC*, the type is assumed to be *fs1b*, otherwise the *s_type* field is used. In the following description, a block is then determined by the type. For the original 512-byte oriented file system, a block is 512-bytes. For the 1024-byte oriented file system, a block is 1024-bytes or two sectors. The operating system takes care of all conversions from logical block numbers to physical sector numbers.

S_state indicates the state of the file system. A cleanly unmounted, not damaged file system is indicated by the FsOKAY state. After a file system has been mounted for update, the state changes to FsACTIVE. A special case is used for the root file system. If the root file system appears damaged at boot time, it is mounted but marked FsBAD. Lastly, after a file system has been unmounted, the state reverts to FsOKAY.

S_isize is the address of the first data block after the i-list; the i-list starts just after the super block, namely in block 2; thus the i-list is *s_isize-2* blocks long. *S_fsize* is the first block not potentially available for allocation to a file. These numbers are used by the system to check for bad block numbers; if an "impossible" block number is allocated from the free list or is freed, a diagnostic is written on the on-line console. Moreover, the free array is cleared, so as to prevent further allocation from a presumably corrupted free list.

The free list for each volume is maintained as follows. The s_free array contains, in $s_free[1], \ldots, s_free[s_nfree-1]$, up to 49 numbers of free blocks. $S_free[0]$ is the block number of the head of a chain of blocks constituting the free list. The first long in each free-chain block is the number (up to 50) of free-block numbers listed in the next 50 longs of this chain member. The first of these 50 blocks is the link to the next member of the chain. To allocate a block: decrement s_nfree , and the new block is $s_free[s_nfree]$. If the new block number is 0, there are no blocks left, so give an error. If s_nfree became 0, read in the block named by the new block number, replace s_nfree array. To free a block, check if s_nfree is 50; if so, copy s_nfree and the s_free array into it, write it out, and set s_nfree to 0. In any event set $s_free[s_nfree]$ to the freed block's number and increment s_nfree .

S_tfree is the total free blocks available in the file system.

 S_ninode is the number of free i-numbers in the s_inode array. To allocate an i-node: if s_ninode is greater than 0, decrement it and return $s_inode[s_ninode]$. If it was 0, read the i-list and place the numbers of all free i-nodes (up to 100) into the s_inode array, then try again. To free an i-node, provided s_ninode is less than 100, place its number into $s_inode[s_ninode]$ and increment s_ninode . If s_ninode is already 100, do not bother to enter the freed i-node into any table. This list of i-nodes is only to speed up the allocation process; the information as to whether the i-node is really free or not is maintained in the i-node itself. *S_tinode* is the total free i-nodes available in the file system.

S_flock and *s_ilock* are flags maintained in the core copy of the file system while it is mounted and their values on disk are immaterial. The value of *s_fmod* on disk is likewise immaterial; it is used as a flag to indicate that the super block has changed and should be copied to the disk during the next periodic update of file system information.

S_ronly is a read-only flag to indicate write-protection.

S_time is the last time the super block of the file system was changed, and is the number of seconds that have elapsed since 00:00 Jan. 1, 1970 (GMT). During a reboot, the *s_time* of the super block for the root file system is used to set the system's idea of the time.

S_fname is the name of the file system and *s_fpack* is the name of the pack.

I-numbers begin at 1, and the storage for i-nodes begins in block 2. Also, i-nodes are 64 bytes long. I-node 1 is reserved for future use. I-node 2 is reserved for the root directory of the file system, but no other i-number has a built-in meaning. Each i-node represents one file. For the format of an i-node and its flags, see *inode*(4).

fspec - format specification in text files

DESCRIPTION

It is sometimes convenient to maintain text files on the UNIX system with non-standard tabs, (i.e., tabs which are not set at every eighth column). Such files must generally be converted to a standard format, frequently by replacing all tabs with the appropriate number of spaces, before they can be processed by UNIX system commands. A format specification occurring in the first line of a text file specifies how tabs are to be expanded in the remainder of the file.

A format specification consists of a sequence of parameters separated by blanks and surrounded by the brackets <: and :>. Each parameter consists of a keyletter, possibly followed immediately by a value. The following parameters are recognized:

- ttabs The t parameter specifies the tab settings for the file. The value of *tabs* must be one of the following:
 - 1. a list of column numbers separated by commas, indicating tabs set at the specified columns;
 - 2. a followed immediately by an integer *n*, indicating tabs at intervals of *n* columns;
 - 3. a followed by the name of a "canned" tab specification.

Standard tabs are specified by t-8, or equivalently, t1,9,17,25, etc. The canned tabs which are recognized are defined by the tabs(1) command.

- ssize The s parameter specifies a maximum line size. The value of *size* must be an integer. Size checking is performed after tabs have been expanded, but before the margin is prepended.
- **m**margin The **m** parameter specifies a number of spaces to be prepended to each line. The value of margin must be an integer.
- **d** The **d** parameter takes no value. Its presence indicates that the line containing the format specification is to be deleted from the converted file.
- **e** The **e** parameter takes no value. Its presence indicates that the current format is to prevail only until another format specification is encountered in the file.

Default values, which are assumed for parameters not supplied, are t-8 and m0. If the s parameter is not specified, no size checking is performed. If the first line of a file does not contain a format specification, the above defaults are assumed for the entire file. The following is an example of a line containing a format specification:

* <:t5,10,15 s72:> *

If a format specification can be disguised as a comment, it is not necessary to code the d parameter.

fstab - file-system-table

DESCRIPTION

The **/etc/fstab** file contains information about file systems for use by **mount (1M)** and **mountall(1M)**. Each entry in **/etc/fstab** has the following format:

column 1	block special file name of file system or advertised remote resource
column 2	mount-point directory
column 3	"-r" if to be mounted read-only; "-d[r]" if remote
column 4	(optional) file system type string
column 5+	ignored

White-space separates columns. Lines beginning with "# " are comments. Empty lines are ignored.

A file-system-table might read:

/dev/dsk/c1d0s2 /usr S51K /dev/dsk/c1d1s2 /usr/src -r adv_resource /mnt -d

FILES

/etc/fstab

gettydefs – speed and terminal settings used by getty

DESCRIPTION

The **/etc/gettydefs** file contains information used by getty(1M) to set up the speed and terminal settings for a line. It supplies information on what the *login* prompt should look like. It also supplies the speed to try next if the user indicates the current speed is not correct by typing a *
break* character.

Each entry in /etc/gettydefs has the following format:

label# initial-flags # final-flags # login-prompt #next-label

Each entry is followed by a blank line. The various fields can contain quoted characters of the form b, n, c, etc., as well as nnn, where nnn is the octal value of the desired character. The various fields are:

- *label* This is the string against which *getty* tries to match its second argument. It is often the speed, such as **1200**, at which the terminal is supposed to run, but it need not be (see below).
- *initial-flags* These flags are the initial *ioctl*(2) settings to which the terminal is to be set if a terminal type is not specified to *getty*. The flags that *getty* understands are the same as the ones listed in **/usr/include/sys/termio.h** [see *termio*(7)]. Normally only the speed flag is required in the *initial-flags*. *Getty* automatically sets the terminal to raw input mode and takes care of most of the other flags. The *initial-flag* settings remain in effect until *getty* executes *login*(1).
- final-flags These flags take the same values as the *initial-flags* and are set just prior to getty executes login. The speed flag is again required. The composite flag SANE takes care of most of the other flags that need to be set so that the processor and terminal are communicating in a rational fashion. The other two commonly specified *final-flags* are TAB3, so that tabs are sent to the terminal as spaces, and HUPCL, so that the line is hung up on the final close.
- *login-prompt* This entire field is printed as the *login-prompt*. Unlike the above fields where white space is ignored (a space, tab, or new-line), they are included in the *login-prompt* field.
- *next-label* If this entry does not specify the desired speed, indicated by the user typing a *<break>* character, then *getty* will search for the entry with *next-label* as its *label* field and set up the terminal for those settings. Usually, a series of speeds are linked together in this fashion, into a closed set; For instance, **2400** linked to **1200**, which in turn is linked to **300**, which finally is linked to **2400**.

If getty is called without a second argument, then the first entry of **/etc/gettydefs** is used, thus making the first entry of **/etc/gettydefs** the default entry. It is also used if getty cannot find the specified *label*. If **/etc/gettydefs** itself is missing, there is one entry built into the command

which will bring up a terminal at 300 baud.

It is strongly recommended that after making or modifying **/etc/gettydefs**, it be run through *getty* with the check option to be sure there are no errors.

group – group file

DESCRIPTION

The group file format contains for each group the following information:

group name encrypted password numerical group ID comma-separated list of all users allowed in the group

This is an ASCII file. The fields are separated by colons; each group is separated from the next by a new-line. If the password field is null, no password is demanded.

This file resides in directory **/etc**. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical group ID's to names.

inittab – script for the init process

DESCRIPTION

The *inittab* file supplies the script to *init's* role as a general process dispatcher. The process that constitutes the majority of *init's* process dispatching activities is the line process **/etc/getty** that initiates individual terminal lines. Other processes typically dispatched by *init* are daemons and the shell.

The *inittab* file is composed of entries that are position-dependent and have the following format:

id:rstate:action:process

Each entry is delimited by a new-line; however, a backslash (\) preceding a new-line indicates a continuation of the entry. Up to 512 characters per entry are permitted. Comments may be inserted in the *process* field using the sh(1) convention for comments. Comments for lines that spawn *gettys* are displayed by the *who*(1) command. It is expected that they will contain some information about the line such as the location. There are no limits (other than maximum entry size) imposed on the number of entries within the *inittab* file. The entry fields are:

id This is one or two characters used to uniquely identify an entry.

This defines the *run-level* in which this entry is to be processed. rstate Run-levels effectively correspond to a configuration of processes in the system. That is, each process spawned by init is assigned a run-level or run-levels in which it is allowed to exist. The run*levels* are represented by a number ranging from 0 through 6. As an example, if the system is in *run-level* 1, only those entries having a 1 in the *rstate* field will be processed. When *init* is requested to change *run-levels*, all processes which do not have an entry in the *rstate* field for the target *run-level* will be sent the warning signal (SIGTERM) and allowed a 20-second grace period before being forcibly terminated by a kill signal (SIGKILL). The *rstate* field can define multiple *run-levels* for a process by selecting more than one run-level in any combination from 0-6. If no run-level is specified, then the process is assumed to be valid at all run-levels 0-6. There are three other values, **a**, **b**, and **c**, which can appear in the *rstate* field, even though they are not true run-levels. Entries which have these characters in the *rstate* field are processed only when the *telinit* [see *init*(1M)] process requests them to be run (regardless of the current run-level of the system). They differ from runlevels in that init can never enter run-level **a**, **b**, or **c**. Also, a request for the execution of any of these processes does not change the current run-level. Furthermore, a process started by an **a**, **b**, or **c** command is not killed when *init* changes levels. They are only killed if their line in /etc/inittab is marked off in the action field, their line is deleted entirely from **/etc/inittab**, or *init* goes into the SINGLE USER state.

action Key words in this field tell *init* how to treat the process specified in the *process* field. The actions recognized by *init* are as follows: If the process does not exist, then start the process, respawn do not wait for its termination (continue scanning the *inittab* file); and when it dies, restart the process. If the process currently exists, then do nothing and continue scanning the *inittab* file. wait Upon *init's* entering the *run-level* that matches the entry's rstate, start the process and wait for its termination. All subsequent reads of the *inittab* file while init is in the same run-level will cause init to ignore this entry. once Upon *init's* entering a *run-level* that matches the entry's *rstate*, start the process, do not wait for its termination. When it dies, do not restart the process. If upon entering a new *run-level*, where the process is still running from a previous run-level change, the program will not be restarted. boot The entry is to be processed only at *init's* boot-time read of the *inittab* file. Init is to start the process, not wait for its termination; and when it dies, not restart the process. In order for this instruction to be meaningful, the *rstate* should be the default or it must match init's run-level at boot time. This action is useful for an initialization function following a hardware reboot of the system.

- **bootwait** The entry is to be processed the first time *init* goes from single-user to multi-user state after the system is booted. (If **initdefault** is set to **2**, the process will run right after the boot.) *Init* starts the process, waits for its termination and, when it dies, does not restart the process.
- **powerfail** Execute the process associated with this entry only when *init* receives a power fail signal [SIGPWR see *signal*(2)].
- **powerwait** Execute the process associated with this entry only when *init* receives a power fail signal (SIGPWR) and wait until it terminates before continuing any processing of *inittab*.
- off If the process associated with this entry is currently running, send the warning signal (SIGTERM) and wait 20 seconds before forcibly terminating the process via the kill signal (SIGKILL). If the process is nonexistent, ignore the entry.
- ondemand This instruction is really a synonym for the respawn action. It is functionally identical to respawn but is

given a different keyword in order to divorce its association with *run-levels*. This is used only with the a, b, or c values described in the *rstate* field.

- initdefault An entry with this action is only scanned when *init* initially invoked. *Init* uses this entry, if it exists, to determine which *run-level* to enter initially. It does this by taking the highest *run-level* specified in the **rstate** field and using that as its initial state. If the *rstate* field is empty, this is interpreted as **0123456** and so *init* will enter *run-level* **6**. Additionally, if *init* does not find an **initdefault** entry in /etc/inittab, then it will request an initial *run-level* from the user at reboot time.
- **sysinit** Entries of this type are executed before *init* tries to access the console (i.e., before the **Console Login:** prompt). It is expected that this entry will be used only to initialize devices on which *init* might try to ask the *run-level* question. These entries are executed and waited for before continuing.
- process This is a *sh* command to be executed. The entire **process** field is prefixed with *exec* and passed to a forked *sh* as **sh** -**c** '*exec command*'. For this reason, any legal *sh* syntax can appear in the *process* field. Comments can be inserted with the *;* #*comment* syntax.

inode - format of an i-node

SYNOPSIS

#include <sys/types.h>
#include <sys/ino.h>

DESCRIPTION

An i-node for a plain file or directory in a file system has the following structure defined by $\langle sys/ino.h \rangle$.

```
/* Inode structure as it appears on a disk block. */ struct dinode
```

{

	ushort	dimode;	/* mode and type of file */
	short	di_nlink;	/* number of links to file */
	ushort		/* owner's user id */
		di_gid;	/* owner's group id */
		disize;	/* number of bytes in file */
		,	/* disk block addresses */
	time_t	diatime;	/* time last accessed */
	time_t	dimtime;	/* time last modified */
	timet	dictime;	/* time of last file status change */
};			
/*			
′* th	e 40 addı	ess bytes:	
*	39 used:	13 addresses	
*	of 3 byte	es eacn.	
*/			
•		1 (2) 1	

For the meaning of the defined types off_t and time_t see types(5).

ISSUE(4)

NAME

issue - issue identification file

DESCRIPTION

The file **/etc/issue** contains the *issue* or project identification to be printed as a login prompt. This is an ASCII file which is read by program *getty* and then written to any terminal spawned or respawned from the *lines* file.

FILES

/etc/issue

SEE ALSO

login(1) in the User's Reference Manual.

LDFCN(4)

NAME

ldfcn - common object file access routines

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

DESCRIPTION

The common object file access routines are a collection of functions for reading common object files and archives containing common object files. Although the calling program must know the detailed structure of the parts of the object file that it processes, the routines effectively insulate the calling program from knowledge of the overall structure of the object file.

