CHAPTER 1 DESCRIPTION

The CONTROL DATA* 1604-A is a stored-program, general-purpose digital computer with a large storage capacity, fast computation and transfer speeds, and special provisions for input/output communication. The 1604-A is designed to handle large-volume data processing and to solve large-scale scientific problems. The compact equipment, constructed from solid-state components throughout, is suitable for use in a semipermanent office environment.

1604-A CHARACTERISTICS

Stored-program general-purpose digital computer

Parallel mode of operation

48-bit word, 2 instructions per word

Single address logic

Operation code 6 bits Designator 3 bits Base Execution Address 15 bits

LOGICAL DESCRIPTION

The 1604-A performs calculations and processes data in a parallel binary mode through the step-by-step execution of individual instructions which are stored internally along with the data.

Functionally, the computer may be divided into four major sections. Storage provides internal storage for data and instructions; Control coordinates and sequences all operations for executing an instruction by obtaining the instruction from storage and translating it into commands for the other sections; Arithmetic performs the arithmetic and logical operations required for executing instructions; and Input/Output provides communication between the computer and the external equipment.

The registers in the computer are identified by letters (table 1-1). The arithmetic properties of the registers are detailed in table 1-2. The operational registers usually hold the end result of an operation; their contents are displayed on the console and may be changed manually.

TABLE 1-1. REGISTERS OF THE COMPUTER

^{*} Operational Registers

STORAGE SECTION

The magnetic core storage section of the 1604-A computer provides high-speed, random access storage for 32,768 words. It consists of two independent storage units each with a capacity of 16,384 words. These units operate together during the execution of a stored program and thus are considered as one 32,768 word storage system.

A word is 48 bits in length and is used in two ways: as two 24-bit instructions or as a 48-bit operand (data word). The location of each word in storage is identified by an assigned number or address. When a word is taken (read) from or entered (written) into storage, a reference is made to the storage address which holds the word. All odd storage addresses are located in one storage unit, all even addresses in the other.

The cycle time, or time for a complete storage reference, is 6.4 μ sec. Since the storage cycles of the two sections overlap one another in the execution of a program, the average effective cycle time for random addresses is about 4.8 μ sec.

CONTROL SECTION

The control section directs the operations required to execute instructions and to initiate the exchange of data with external equipment. It also establishes the timing relationships needed to perform the operations in the proper sequence.

The control section acquires a program word from storage, interprets it and sends the necessary commands to other sections. A program word is a pair of 24-bit instructions which together occupy one storage location as a 48-bit word. The higher-order 24 bits are the upper instruction; the remaining 24 bits, the lower instruction.

Instruction Format

f (6 bits)	b (3 bits)	m, y, or k (15 bits)
Operation Code	Index Designator	Base Execution Address

Each of the 62 instructions has a unique 6-bit operation code which specifies the operation to be performed.

The index designator generally specifies one of the six index registers whose content is to be added to the execution address. This process is called address modification. However, the index designator may also specify indirect addressing or a condition for jump and stop instructions.

The execution address may be used in one of three ways: as an address, m, of an operand; as an operand, y; or as a shift count, k.

The eight operational registers in the control section are P, U^1 and B^1 through B^6 .

The program address register (P) is a two's complement additive counter. It provides program continuity by generating in sequence the storage addresses which contain the individual program steps. Usually at the completion of each two instructions the count in P is advanced by one to specify the address of the next program word.

The program control register (U¹) holds a program word while the two instructions contained in it are executed. The upper instruction is executed first followed by the lower instruction.

After executing an instruction, a half exit, full exit, or jump exit is performed. A half exit allows the lower instruction of a program word to be executed. A full exit advances the count in P by one and executes the upper instruction of the new program word specified by the contents of P. A jump exit allows a new sequence of instructions to be executed; the storage location of the new instruction is specified by the execution address of the jump instruction. The execution address, in this case, is entered into P and specifies the starting location of a new sequence of program words.

The auxiliary program control register (U^2) is a 15-bit subtractive accumulator used primarily in the modification of the base execution address. The contents of the specified index register are transmitted to the Address Buffer register (R), which has provisions for counting, complementing and storing. The contents of R are then added to the contents of R which holds the execution address.

Index registers B^1 through B^6 are 15-bit registers used to modify the base execution address when relative addressing is used. The index registers are also used to designate the number of words in search and transfer instructions and for other indexing operations.

ARITHMETIC SECTION

The arithmetic section of the 1604-A computer consists of two operational registers. A and Q, and one secondary register, X.

TABLE 1-2. ARITHMETIC PROPERTIES OF REGISTERS

Register	No. of Stages	Modulus	Complement Notation*	Arithmetic	Result
A	48	2 ⁴⁸ -1	one's	subtractive	signed**
Q	48	2 ⁴⁸ -1	one's		signed
U^2	15	2 ¹⁵ -1	one's	subtractive	signed
P	15	215	two*s	additive	unsigned
R	15	215	two¹s	subtractive	unsigned

The A register (Accumulator) is the principal arithmetic register. Some of the more important functions of A are:

- 1) Arithmetic operation A initially holds one of the operands in addition, subtraction, multiplication and division. The result is usually held in A.
- 2) Shifting A may be shifted to the right or left separately or in conjunction with Q. Right shifting is open-ended; the lowest bits are discarded and sign extended. Left shifting is circular; the highest order bit appears in the lowest order stage after each shift; all other bits move one place to the left.
- 3) Control for conditional instructions A holds the word which conditions jump and search instructions.

The Q register is an Auxiliary Arithmetic register and is generally used in conjunction with the A register. The principal functions of Q are:

- 1) Providing temporary storage of contents of A while A is used for another arithmetic operation.
- 2) Forming a double-length register, AQ or QA.
- 3) Shifting to the right or left, separately or in conjunction with A.
- 4) Participating with the A register in multiplication, division and logical product operations (masking).

^{*} Refer to Appendix

^{**} The result of an arithmetic operation in A satisfies $A \le 2^{47}$ -1 since A always is treated as a signed quantity. When the result in A is zero, it is always represented by 000...00 except when 111...11 is added to 111...11 or 000...00 is subtracted from 111...11. In these cases the result is 111...11 (negative zero).

The X (Exchange) register is used in the exchange of data between storage and the arithmetic section. X provides one of the inputs to the accumulator borrow pyramid.

INPUT/OUTPUT

The input/output section controls the flow of data to and from the computer. Data is transmitted in one of two ways: High Speed Transfer or Buffering.

High speed transfer operations are controlled directly by the program (Search and Transfer Sequence) and are used to transfer data between computers or between a 1604-A and high speed external equipment (e.g., a line printer). I/O channel number 7 is used for high speed transfer.

Buffering is an asynchronous transmission of data on I/O channels 1 through 6. Once a buffer operation has been initiated by the program, buffering and program operations proceed concurrently. Computation continues while buffering takes place at rate dependent on the external equipment. Buffering and program operations share access to computer storage; buffer operations have priority. High speed transfer is a program operation.

The buffer channels are paired with input on odd channels and output on even channels:

Input		Output	
Channel	1	Channel 2	2
Channel	3	Channel 4	1
Channel	5	Channel	6

All six channels may be used concurrently. Each channel may be connected to several external equipments (figure 1-1) but only one equipment may use a channel at any instant. All I/O operations are parallel transmission of 48-bit words.

PROGRAM COMPATIBILITY

The 1604/1604-A switch enables the 1604-A to run programs written for the 1604. A red background light in the leftmost digit of the P register indicates that the switch is in the 1604 position.

Experience to date has shown only two areas of program incompatibility between the 1604 and the 1604-A:

- 1) In the 1604, the EXF code 74.004001 locks out all interrupts; in the 1604-A, this code locks out only external interrupts. (See Appendix, page 29 for internal interrupt codes).
- 2) In the 1604-A, when reading input words into buffer control word addresses (e.g., Auto Load operation), the fast 1604-A control word registers require that the upper address of the input word be the control word address plus one.

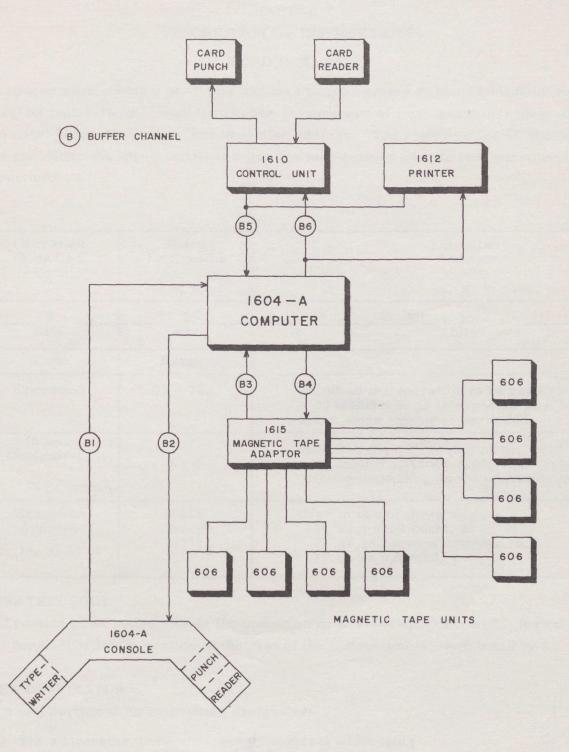

Figure 1-1. Typical 1604-A System

CHAPTER 2 DESCRIPTION OF INSTRUCTIONS

WORD FORMAT

A computer word consists of 48 bits and may be interpreted as one 48-bit data word or two 24-bit instructions. Each instruction is composed of three parts or codes: operation code, index designator, and execution address. The higher-order 24 bits of the word are called the upper instruction and the lower-order 24-bits are called the lower instruction.

bit 47		bit 24
Operation (Function) Code	Index Designator	Execution Address
f	b, j	m, y, k
bits	3 bits	15 bits
Code	Range	
Operation f	01 - 7	Specifies the operation to be performed. A 00 code is interpreted as a fault, which stops computer operation.
Index Designator b, j	0 - 7	Specifies the addressing mode, jump or stop condition, index register or external function depending on the operation code.
Execution Address m, y, k	00000 through 77777 ₈	Used in one of three ways: 1) as a shift count, k 2) as an operand address, m 3) as an operand, y

OPERATION CODE

The f portion of an instruction is the operation code which specifies which instruction is to be done. The interpretation of the rest of the instruction is conditioned by f.

INDEX DESIGNATOR

The b or j portion of an instruction designates:

1) The addressing mode b = 0 direct addressing b = 1-6 relative addressing b = 7 indirect addressing

2) The condition for jump or stop instructions (see Jumps and Stops, page 2-27).

3) The type of EXF instruction = 0 select = 1-6 activate sense

4) The index register in index instructions

EXECUTION ADDRESS

The base execution address may be used as: (1) a shift count, k; (2) an operand, y: (3) an address of an operand, m, in storage; (4) an external function code (chapter 3). The execution address may also be modified or unmodified depending on the instruction and index designator. If unmodified, the address is represented by the lower-case symbol k, y, or m; if the address is modified the symbols are capitalized. The following examples point out the relationship between the unmodified and modified execution address.

The modified shift count K is represented by:

1) $K = k + (B^b)$ where: K = modified shift count

= unmodified shift count (execution address) (Bb) = contents of index register b.

If the index designator = 0, then K = k.

The modified operand Y is represented by:

2) $Y = y + (B^{D})$ where: = modified operand

= unmodified operand (execution address)

(Bb) = contents of index register b.

If the index designator = 0, then Y = y.

The modified operand address M is represented by:

3) $M = m + (B^D)$ where: M = modified address of operand

= unmodified address of operand (execution address) m_b = unmodified address of operation (B^b) = contents of index register b.

If the index designator = 0, then M = m. Note that (3) is the only case in which the execution address is interpreted as an address of an operand.

ADDRESS MODIFICATION

The three possible modes of address modification are identified by the index designators as follows:

No Address Modification. In this mode the execution address is inter-1) b = 0preted without modification; nothing is added to or subtracted from it. (Direct addressing.)

- 2) b = 1-6 Relative Address Modification. In this mode the execution address is modified and is equal to the initial execution address plus the contents of the designated index register. One's complement arithmetic is used in determining the modified execution address.
- 3) b = 7 Indirect Addressing. In this mode the base execution address specifies the address of the operand address rather than the operand. The 48-bit word is read from storage and the lower-order 18 bits of the word are interpreted as the b designator (3 bits) and execution address (15 bits) of the present instruction. The new index designator may refer to any one of the three modes.

Examples:

1) No Address Modification

f b m LDA 0 address

This instruction is interpreted as load accumulator from the storage location designated by the sum of the execution address and the contents of the specified index register, B^b . Since b = 0, no index register is designated and m specifies the storage location whose contents are loaded into A.

2) Relative Address Modification

f b m LDA 6 address $(B^6) = 00001_8$

In this example, the accumulator is loaded from the storage location designated by the execution address plus the contents of index register 6. Therefore, the contents of the storage location named by the execution address plus 00001_8 is loaded into the accumulator. $M = m + (B^b)$.

B) Indirect Addressing

Current Instruction = LDA 7 00100, (00100) = FAD 0 00300 FMU 6 00200 (B⁶) = 00001₈

When the b designator of the current instruction is 7, the mode is indirect addressing. The lower 18 bits of the contents of the storage location designated by the execution address, 00100, are read from storage into the U¹ register where they are interpreted as the index designator and execution address of the current instruction.

The index designator is inspected again and because it is not 0 or 7 the relative address mode exists. (Note that the new index designator could reference any one of the three modes of address modification.) The execution address, 00200, plus the contents of B^6 , 00001 $_8$ specify the storage location whose contents will be loaded into the accumulator. $M = 00200_8 + (00001_8) = 00201_8$

EXECUTION OF A PAIR OF INSTRUCTIONS

Example: f b m f b m $(00300) = LDA \ 0 \ 00310$ ADD 1 00210 $(00301) = STA \ 0 \ 00400$ SLS 0 00301 $(B^1) = 00101_8$

The P register holds address 00300 (an even lowest bit indicates the address of the program step is in the even storage unit). The storage reference is initiated; the 48-bit word is read from address 00300 and entered into ${\tt U}^1$. Computer operation is now dependent upon the interpretation of the 24-bit instruction in the upper half of ${\tt U}^1$.

The operation code, LDA, and the index designator, 0, are translated. The function of the upper instruction, LDA, is to load the A register with the contents of the designated storage location. Because the index designator is 0, the execution address is not modified. The translation of the operation code initiates the sequence of the commands which execute the instruction and the operand in address 00310 is loaded into A.

The lower instruction in U^1 is transferred to U^1 upper and translated. The ADD instruction causes the quantity in storage location M to be added to the contents of the A register. Since the index designator is not 0 or 7, the contents of the index register are added to the execution address to form M. $M = m + (B^b) = 00210_8 + 00101_8 = 00311_8$. The contents of storage address 00311 are added to the contents of the A register completing the instruction. The contents of the P register are increased by one and the pair of instructions at address 00301 is read from storage and executed.

INSTRUCTIONS

The 62 computer instructions are described on the following pages (EXF instructions are discussed in detail in chapter three). The title line contains the numeric code, the mnemonic code and format, name, and average execution time of the instruction. Abbreviations and symbols are defined as follows:

A	Accumulator
An	The binary digit in position n of the A register
→	Transmit to
b	Index designator
Bb	Designated index register
Exit (Full)	Proceed to upper instruction of next program step
Half exit	Proceed to lower instruction of same program step
j	The condition designator for jump and stop instructions
k	Unmodified shift count
K	Modified shift count. K = k + (Bb)
LA	Lower address - execution address portion of lower instruction of a program step
m	Unmodified operand address
M	Modified operand address. M = m + (Bb)
()	Contents of a register or storage location
()'	One's complement of contents of a register or storage location
()f	Final contents of a register or storage location
()i	Initial contents of a register or storage location
Q	Auxiliary arithmetic register
UA	Upper address
X	Exchange register
У	Unmodified operand
Y	Modified operand. $Y = y + (B^b)$

INSTRUCTION EXECUTION TIME

The time needed to execute an instruction varies from application to application because of the following factors.

If the instruction occupies the upper position in an instruction word, the time needed to read the word from storage must be considered.

If consecutive storage references are made to the same storage unit (even-even or odd-odd) the read access time from storage will be maximized.

If indirect addressing is specified, at least one additional reference will be needed to complete the instruction. (The new index designator may itself specify indirect addressing.)

If buffer operations are using storage, an instruction must wait until storage is released.

If a storage reference is made at the end of the preceding instruction, execution of the next instruction may be delayed.

The instruction execution times listed on the following pages were compiled by averaging the times for a long list of the same instructions. The list was arranged for typical values of the factors.