The interface between the calling program and the object file access routines is based on the defined type LDFILE, defined as **struct ldfile**, declared in the header file **ldfcn.h**. The primary purpose of this structure is to provide uniform access to both simple object files and to object files that are members of an archive file.

The function ldopen(3X) allocates and initializes the LDFILE structure and returns a pointer to the structure to the calling program. The fields of the LDFILE structure may be accessed individually through macros defined in **ldfcn.h**. The fields contain the following information:

LDFILE *ldptr;

TYPE(ldptr) The file magic number used to distinguish between archive members and simple object files.

- IOPTR(ldptr) The file pointer returned by *fopen* and used by the standard input/output functions.
- OFFSET(ldptr) The file address of the beginning of the object file; the offset is non-zero if the object file is a member of an archive file.

HEADER(ldptr) The file header structure of the object file.

The object file access functions themselves may be divided into four categories:

(1) functions that open or close an object file

ldopen(3X) and ldaopen[see ldopen(3X)] open a common object file ldclose(3X) and ldaclose[see ldclose(3X)] close a common object file

(2) functions that read header or symbol table information

ldahread(3X)

read the archive header of a member of an archive file

ldfhread(3X)

read the file header of a common object file

ldshread(3X) and *ldnshread*[see *ldshread*(3X)]

read a section header of a common object file

ldtbread(3X)

read a symbol table entry of a common object file *ldgetname*(3X)

retrieve a symbol name from a symbol table entry or from the string table

(3) functions that position an object file at (seek to) the start of the section, relocation, or line number information for a particular section.

ldohseek(3X)

seek to the optional file header of a common object file

ldsseek(3X) and *ldnsseek*[see *ldsseek*(3X)]

seek to a section of a common object file

ldrseek(3X) and *ldnrseek*[see *ldrseek*(3X)]

seek to the relocation information for a section of a common object file

ldlseek(3X) and *ldnlseek*[see *ldlseek*(3X)]

seek to the line number information for a section of a common object file

ldtbseek(3X)

seek to the symbol table of a common object file

(4) the function *ldtbindex*(3X) which returns the index of a particular common object file symbol table entry.

These functions are described in detail on their respective manual pages.

All the functions except ldopen(3X), ldgetname(3X), ldtbindex(3X), return either **SUCCESS** or **FAILURE**, both constants defined in **ldfcn.h**. The ldopen(3X) and ldaopen[(see ldopen(3X)]] functions both return pointers to an **LDFILE** structure.

Additional access to an object file is provided through a set of macros defined in **ldfcn.h**. These macros parallel the standard input/output file reading and manipulating functions, translating a reference of the **LDFILE** structure into a reference to its file descriptor field.

The following macros are provided:

GETC(ldptr) FGETC(ldptr) GETW(ldptr) UNGETC(c, ldptr) FGETS(s, n, ldptr) FREAD((char *) ptr, sizeof (*ptr), nitems, ldptr) FSEEK(ldptr, offset, ptrname) FTELL(ldptr) REWIND(ldptr) FEOF(ldptr) FERROR(ldptr)

FILENO(ldptr) SETBUF(ldptr, buf) STROFFSET(ldptr)

The STROFFSET macro calculates the address of the string table. See the manual entries for the corresponding standard input/output library functions for details on the use of the rest of the macros.

The program must be loaded with the object file access routine library **libld.a**.

SEE ALSO

fseek(3S), ldahread(3X), ldclose(3X), ldgetname(3X), ldfhread(3X), ldlread(3X), ldlseek(3X), ldohseek(3X), ldopen(3X), ldrseek(3X), ldlseek(3X), ldshread(3X), ldtbindex(3X), ldtbread(3X), ldtbseek(3X), stdio(3S), intro(5).

WARNING

The macro **FSEEK** defined in the header file **ldfcn.h** translates into a call to the standard input/output function *fseek*(3S). **FSEEK** should not be used to seek from the end of an archive file, since the end of an archive file may not be the same as the end of one of its object file members!

limits - file header for implementation-specific constants

SYNOPSIS

#include <limits.h>

DESCRIPTION

The header file < limits.h> is a list of magnitude limitations imposed by a specific implementation of the operating system. All values are specified in decimal.

#define	ARG_MAX	5120	<pre>/* max length of arguments to exec */</pre>
#define	CHAR_BIT	8	/* # of bits in a "char" */
#define	CHAR_MAX	127	/* max integer value of a "char" */
#define	CHAR_MIN	-128	/* min integer value of a "char" */

#define WORD_BIT	16 /* 80286 only, # of	bits in	
	a "word" or "	int" */	

linenum – line number entries in a common object file

SYNOPSIS

#include <linenum.h>

DESCRIPTION

The *cc* command generates an entry in the object file for each C source line on which a breakpoint is possible [when invoked with the $-\mathbf{g}$ option; see *cc*(1)]. Users can then reference line numbers when using the appropriate software test system [see *sdb*(1)]. The structure of these line number entries appears below.

struct {	lineno		
	union		
	{		
		long	lsymndx ;
		long long	l_paddr ;
	}	Ū	l_addr ;
	unsigne	ed short	llnno ;
};			

Numbering starts with one for each function. The initial line number entry for a function has *l_lnno* equal to zero, and the symbol table index of the function's entry is in *l_symndx*. Otherwise, *l_lnno* is non-zero, and *l_paddr* is the physical address of the code for the referenced line. Thus the overall structure is the following:

l_addr	l_lnno
function symtab index physical address physical address 	0 line line
function symtab index physical address physical address 	0 line line

SEE ALSO

cc(1), sdb(1), a.out(4).

MNTTAB(4)

NAME

mnttab - mounted file system table

SYNOPSIS

#include <mnttab.h>

};

DESCRIPTION

The *mnttab* file format resides in directory **/etc** and contains a table of devices, mounted by the *mount*(1M) command, in the following structure as defined by **<mnttab.h**>:

Each entry is 70 bytes in length; the first 32 bytes are the null-padded name of the place where the *special file* is mounted; the next 32 bytes represent the null-padded root name of the mounted special file; the remaining 6 bytes contain the mounted *special file*'s read/write permissions and the date on which it was mounted.

The maximum number of entries in *mnttab* is based on the system parameter **NMOUNT**, which defines the number of allowable mounted special files.

SEE ALSO

mount(1M), setmnt(1M) in the System Administrator's Reference Manual.

passwd – password file

DESCRIPTION

The *passwd* file format contains for each user the following information:

login name encrypted password numerical user ID numerical group ID GCOS job number, box number, optional GCOS user ID initial working directory program to use as shell

This is an ASCII file. Each field within each user's entry is separated from the next by a colon. The GCOS field is used only when communicating with that system, and in other installations can contain any desired information. Each user is separated from the next by a new-line. If the password field is null, no password is demanded; if the shell field is null, the shell itself is used.

This file resides in directory **/etc**. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical user IDs to names.

The encrypted password consists of 13 characters chosen from a 64character alphabet (., /, 0-9, A-Z, a-z), except when the password is null, in which case the encrypted password is also null. Password aging is effected for particular users if their encrypted passwords in the password file are followed by a comma and a non-null string of characters from the above alphabet. (Such a string must be introduced in the first instance by the super-user.)

The first character of the age, *M* say, denotes the maximum number of weeks for which a password is valid. A user who attempts to login after his password has expired will be forced to supply a new one. The next character, *m* say, denotes the minimum period in weeks which must expire before the password may be changed. The remaining characters define the week (counted from the beginning of 1970) when the password was last changed. (A null string is equivalent to zero.) *M* and *m* have numerical values in the range 0–63 that correspond to the 64-character alphabet shown above (i.e., / = 1 week; $\mathbf{z} = 63$ weeks). If m = M = 0 (derived from the string . or ...) users will be forced to change their passwords the next time they log in (and the "age" will disappear from their entry in the password file). If m > M (signified, e.g., by the string ./) only the super-user will be able to change the password.

FILES

/etc/passwd

a64l(3C), getpwent(3C), group(4). login(1), passwd(1) in the User's Reference Manual.

plot – graphics interface

DESCRIPTION

Files of this format are produced by routines described in plot(3X) and are interpreted for various devices by commands described in tplot(1G). A graphics file is a stream of plotting instructions. Each instruction consists of an ASCII letter usually followed by bytes of binary information. The instructions are executed in order. A point is designated by four bytes representing the **x** and **y** values; each value is a signed integer. The last designated point in an **l**, **m**, **n**, or **p** instruction becomes the "current point" for the ney⁺ instruction.

Each of the following descriptions begins with the name of the corresponding routine in plot(3X).

m move: The next four bytes give a new current point.

- **n** cont: Draw a line from the current point to the point given by the next four bytes [see *tplot*(1G)].
- **p** point: Plot the point given by the next four bytes.
- 1 line: Draw a line from the point given by the next four bytes to the point given by the following four bytes.
- t label: Place the following ASCII string so that its first character falls on the current point. The string is terminated by a new-line.
- e erase: Start another frame of output.
- f linemod: Take the following string, up to a new-line, as the style for drawing further lines. The styles are "dotted", "solid", "longdashed", "shortdashed", and "dotdashed". Effective only for the -T4014 and -Tver options of *tplot*(1G) (TEKTRONIX 4014 terminal and Versatec plotter).
- **s** space: The next four bytes give the lower left corner of the plotting area; the following four give the upper right corner. The plot will be magnified or reduced to fit the device as closely as possible.

Space settings that exactly fill the plotting area with unity scaling appear below for devices supported by the filters of *tplot*(1G). The upper limit is just outside the plotting area. In every case the plotting area is taken to be square; points outside may be displayable on devices whose face is not square.

DASI 300	space(0, 0, 4096, 4096);
DASI 300s	space(0, 0, 4096, 4096);
DASI 450	space(0, 0, 4096, 4096);
TEKTRONIX 4014	space(0, 0, 3120, 3120);
Versatec plotter	space(0, 0, 2048, 2048);

SEE ALSO

plot(3X), gps(4), term(5).
graph(1G), tplot(1G) in the User's Reference Manual.

WARNING

The plotting library plot(3X) and the curses library curses(3X) both use the names erase() and move(). The curses versions are macros. If you need both libraries, put the plot(3X) code in a different source file than the curses(3X) code, and/or #undef move() and erase() in the plot(3X) code.

pnch - file format for card images

DESCRIPTION

The PNCH format is a convenient representation for files consisting of card images in an arbitrary code.

A PNCH file is a simple concatenation of card records. A card record consists of a single control byte followed by a variable number of data bytes. The control byte specifies the number (which must lie in the range 0-80) of data bytes that follow. The data bytes are 8-bit codes that constitute the card image. If there are fewer than 80 data bytes, it is understood that the remainder of the card image consists of trailing blanks.

PROFILE(4)

NAME

profile - setting up an environment at login time

SYNOPSIS

/etc/profile \$HOME/.profile

DESCRIPTION

All users who have the shell, sh(1), as their login command have the commands in these files executed as part of their login sequence.

/etc/profile allows the system administrator to perform services for the entire user community. Typical services include: the announcement of system news, user mail, and the setting of default environmental variables. It is not unusual for */etc/profile* to execute special actions for the **root** login or the su(1M) command. Computers running outside the Eastern time zone should have the line

. /etc/TIMEZONE

included early in */etc/profile* [see timezone(4)].

The file *\$HOME/.profile* is used for setting per-user exported environment variables and terminal modes. The following example is typical (except for the comments):

```
# Make some environment variables global
export MAIL PATH TERM
# Set file creation mask
umask 027
# Tell me when new mail comes in
MAIL=/usr/mail/$LOGNAME
# Add my /bin directory to the shell search sequence
PATH=$PATH:$HOME/bin
# Set terminal type
while :
            echo "terminal: \c"
do
            read TERM
            if [ -f ${TERMINFO:-/usr/lib/terminfo}/?/$TERM ]
            then break
            elif [ -f /usr/lib/terminfo/?/$TERM ]
            then break
            else echo "invalid term $TERM" 1>&2
            fi
done
# Initialize the terminal and set tabs
# The environmental variable TERM must have been exported
# before the "tput init" command is executed.
tput init
\# Set the erase character to backspace
stty erase '<sup>^</sup>H' echoe
```

PROFILE(4)

FILES

/etc/TIMEZONEtimezone environment \$HOME/.profile user-specific environment /etc/profile system-wide environment

SEE ALSO

terminfo(4), timezone(4), environ(5), term(5). env(1), login(1), mail(1), sh(1), stty(1), su(1M), tput(1) in the User's Reference Manual. su(1M) in the System Administrator's Reference Manual. User's Guide.

Chapter 10 in the Programmer's Guide.

NOTES

Care must be taken in providing system-wide services in */etc/profile*. Personal *.profile* files are better for serving all but the most global needs.

reloc - relocation information for a common object file

SYNOPSIS

#include <reloc.h>

DESCRIPTION

Object files have one relocation entry for each relocatable reference in the text or data. If relocation information is present, it will be in the following format.

struct {	reloc		
C	long	r_vaddr ;	/* (virtual) address of reference */
	long	r_symndx ;	/* index into symbol table */
	short	r_type ;	/* relocation type */
};			
#define	R_DIR16	01	/* 80286 computer only */
#define	R_REL16	02	/* 80286 computer only */
#define	R_SEG12	011	/* 80286 computer only */
#define	R_PCRLONG	024	/* 80386 computer only */

As the link editor reads each input section and performs relocation, the relocation entries are read. They direct how references found within the input section are treated.

- R_DIR16 (80286 computer only) A direct 16-bit reference to the symbol's virtual address.
- R_REL16 (80286 computer only) A "PC-relative" 16-bit reference to the symbol's virtual address. Relative references occur in instructions such as jumps and calls. The actual address used is obtained by adding a constant to the value of the program counter at the time the instruction is executed.
- R_SEG12 (80286 computer only) A direct 16-bit reference to the segment-selector bits of a 32-bit virtual address.
- R_PCRLONG (80386 computer only) A "PC-relative" 32-bit reference to the symbol's virtual address.

More relocation types exist for other processors. Equivalent relocation types on different processors have equal values and meanings. New relocation types will be defined (with new values) as they are needed.

Relocation entries are generated automatically by the assembler and automatically used by the link editor. Link editor options exist for both preserving and removing the relocation entries from object files.

rfmaster - Remote File Sharing name server master file

DESCRIPTION

The **rfmaster** file is an ASCII file that identifies the hosts that are responsible for providing primary and secondary domain name service for Remote File Sharing domains. This file contains a series of records, each terminated by a new-line; a record may be extended over more than one line by escaping the new-line character with a backslash ("\"). The fields in each record are separated by one or more tabs or spaces. Each record has three fields:

name type data

The type field, which defines the meaning of the *name* and *data* fields, has three possible values:

- **p** The **p** type defines the primary domain name server. For this type, *name* is the domain name and *data* is the full host name of the machine that is the primary name server. The full host name is specified as *domain.nodename*. There can be only one primary name server per domain.
- **s** The **s** type defines a secondary name server for a domain. *Name* and *data* are the same as for the **p** type. The order of the **s** entries in the **rfmaster** file determines the order in which secondary name servers take over when the current domain name server fails.
- **a** The **a** type defines a network address for a machine. *Name* is the full domain name for the machine and *data* is the network address of the machine. The network address can be in plain ASCII text or it can be preceded by a \x to be interpreted as hexadecimal notation. (See the documentation for the particular network you are using to determine the network addresses you need.)