DATA TRANSMISSION

- 1) Relative addressing does not take place during LIU, LIL, SIU or SIL instructions. Only direct and indirect addressing are recognized.
- 2) All modes of address modification apply to the remaining data transmission instructions.
- 3) During the execution of data transmission instructions, one storage reference is made. If indirect addressing is designated, at least two storage references are made.
- LDA bm 12 Load A

7.2 µsec

Replaces the contents of A with a 48-bit operand contained in storage location M. The initial contents of A are changed during execution; the contents of M remain unchanged.

LAC bm i3 Load A Complement

7.2 µsec

Replaces the contents of A with the complement of a 48-bit operand contained in storage location M. The initial contents of A are changed during execution; the contents of M remain unchanged.

LDQ bm 16 Load Q

7.2 µsec

Replaces the contents of Q with a 48-bit operand contained in storage location M. The initial contents of Q are changed during execution; the contents of address M remain unchanged.

LQC bm 17 Load Q Complement

7.2 µsec

Replaces the contents of Q with the complement of a 48-bit operand contained in storage location M. The initial contents of Q are changed during execution; the contents of address M remain unchanged.

STA bm 20

Store A

7.2 µsec

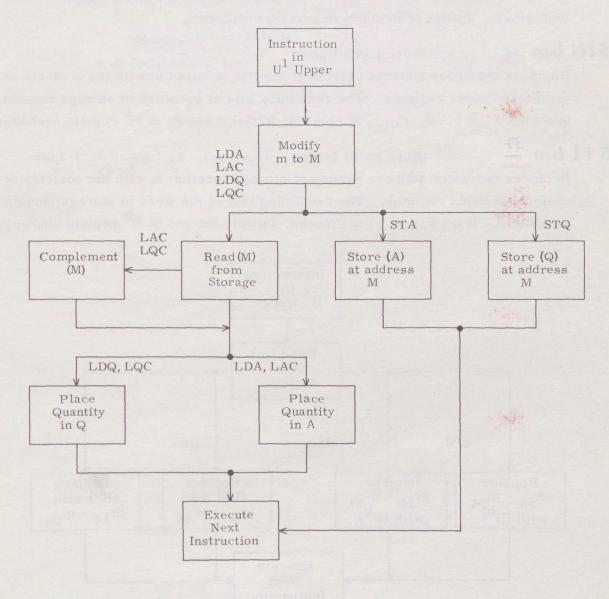

Replaces the contents of the designated storage location, M, with the contents of A. The initial contents of A remain unchanged.

STQ bm 21

Store Q

7.2 µsec

Replaces the contents of the designated storage location, M, with the contents of Q. The initial contents of Q remain unchanged.

LDA, LAC, LDQ, LQC, STA, and STQ

SHIFTING

- 1) All modes of address modification apply to these instructions.
- 2) If the modified shift count, K, is greater than 127₁₀, a fault indicator is set. Regardless of the magnitude of count, however, the required number of shifts is executed. (K is reduced by one count for each shift executed and when K = 0, shifting stops.)
- 3) Shifting must be completed before an input/output or interrupt request can be processed. (See chapter three.)

ARSbk 01 A Right Shift

2.8 + .4s* µsec

Shifts contents of A to the right K places. The sign is extended and the lower bits are discarded. The largest practical shift count is 47_{10} since the register is now an extension of the sign bit.

QRSbk 02 Q Right Shift

 $2.8 + .4s \, \mu sec$

Shifts contents of Q to the right K places. The sign is extended and the lower bits are discarded. The largest practical shift count is 47_{10} since the register is now an extension of the sign bit.

LRSbk 03 Long Right Shift

 $2.8 + .4s \, \mu sec$

Shifts contents of AQ to the right K places as one 96-bit register. The A register is considered as the leftmost 48 bits and the Q register as the rightmost 48 bits. The sign of A is extended. The lower order bits of A replace the higher order bits of Q and the lower order bits of Q are discarded. The largest practical shift count is 95_{10} since AQ is now an extension of the sign of A.

ALSbk 05 A Left Shift

 $2.8 + .4s \, \mu sec$

Shifts contents of A to the left K places, left circular. The higher order bits of A replace the lower order bits. The largest practical shift count 48_{10} returns the register to its original state.

^{*}s = Number of positions shifted

QLSbk 06 Q Left Shift

 $2.8 + .4s \, \mu sec$

Shifts contents of Q to the left K places, left circular. The higher order bits of Q replace the lower order bits. The largest practical shift count 48₁₀ returns the register to its original state.

LLSbk 07 Long Left Shift

 $2.8 + .4s \, \mu sec$

Shifts contents of AQ to the left K places, left circular, as one 96-bit register. The higher order bits of A replace the lower order bits of Q and the higher order bits of Q replace the lower order bits of A. The largest practical shift count 96₁₀ returns AQ to its original state.

Shift Instructions

ADDRESS MODIFICATION

- 1) All modes of address modification apply to SAU and SAL instructions.
- 2) Relative addressing cannot be used for ISK or IJP instructions. Only direct or indirect addressing are used.

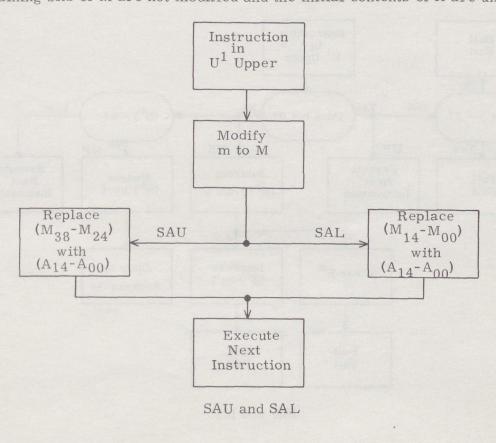

SAU bm 60 Substitute Address Upper

Replaces the upper address portion of M with the lower-order 15 bits of A. Remaining bits of M are not modified and the initial contents of A are unchanged.

32146 = XXX 27826 XXX XXXXX

7.2 µsec

SALbm 61 Substitute Address Lower 7.2 μ sec Replaces the lower address portion of M with the lower-order 15 bits of A. Remaining bits of M are not modified and the initial contents of A are unchanged.

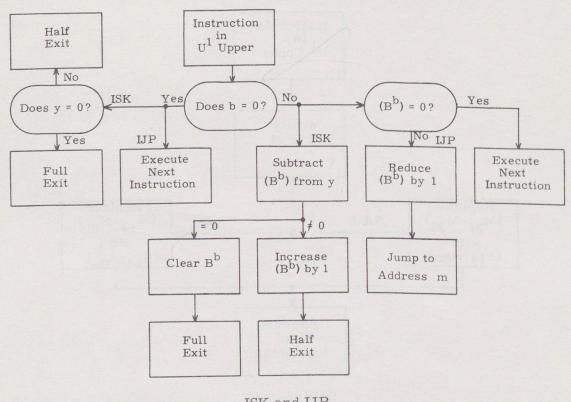

ISK by 54 Index Skip Vergleich der Adressen von β and β
7.2 μsec

Compares (B^b) with y. If the two quantities are equal, B^b is cleared and a full exit is performed. If the quantities are unequal, (B^b) is increased one count in the R register and a half exit is performed. Because the R register is a two's complement subtractive counter, it is possible to count through negative zero and positive zero. (See appendix.) If b = 0 and $y \neq 0$, a half exit is taken. If b = 0 and y = 0, a full exit is taken. ISK is usually restricted to the upper instruction. If used as a lower instruction it will half exit upon itself until the full exit condition is satisfied; if b = 0 and $y \neq 0$, the condition will never be satisfied.

IJPbm 55 Index Jump Examines (Bb). If this quantity is not zero, the quantity is reduced one count and

Examines (B^b). If this quantity is not zero, the quantity is reduced one count and a jump is executed to address m. The counting operation is performed in the R register but negative zero is not generated because IJP terminates at positive zero. (See appendix.) The index jump can be used in the upper or lower instruction without reservation; it executes a normal jump upon satisfaction of the jump condition.

ISK and IJP

ARITHMETIC

- 1) All modes of address modification apply to these instructions.
- 2) One storage reference is made for each instruction unless indirect addressing is designated. In this case, at least two references are made.

FIXED

3) If the capacity of the A register \pm (2^{47} -1) is exceeded during the execution of the instructions an arithmetic overflow fault is produced. When executing the DVI or DVF instructions, if the result exceeds the capacity of the Q register \pm (2^{47} -1) a divide fault is produced. (Refer to appendix.)

ADD bm 14 Add

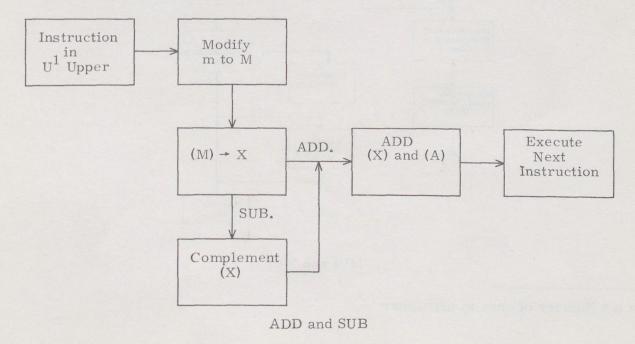

7.2 µsec

Adds a 48-bit operand obtained from storage location M to contents of A. A negative zero may be produced by this instruction if (A) and (M) are initially negative zero. The contents of storage address M remain unchanged.

SUBbm 15 Subtract

7.2 µsec

Obtains a 48-bit operand from storage location M and subtracts it from the initial contents of A. A negative zero will be produced if the initial contents of A are negative zero and that of storage location M are positive zero. The contents of address M remain unchanged.

MUIbm 24 Multiply Integer

 $25.2 + .8n* \mu sec$

03

1

MULP

Forms a 96-bit product from two 48-bit operands. The multiplier must be loaded into A prior to execution of the instruction. The execution address specifies the storage location of the multiplicand. The product is contained in QA as a 96-bit quantity. The operands are considered as integers and therefore the binary point is assumed to be at the lower order (right hand) end of the A register.

MUI and MUF

^{*} n = Number of ones in multiplier

25 000 100

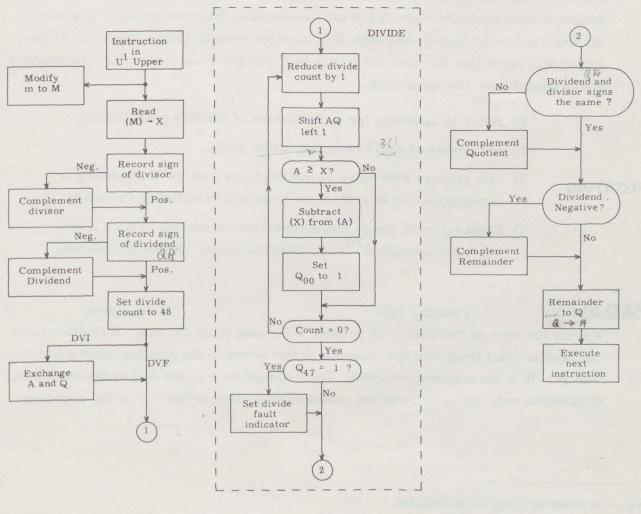

x[0-03]

DVIbm 25

Divide Integer

65.2 μsec

Divides a 96-bit integer dividend by a 48-bit integer divisor. The 96-bit dividend must be formed in the QA register prior to executing the instruction. If a 48-bit dividend is loaded into A, the sign of Q must be set. That is, the sign of the dividend in A must be extended throughout Q. The 48-bit divisor is read from the storage location specified by the execution address. The quotient is formed in A and the remainder is left in Q at the end of the operation. Dividend and remainder have the same sign.

DVI and DVF

5-1 and illegabiles

MUF bm 26

Multiply Fractional

 $25.2 + .8n* \mu sec$

Forms a 96-bit product from two 48-bit operands. The operands are treated as fractions with the binary point immediately to the right of the sign bit. The multiplier must be loaded into A prior to executing the instruction. The multiplicand is read into X from the storage location specified by M. The 96-bit product is contained in AQ.

DVFbm 27

Divide Fractional

65.2 µsec

Divides a 96-bit quantity by a 48-bit divisor. All operands are treated as fractions with the binary point immediately to the right of the sign bit. The 96-bit dividend must be loaded into AQ prior to executing this instruction. If a 48-bit dividend is loaded into Q, the sign of Q must be extended throughout A. At the end of this operation the quotient is left in A and the remainder in Q. Remainder and dividend have the same sign.

- 1) Refer to appendix for a discussion of floating point format.
- 2) All modes of address modification apply.

FLOATING

- 3) One storage reference is made unless indirect addressing is designated. In this case, at least two references are made.
- 4) Floating point range faults (overflow-underflow) occur if the exponent exceeds 2¹⁰-1 in absolute value. Refer to appendix.

FAD bm 30

Floating Add

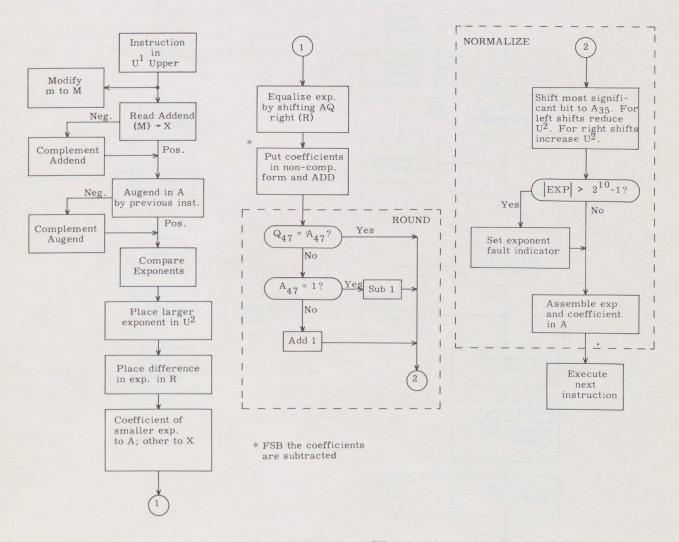

18.8 µsec

Forms the sum of two operands packed in floating point format. A floating point operand is read from storage location M and added to the floating point word in A. The result is normalized, rounded, and retained in A at the end of the operation. Q contains only the residue of the rounding operation at the end of the sequence.

^{*}n = Number of ones in multiplier

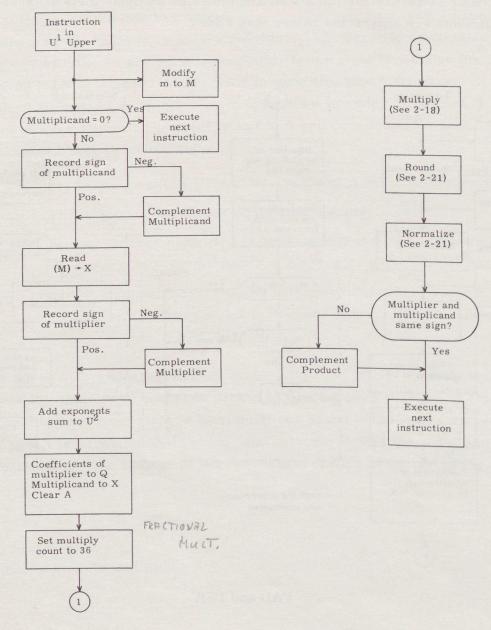

Forms the difference of two 48-bit operands in floating point format. The subtrahend is acquired from storage address M and is subtracted from the minuend in A. The result is rounded and normalized if necessary and retained in A. The residue from the rounding operation is left in Q at the end of the sequence.

The basic steps executed in a FSB are the same as those for FAD except the coefficients are subtracted rather than added.

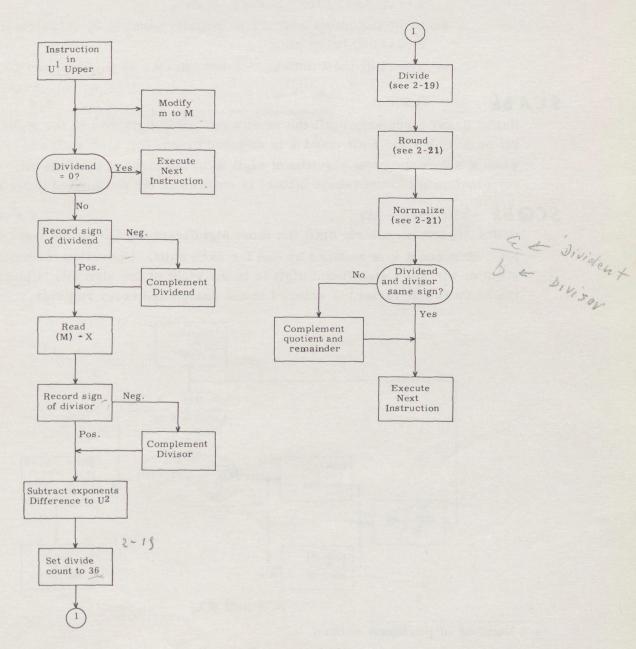

FAD and FSB

Forms the product of an operand in floating point format with the previous contents of A also in floating point format. The operand is read from storage location M. The product is rounded and normalized if necessary and retained in A. The residue from the rounding operation is left in Q at the end of the sequence.