There are at least two lines in the **rfmaster** file per domain name server: one \mathbf{p} and one \mathbf{a} line, to define the primary and its network address. There should also be at least one secondary name server in each domain.

This file is created and maintained on the primary domain name server. When a machine other than the primary tries to start Remote File Sharing, this file is read to determine the address of the primary. If **rfmaster** is missing, the **-p** option of **rfstart** must be used to identify the primary. After that, a copy of the primary's **rfmaster** file is automatically placed on the machine.

Domains not served by the primary can also be listed in the **rfmaster** file. By adding primary, secondary, and address information for other domains on a network, machines served by the primary will be able to share resources with machines in other domains.

A primary name server may be a primary for more than one domain. However, the secondaries must then also be the same for each domain served by the primary.

Example

An example of an **rfmaster** file is shown below. (The network address examples, *comp1.serve* and *comp2.serve*, are STARLAN network addresses.)

ccs	р	ccs.comp1
CCS	s	ccs.comp2
ccs.comp2	а	comp2.serve
ccs.comp1	а	comp1.serve

NOTE: If a line in the **rfmaster** file begins with a **#** character, the entire line will be treated as a comment.

sccsfile - format of SCCS file

DESCRIPTION

An SCCS (Source Code Control System) file is an ASCII file. It consists of six logical parts: the *checksum*, the *delta table* (contains information about each delta), *user names* (contains login names and/or numerical group IDs of users who may add deltas), *flags* (contains definitions of internal keywords), *comments* (contains arbitrary descriptive information about the file), and the *body* (contains the actual text lines intermixed with control lines).

Throughout an SCCS file there are lines which begin with the **ASCII SOH** (start of heading) character (octal 001). This character is hereafter referred to as *the control character* and will be represented graphically as (a). Any line described below which is not depicted as beginning with the control character is prevented from beginning with the control character.

Entries of the form DDDDD represent a five-digit string (a number between 00000 and 99999).

Each logical part of an SCCS file is described in detail below.

Checksum

The checksum is the first line of an SCCS file. The form of the line is:

@hDDDDD

The value of the checksum is the sum of all characters, except those of the first line. The **@h** provides a *magic number* of (octal) 064001.

Delta table

The delta table consists of a variable number of entries of the form:

@s DDDDD/DDDDD/DDDDD

@d <type> <SCCS ID> yr/mo/da hr:mi:se <pgmr> DDDDD DDDDD
@i DDDDD ...
@x DDDDD ...
@g DDDDD ...
@m <MR number>
...
...
@c <comments> ...
...
@c The first line (@s) contains the number of lines

inserted/deleted/unchanged, respectively. The second line (@d) contains the type of the delta (currently, normal: **D**, and removed: **R**), the SCCS ID of the delta, the date and time of creation of the

delta, the login name corresponding to the real user ID at the time the delta was created, and the serial numbers of the delta and its predecessor, respectively.

The **@i**, **@x**, and **@g** lines contain the serial numbers of deltas included, excluded, and ignored, respectively. These lines are optional.

The **@m** lines (optional) each contain one **MR** number associated with the delta; the **@c** lines contain comments associated with the delta.

The @e line ends the delta table entry.

User names

The list of login names and/or numerical group IDs of users who may add deltas to the file, separated by new-lines. The lines containing these login names and/or numerical group IDs are surrounded by the bracketing lines **@u** and **@U**. An empty list allows anyone to make a delta. Any line starting with a ! prohibits the succeeding group or user from making deltas.

```
Flags
```

Keywords used internally. [See *admin*(1) for more information on their use.] Each flag line takes the form:

(**Of** <flag> <optional text>

The following flags are defined:

@ f t	<type of="" program=""></type>
@f v	<program name=""></program>
@ f i	<keyword string=""></keyword>
@f b	
@ f m	<module name=""></module>
@ f f	<floor></floor>
@f c	<ceiling></ceiling>
@f d	<default-sid></default-sid>
@ f n	
@ f j	
@f 1	<lock-releases></lock-releases>
@ f q	<user-defined></user-defined>
@f z	<reserved for="" in="" interfaces="" use=""></reserved>

The **t** flag defines the replacement for the %Y% identification keyword. The **v** flag controls prompting for **MR** numbers in addition to comments; if the optional text is present, it defines an **MR** number validity checking program. The **i** flag controls the warning/error aspect of the "No id keywords" message. When the **i** flag is not present, this message is only a warning; when the **i** flag is present, this message will cause a "fatal" error (the file will not be gotten, or the delta will not be made). When the **b** flag is present the **-b**

keyletter may be used on the get command to cause a branch in the delta tree. The **m** flag defines the first choice for the replacement text of the %M% identification keyword. The f flag defines the "floor" release; the release below which no deltas may be added. The c flag defines the "ceiling" release; the release above which no deltas may be added. The d flag defines the default SID to be used when none is specified on a get command. The **n** flag causes delta to insert a "null" delta (a delta that applies no changes) in those releases that are skipped when a delta is made in a *new* release (e.g., when delta 5.1 is made after delta 2.7, releases 3 and 4 are skipped). The absence of the \mathbf{n} flag causes skipped releases to be completely empty. The j flag causes get to allow concurrent edits of the same base SID. The I flag defines a *list* of releases that are *locked* against editing [get(1) with the **-e** keyletter]. The **q** flag defines the replacement for the Q defines the replacement for the Qflag is used in certain specialized interface programs.

Comments

Arbitrary text is surrounded by the bracketing lines @t and @T. The comments section typically will contain a description of the file's purpose.

Body

The body consists of text lines and control lines. Text lines do not begin with the control character, control lines do. There are three kinds of control lines: *insert*, *delete*, and *end*, represented by:

@I DDDDD @D DDDDD @E DDDDD

respectively. The digit string is the serial number corresponding to the delta for the control line.

admin(1), delta(1), get(1), prs(1).

scnhdr - section header for a common object file

. .

SYNOPSIS

#include <scnhdr.h>

DESCRIPTION

Every common object file has a table of section headers to specify the layout of the data within the file. Each section within an object file has its own header. The C structure appears below.

struct	scnhdr		
{			
	char	sname[SYN	/NMLEN]; /* section name */
	long	s_paddr;	/* physical address */
	long	s_vaddr;	/* virtual address */
	long	ssize;	/* section size */
	long	sscnptr;	/* file ptr to raw data */
	long	s_relptr;	/* file ptr to relocation */
	long	s_lnnoptr;	/* file ptr to line numbers */
	unsigned short	s_nreloc;	/* # reloc entries */
	unsigned short	snlnno;	/* # line number entries */
	long	s_flags;	/* flags */
};	0	J ,	, , ,

};

File pointers are byte offsets into the file; they can be used as the offset in a call to FSEEK [see *ldfcn*(4)]. If a section is initialized, the file contains the actual bytes. An uninitialized section is somewhat different. It has a size, symbols defined in it, and symbols that refer to it. But it can have no relocation entries, line numbers, or data. Consequently, an uninitialized section has no raw data in the object file, and the values for s_scnptr, s_relptr, s_lnnoptr, s_nreloc, and s_nlnno are zero.

SEE ALSO

ld(1), fseek(3S), a.out(4).

- 1 -

scr_dump - format of curses screen image file.

SYNOPSIS

scr_dump(file)

DESCRIPTION

The *curses*(3X) function *scr_dump*() will copy the contents of the screen into a file. The format of the screen image is as described below.

The name of the tty is 20 characters long and the modification time (the *mtime* of the tty that this is an image of) is of the type *time_t*. All other numbers and characters are stored as *chtype* (see **<curses.h>**). No new-lines are stored between fields.

Only as many characters as are in a line will be listed. For example, if the *<line length>* is **0**, there will be no characters following *<line length>*. If *<labels*?> is TRUE, following it will be

<number of labels> <label width> <chars in label 1> <chars in label 2>

SEE ALSO

curses(3X).

syms - common object file symbol table format

SYNOPSIS

#include <syms.h>

DESCRIPTION

Common object files contain information to support symbolic software testing [see sdb(1)]. Line number entries, *linenum*(4), and extensive symbolic information permit testing at the *C* source level. Every object file's symbol table is organized as shown below.

> File name 1. Function 1. Local symbols for function 1. Function 2. Local symbols for function 2.

> > Static externs for file 1.

File name 2.

Function 1. Local symbols for function 1. Function 2. Local symbols for function 2.

Static externs for file 2.

•••

Defined global symbols. Undefined global symbols.

The entry for a symbol is a fixed-length structure. The members of the structure hold the name (null padded), its value, and other information. The C structure is given below.

#define SYMNMLEN #define FILNMLEN #define DIMNUM	1 8 14 4	
struct syment		
union		/* all ways to get symbol name */
{ char struct {	nname[SY]	MNMLEN]; /* symbol name */
long		/* == 0L when in string table */
long }n_n;	noffset;	/* location of name in table */
char	*_n_nptr[2];	/* allows overlaying */
} _n; long	n_value;	/* value of symbol */

ł

<pre>short unsigned short char char };</pre>	n_scnum; n_type; n_sclass; n_numaux;	/* section number */ /* type and derived type */ /* storage class */ /* number of aux entries */
#define n_name #define n_zeroes #define n_offset #define n_nptr	_nn_name _nn_nn_ _nn_nn_[1]	offset

Meaningful values and explanations for them are given in both syms.h and Common Object File Format. Anyone who needs to interpret the entries should seek more information in these sources. Some symbols require more information than a single entry; they are followed by auxiliary entries that are the same size as a symbol entry. The format follows.

```
union auxent
     struct
      {
            long
                            x_tagndx;
            union
            {
                    struct
                    {
                            unsigned short x_lnno;
                            unsigned short x_size;
                    } x_lnsz;
                    long
                            x_fsize;
            } x_misc;
            union
            {
                    struct
                    {
                            long
                                    x_lnnoptr;
                            long
                                    x_endndx;
                    }
                            x_fcn;
                   struct
                    {
                            unsigned short x_dimen[DIMNUM];
                    }
                            x_ary;
            }
                            x__fcnary;
            unsigned short x_tvndx;
      }
            x_sym;
     struct
      {
            char
                   x_fname[FILNMLEN];
      }
            x_file;
     struct
     {
```

```
long x_scnlen;
unsigned short x_nreloc;
unsigned short x_nlinno;
} x_scn;
struct
{
long x_tvfill;
unsigned short x_tvlen;
unsigned short x_tvran[2];
} x_tv;
```

Indexes of symbol table entries begin at zero.

sdb(1), a.out(4), linenum(4).

};

"Common Object File Format" in the Programming Guide.

WARNINGS

On machines on which **int**s are equivalent to **long**s, all **long**s have their type changed to **int**. Thus the information about which symbols are declared as **long**s and which, as **int**s, does not show up in the symbol table.

system - system configuration information

DESCRIPTION

A system file specifies the configuration of a kernel; see mkunix(1M) for details of its use. In the syntax given below, the following non-terminals are used:

<name> := alphanumeric sequence

<string> := "alphanumeric sequence"

<number> := decimal number

White space may be inserted anywhere, and comments begin with an asterisk and end at the end of the line.

rootdev = <number>, <number>

The root device has the given major and minor numbers. This line is required.

pipedev = <number>, <number>

The pipe device has the given major and minor numbers. This line is required.

swapdev = <number>, <number>

The swap device has the given major and minor numbers.

dumpdev = <number>, <number>

The dump device has the given major and minor numbers.

modules = <name>[,<name>]...

List of modules to be included in the system. This line is required.

<name> = <number>

or

<name> = <string>

Tunable parameter overrides; <name> should be the name of a tunable parameter defined in a space.c file or in

/usr/include/sys/kdef.h. There may be zero or more lines of this form.

FILES

\$CONF/systems/system.suffix

SEE ALSO

mkunix(1M), config(1M), config(4).

TERM(4)

NAME

term – format of compiled term file.

SYNOPSIS

/usr/lib/terminfo/?/*

DESCRIPTION

Compiled *terminfo*(4) descriptions are placed under the directory /usr/lib/terminfo. In order to avoid a linear search of a huge UNIX system directory, a two-level scheme is used: /usr/lib/terminfo/c/name where *name* is the name of the terminal, and *c* is the first character of *name*. Thus, **att4425** can be found in the file /usr/lib/terminfo/a/att4425. Synonyms for the same terminal are implemented by multiple links to the same compiled file.

The format has been chosen so that it will be the same on all hardware. An 8-bit byte is assumed, but no assumptions about byte ordering or sign extension are made. Thus, these binary *terminfo*(4) files can be transported to other hardware with 8-bit bytes.

Short integers are stored in two 8-bit bytes. The first byte contains the least significant 8 bits of the value, and the second byte contains the most significant 8 bits. (Thus, the value represented is 256*second+first.) The value -1 is represented by **0377,0377**, and the value -2 is represented by **0376,0377**; other negative values are illegal. Computers where this does not correspond to the hardware read the integers as two bytes and compute the result, making the compiled entries portable between machine types. The -1 generally means that a capability is missing from this terminal. The -2 means that the capability has been cancelled in the *terminfo*(4) source and also is to be considered missing.

The compiled file is created from the source file descriptions of the terminals [see the –I option of infocmp(1M)] by using the terminfo(4) compiler, tic(1M), and read by the routine **setupterm()**. [See *curses*(3X).] The file is divided into six parts: the header, terminal names, Boolean flags, numbers, strings, and string table.

The header section begins the file. This section contains six short integers in the format described below. These integers are: (1) the magic number (octal **0432**); (2) the size, in bytes, of the names section; (3) the number of bytes in the Boolean section; (4) the number of short integers in the numbers section; (5) the number of offsets (short integers) in the strings section; (6) the size, in bytes, of the string table.

The terminal names section comes next. It contains the first line of the *terminfo*(4) description, listing the various names for the terminal, separated by the bar (1) character [see *term*(5)]. The section is terminated with an ASCII NUL character.

The Boolean flags have one byte for each flag. This byte is either 0 or 1 as the flag is present or absent. The value of 2 means that the flag has been cancelled. The capabilities are in the same order as the file <term.h>.

Between the Boolean section and the number section, a null byte will be inserted, if necessary, to ensure that the number section begins on an even byte. All short integers are aligned on a short word boundary.

The numbers section is similar to the Boolean flags section. Each capability takes up two bytes, and is stored as a short integer. If the value represented is -1 or -2, the capability is taken to be missing.

The strings section is also similar. Each capability is stored as a short integer, in the format above. A value of -1 or -2 means the capability is missing. Otherwise, the value is taken as an offset from the beginning of the string table. Special characters in \hat{x} or $\langle c$ notation are stored in their interpreted form, not the printing representation. Padding information ((n-2)) and parameter information ((n-2)) are stored intact in uninterpreted form.

The final section is the string table. It contains all the values of string capabilities referenced in the string section. Each string is null terminated.