FMU

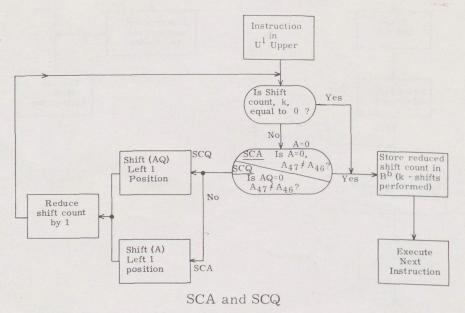

Forms the quotient of two 48-bit operands in floating point format. The dividend must be loaded into A prior to executing this instruction. The divisor is read from the storage location specified by M. The quotient is rounded and normalized if necessary and retained in A at the end of the operation. The residue from the rounding operation is left in Q at the end of the operation.

- 1) Address modification does not apply. Rather, the index register is used to preserve the scale factor.
- 2) If b = 0, scaling is executed but the scale factor is lost.
- 3) If b = 7, indirect addressing is used and at least one storage reference is made.
- 4) If (A) i is already scaled or equal to positive or negative zero, $k \rightarrow B^b$ and scaling is not executed.
- 5) If the execution address is initially equal to 0, B^b is cleared and no scaling takes place.
- 6) The shift fault indicator is not affected by this instruction.

SCAbk 34 Scale A problem of the sign of th

SCQ bk 35 Scale AQ 2.8 + .4s μ sec Shifts AQ left circularly until the most significant digit is to the right of the sign bit. Shift count k is reduced by one for each shift. Operation terminates when k = 0 or the most significant digit is to the right of the sign bit. Upon termination the count (scale factor) is entered in the designated index register.

^{*}s = Number of positions shifted

SCALE

^{**}When a negative number is being scaled, "0's" are significant digits.

- 1) All modes of address modification apply to ENQ, ENA, and INA instructions.
- 2) Relative addressing cannot be used for ENI and INI instructions. Only direct and indirect addressing are used.
- 3) No storage reference is made during these instructions unless indirect addressing is designated. In this case, at least one storage reference is made.

ENQ by 04

Enter Q

3.0 µsec

The 15-bit operand, Y, is entered into Q and its highest order bit is extended in . the remaining 33 bits. The largest positive 15-bit operand that can be entered into Q is 37777₈ (2¹⁴-1) and its "0" bit will be duplicated in each of the remaining 33 bits of Q. Negative zero will be formed in Q if:

Red enfolgt mie bei Rechtsverschiebe

ENAby 10

Enter A

3.0 µsec

The 15-bit operand, Y, is entered into the A register and its highest order bit is extended in the remaining 33 bits. The largest positive 15-bit operand that can be entered into A is 37777_8 (2^{14} -1) and the "0" bit will be duplicated in each of the remaining 33 bits. Negative zero will be formed in A if:

1)
$$(B^b) = 77777_8$$
 and $y = 77777_8$ or

2)
$$b = 0$$
 and $y = 77777_8$.

INA by 11

Increase A

3.0 µsec

Adds Y to A. The 15-bit operand Y is placed in X and its highest order bit is extended in the remaining 33 bits. The operand in X is added to (A).

$$A = 1$$

$$X = 7$$

No Address

JUMPS AND STOPS

NORMAL

- 1) Address modification does not apply to these instructions.
- 2) One storage reference is made.

A jump instruction causes a current program sequence to terminate and initiates a new sequence at a different location in storage. The Program Address register, P, provides the continuity between program steps and always contains the storage location of the current program step.

When a jump instruction occurs, P is cleared and a new address is entered. In all jump instructions, the execution address, m, specifies the beginning address of the new program sequence. The word at address m is read from storage, placed in U¹ and the upper instruction (first instruction of the new sequence) is executed.

Some of the jump instructions are conditional upon a register containing a specific value or upon the position of an operator's jump or stop key on the console. If the criterion is satisfied, the jump is made to location m. If it is not satisfied, the program proceeds in its regular sequence to the next instruction.

A jump instruction may appear in either position in a program step. If the jump instruction appears in the first (upper) part of the program step and the jump is taken, the second (lower) part of the program step is not executed. If the instruction appears in the lower part, the upper part is executed in the normal manner.

AJPim 22 A Jump

7.2 µsec

Jumps to m if the conditions of the A register specified by the jump designator, j, exist. If not, the next instruction is executed.

j = 0 Jump if (A) = 0

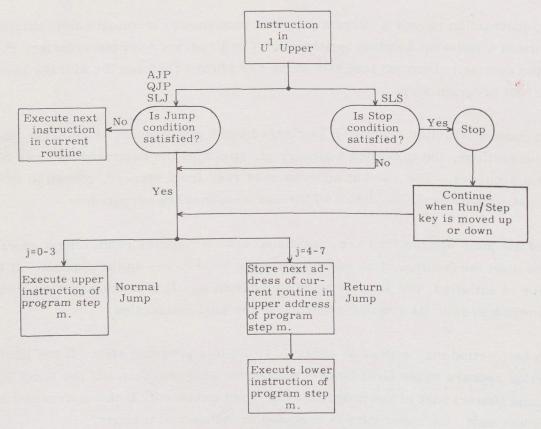

j = 1 Jump if (A) $\neq 0$

j = 2 Jump if (A) = +

j = 3 Jump if (A) = -

When (A) is negative zero the interpretation is:

- j = 0 The jump is executed because, in this case, negative zero is recognized as positive zero.
- j = 1 The jump is not executed.
- j = 2 The jump is not executed because the sign bit is a "1".
- j = 3 The jump is executed because the sign bit is a "1".

AJP, QJP, SLJ, and SLS

QJPjm 23

Q Jump

7.2 µsec

Jumps to m if the condition of the Q register specified by the jump designator, j, exists. If not, the next instruction is executed.

j = 0 Jump if (Q) = 0

j = 1 Jump if (Q) $\neq 0$

j = 2 Jump if (Q) = +

j = 3 Jump if (Q) = -

When (Q) is negative zero the AJP interpretation applies.

SLJim 75

Selective Jump

7.2 µsec

Jumps to m if the condition of the jump keys specified by j exists. If not, the next instruction is executed.

j = 0 Jump unconditionally

j = 1 Jump if jump key 1 is set

j = 2 Jump if jump key 2 is set

j = 3 Jump if jump key 3 is set

SLS jm 76

Selective Stop

 $7.2 \mu sec$

Stops at present step in the sequence if the condition of the stop key specified by j exists. If the stop condition exists, the stop is executed, and the jump is executed unconditionally when the Run/Step key is moved to the RUN or STEP position. If the stop condition is not satisfied, the jump is executed unconditionally.

j = 0 Stop unconditionally

j = 1 Stop if stop key 1 is set

j = 2 Stop if stop key 2 is set

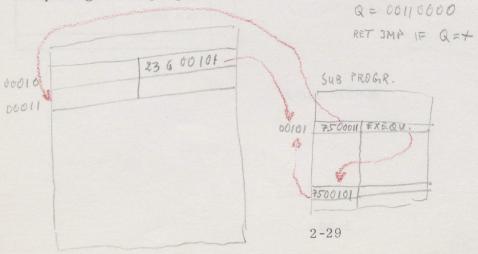

j = 3 Stop if stop key 3 is set

Næle dem stop mind dann in die amgegebene Ador. gespringen

RETURN JUMP

- 1) Address modification does not apply to these instructions.
- 2) One storage reference is made.

A return jump begins a new program sequence at the lower instruction portion of the program step to which the jump is made. At the same time, the address portion of the upper instruction of that program step is replaced with the address of the next program step in the main program. This instruction allows a return to the main program after completing the subprogram sequence.

Executes a return jump to storage location m if the condition of the A register specified by j exists. If not, the next instruction is executed.