Note that it is possible for **setupterm()** to expect a different set of capabilities than are actually present in the file. Either the data base may have been updated since **setupterm()** has been recompiled (resulting in extra unrecognized entries in the file) or the program may have been recompiled more recently than the data base was updated (resulting in missing entries). The routine **setupterm()** must be prepared for both possibilities – this is why the numbers and sizes are included. Also, new capabilities must always be added at the end of the lists of Boolean, number, and string capabilities.

As an example, an octal dump of the description for the AT&T Model 37 KSR is included:

37|tty37|AT&T model 37 teletype,

hc, os, xon, bel=^G, cr=\r, cub1=\b, cud1=\n, cuu1=\E7, hd=\E9, hu=\E8, ind=n,

TERM(4)

0001240 \n \0 \n \0 007 \0 \b \0 033 8 \0 033 9 \0 033 7 0001260 \0 \0 0 0001261

Some limitations: total compiled entries cannot exceed 4096 bytes; all entries in the name field cannot exceed 128 bytes.

terminfo - terminal capability data base

SYNOPSIS

/usr/lib/terminfo/?/*

DESCRIPTION

The *terminfo* file format is a compiled data base [see *tic*(1M)] describing the capabilities of terminals. Terminals are described in *terminfo* source descriptions by giving a set of capabilities which they have, by describing how operations are performed, by describing padding requirements, and by specifying initialization sequences. This data base is used by applications programs, such as vi(1) and *curses*(3X), so they can work with a variety of terminals without changes to the programs. To obtain the source description for a terminal, use the **-I** option of *infocmp*(1M).

Entries in *terminfo* source files consist of a number of comma-separated fields. White space after each comma is ignored. The first line of each terminal description in the *terminfo* data base gives the name by which *terminfo* knows the terminal, separated by bar (1) characters. The first name given is the most common abbreviation for the terminal [this is the one to use to set the environment variable **TERM** in *\$HOME/.profile*; see *profile*(4)], the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should contain no blanks and must be unique in the first 14 characters; the last name may contain blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, for example, for the AT&T 4425 terminal, **att4425**. Modes that the hardware can be in, or user preferences, should be indicated by appending a hyphen and an indicator of the mode. See *term*(5) for examples and more information on choosing names and synonyms.

CAPABILITIES

In the table below, the **Variable** is the name by which the C programmer (at the *terminfo* level) accesses the capability. The **Capname** is the short name for this variable used in the text of the data base. It is used by a person updating the data base and by the tput(1) command when asking what the value of the capability is for a particular terminal. The **Termcap Code** is a two-letter code that corresponds to the old *termcap* capability name.

Capability names have no hard length limit, but an informal limit of 5 characters has been adopted to keep them short. Whenever possible, names are chosen to be the same as or similar to the ANSI X3.64-1979 standard. Semantics are also intended to match those of the specification.

All string capabilities listed below may have padding specified, with the exception of those used for input. Input capabilities, listed under the **Strings** section in the table below, have names beginning with **key**... The following indicators may appear at the end of the **Description** for a variable.

- 1 -

TERMINFO(4)

- (G) indicates that the string is passed through tparm() with parameters (parms) as given $(\#_i)$.
- (*) indicates that padding may be based on the number of lines affected.
- $(\#_i)$ indicates the i^{th} parameter.

Variable	Cap- name	Termcap Code	Description
Booleans:			
auto_left_margin	bw	bw	cub1 wraps from column 0 to last column
auto_right_margi:1	am	am	Terminal has automatic margins
no_esc_ctlc	xsb	xb	Beehive (f1=escape, f2=ctrl C)
ceol_standout_glitch	xhp	xs	Standout not erased by overwriting (hp)
eat_newline_glitch	xenl	xn	New-line ignored after 80 cols (<i>Concept</i>)
erase_overstrike	eo	eo	Can erase overstrikes with a blank
generic_type	gn	gn	Generic line type (e.g., dialup, switch)
hard_copy	hc	hc	Hardcopy terminal
hard_cursor	chts	HC	Cursor is hard to see
has_meta_key	km	km	Has a meta key (shift, sets parity bit)
hasstatusline	hs	hs	Has extra "status line"
insert_null_glitch	in	in	Insert mode distinguishes nulls
memory_above	da	da	Display may be retained above the screen
memory_below	db	db	Display may be retained below the screen
move_insert_mode	mir	mi	Safe to move while in insert mode
move_standout_mode	msgr	ms	Safe to move in standout modes
needs_xon_xoff	nxon	nx	Padding won't work, xon/xoff required
non_rev_rmcup	nrrmc	NR	smcup does not reverse rmcup
no_pad_char	npc	NP	Pad character doesn't exist
over_strike	OS	os	Terminal overstrikes on hard-copy terminal
prtr_silent	mc5i	5i	Printer won't echo on screen
status_line_esc_ok	eslok	es	Escape can be used on the status line
dest_tabs_magic_smso	xt	xt	Destructive tabs, magic smso char (t1061)
tilde_glitch	hz	hz	Hazeltine; can't print tildes(~)
transparent_underline	ul	ul	Underline character overstrikes
xon_xoff	xon	хо	Terminal uses xon/xoff handshaking
Numbers:	,		
columns	cols	co	Number of columns in a line
init_tabs	it	it	Tabs initially every # spaces
label_height	lh	lh	Number of rows in each label

label_width	lw	lw	Number of cols in each label
lines	lines	li	Number of lines on screen or page
lines_of_memory	lm	lm	Lines of memory if > lines ; 0 means
			varies
magic_cookie_glitch	xmc	sg	Number blank chars left by
			smso or rmso
num_labels	nlab	NI	Number of labels on
			screen (start at 1)
paddingbaudrate	pb	pb	Lowest baud rate where padding
			needed
virtual_terminal	vt	vt	Virtual terminal number
			(UNIX system)
width_status_line	wsl	ws	Number of columns in status line
Strings:			
acschars	acsc	ac	Graphic charset pairs
			aAbBcC - def=vt100+
back_tab	cbt	bt	Back tab
bell	bel	bl	Audible signal (bell)
carriage_return	cr	cr	Carriage return (*)
change_scroll_region	csr	CS	Change to lines #1 thru #2
			(vt100) (G)
char_padding	rmp	rP	Like ip but when in replace mode
clear_all_tabs	tbc	ct	Clear all tab stops
clear_margins	mgc	MC	Clear left and right soft margins
clear_screen	clear	cl	Clear screen and home cursor (*)
clr_bol	el1	cb	Clear to beginning of line, inclusive
clr_eol	el	ce	Clear to end of line
clr_eos	ed	cd	Clear to end of display (*)
column_address	hpa	ch	Horizontal position absolute (G)
commandcharacter	cmdch	CC	Term. settable cmd char in prototype
cursor_address	cup	cm	Cursor motion to row #1 col #2 (G)
cursor_down	cud1	do	Down one line
cursor_home	home	ho	Home cursor (if no cup)
cursor_invisible	civis	vi	Make cursor invisible
cursor_left	cub1	le	Move cursor left one space
cursor_mem_address	mrcup	CM	Memory relative cursor
			addressing (G)
cursornormal	cnorm	ve	Make cursor appear normal
			(undo vs/vi)
cursor_right	cuf1	nd	Non-destructive space (cursor right)
cursor_to_ll	11	11	Last line, first column (if no cup)
cursor_up	cuu1	up	Upline (cursor up)
cursor_visible	cvvis	vs	Make cursor very visible
delete_character	dch1	dc	Delete character (*)
delete_line	dl1	dl	Delete line (*)
dis_status_line	dsl	ds	Disable status line
down_half_line	hd	hd	Half-line down (forward 1/2 linefeed)
enaacs	enacs	eA	Enable alternate char set
enter_alt_charset_mode	smacs	as	Start alternate character set

enter_am_mode	smam	SA	Turn on automatic margins
enter_blink_mode	blink	mb	Turn on blinking
enter_bold_mode	bold	md	Turn on bold (extra bright) mode
entercamode	smcup	ti	String to begin programs that
	1		use cup
enter_delete_mode	smdc	dm	Delete mode (enter)
enter_dim_mode	dim	mh	Turn on half-bright mode
enter_insert_mode	smir	im	Insert mode (enter);
enter_protected_mode	prot	mp	Turn on protected mode
enter_reverse_mode	rev	mr	Turn on reverse video mode
enter_secure_mode	invis	mk	Turn on blank mode
			(chars invisible)
enter_standout_mode	smso	so	Begin standout mode
enter_underline_mode	smul	us	Start underscore mode
enter_xon_mode	smxon	SX	Turn on xon/xoff handshaking
erasechars	ech	ec	Erase #1 characters (G)
exit_alt_charset_mode	rmacs	ae	End alternate character set
exit_am_mode	rmam	RA	Turn off automatic margins
exit_attribute_mode	sgr0	me	Turn off all attributes
exit_ca_mode	rmcup	te	String to end programs that use cup
exit_delete_mode	rmdc	ed	End delete mode
exit_insert_mode	rmir	ei	End insert mode
exit_standout_mode	rmso	se	End standout mode
exit_underline_mode	rmul	ue	End underscore mode
exit_xon_mode	rmxon	RX	Turn off xon/xoff handshaking
flashscreen	flash	vb	Visible bell (may not move cursor)
form_feed	ff	ff	Hardcopy terminal page eject (*)
from_status_line	fsl	fs	Return from status line
init_1string	is1	i1	Terminal initialization string
init_2string	is2	is	Terminal initialization string
init_3string	is3	i3	Terminal initialization string
init_file	if	if	Name of initialization file
			containing is
init_prog	iprog	iP	Path name of program for init
insert_character	ich1	ic	Insert character
insert_line	il1	al	Add new blank line (*)
insert_padding	ip	ip	Insert pad after character inserted (*)
key_a1	ka1	K1	KEY_A1, 0534, Upper left of keypad
key_a3	ka3	K3	KEY_A3, 0535, Upper right of
			keypad
key_b2	kb2	K2	KEY_B2, 0536, Center of keypad
key_backspace	kbs	kb	KEY_BACKSPACE, 0407, Sent by
			backspace key
key_beg	kbeg	@1	KEY_BEG, 0542, Sent by beg(inning)
	-		key
key_btab	kcbt	kB	KEY_BTAB, 0541, Sent by back-tab
			key
key_c1	kc1	K4	KEY_C1, 0537, Lower left of keypad
key_c3	kc3	K5	KEY_C3, 0540, Lower right of
			keypad

key_cancel	kcan	@2	KEY_CANCEL, 0543, Sent by cancel
key_catab	ktbc	ka	key KEY_CATAB, 0526, Sent by
kov door	kclr	kC	clear-all-tabs key KEY_CLEAR, 0515, Sent by
key_clear	KCII	ĸĊ	clear-screen or erase key
key_close	kclo	@3	KEY_CLOSE, 0544, Sent by
		e	close key
keycommand	kcmd	@4	KEY_COMMAND, 0545, Sent by
-		-	cmd (command) key
key_copy	kcpy	@5	KEY_COPY, 0546, Sent by copy key
key_create	kcrt	@6	KEY_CREATE, 0547, Sent by create
			key
keyctab	kctab	kt	KEY_CTAB, 0525, Sent by clear-tab
		. –	key
key_dc	kdch1	kD	KEY_DC, 0512, Sent by
			delete-character key
key_dl	kdl1	kL	KEY_DL, 0510, Sent by
	1 11	1. 4	delete-line key
key_down	kcud1	kd	KEY_DOWN, 0402, Sent by
1	1	kM	terminal down-arrow key
key_eic	krmir	KIVI	KEY_EIC, 0514, Sent by rmir or smir in insert mode
key and	kend	@7	KEY_END, 0550, Sent by end key
key_end	kent	@8	KEY_ENTER, 0527, Sent by
key_enter	Kent	<u>w</u> o	enter/send key
key_eol	kel	kE	KEY_EOL, 0517, Sent by
Key_eoi	NCI	KL	clear-to-end-of-line key
key_eos	ked	kS	KEY_EOS, 0516, Sent by
key_cos	neu	RO	clear-to-end-of-screen key
key_exit	kext	@9	KEY_EXIT, 0551, Sent by exit key
key_f0	kf0	k0	KEY_F(0), 0410, Sent by function
3			key f0
key_f1	kf1	k1	KEY_F(1), 0411, Sent by function
			key f1
key_f2	kf2	k2	KEY_F(2), 0412, Sent by function
			key f2
key_f3	kf3	k3	KEY_F(3), 0413, Sent by function
			key f3
key_f4	kf4	k4	KEY_F(4), 0414, Sent by function
			key f4
key_f5	kf5	k5	KEY_F(5), 0415, Sent by function
			key f5
key_f6	kf6	k6	KEY_F(6), 0416, Sent by function
1 (7	1 (7	1.7	key f6
key_f7	kf7	k7	KEY_F(7), 0417, Sent by function
1	1.00	1.0	key f7
key_f8	kf8	k8	KEY_F(8), 0420, Sent by function
			key f8

SAMPLE ENTRY

The following entry, which describes the *Concept*-100 terminal, is among the more complex entries in the *terminfo* file as of this writing.

concept100 | c100 | concept | c104 | c100-4p | concept 100, am, db, eo, in, mir, ul, xenl, cols#80, lines#24, pb#9600, vt#8, bel=^G, blank=\EH, blink=\EC, clear=^L\$<2*>, $cnorm=\Ew, cr=^M$<9>, cub1=^H, cud1=^J,$ cuf 1=E=, cup=Ea%p1%' '%+%c%p2%' '%+%c,cuu1=E;, cvvis=EW, $dch1=E^A$<16*>$, dim=EE, dl1=\E^B\$<3*>, ed=\E^C\$<16*>, e1=\E^U\$<16>, flash=\Ek\$<20>\EK, ht=\t\$<8>, i11=\E^R\$<3*>, ind=^J, .ind=^J\$<9>, ip=\$<16*>, is2=EUEEEE7E5E8E1ENHEEEE0E0A7Ekbs=^h, kcub1=\E>, kcud1=\E<, kcuf1=\E=. kcuu1=\E:. kf1=\E5, kf2=\E6, kf3=\E7, khome=\E?, prot=\EI, rep=\Er%p1%c%p2%' '%+%c\$<.2*>. rev=\ED, rmcup=\Ev\s\s\s\s $<6>\Ep\r\n,$ rmir=\E\0, rmkx=\Ex, rmso=\Ed\Ee, rmul=\Eq, rmul=\Eq. sqr0=\EN\0, smcup=\EU\Ev\s\s8p\Ep\r, smir=\E^P, smkx=\EX, smso=\EE\ED, smul=\EG,

Entries may continue onto multiple lines by placing white space at the beginning of each line except the first. Lines beginning with "#" are taken as comment lines. Capabilities in *terminfo* are of three types: Boolean capabilities which indicate that the terminal has some particular feature, numeric capabilities giving the size of the terminal or particular features, and string capabilities, which give a sequence which can be used to perform particular terminal operations.

Types of Capabilities

All capabilities have names. For instance, the fact that the *Concept* has *automatic margins* (i.e., an automatic return and linefeed when the end of a line is reached) is indicated by the capability **am**. Hence the description of the *Concept* includes **am**. Numeric capabilities are followed by the character '#' and then the value. Thus **cols**, which indicates the number of columns the terminal has, gives the value **80** for the *Concept*. The value may be specified in decimal, octal, or hexadecimal using normal C conventions.

Finally, string-valued capabilities, such as **el** (clear to end of line sequence) are given by the two- to five-character capname, an '=', and then a string ending at the next following comma. A delay in milliseconds may appear anywhere in such a capability, enclosed in <...> brackets, as in **el**=**EK\$**<**3>**, and padding characters are supplied by **tputs**() [see *curses*(3X)] to provide this delay. The delay can be either a number, e.g., **20**, or a number followed by an '*' (i.e., **3***), a '/' (i.e., **5**/), or both (i.e., **10***/). A '*' indicates that the padding required is proportional to the number of lines affected by the operation, and the amount given is the per-affected-unit padding required. (In the case of insert character, the factor is still the number of lines affected. This is always one unless the terminal has **in** and the software uses it.) When a '*' is specified, it is sometimes useful to give a

delay of the form **3.5** to specify a delay per unit to tenths of milliseconds. (Only one decimal place is allowed.) A '/' indicates that the padding is mandatory. Otherwise, if the terminal has **xon** defined, the padding information is advisory and will only be used for cost estimates or when the terminal is in raw mode. Mandatory padding will be transmitted regardless of the setting of **xon**.

A number of escape sequences are provided in the string valued capabilities for easy encoding of characters there. Both \E and \e map to an ESCAPE character, \hat{x} maps to a control-x for any appropriate x, and the sequences \n, \l, \r, \t, \b, \f, and \s give a new-line, linefeed, return, tab, backspace, formfeed, and space, respectively. Other escapes include: \ for caret (); \\ for backslash (\); \, for comma (,); \: for colon (:); and \0 for null. (\0 will actually produce \200, which does not terminate a string but behaves as a null character on most terminals.) Finally, characters may be given as three octal digits after a backslash (e.g., \123).

Sometimes individual capabilities must be commented out. To do this, put a period before the capability name. For example, see the second **ind** in the example above. Note that capabilities are defined in a left-to-right order and, therefore, a prior definition will override a later definition.

Preparing Descriptions

The most effective way to prepare a terminal description is by imitating the description of a similar terminal in *terminfo* and to build up a description gradually, using partial descriptions with **vi**(1) to check that they are correct. Be aware that a very unusual terminal may expose deficiencies in the ability of the **terminfo** file to describe it or the inability of **vi**(1) to work with that terminal. To test a new terminal description, set the environment variable **TERMINFO** to a pathname of a directory containing the compiled description you are working on and programs will look there rather than in */usr/lib/terminfo*. To get the padding for insert-line correct (if the terminal manufacturer did not document it) a severe test is to comment out **xon**, edit a large file at 9600 baud with **vi**(1), delete 16 or so lines from the middle of the screen, then hit the **u** key several times quickly. If the display is corrupted, more padding is usually needed. A similar test can be used for insert-character.

Basic Capabilities

The number of columns on each line for the terminal is given by the **cols** numeric capability. If the terminal has a screen, then the number of lines on the screen is given by the **lines** capability. If the terminal wraps around to the beginning of the next line when it reaches the right margin, then it should have the **am** capability. If the terminal can clear its screen, leaving the cursor in the home position, then this is given by the **clear** string capability. If the terminal overstrikes (rather than clearing a position when a character is struck over) then it should have the **os** capability. If the terminal is a printing terminal, with no soft copy unit, give it both **hc** and **os**. (**os** applies to storage scope terminals, such as Tektronix 4010 series, as well as hard-copy and APL terminals.) If there is a code to move the cursor to the left edge of the current row, give this as **cr**. (Normally this will be carriage return, control M.) If there is a code to produce an audible signal (bell,

beep, etc.) give this as **bel**. If the terminal uses the xon-xoff flow-control protocol, like most terminals, specify **xon**.

If there is a code to move the cursor one position to the left (such as backspace) that capability should be given as **cub1**. Similarly, codes to move to the right, up, and down should be given as **cuf1**, **cuu1**, and **cud1**. These local cursor motions should not alter the text they pass over; for example, you would not normally use "**cuf1**=\s" because the space would erase the character moved over.

A very important point here is that the local cursor motions encoded in *terminfo* are undefined at the left and top edges of a screen terminal. Programs should never attempt to backspace around the left edge, unless **bw** is given, and should never attempt to go up locally off the top. In order to scroll text up, a program will go to the bottom left corner of the screen and send the **ind** (index) string.

To scroll text down, a program goes to the top left corner of the screen and sends the **ri** (reverse index) string. The strings **ind** and **ri** are undefined when not on their respective corners of the screen.

Parameterized versions of the scrolling sequences are **indn** and **rin**, which have the same semantics as **ind** and **ri** except that they take one parameter and scroll that many lines. They are also undefined except at the appropriate edge of the screen.

The **am** capability tells whether the cursor sticks at the right edge of the screen when text is output, but this does not necessarily apply to a **cuf1** from the last column. The only local motion which is defined from the left edge is if **bw** is given, then a **cub1** from the left edge will move to the right edge of the previous row. If **bw** is not given, the effect is undefined. This is useful for drawing a box around the edge of the screen, for example. If the terminal has switch-selectable automatic margins, the *terminfo* file usually assumes that this is on; i.e., **am**. If the terminal has a command which moves to the first column of the next line, that command can be given as **nel** (new-line). It does not matter if the command clears the remainder of the current line, so if the terminal has no **cr** and **lf** it may still be possible to craft a working **nel** out of one or both of them.

These capabilities suffice to describe hardcopy and screen terminals. Thus the model 33 teletype is described as

331tty331tty1model 33 teletype, bel=[°]G, cols#72, cr=[°]M, cud1=[°]J, hc, ind=[°]J, os,

while the Lear Siegler ADM-3 is described as

adm31lsi adm3, am, bel=^G, clear=^Z, cols#80, cr=^M, cub1=^H, cud1=^I, ind=^I, lines#24,

Parameterized Strings

Cursor addressing and other strings requiring parameters in the terminal are described by a parameterized string capability, with **printf**(3S)-like escapes (%x) in it. For example, to address the cursor, the **cup** capability is given, using two parameters: the row and column to address to. (Rows and columns are numbered from zero and refer to the physical screen visible to

the user, not to any unseen memory.) If the terminal has memory-relative cursor addressing, that can be indicated by **mrcup**.

The parameter mechanism uses a stack and special % codes to manipulate it in the manner of a Reverse Polish Notation (postfix) calculator. Typically a sequence will push one of the parameters onto the stack and then print it in some format. Often more complex operations are necessary. Binary operations are in postfix form with the operands in the usual order. That is, to get x–5 one would use $gx \{5\}$ %–.

The % encodings have the following meanings:

%%	outputs '%'
%[[:]flags][u	vidth[.precision]][doxXs]
	as in printf, flags are [-+#] and space
%с	print pop() gives %c

%p[1-9]	push i th parm
%P[a-z]	set variable [a-z] to pop()
%g[a-z]	get variable [a-z] and push it
%'C'	push char constant c
$\{nn\}$	push decimal constant nn
%1	push strlen(pop())

%+ %- %* %/ %m

	arithmetic (%m is mod): push(pop() op pop())
%& %I %^	bit operations: push(pop() op pop())
%= %> %<	logical operations: push(pop() op pop())
%A %O	logical operations: and, or
%! %~	unary operations: push(op pop())
%i	(for ANSI terminals)
	add 1 to first parm, if one parm present,
	or first two parms, if more than one parm present

%? expr %t thenpart %e elsepart %;

if-then-else, %e elsepart is optional; else-if's are possible ala Algol 68: %? c_1 %t b_1 %e c_2 %t b_2 %e c_3 %t b_3 %e c_4 %t b_4 %e b_5 %; c_1 are conditions, b_1 are bodies.

If the "-" flag is used with "%[doxXs]", then a colon (:) must be placed between the "%" and the "-" to differentiate the flag from the binary "%-" operator, e.g., "%:-16.16s".

Consider the Hewlett-Packard 2645, which, to get to row 3 and column 12, needs to be sent **E&a12c03Y** padded for 6 milliseconds. Note that the order of the rows and columns is inverted here, and that the row and column are zero-padded as two digits. Thus its **cup** capability is "**cup**=\E&a%p2%2.2dc%p1%2.2dY\$<6>".

The Micro-Term ACT-IV needs the current row and column sent preceded by a T, with the row and column simply encoded in binary,

"cup= T%p1%c%p2%c". Terminals which use "%c" need to be able to

backspace the cursor (**cub1**), and to move the cursor up one line on the screen (**cuu1**). This is necessary because it is not always safe to transmit \n , \hat{D} , and \r , as the system may change or discard them. (The library routines dealing with *terminfo* set tty modes so that tabs are never expanded, so \t is safe to send. This turns out to be essential for the Ann Arbor 4080.)

A final example is the LSI ADM-3a, which uses row and column offset by a blank character, thus "**cup**=\E=%p1%'\s'%+%c%p2%'\s'%+%c". After sending "\E=", this pushes the first parameter, pushes the ASCII value for a space (32), adds them (pushing the sum on the stack in place of the two previous values), and outputs that value as a character. Then the same is done for the second parameter. More complex arithmetic is possible using the stack.

Cursor Motions

If the terminal has a fast way to home the cursor (to very upper left corner of screen) then this can be given as **home**; similarly a fast way of getting to the lower left corner can be given as **ll**; this may involve going up with **cuu1** from the home position, but a program should never do this itself (unless **ll** does) because it can make no assumption about the effect of moving up from the home position. Note that the home position is the same as addressing to (0,0): to the top left corner of the screen, not of memory. (Thus, the \EH sequence on Hewlett-Packard terminals cannot be used for **home** without losing some of the other features on the terminal.)

If the terminal has row or column absolute-cursor addressing, these can be given as single parameter capabilities **hpa** (horizontal position absolute) and **vpa** (vertical position absolute). Sometimes these are shorter than the more general two-parameter sequence (as with the Hewlett-Packard 2645) and can be used in preference to **cup**. If there are parameterized local motions (e.g., move *n* spaces to the right) these can be given as **cud**, **cub**, **cuf**, and **cuu** with a single parameter indicating how many spaces to move. These are primarily useful if the terminal does not have **cup**, such as the Tektronix 4025.

Area Clears

If the terminal can clear from the current position to the end of the line, leaving the cursor where it is, this should be given as **el**. If the terminal can clear from the beginning of the line to the current position inclusive, leaving the cursor where it is, this should be given as **el1**. If the terminal can clear from the current position to the end of the display, then this should be given as **ed**. **ed** is only defined from the first column of a line. (Thus, it can be simulated by a request to delete a large number of lines, if a true **ed** is not available.)

Insert/delete line

If the terminal can open a new blank line before the line where the cursor is, this should be given as **il1**; this is done only from the first position of a line. The cursor must then appear on the newly blank line. If the terminal can delete the line which the cursor is on, then this should be given as **dl1**; this is done only from the first position on the line to be deleted. Versions of **il1** and **dl1** which take a single parameter and insert or delete that many lines can be given as **il** and **dl**.

If the terminal has a settable destructive scrolling region (like the VT100), the command to set this can be described with the **csr** capability, which takes two parameters: the top and bottom lines of the scrolling region. The cursor position is, alas, undefined after using this command. It is possible to get the effect of insert or delete line using this command—the **sc** and **rc** (save and restore cursor) commands are also useful. Inserting lines at the top or bottom of the screen can also be done using **ri** or **ind** on many terminals without a true insert/delete line, and is often faster even on terminals with those features.

To determine whether a terminal has destructive scrolling regions or nondestructive scrolling regions, create a scrolling region in the middle of the screen, place data on the bottom line of the scrolling region, move the cursor to the top line of the scrolling region, and do a reverse index (**ri**) followed by a delete line (**dl1**) or index (**ind**). If the data that was originally on the bottom line of the scrolling region was restored into the scrolling region by the **dl1** or **ind**, then the terminal has non-destructive scrolling regions. Otherwise, it has destructive scrolling regions. Do not specify **csr** if the terminal has non-destructive scrolling regions, unless **ind**, **ri**, **indn**, **rin**, **dl**, and **dl1** all simulate destructive scrolling.

If the terminal has the ability to define a window as part of memory, which all commands affect, it should be given as the parameterized string **wind**. The four parameters are the starting and ending lines in memory and the starting and ending columns in memory, in that order.

If the terminal can retain display memory above, then the **da** capability should be given; if display memory can be retained below, then **db** should be given. These indicate that deleting a line or scrolling a full screen may bring non-blank lines up from below or that scrolling back with **ri** may bring down non-blank lines.

Insert/Delete Character

There are two basic kinds of intelligent terminals with respect to insert/delete character operations which can be described using terminfo. The most common insert/delete character operations affect only the characters on the current line and shift characters off the end of the line rigidly. Other terminals, such as the Concept 100 and the Perkin Elmer Owl, make a distinction between typed and untyped blanks on the screen, shifting upon an insert or delete only to an untyped blank on the screen which is either eliminated or expanded to two untyped blanks. You can determine the kind of terminal you have by clearing the screen and then typing text separated by cursor motions. Type "abc def" using local cursor motions (not spaces) between the **abc** and the **def**. Then position the cursor before the **abc** and put the terminal in insert mode. If typing characters causes the rest of the line to shift rigidly and characters to fall off the end, then your terminal does not distinguish between blanks and untyped positions. If the **abc** shifts over to the **def** which then move together around the end of the current line and onto the next as you insert, you have the second type of terminal and should give the capability **in**, which stands for "insert null".

While these are two logically separate attributes (one line versus multiline insert mode and special treatment of untyped spaces) we have seen no terminals whose insert mode cannot be described with the single attribute.

terminfo can describe both terminals which have an insert mode and terminals which send a simple sequence to open a blank position on the current line. Give as **smir** the sequence to get into insert mode. Give as **rmir** the sequence to leave insert mode. Now give as **ich1** any sequence needed to be sent just before sending the character to be inserted. Most terminals with a true insert mode will not give **ich1**; terminals which send a sequence to open a screen position should give it here. (If your terminal has both, insert mode is usually preferable to ich1. Do not give both unless the terminal actually requires both to be used in combination.) If post-insert padding is needed, give this as a number of milliseconds padding in **ip** (a string option). Any other sequence which may need to be sent after an insert of a single character may also be given in ip. If your terminal needs both to be placed into an 'insert mode' and a special code to precede each inserted character, then both **smir/rmir** and **ich1** can be given, and both will be used. The **ich** capability, with one parameter, n, will repeat the effects of ich1 *n* times.

If padding is necessary between characters typed while not in insert mode, give this as a number of milliseconds padding in **rmp**.

It is occasionally necessary to move around while in insert mode to delete characters on the same line (e.g., if there is a tab after the insertion position). If your terminal allows motion while in insert mode you can give the capability **mir** to speed up inserting in this case. Omitting **mir** will affect only speed. Some terminals (notably Datamedia's) must not have **mir** because of the way their insert mode works.

Finally, you can specify **dch1** to delete a single character, **dch** with one parameter, n, to delete n characters, and delete mode by giving **smdc** and **rmdc** to enter and exit delete mode (any mode the terminal needs to be placed in for **dch1** to work).