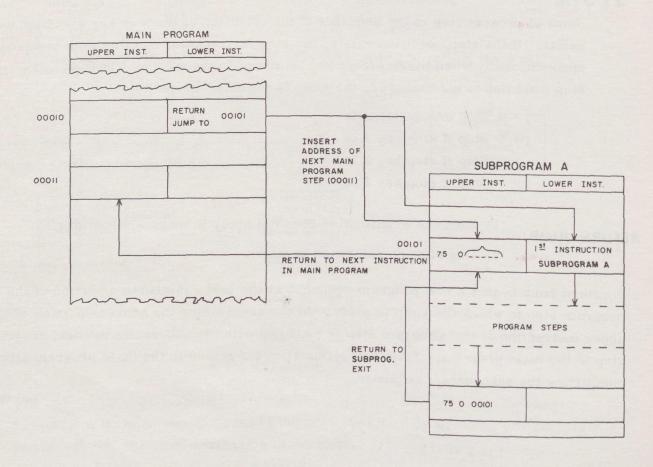

j = 4 Return jump if (A) = 0

j = 5 Return jump if (A) $\neq 0$

j = 6 Return jump if (A) = +

j = 7 Return jump if (A) = -

Note: If (A) = negative zero, refer to the AJP instruction.

Return Jump

QJP jm 23

Q Jump

7.2 µsec

Executes a return jump to storage location m if the condition of the Q register specified by j exists. If not, the next instruction is executed.

- j = 4 Return jump if (Q) = 0
- j = 5 Return jump if $(Q) \neq 0$
- j = 6 Return jump if (Q) = +
- j = 7 Return jump if (Q) = -

Note: If (Q) = negative zero, refer to the AJP instruction.

SLJ jm 75

Selective Jump

 $7.2 \mu sec$

Executes a return jump to storage location m on condition j where condition j represents the setting of the jump keys. If the condition is not satisfied, the next instruction is executed.

- j = 4 Return jump unconditionally
- j = 5 Return jump if jump key 1 is set
- j = 6 Return jump if jump key 2 is set
- j = 7 Return jump if jump key 3 is set

Note: The set position of a jump key is in the up position.

SLS jm 76 S

Selective Stop

7.2 µsec

Stops on condition j and executes a return jump to storage location m if the Run/ Step key is moved in the RUN or STEP position. If the stop condition is satisfied, the stop is executed and the return jump is executed when the Run/Step key is moved in either position. If the stop condition is not satisfied, the stop is not executed and the return jump is executed unconditionally.

- i = 4 Stop unconditionally
- j = 5 Stop if stop key 1 is set
- j = 6 Stop if stop key 2 is set
- j = 7 Stop if stop key 3 is set

STORAGE TEST

- 1) All modes of address modification apply to these instructions.
- 2) At least one storage reference is made unless indirect addressing is designated in which case at least two storage references are made.

SSKbm 36 Storage Skip

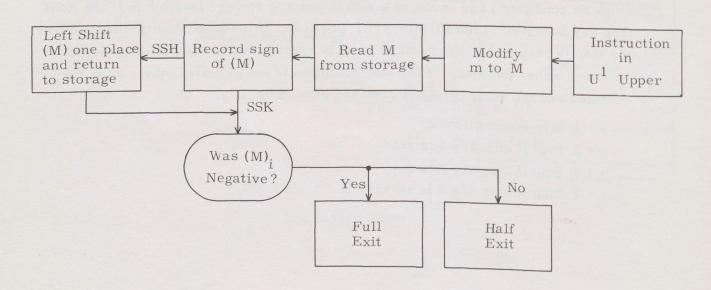

8.8 µsec

Senses the sign bit of the operand in storage location M. If the sign is negative, a full exit is taken. If the sign is positive, a half exit is taken. The contents of the operational registers are left unmodified. SSK is usually restricted to an upper instruction. If used as a lower instruction and the sign of (M) is negative, a full exit will be executed. If the sign is positive, it will half exit upon itself and never execute a full exit.

SSH bm 37 Storage Shift

12.8 µsec

Senses the sign bit of the quantity in storage location M. If the sign bit is negative a full exit is taken, and if the quantity is positive a half exit is taken. In either case the quantity is shifted left circularly one bit before the exit. This instruction is usually restricted to the upper position. If used as a lower instruction and the sign of (m) is positive, the instruction will half exit upon itself until a negative sign bit is found. The contents of the operational registers are left unmodified.

SSH and SSK

LOGICAL

- 1) All modes of address modification apply to these instructions.
- 2) The LDL, ADL, SBL and STL instructions achieve their result by forming a logical product. A logical product is a bit by bit multiplication of two binary numbers (logical AND condition):

$$0 \times 0 = 0$$
 $1 \times 0 = 0$ $0 \times 1 = 0$ $1 \times 1 = 1$

- 3) A logical product is used, in many cases, to select specific portions of an operand for entry into another operation. For example, if only a specific portion of an operand in storage is to be added to (A), as the operand passes through X it is subjected to a mask comprised of a predetermined pattern of "0's" and "1's". Forming the logical product of (X) and the mask causes X to retain the original contents only in those stages which have corresponding "1's" in the mask. When only the selected bits remain in X, the instruction proceeds to conclusion.
- Selective Set to Selective Set $7.2~\mu sec$ Sets the individual bits of A to "1" where there are corresponding "1's" in the word at storage location M. "0" bits in the word at storage location M do not modify the corresponding bits in A. In a bit by bit comparison of (A) and (M) there are four possible combinations of bits.

1)
$$(A)_{i} = 1$$
 2) $(A)_{i} = 1$ 3) $(A)_{i} = 0$ 4) $(A)_{i} = 0$ $(M)_{i} = 1$ $(M)_{i} = 0$ $(M)_{i} = 1$ $(M)_{i} = 0$ $(M)_{i} = 1$ $(A)_{f} = 1$ $(A)_{f} = 0$ $(M)_{f} = 1$ $(M)_{f} = 0$

Individual bits of A are complemented where there are corresponding "1's" in the word at storage location M. If the corresponding bits at M are "0's", the associated bits of A remain unchanged.

1)
$$(A)_{i} = 1$$
 2) $(A)_{i} = 1$ 3) $(A)_{i} = 0$ $(M)_{i} = 1$ $(A)_{f} = 0$ $(A)_{f} = 1$ $(A)_{f} = 1$ $(A)_{f} = 1$ $(A)_{f} = 1$

SCL bm 41

Selective Clear

7.2 µsec

4) $(A)_{i} = 0$

 $(M)_i = 0$

 $(A)_f = 0$

 $(M)_f = 0$

Clears individual bits of A where there are corresponding "1's" in the word at storage location M. If the corresponding bits at M are "0's", the associated bits of A remain unchanged.

In a bit by bit comparison of (A) and (M) there are four possible combinations of bits.

1)
$$(A)_{i} = 1$$
 2) $(A)_{i} = 1$ 3) $(A)_{i} = 0$ 4) $(A)_{i} = 0$ $(M)_{i} = 1$ $(M)_{i} = 0$ $(M)_{i} = 1$ $(M)_{i} = 0$ $(A)_{f} = 0$

SCM, SST, and SCL

Sihe 5.5-9

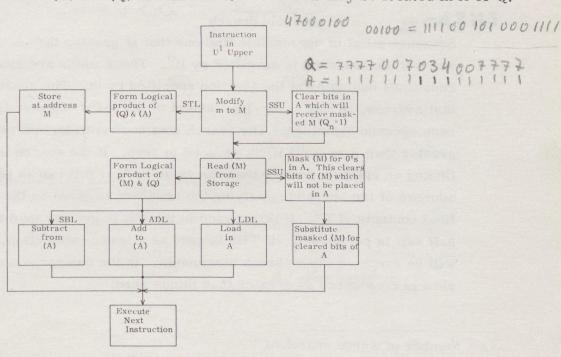

SSU bm 43

Selective Substitute

7.4 µsec

Substitutes selected portions of an operand at storage address M into the A register where there are corresponding "1's" in the Q register (mask). The portions of A not masked by "1's" in Q are left unmodified.

- Loads A with the logical product of Q and the contents of the designated storage location, M. The operand can be in either Q or M.
- ADL bm 45 Add Logical Logical Product of Q and the quantity in location M; the mask may be in Q or storage. Once the logical product is formed addition follows normal rules (appendix).
- SBLbm 46 Subtract Logical 7.4 μ sec Subtracts from A the logical product of the Q register and the quantity in storage location M. The mask may be in Q or storage. When the logical product is formed, the subtraction proceeds in the normal manner. (See appendix.)
- STLbm 47 Store Logical 7.2 μ sec Replaces the bits in storage location M with the logical product of Q and A registers. Neither (A) nor (Q) are modified. The mask may be located in A or Q.

ADL, LKL, SBL, SSU, and STL

STORAGE SEARCH

- 1) If b = 0 in the following instructions only the word at storage location m will be searched.
- 2) If b = 7, indirect addressing is used to obtain the execution address and b designator.
- 3) If $(B^b) = 0$, no search is made.