A command to erase n characters (equivalent to outputting n blanks without moving the cursor) can be given as **ech** with one parameter.

Highlighting, Underlining, and Visible Bells

If your terminal has one or more kinds of display attributes, these can be represented in a number of different ways. You should choose one display form as *standout mode* [see *curses*(3X)], representing a good, high contrast, easy-on-the-eyes format for highlighting error messages and other attention-getters. (If you have a choice, reverse-video plus half-bright is good, or reverse-video alone; however, different users have different preferences on different terminals.) The sequences to enter and exit standout mode are given as **smso** and **rmso**, respectively. If the code to change into or out of standout mode leaves one or even two blank spaces on the screen, as the TVI 912 and Teleray 1061 do, then **xmc** should be given to tell how many spaces are left.

Codes to begin underlining and end underlining can be given as **smul** and **rmul** respectively. If the terminal has a code to underline the current

character and move the cursor one space to the right, such as the Micro-Term MIME, this can be given as **uc**.

Other capabilities to enter various highlighting modes include **blink** (blinking), **bold** (bold or extra-bright), **dim** (dim or half-bright), **invis** (blanking or invisible text), **prot** (protected), **rev** (reverse-video), **sgr0** (turn off all attribute modes), **smacs** (enter alternate-character-set mode), and **rmacs** (exit alternate-character-set mode). Turning on any of these modes singly may or may not turn off other modes. If a command is necessary before alternate character set mode is entered, give the sequence in **enacs** (enable alternate-character-set mode).

If there is a sequence to set arbitrary combinations of modes, this should be given as **sgr** (set attributes), taking nine parameters. Each parameter is either **0** or non-zero, as the corresponding attribute is on or off. The nine parameters are, in order: standout, underline, reverse, blink, dim, bold, blank, protect, alternate character set. Not all modes need be supported by **sgr**, only those for which corresponding separate attribute commands exist. (See the example at the end of this section.)

Terminals with the "magic cookie" glitch (**xmc**) deposit special "cookies" when they receive mode-setting sequences, which affect the display algorithm rather than having extra bits for each character. Some terminals, such as the Hewlett-Packard 2621, automatically leave standout mode when they move to a new line or the cursor is addressed. Programs using standout mode should exit standout mode before moving the cursor or sending a newline, unless the **msgr** capability, asserting that it is safe to move in standout mode, is present.

If the terminal has a way of flashing the screen to indicate an error quietly (a bell replacement), then this can be given as **flash**; it must not move the cursor. A good flash can be done by changing the screen into reverse video, pad for 200 ms, then return the screen to normal video.

If the cursor needs to be made more visible than normal when it is not on the bottom line (to make, for example, a non-blinking underline into an easier to find block or blinking underline) give this sequence as **cvvis**. The Boolean **chts** should also be given. If there is a way to make the cursor completely invisible, give that as **civis**. The capability **cnorm** should be given which undoes the effects of either of these modes.

If the terminal needs to be in a special mode when running a program that uses these capabilities, the codes to enter and exit this mode can be given as **smcup** and **rmcup**. This arises, for example, from terminals like the *Concept* with more than one page of memory. If the terminal has only memory relative cursor addressing and not screen-relative cursor addressing, a one screen-sized window must be fixed into the terminal for cursor addressing to work properly. This is also used for the Tektronix 4025, where **smcup** sets the command character to be the one used by **terminfo**. If the **smcup** sequence will not restore the screen after an **rmcup** sequence is output (to the state prior to outputting **rmcup**), specify **nrrmc**.

If your terminal generates underlined characters by using the underline character (with no special codes needed) even though it does not otherwise overstrike characters, then you should give the capability **u**l. For terminals where a character overstriking another leaves both characters on the screen, give the capability **os**. If overstrikes are erasable with a blank, then this should be indicated by giving **eo**.

Example of highlighting: assume that the terminal under question needs the following escape sequences to turn on various modes.

tparm parameter	attribute	escape sequence
	none	\E[0m
p1	standout	\E[0;4;7m
p2	underline	\E[0;3m
p3	reverse	\E[0;4m
p4	blink	\E[0;5m
p5	dim	\E[0;7m
p6	bold	\E[0;3;4m
p7	invis	\E[0;8m
p8	protect	not available
p9	altcharset	O (off) N(on)

Note that each escape sequence requires a **0** to turn off other modes before turning on its own mode. Also note that, as suggested above, *standout* is set up to be the combination of *reverse* and *dim*. Also, since this terminal has no *bold* mode, *bold* is set up as the combination of *reverse* and *underline*. In addition, to allow combinations, such as *underline+blink*, the sequence to use would be E[0;3;5m. The terminal doesn't have *protect* mode, either, but that cannot be simulated in any way, so **p8** is ignored. The *altcharset* mode is different in that it is either O or N depending on whether it is off or on. If all modes were to be turned on, the sequence would be E[0;3;4;5;7;8m N.

Now look at when different sequences are output. For example, ;3 is output when either **p2** or **p6** is true, that is, if either *underline* or *bold* modes are turned on. Writing out the above sequences, along with their dependencies, gives the following:

sequence	when to output	terminfo translation
\E[0	always	\E[0
;3	if p2 or p6	%?%p2%p6%l%t;3%;
;4	if p1 or p3 or p6	%?%p1%p3%l%p6%l%t;4%;
;5	if p4	%?%p4%t;5%;
;7	if p1 or p5	%?%p1%p5%l%t;7%;
;8	if p7	%?%p7%t;8%;
m	always	m
N or O	if p9	%?%p9%t^N%e^O%;

Putting this all together into the **sgr** sequence gives:

sgr=\E[0%?%p2%p6%**i**%t;3%;%?%p1%p3%**i**%p6%**i**%t;4%;%?%p5%t;5%;%?%p1% p5%**i**%t;7%;%?%p7%t;8%;m%?%p9%t[°]N%e[°]O%;,

Keypad

If the terminal has a keypad that transmits codes when the keys are pressed, this information can be given. Note that it is not possible to handle terminals where the keypad only works in local (this applies, for example, to the unshifted Hewlett-Packard 2621 keys). If the keypad can be set to transmit or not transmit, give these codes as **smkx** and **rmkx**. Otherwise the keypad is assumed to always transmit.

The codes sent by the left arrow, right arrow, up arrow, down arrow, and home keys can be given as kcub1, kcuf1, kcuu1, kcud1, and khome respectively. If there are function keys such as f0, f1, ..., f63, the codes they send can be given as kf0, kf1, ..., kf63. If the first 11 keys have labels other than the default f0 through f10, the labels can be given as **lf0**, **lf1**, ..., **lf10**. The codes transmitted by certain other special keys can be given: kll (home down), **kbs** (backspace), **ktbc** (clear all tabs), **kctab** (clear the tab stop in this column), kclr (clear screen or erase key), kdch1 (delete character), kdl1 (delete line), krmir (exit insert mode), kel (clear to end of line), ked (clear to end of screen), kich1 (insert character or enter insert mode), kil1 (insert line), knp (next page), kpp (previous page), kind (scroll forward/down), kri (scroll backward/up), khts (set a tab stop in this column). In addition, if the keypad has a 3 by 3 array of keys including the four arrow keys, the other five keys can be given as ka1, ka3, kb2, kc1, and kc3. These keys are useful when the effects of a 3 by 3 directional pad are needed. Further keys are defined above in the capabilities list.

Strings to program function keys can be given as **pfkey**, **pfloc**, and **pfx**. A string to program their soft-screen labels can be given as **pln**. Each of these strings takes two parameters: the function key number to program (from 0 to 10) and the string to program it with. Function key numbers out of this range may program undefined keys in a terminal-dependent manner. The difference between the capabilities is that **pfkey** causes pressing the given key to be the same as the user typing the given string; **pfloc** causes the string to be transmitted to the computer. The capabilities **nlab**, **lw** and **lh** define how many soft labels there are and their width and height. If there are commands to turn the labels on and off, give them in **smln** and **rmln**. **smln** is normally output after one or more **pln** sequences to make sure that the change becomes visible.

Tabs and Initialization

If the terminal has hardware tabs, the command to advance to the next tab stop can be given as **ht** (usually control I). A "backtab" command which moves leftward to the next tab stop can be given as **cbt**. By convention, if the teletype modes indicate that tabs are being expanded by the computer rather than being sent to the terminal, programs should not use **ht** or **cbt** even if they are present, since the user may not have the tab stops properly set. If the terminal has hardware tabs which are initially set every *n* spaces when the terminal is powered up, the numeric parameter **it** is given, showing the number of spaces the tabs are set to. This is normally used by **tput init** [see *tput*(1)] to determine whether to set the mode for hardware tab expansion and whether to set the tab stops. If the terminal has tab stops that can be saved in nonvolatile memory, the *terminfo* description can assume that they are properly set. If there are commands to set and clear tab stops, they can be given as **tbc** (clear all tab stops) and **hts** (set a tab stop in the current column of every row).

Other capabilities include: **is1**, **is2**, and **is3** initialization strings for the terminal; **iprog**, the path name of a program to be run to initialize the terminal; and **if**, the name of a file containing long initialization strings. These strings are expected to set the terminal into modes consistent with the rest of the *terminfo* description. They must be sent to the terminal each time the user logs in and be output in the following order: run the program **iprog**; output **is1**; output **is2**; set the margins using **mgc**, **smgl**, and **smgr**; set the tabs using **tbc** and **hts**; print the file **if**; and finally output **is3**. This is usually done using the **init** option of *tput*(1); see *profile*(4).

Most initialization is done with is2. Special terminal modes can be set up without duplicating strings by putting the common sequences in is2 and special cases in is1 and is3. Sequences that do a harder reset from a totally unknown state can be given as rs1, rs2, rf, and rs3, analogous to is1, is2, is3, and if. (The method using files, if and rf, is used for a few terminals, from */usr/lib/tabset/**; however, the recommended method is to use the initialization and reset strings.) These strings are output by tput reset, which is used when the terminal gets into a wedged state. Commands are normally placed in rs1, rs2, rs3, and rf only if they produce annoying effects on the screen and are not necessary when logging in. For example, the command to set a terminal into 80-column mode would normally be part of is2, but on some terminals it causes an annoying glitch on the screen and is not normally needed, since the terminal is usually already in 80-column mode.

If a more complex sequence is needed to set the tabs than can be described by using **tbc** and **hts**, the sequence can be placed in **is2** or **if**.

If there are commands to set and clear margins, they can be given as **mgc** (clear all margins), **smgl** (set left margin), and **smgr** (set right margin).

Delays

Certain capabilities control padding in the *tty*(7) driver. These are primarily needed by hard-copy terminals, and are used by **tput init** to set tty modes appropriately. Delays embedded in the capabilities **cr**, **ind**, **cub1**, **ff**, and **tab** can be used to set the appropriate delay bits to be set in the tty driver. If **pb** (padding baud rate) is given, these values can be ignored at baud rates below the value of **pb**.

Status Lines

If the terminal has an extra "status line" that is not normally used by software, this fact can be indicated. If the status line is viewed as an extra line below the bottom line, into which one can cursor address normally (such as the Heathkit h19's 25th line, or the 24th line of a VT100 which is set to a 23-line scrolling region), the capability **hs** should be given. Special strings that go to a given column of the status line and return from the status line can be given as **tsl** and **fsl**. (**fsl** must leave the cursor position in the same place it was in before **tsl**. If necessary, the **sc** and **rc** strings can be included in **tsl** and **fsl** to get this effect.) The capability **tsl** takes one parameter, which is the column number of the status line the cursor is to be moved to.

If escape sequences and other special commands, such as tab, work while in the status line, the flag **eslok** can be given. A string which turns off the status line (or otherwise erases its contents) should be given as **dsl**. If the terminal has commands to save and restore the position of the cursor, give them as **sc** and **rc**. The status line is normally assumed to be the same width as the rest of the screen, e.g., **cols**. If the status line is a different width (possibly because the terminal does not allow an entire line to be loaded) the width, in columns, can be indicated with the numeric parameter **wsl**.

Line Graphics

If the terminal has a line-drawing, alternate character set, the mapping of glyph to character would be given in **acsc**. The definition of this string is based on the alternate character set used in the DEC VT100 terminal, extended slightly with some characters from the AT&T 4410v1 terminal.

glyph name	vt100+
0.11	character
arrow pointing right	+
arrow pointing left	,
arrow pointing down	
solid square block	0
lantern symbol	I
arrow pointing up	
diamond	1
checker board (stipple)	а
degree symbol	f
plus/minus	g
board of squares	g h
lower right corner	j
upper right corner	k
upper left corner	1
lower left corner	m
plus	n
scan line 1	0
horizontal line	q
scan line 9	s
left tee (⊢)	t
right tee (–)	u
bottom tee (\bot)	v
top tee (†)	w
vertical line	x
bullet	~

The best way to describe a new terminal's line graphics set is to add a third column to the above table with the characters for the new terminal that produce the appropriate glyph when the terminal is in the alternate character set mode. For example,

glyph name	vt100+ char	new tty char
upper left corner	1	R
lower left corner	m	F
upper right corner	k	Т
lower right corner	i	G
horizontal line	ģ	,
vertical line	x	

Now write down the characters left to right, as in "acsc=lRmFkTjGq\,x.".

Miscellaneous

If the terminal requires other than a null (zero) character as a pad, then this can be given as **pad**. Only the first character of the **pad** string is used. If the terminal does not have a pad character, specify **npc**.

If the terminal can move up or down half a line, this can be indicated with **hu** (half-line up) and **hd** (half-line down). This is primarily useful for superscripts and subscripts on hardcopy terminals. If a hardcopy terminal can eject to the next page (form feed), give this as **ff** (usually control L).

If there is a command to repeat a given character a given number of times (to save time transmitting a large number of identical characters) this can be indicated with the parameterized string **rep**. The first parameter is the character to be repeated and the second is the number of times to repeat it. Thus, **tparm(repeat_char, 'x', 10)** is the same as **xxxxxxxxx**.

If the terminal has a settable command character, such as the Tektronix 4025, this can be indicated with **cmdch**. A prototype command character is chosen which is used in all capabilities. This character is given in the **cmdch** capability to identify it. The following convention is supported on some UNIX systems: If the environment variable CC exists, all occurrences of the prototype character are replaced with the character in CC.

Terminal descriptions that do not represent a specific kind of known terminal, such as **switch**, **dialup**, **patch**, and **network**, should include the **gn** (generic) capability so that programs can complain that they do not know how to talk to the terminal. (This capability does not apply to **virtual** terminal descriptions for which the escape sequences are known.) If the terminal is one of those supported by the UNIX system virtual terminal protocol, the terminal number can be given as **vt**. A line-turn-around sequence to be transmitted before doing reads should be specified in **rfi**.

If the terminal uses xon/xoff handshaking for flow control, give **xon**. Padding information should still be included so that routines can make better decisions about costs, but actual pad characters will not be transmitted.

Sequences to turn on and off xon/xoff handshaking may be given in **smxon** and **rmxon**. If the characters used for handshaking are not \hat{S} and \hat{Q} , they may be specified with **xonc** and **xoffc**.

If the terminal has a "meta key" which acts as a shift key, setting the 8th bit of any character transmitted, this fact can be indicated with \mathbf{km} . Otherwise, software will assume that the 8th bit is parity and it will usually be cleared. If strings exist to turn this "meta mode" on and off, they can be given as **smm** and **rmm**.

If the terminal has more lines of memory than will fit on the screen at once, the number of lines of memory can be indicated with Im. A value of Im#0 indicates that the number of lines is not fixed, but that there is still more memory than fits on the screen.

Media copy strings which control an auxiliary printer connected to the terminal can be given as **mc0**: print the contents of the screen, **mc4**: turn off the printer, and **mc5**: turn on the printer. When the printer is on, all text sent to the terminal will be sent to the printer. A variation, **mc5p**, takes one parameter and leaves the printer on for as many characters as the value of the parameter, then turns the printer off. The parameter should not exceed 255. If the text is not displayed on the terminal screen when the printer is on, specify **mc5i** (silent printer). All text, including **mc4**, is transparently passed to the printer while an **mc5p** is in effect.

Special Cases

The working model used by *terminfo* fits most terminals reasonably well. However, some terminals do not completely match that model, requiring special support by *terminfo*. These are not meant to be construed as deficiencies in the terminals; they are just differences between the working model and the actual hardware. They may be unusual devices or, for some reason, do not have all the features of the *terminfo* model implemented.

Terminals which can not display tilde (~) characters, such as certain Hazeltine terminals, should indicate **hz**.

Terminals which ignore a linefeed immediately after an **am** wrap, such as the *Concept* 100, should indicate **xenl**. Those terminals whose cursor remains on the right-most column until another character has been received, rather than wrapping immediately upon receiving the right-most character, such as the VT100, should also indicate **xenl**.

If **el** is required to get rid of standout (instead of writing normal text on top of it), **xhp** should be given.

Those Teleray terminals whose tabs turn all characters moved over to blanks, should indicate **xt** (destructive tabs). This capability is also taken to mean that it is not possible to position the cursor on top of a "magic cookie" therefore, to erase standout mode, it is instead necessary to use delete and insert line.

Those Beehive Superbee terminals which do not transmit the escape or control–C characters, should specify **xsb**, indicating that the f1 key is to be used for escape and the f2 key for control–C.

Similar Terminals

If there are two very similar terminals, one can be defined as being just like the other with certain exceptions. The string capability **use** can be given with the name of the similar terminal. The capabilities given before **use** override those in the terminal type invoked by **use**. A capability can be canceled by placing xx to the left of the capability definition, where xx is the capability. For example, the entry

att4424-2|Teletype 4424 in display function group ii, rev@, sgr@, smul@, use=att4424,

defines an AT&T 4424 terminal that does not have the **rev**, **sgr**, and **smul** capabilities, and hence cannot do highlighting. This is useful for different modes for a terminal, or for different user preferences. More than one **use** capability may be given.

FILES

/usr/lib/terminfo/?/*	compiled terminal description data base
/usr/lib/.COREterm/?/*	subset of compiled terminal description data
/usr/lib/tabset/*	base tab settings for some terminals, in a format appropriate to be output to the terminal (escape sequences that set margins and tabs)

Chapter 10 of the *Programmer's Guide*.

WARNING

As described in the "Tabs and Initialization" section above, a terminal's initialization strings, **is1**, **is2**, and **is3**, if defined, must be output before a curses(3X) program is run. An available mechanism for outputting such strings is **tput init** (see *tput*(1) and *profile*(4)).

Tampering with entries in /usr/lib/.COREterm/?/* or /usr/lib/terminfo/?/* (for example, changing or removing an entry) can affect programs such as vi(1) that expect the entry to be present and correct. In particular, removing the description for the "dumb" terminal will cause unexpected problems.

NOTE

The *termcap* data base (from earlier releases of UNIX System V) may not be supplied in future releases.

timezone - set default system time zone

SYNOPSIS

/etc/TIMEZONE

DESCRIPTION

This file sets and exports the time zone environmental variable TZ.

This file is "dotted" into other files that must know the time zone.

EXAMPLES

/etc/TIMEZONE for the east coast:

Time Zone TZ=EST5EDT export TZ

SEE ALSO

ctime(3C), profile(4). rc2(1M) in the System Administrator's Reference Manual.

unistd - file header for symbolic constants

SYNOPSIS

#include <unistd.h>

DESCRIPTION

The header file *<unistd.h>* lists the symbolic constants and structures not already defined or declared in some other header file.

/* Symbolic constants for the "access" routine: */

#define R_OK	4	<pre>/*Test for Read permission */</pre>
#define W_OK	2	/*Test for Write permission */
#define X_OK	1	/*Test for eXecute permission */
#define F_OK	0	/*Test for existence of File */
#define F_ULOCK	0	<pre>/*Unlock a previously locked region */</pre>
#define F_LOCK	1	/*Lock a region for exclusive use */
#define F_TLOCK	2	/*Test and lock a region for exclusive use */
#define F_TEST	3	/*Test a region for other processes locks */

/*Symbolic constants for the "lseek" routine: */

#define SEEK_SET	0	/* Set file pointer to "offset" */
#define SEEK_CUR	1	/* Set file pointer to current plus "offset" */
#define SEEK_END	2	/* Set file pointer to EOF plus "offset" */

/*Path names:*/

#define GF_PATH	<pre>/etc/group /*Path name of the group file */</pre>
#define PF_PATH	/etc/passwd/*Path name of the passwd file */

UTMP(4)

NAME

utmp, wtmp - utmp and wtmp entry formats

SYNOPSIS

#include <sys/types.h>
#include <utmp.h>

DESCRIPTION

These files, which hold user and accounting information for such commands as *who*(1), *write*(1), and *login*(1), have the following structure as defined by **<utmp.h>**:

```
#define
           UTMP_FILE
                          "/etc/utmp"
                          "/etc/wtmp"

INTRO(5)

NAME

intro – introduction to miscellany

DESCRIPTION

This section describes miscellaneous facilities such as macro packages, character set tables, etc.

c.scii - map of ASCII character set

DESCRIPTION

ascii is a map of the ASCII character set, giving both octal and hexadecimal equivalents of each character, to be printed as needed. It contains:

environ – user environment

DESCRIPTION

An array of strings called the "environment" is made available by exec(2) when a process begins. By convention, these strings have the form "name=value". The following names are used by various commands:

- PATH The sequence of directory prefixes that sh(1), time(1), nice(1), nohup(1), etc., apply in searching for a file known by an incomplete path name. The prefixes are separated by colons (:). Login(1) sets PATH=:/bin:/usr/bin.
- HOME Name of the user's login directory, set by *login*(1) from the password file *passwd*(4).
- **TERM** The kind of terminal for which output is to be prepared. This information is used by commands, such as mm(1) or tplot(1G), which may exploit special capabilities of that terminal.
- TZ Time zone information. The format is xxxnzzz where xxx is standard local time zone abbreviation, n is the difference in hours from GMT, and zzz is the abbreviation for the daylight-saving local time zone, if any; for example, EST5EDT.

Further names may be placed in the environment by the *export* command and "name=value" arguments in sh(1), or by *exec*(2). It is unwise to conflict with certain shell variables that are frequently exported by **.profile** files: MAIL, PS1, PS2, IFS.

SEE ALSO

exec(2).

env(1), login(1), sh(1), nice(1), nohup(1), time(1), tplot(1G) in the User's Reference Manual.

mm(1) in the DOCUMENTER'S WORKBENCH Software Release 2.0 Technical Discussion and Reference Manual.

fcntl – file control options

SYNOPSIS

#include <fcntl.h>

DESCRIPTION

The *fcntl*(2) function provides for control over open files. This include file describes *requests* and *arguments* to *fcntl* and *open*(2).

```
/* Flag values accessible to open(2) and fcntl(2) */
        /* (The first three can only be set by open) */
        #define O_RDONLY 0
        #define O_WRONLY 1
        #define O__RDWR
                             2
        #define O_NDELAY 04
                                      /* Non-blocking I/O */
        #define O_APPEND 010
                                       /* append (writes guaranteed at the end) */
       #define O_SYNC
                             020
                                      /* synchronous write option */

jagent – host control of windowing terminal

SYNOPSIS

#include <sys/jioctl.h>

ioctl (cntlfd, JAGENT, &arg)

int cntlfd struct bagent arg

DESCRIPTION

The *ioctl*(2) system call, when performed on an xt(7) device with the **JAGENT** request, allows a host program to send information to a windowing terminal.

ioctl has three arguments:

cntlfd the *xt*(7) control channel file descriptor

- **JAGENT** the *xt*(7) *ioctl*(2) request to invoke a windowing terminal agent routine.
- arg the address of a *bagent* structure, defined in **<sys/jioctl.h**> as follows:

struct bagent {
 long size; /* size of src in & dest out */
 char *src; /* the source byte string */
 char *dest; /* the destination byte string */
};

The *src* pointer must be initialized to point to a byte string which is sent to the windowing terminal. See *layers*(5) for a list of **JAGENT** strings recognized by windowing terminals. Likewise, the *dest* pointer must be initialized to the address of a buffer to receive a byte string returned by the terminal. When *ioctl*(2) is called, the *size* argument must be set to the length of the *src* string. Upon return, *size* is set by *ioctl*(2) to the length of the destination byte string, *dest*.

RETURN VALUE

Upon successful completion, the size of the destination byte string is returned. If an error occurs, -1 is returned.

layers – protocol used between host and windowing terminal under *layers*(1)

SYNOPSIS

#include <sys/jioctl.h>

DESCRIPTION

The *layers* are asynchronous windows supported by the operating system in a windowing terminal. Communication between the UNIX system processes and terminal processes under *layers*(1) occurs via multiplexed channels managed by the respective operating systems using a protocol as specified in *xtproto*(5).

The contents of packets transferring data between a UNIX system process and a layer are asymmetric. Data sent from the UNIX system to a particular terminal process is undifferentiated and it is up to the terminal process to interpret the contents of packets.

Control information for terminal processes is sent via channel 0. Process 0 in the windowing terminal performs the designated functions on behalf of the process connected to the designated channel. These packets take the form:

command, channel

except for *timeout* and *jagent* information which take the form

command, data...

The commands are the bottom eight bits extracted from the following **ioctl**(2) codes:

- **JBOOT** Prepare to load a new terminal program into the designated layer.
- **JTERM** Kill the downloaded layer program and restore the default window program.
- **JTIMO** Set the timeout parameters for the protocol. The data consist of two bytes: the value of the receive timeout in seconds and the value of the transmit timeout in seconds.
- **JTIMOM** Set the timeout parameters for the protocol. The data consist of four bytes in two groups: the value of the receive timeout in milliseconds (the low eight bits followed by the high eight bits) and the value of the transmit timeout (in the same format).

JZOMBOOT

Like JBOOT, but do not execute the program after loading.

JAGENT Send a source byte string to the terminal agent routine and wait for a reply byte string to be returned.

The data are from a *bagent* structure [see *jagent*(5)] and consist of a one-byte size field followed by a two-byte agent command

code and parameters. Two-byte integers transmitted as part of an agent command are sent with the high-order byte first. The response from the terminal is generally identical to the command packet, with the two command bytes replaced by the return code: **0** for success, -1 for failure. Note that the routines in the *libwindows*(3X) library all send parameters in an *agentrect* structure. The agent command codes and their parameters are as follows:

A_NEWLAYER	followed by a two-byte channel number and a rectangle structure (four two-byte coordinates).
A_CURRENT	followed by a two-byte channel number.
ADELETE	followed by a two-byte channel number.
А_ТОР	followed by a two-byte channel number.
A_BOTTOM	followed by a two-byte channel number.
A_MOVE	followed by a two-byte channel number and a point to move to (two two-byte coordinates).
A_RESHAPE	followed by a two-byte channel number and the new rectangle (four two-byte coordinates).
A_NEW	followed by a two-byte channel number and a rectangle structure (four two-byte coordinates).
A_EXIT	no parameters needed.
A_ROMVERSION	I

no parameters needed. The response packet contains the size byte, two-byte return code, two unused bytes, and the parameter part of the terminal id string (e.g., "8;7;3").

Packets from the windowing terminal to the UNIX system all take the following form:

command, data...

The single-byte commands are as follows:

C_SENDCHAR	Send the next byte to the UNIX system process.
------------	--

C_NEW Create a new UNIX system process group for this layer. Remember the window size parameters for this layer. The data for this command is in the form described by the *jwinsize* structure. The size of the window is specified by two 2-byte integers, sent low byte first.

C_UNBLK Unblock transmission to this layer. There is no data for this command.

LAYERS(5)	(AT&T Windowing Utilities)	LAYERS(5)
C_DELETE	Delete the UNIX system process this layer. There is no data for t

math - math functions and constants

SYNOPSIS

#include <math.h>

DESCRIPTION

This file contains declarations of all the functions in the Math Library (described in Section 3M), as well as various functions in the C Library (Section 3C) that return floating-point values.

It defines the structure and constants used by the *matherr*(3M) errorhandling mechanisms, including the following constant used as an errorreturn value:

HUGE The maximum value of a single-precision floatingpoint number.

The following mathematical constants are defined for user convenience:

M_E	The base of natural logarithms (e).
M_LOG2E	The base-2 logarithm of e .
M_LOG10E	The base-10 logarithm of e .
M_LN2	The natural logarithm of 2.
M_LN10	The natural logarithm of 10.
M_PI	π , the ratio of the circumference of a circle to its diameter.
M_PI_2	$\pi/2.$
M_PI_4	$\pi/4.$
M_1_PI	$1/\pi$.
M_2_PI	$2/\pi$.
M_2_SQRTPI	$2/\sqrt{\pi}$.
M_SQRT2	The positive square root of 2.
M_SQRT1_2	The positive square root of $1/2$.

For the definitions of various machine-dependent "constants," see the description of the $\langle values.h \rangle$ header file.

PROF(5)

NAME

prof – profile within a function

SYNOPSIS

#define MARK #include <prof.h>

void MARK (name)

DESCRIPTION

MARK will introduce a mark called *name* that will be treated the same as a function entry point. Execution of the mark will add to a counter for that mark, and program-counter time spent will be accounted to the immediately preceding mark or to the function if there are no preceding marks within the active function.

Name may be any combination of numbers or underscores. Each *name* in a single compilation must be unique, but may be the same as any ordinary program symbol.

For marks to be effective, the symbol MARK must be defined before the header file < prof.h > is included. This may be defined by a preprocessor directive as in the synopsis or by a command line argument, i.e:

cc -p -DMARK foo.c

If MARK is not defined, the *MARK*(name) statements may be left in the source files containing them and will be ignored.

EXAMPLE

In this example, marks can be used to determine how much time is spent in each loop. Unless this example is compiled with *MARK* defined on the command line, the marks are ignored.

```
#include <prof.h>
foo()
{
    int i, j;
    .
    .
    MARK(loop1);
    for (i = 0; i < 2000; i++) {
        ...
    }
    MARK(loop2);
    for (j = 0; j < 2000; j++) {
        ...
    }
}
SEE ALSO
</pre>
```

REGEXP(5)

NAME

regexp – regular expression compile and match routines

SYNOPSIS

#define INIT <declarations>
#define GETC() <getc code>
#define PEEKC() <peekc code>
#define UNGETC(c) <ungetc code>
#define RETURN(pointer) <return code>
#define ERROR(val) <error code>

#include <regexp.h>

char *compile (instring, expbuf, endbuf, eof) char *instring, *expbuf, *endbuf; int eof;

int step (string, expbuf) char *string, *expbuf;

extern char *loc1, *loc2, *locs;

extern int circf, sed, nbra;

DESCRIPTION

This page describes general-purpose, regular expression matching routines in the form of ed(1), defined in **<regexp.h>**. Programs such as ed(1), sed(1), grep(1), expr(1), etc., which perform regular expression matching use this source file. In this way, only this file need be changed to maintain regular expression compatibility.