1642 00100 00100 = 0

Equality Search EQS bm 64

[4.0 + 3.6r* usec Searches a list of operands to find one that is equal to A. The number of items to be searched is specified by Bb. These items are in sequential addresses beginning at the location specified by m. The search begins with the last address, $m + B^{b} - 1$, B^{b} is reduced one count for each word that is searched until an operand is found that equals A or until B equals zero. If the search is terminated by finding an operand that equals A, a full exit is made. The address of the operand satisfying this condition is given by the sum of m and the final contents of Bb. If no operand is found that equals A, a half exit is taken. Positive zero and minus zero are recognized as the same quantity. When EQS is used as a lower instruction, the next instruction will always be executed when the search terminates.

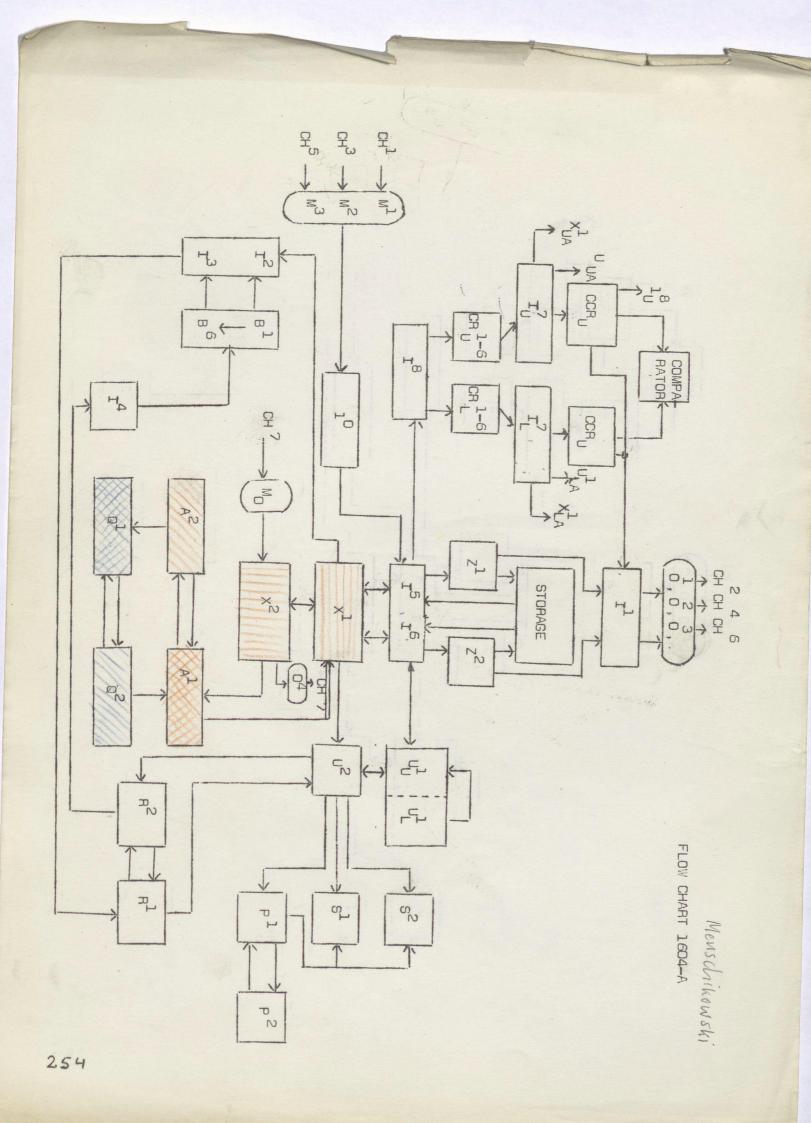

T H S bm 65

LM>> A sein

 $4.0 + 3.6 r \mu sec$

Searches a list of operands to find one that is greater than A. The number of items to be searched is specified by Bb. These items are located in sequential addresses beginning at the location specified by m. The search begins with the last address, m + Bb - 1. The content of the index register is reduced by one for each operand examined. The search continues until an operand is reached that is greater than A or until Bb is reduced to zero. If the search is terminated by finding an operand greater than the value in A, a full exit is performed. The address of the operand satisfying the condition is given by the sum of m and the final contents of Bb. If no operand in the list is greater than the value in A, a half exit is performed. If THS is used as a lower instruction, the next instruction will be executed when search terminates. In the comparison made here positive zero is considered as greater than minus zero.

^{*}r = Number of words searched

MEQ bm 66

Masked Equality Search

 $4.0 + 3.6r* \mu sec$

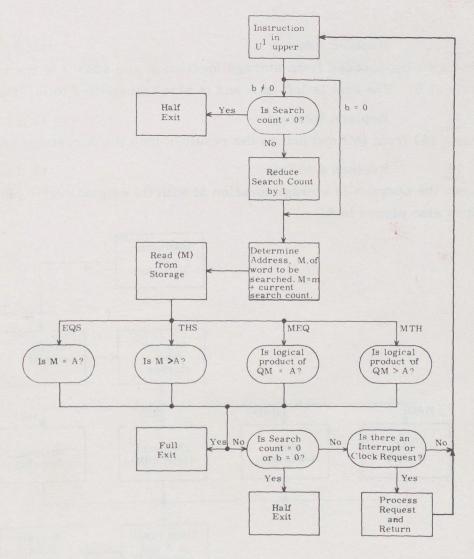

Searches a list of operands to find one such that the logical product of (Q) and (M) is equal to (A). This instruction, except for the mask, operates in the same manner as an equality search.

MTH bm 67

Masked Threshold Search

 $4.0 + 3.6 r \mu sec$

Searches a list of operands to find one such that the logical product of (Q) and (M) is greater than (A). Except for the mask, this instruction operates in the same manner as the threshold search.

Search

^{*}r = Number of words searched

REPLACE

- 1) All modes of address modification apply to these instructions.
- 2) During the execution of the replace instructions, two storage references are made.

 If indirect addressing is designated, at least three references are made.
- 3) If the capacity of the A register \pm (2^{47} -1) is exceeded during the execution of the following instructions, an arithmetic overflow fault is produced. (Refer to appendix.)

RAD bm 70 Replace Add

13.2 μsec

Obtains a 48-bit operand from storage location M and adds it to the initial contents of A. The sum is left in A and is also transmitted to location M.

RSB bm 71 Replace Subtract

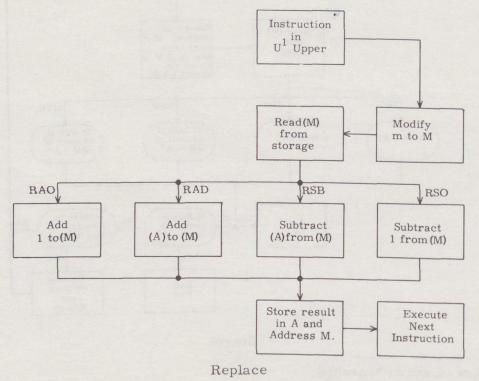

13.2 µse

Subtracts (A) from (M) and places the result in both the A register and location M.

RAO bm 72 Replace Add One

13.2 µsec

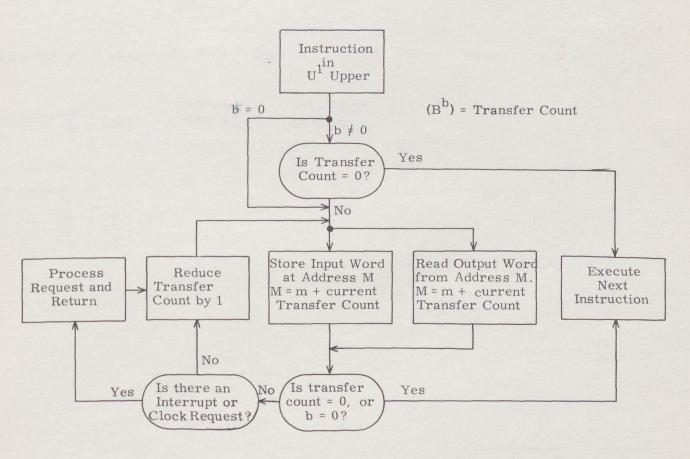

Replaces the operand in storage location M with its original value plus one. The result is also placed in A.

Replaces the operand in storage location M with its original contents minus one. The difference is also left in A; the original contents of A and M are destroyed.