The interface to this file is unpleasantly complex. Programs that include this file must have the following five macros declared before the "#include <regexp.h>" statement. These macros are used by the *compile* routine.

- GETC() Return the value of the next character in the regular expression pattern. Successive calls to GETC() should return successive characters of the regular expression.
- PEEKC() Return the next character in the regular expression. Successive calls to PEEKC() should return the same character [which should also be the next character returned by GETC()].
- UNGETC(c) Cause the argument c to be returned by the next call to GETC() [and PEEKC()]. No more than one character of pushback is ever needed, and this character is guaranteed to be the last character read by GETC(). The value of the macro UNGETC(c) is always ignored.
- RETURN(*pointer*) This macro is used on normal exit of the *compile* routine. The value of the argument *pointer* is a pointer to the character after the last character of the compiled regular expression. This is useful to programs which have memory allocation to manage.

ERROR(val)	This is the abnormal return from the <i>compile</i> routine. The argument <i>val</i> is an error number (see table below for meanings). This call should never return.		
ERROR	MEANING		
11	Range endpoint too large. Bad number.		
16			
25	"\digit" out of range.		
36	Illegal or missing delimiter.		
41	No remembered search string.		
42	() imbalance.		
43	Too many \(.		
44	More than 2 numbers given in $\setminus \{ \setminus \}$.		
45	} expected after \.		
46	First number exceeds second in $\{ \}$.		
49	[] imbalance.		
50	Regular expression overflow.		
	· · · · · · · · · · · · · · · · · · ·		

The syntax of the *compile* routine is as follows:

compile(instring, expbuf, endbuf, eof)

The first parameter *instring* is never used explicitly by the *compile* routine but is useful for programs that pass down different pointers to input characters. It is sometimes used in the INIT declaration (see below). Programs which call functions to input characters or have characters in an external array can pass down a value of ((char *) 0) for this parameter.

The next parameter *expbuf* is a character pointer. It points to the place where the compiled regular expression will be placed.

The parameter *endbuf* is one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (*endbuf–expbuf*) bytes, a call to ERROR(50) is made.

The parameter *eof* is the character which marks the end of the regular expression. For example, in ed(1), this character is usually a /.

Each program that includes this file must have a **#define** statement for INIT. This definition will be placed right after the declaration for the function *compile* and the opening curly brace ({). It is used for dependent declarations and initializations. Most often it is used to set a register variable to point the beginning of the regular expression so that this register variable can be used in the declarations for GETC(), PEEKC(), and UNGETC(). Otherwise it can be used to declare external variables that might be used by GETC(), PEEKC(), and UNGETC(). See the example below of the declarations taken from *grep*(1).

There are other functions in this file which perform actual regular expression matching, one of which is the function *step*. The call to *step* is as follows:

step(string, expbuf)

The first parameter to *step* is a pointer to a string of characters to be checked for a match. This string should be null-terminated.

The second parameter *expbuf* is the compiled regular expression which was obtained by a call of the function *compile*.

The function *step* returns non-zero if the given string matches the regular expression, and zero if the expressions do not match. If there is a match, two external character pointers are set as a side effect to the call to *step*. The variable set in *step* is *loc1*. This is a pointer to the first character that matched the regular expression. The variable *loc2*, which is set by the function *advance*, points to the character after the last character that matches the regular expression. Thus if the regular expression matches the entire line, *loc1* will point to the first character of *string*, and *loc2* will point to the null at the end of *string*.

Step uses the external variable *circf* which is set by *compile* if the regular expression begins with $\hat{}$. If this is set, then *step* will try to match the regular expression to the beginning of the string only. If more than one regular expression is to be compiled before the first is executed, the value of *circf* should be saved for each compiled expression, and *circf* should be set to that saved value before each call to *step*.

The function *advance* is called from *step* with the same arguments as *step*. The purpose of *step* is to step through the *string* argument and call *advance* until *advance* returns non-zero indicating a match or until the end of *string* is reached. If one wants to constrain *string* to the beginning of the line in all cases, *step* need not be called; simply call *advance*.

When *advance* encounters a * or $\{ \}$ sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, *advance* will back up along the string until it finds a match or reaches the point in the string that initially matched the * or $\{ \}$. It is sometimes desirable to stop this backing up before the initial point in the string is reached. If the external character pointer *locs* is equal to the point in the string at sometime during the backing up process, *advance* will break out of the loop that backs up and will return zero. This is used by *ed*(1) and *sed*(1) for substitutions done globally (no. just the first occurrence, but the whole line) so, for example, expressions like s/y*//g do not loop forever.

The additional external variables *sed* and *nbra* are used for special purposes.

EXAMPLES

The following is an example of how the regular expression macros and calls look from *grep*(1):

#define INIT	register char *sp = instring;
#define GETC()	(*sp++)
#define PEEKC()	(*sp)
#define UNGETC(c)	(sp)
#define RETURN(c)	return;
#define ERROR(c)	regerr()

#include <regexp.h>

term – conventional names for terminals

DESCRIPTION

These names are used by certain commands [e.g., tabs(1), tput(1), vi(1) and curses(3X)] and are maintained as part of the shell environment in the environment variable **TERM** [see sh(1), profile(4), and environ(5)].

Entries in *terminfo*(4) source files consist of a number of comma-separated fields. [To obtain the source description for a terminal, use the -I option of *infocmp*(1M).] White space after each comma is ignored. The first line of each terminal description in the *terminfo*(4) data base gives the names by which *terminfo*(4) knows the terminal, separated by bar (1) characters. The first name given is the most common abbreviation for the terminal [this is the one to use to set the environment variable TERMINFO in \$HOME/.profile; see profile(4)], the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should contain no blanks and must be unique in the first 14 characters; the last name may contain blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, for example, for the AT&T 4425 terminal, **att4425**. This name should not contain hyphens, except that synonyms may be chosen that do not conflict with other names. Up to 8 characters, chosen from [a–z0–9], make up a basic terminal name. Names should generally be based on original vendors, rather than local distributors. A terminal acquired from one vendor should not have more than one distinct basic name. Terminal sub-models, operational modes that the hardware can be in, or user preferences, should be indicated by appending a hyphen and an indicator of the mode. Thus, an AT&T 4425 terminal in 132 column mode would be **att4425-w**. The following suffixes should be used where possible:

Suffix	Meaning	Example
-w	Wide mode (more than 80 columns)	att4425-w
-am	With auto. margins (usually default)	vt100-am
-nam	Without automatic margins	vt100–nam
-n	Number of lines on the screen	aaa–60
-na	No arrow keys (leave them in local)	c100–na
–n p	Number of pages of memory	c100-4p
-rv	Reverse video	att4415-rv

To avoid conflicts with the naming conventions used in describing the different modes of a terminal (e.g., -w), it is recommended that a terminal's root name not contain hyphens. Further, it is good practice to make all terminal names used in the *terminfo*(4) data base unique. Terminal entries that are present only for inclusion in other entries via the **use**= facilities should have a '+' in their name, as in **4415+nl**.

Some of the known terminal names may include the following (for a complete list, type: **ls -C** /usr/lib/terminfo/?):

2621,hp2621 2631 2631-c 2631-е 2640,hp2640 2645,hp2645 3270 33,tty33 35,ttv35 37,tty37 4000a 4014,tek4014 40,tty40 43,tty43 4410,5410 4410-nfk,5410-nfk 4410-nsl,5410-nsl 4410-w,5410-w 4410v1,5410v1 4410v1-w,5410v1-w 4415,5420 4415-nl,5420-nl 4415-rv,5420-rv 4415-rv-nl,5420-rv-nl 4415-w,5420-w 4415-w-nl,5420-w-nl 4415-w-rv,5420-w-rv 4415-w-rv-nl,5420-w-rv-nl 4418,5418 4418-w,5418-w 4420 4424 4424-2 4425,5425 4425-fk,5425-fk 4425-nl,5425-nl 4425-w.5425-w

types – primitive system data types

SYNOPSIS

#include <sys/types.h>

DESCRIPTION

The data types defined in the include file are used in UNIX system code; some data of these types are accessible to user code:

80386 computer	
typedef struct { int r[1];	} *physadr;
typedef long	daddrt;
typedef char *	caddr_t;
typedef unsigned char	unchar;
typedef unsigned short	ushort;
typedef unsigned int	uint;
typedef unsigned long	ulong;
typedef ushort	ino_t;
typedef short	cnt_t;
typedef long	timet;
typedef int	label_t[6];
typedef short	dev_t;
typedef long	off_t;
typedef long	paddr_t;
typedef int	key_t;
typedef unsigned char	uset;
typedef short	sysid_t;
typedef short	index_t;
typedef short	lock_t;
typedef unsigned int	sizet;
typedef unsigned int	sizet;
	size_t;
80286 computer	
80286 computer typedef struct { int r[1];	} *physadr;
80286 computer typedef struct { int r[1]; typedef long	} *physadr; daddr_t;
80286 computer typedef struct { int r[1]; typedef long typedef char *	} *physadr; daddr_t; caddr_t;
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char	<pre>} *physadr; daddr_t; caddr_t; unchar;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned int	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned int typedef unsigned long	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint; ulong;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned int typedef unsigned long typedef ushort	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint; ulong; ino_t;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned int typedef unsigned long typedef ushort typedef short	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint; ulong; ino_t; cnt_t;</pre>
80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned long typedef unsigned long typedef short typedef short typedef long	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint; ulong; ino_t; cnt_t; time_t;</pre>

80286 computer typedef struct { int r[1]; typedef long typedef char * typedef unsigned char typedef unsigned short typedef unsigned long typedef ushort typedef short typedef long typedef int typedef short typedef long typedef short typedef long typedef long	<pre>} *physadr; daddr_t; caddr_t; unchar; ushort; uint; ulong; ino_t; cnt_t; time_t; label_t[7]; dev_t; off_t;</pre>

typedef short	sysid_t;
typedef short	index_t;
typedef short	lock_t;
typedef unsigned int	size_t;

The form $daddr_t$ is used for disk addresses except in an i-node on disk, see fs(4). Times are encoded in seconds since 00:00:00 GMT, January 1, 1970. The major and minor parts of a device code specify kind and unit number of a device and are installation-dependent. Offsets are measured in bytes from the beginning of a file. The *label_t* variables are used to save the processor state while another process is running.

fs(4).

values - machine-dependent values

SYNOPSIS

#include <values.h>

DESCRIPTION

This file contains a set of manifest constants, conditionally defined for particular processor architectures.

The model assumed for integers is binary representation (one's or two's complement), where the sign is represented by the value of the high-order bit.

BITS(type)	The number of bits in a specified type (e.g., int).		
HIBITS	The value of a short integer with only the high-order bit set (in most implementations, 0x8000).		
HIBITL	The value of a long integer with only the high-order bit set (in most implementations, 0x80000000).		
HIBITI	The value of a regular integer with only the high- order bit set (usually the same as HIBITS or HIBITL).		
MAXSHORT		mum value of a signed short integer (in most tations, $0x7FFF = 32767$).	
MAXLONG	The maximum value of a signed long integer (in m implementations, $0x7FFFFFFF = 2147483647$).		
MAXINT	The maximum value of a signed regular integer (usu- ally the same as MAXSHORT or MAXLONG).		
MAXFLOAT, LN_MAXFLOAT		The maximum value of a single-precision floating-point number and its natural loga-rithm.	
MAXDOUBLE, LN_MA	XDOUBLE	The maximum value of a double-precision floating-point number and its natural loga-rithm.	
MINFLOAT, LN_MINFLOAT		The minimum positive value of a single- precision floating-point number and its natural logarithm.	
MINDOUBLE, LN_MINDOUBLE		The minimum positive value of a double- precision floating-point number and its natural logarithm.	
FSIGNIF	The number of significant bits in the mantissa of a single-precision, floating-point number.		
DSIGNIF		ber of significant bits in the mantissa of a ecision, floating-point number.

VARARGS(5)

VARARGS(5)

NAME

varargs - handle variable argument list

SYNOPSIS

#include <varargs.h>

```
va_alist
va_dcl
```

void va_start(pvar) va_list pvar; type va_arg(pvar, type)

```
va_list pvar;
```

void va_end(pvar)

va_list pvar;

DESCRIPTION

This set of macros allows portable procedures that accept variable argument lists to be written. Routines that have variable argument lists [such as printf(3S)] but do not use *varargs* are inherently nonportable, as different machines use different argument-passing conventions.

va_alist is used as the parameter list in a function header.

va_dcl is a declaration for va_alist. No semicolon should follow va_dcl.

va_list is a type defined for the variable used to traverse the list.

va_start is called to initialize *pvar* to the beginning of the list.

va_arg will return the next argument in the list pointed to by *pvar*. *Type* is the type the argument is expected to be. Different types can be mixed, but it is up to the routine to know what type of argument is expected, as it cannot be determined at runtime.

va_end is used to clean up.

Multiple traversals, each bracketed by *va_start* ... *va_end*, are possible.

EXAMPLE

This example is a possible implementation of *execl*(2).

```
va_start(ap);
file = va_arg(ap, char *);
while ((args[argno++] = va_arg(ap, char *)) != (char *)0)
;
va_end(ap);
return execv(file, args);
```

SEE ALSO

exec(2), printf(3S), vprintf(3S).

}

NOTES

It is up to the calling routine to specify how many arguments there are, since it is not always possible to determine this from the stack frame. For example, *execl* is passed a zero pointer to signal the end of the list. *Printf* can tell how many arguments are there by the format.

It is non-portable to specify a second argument of *char*, *short*, or *float* to va_arg , since arguments seen by the called function are not *char*, *short*, or *float*. C converts *char* and *short* arguments to *int* and converts *float* arguments to *double* before passing them to a function.

xtproto - multiplexed channels protocol used by xt(7) driver

DESCRIPTION

The xt(7) driver contains routines which implement a multiplexed, multibuffered, full-duplex protocol with guaranteed delivery of ordered data via an 8-bit byte data stream. This protocol is used for communication between multiple UNIX system host processes and an AT&T windowing terminal operating under *layers*(1).

The protocol uses packets with a 2-byte header containing a 3-bit sequence number, 3-bit channel number, control flag, and data size. The data part of a packet may not be larger than 32 bytes. The trailer contains a CRC-16 code in 2 bytes. Each channel is double-buffered.

Correctly received packets in sequence are acknowledged with a control packet containing an ACK; however, out of sequence packets generate a control packet containing a NAK, which will cause the retransmission in sequence of all unacknowledged packets.

Unacknowledged packets are retransmitted after a timeout interval which is dependent on baud rate. Another timeout parameter specifies the interval after which incomplete receive packets are discarded.