TRANSFER

- 1) Relative address modification is not used for the following instructions. Only direct and indirect addressing can be used.
- 2) The index registers contain the number of words to be transferred into or out of the computer via channel 7.
- 3) When a transfer is in progress all other computer operations stop except the processing of input/output requests. A transfer is stopped temporarily to process interrupter clock requests.
- 4) If b = 0, one word is transferred to or from address m.

Transfer

Dan 1. eigegebene Vort steht auf der litzten speisherzelle 4.0 + 4.8 r* usec die angegeben ist

INT bm 62

Input Transfer

Transfers a block of data from an external equipment into storage. The number of words to be transferred is specified by B^b . These words are stored in sequential addresses beginning at the location specified by the execution address, m. The transfer begins by storing the first input word in the last address in the sequence, $m + B^b$ -1. As each word is transferred, B^b is reduced by one until it is equal to zero.

OUT bm 63

Output Transfer

 $4.0 + 4.8 r \mu sec$

Transfers a block of data from computer storage to an external equipment. The number of words to be transferred is specified by B^b . The words to be transferred are located in sequential addresses beginning at the location specified by the execution address, m. The transfer begins by obtaining the first output word from the last address, $m + B^b$ -1. As each word is transferred B^b is reduced by one until it is equal to zero.

CHAPTER 3 INPUT/OUTPUT

METHODS OF DATA EXCHANGE

The computer communicates with external equipment via a single transfer channel and six buffer channels. The transfer channel which provides for high speed communication is program initiated and controlled. The buffer channels provide for the normal exchange of data and, although program initiated, operate independently of the program.

HIGH SPEED TRANSFER CHANNEL

The high speed transfer channel (channel 7) handles both input and output communications between the computer and high speed equipments. The transfer rate is usually dependent on the speed of the external equipment as the computer can perform transfers at a maximum (approximate) rate of one word every 4.8 μ sec.

As many as five different equipments (optimum conditions) may be connected to the transfer channel. However, only one equipment can use the channel at any given instant and the current transfer operation must be completed before a different equipment can use the channel.

BUFFER CHANNELS

The six independent buffer channels are grouped in three pairs:

Input:	Channel 1	Output:	Channel	2
	Channel 3		Channel	4
	Channel 5		Channel	6

All six buffer channels can communicate concurrently with external equipments. This is accomplished by an auxiliary scanner which processes only one channel at a given instant - so that when more than one channel is active each channel is given a turn in rotation to buffer one word of information. The rate of data flow on each buffer channel is determined by the operating speed of the external equipment connected to that channel. A maximum of five equipments may be connected to a buffer channel-pair.

INITIATION AND CONTROL OF DATA EXCHANGE

TRANSFER 63

A transfer operation is initiated and controlled by the computer program. An INT or OUT instruction transfers the number of words designated by the contents of an index register. The starting storage location of the transfer is specified by the execution address of the instruction. (See chapter 2 for a discussion of the INT or OUT instructions).

All computer operations, with the exception of previously initiated buffers and processing of interrupt or clock requests, stop while the transferring of words is in progress (refer to page 3-6).

BUFFER

A buffer operation transmits a block of data to or from 1604-A core storage. The size and location of the block of data is defined by a buffer control word.

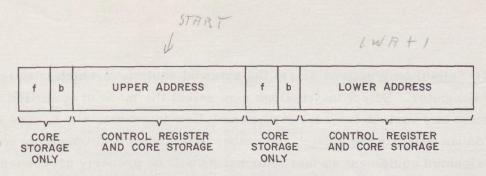

Buffer Control Word

Each of the six buffer channels is assigned a buffer control word which controls operations on that channel. The lower address portion of a control word holds the terminal address (one greater than the address of the last word to be buffered). Before a buffer operation is initiated, the terminal address must be entered into the control word by a write instruction (store, substitute, etc). The upper address of a buffer control word holds the current address of a buffer operation. The starting address (address of first word buffered) is automatically entered into the upper address of the control word by the EXF Activate command.* After each word of a buffer operation is transmitted the upper address portion of the control word is automatically increased by one; thus the upper address is the current address (address of next word to be buffered). When the upper and lower addresses of a control word are equal the buffer halts.

The buffer control words are assigned core storage addresses but the address portions are held in 30-bit FF registers called Control registers (CR).

Channel	Control Register	Address of Control Word
1	the research of 11 and the	00001
2	2	00002
3	3	00003
4	4	00004
5	5	00005
6	6	00006

^{*} When reading input words into buffer control word addresses (e.g., Auto Load operation) the upper address of the input word must be the control word address plus one.

BUFFER CONTROL WORD STRUCTURE

When a storage reference is made to one of the buffer control words (00001-6) the address portion is read from or written into the corresponding CR. Because the addresses are contained in the FFs, the control words are destroyed when power is turned off. For programming purposes the buffer control words (addresses 00001-6) are treated as normal core storage addresses.

External Function (EXF) instructions

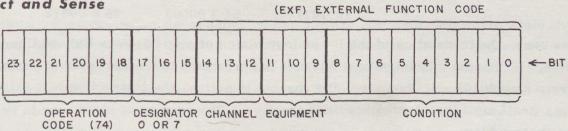

The EXF instructions initiate a buffer, sense for specified conditions, and select operations and equipment. EXF codes are listed in appendix 6.

There are three kinds of external instructions:

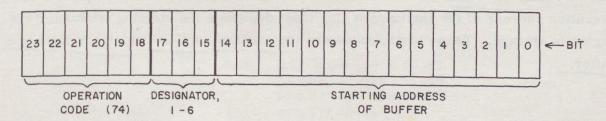

Select 74 0 XXXXX Sense 74 7 XXXXX Activate de CHANAL 74 j XXXXX where j = 1-6

The composition of an external function instruction is shown below.

Select and Sense

Activate

The 74 0 (EXF Select) instructions select the external equipment which is to communicate with the computer. Select instructions also select the mode of operation of external equipment and various internal conditions (allow interrupts etc.). The select instructions do not activate the buffer, but rather establish initial operating conditions within the designated equipment so that information will be properly processed when the buffer is activated.

The 74 7 (EXF Sense) instructions sense the condition of an external equipment or the internal conditions of the computer and will execute a full exit or half exit depending on the presence or absence of the condition.

The location of a 74 7 instruction within an instruction word determines whether a skip or a wait will be performed.

When used in the upper instruction position (Example 1) a 74 7 is a skip instruction.

Example 1:	(00010)	74 7 00010	75 0 40000
	(00011)	53 1 00005	16 1 00032

In this example the translation of the upper instruction of a program step 00010 is Exit on Channel 1 active. If channel 1 is active the next instruction to be executed would be the upper instruction of step 00011, i.e., 53 1 00005. If channel 1 were inactive, the lower instruction of step 00010 would be executed.

When used in the lower position (Example 2) a 74 7 is a wait instruction.

Example 2:	(00100)	74 2 00600	74 7 00021
	(00101)	54 2 00005	75 0 00072

In this case, the translation of the lower instruction of step 00100 is Exit on Channel 2 inactive. If channel 2 is inactive a full exit is performed to the next pair of instructions, program step 00101. If, however, the channel is active, the instruction half exists and repeats itself until the channel becomes inactive. The sensing of conditions in no way alters the condition.

The 74 j (EXF Activate) instructions activate buffer channel j where j equals 1-6. The execution address of the instruction, m, must designate the starting address of the region in storage. These instructions are the only instructions which can initiate a buffer.

The following steps should be completed prior to initiating a buffer operation.

- (1) Sense for channel inactive.
- (2) Select the external equipment and its mode of operation.
- 3) Sense for equipment ready.
- 4) Store the terminal address in the buffer control word.

Sensing for equipment ready may involve a number of conditions and varies with the different types of external equipments.

A buffer channel is active while data is being buffered. A buffer channel is inactive if the previous input/output operation has been completed.

The buffer must be satisfied (current address = terminating address) to inactivate the channel. This can be accomplished by activating the channel (74 j instruction) at the terminal address. This makes the channel inactive but no additional information is transmitted.

Auxiliary Scanner

After being initiated by the main program, data exchange on each buffer channel is controlled by the buffer control section. In order that one buffer channel may not monopolize buffer control, an auxiliary scanner is used to initiate each one word buffer. The auxiliary scanner samples each buffer channel in the order: 1-3-2-6-4-5. When the scanner detects an auxiliary request from one of the buffer channels it stops and initiates a one-word buffer operation. Thus each channel has equal priority.

During a buffer operation the scanner can scan up to four more channels while the present operation is being carried out. However, if another action request is detected, another buffer operation is initiated when the first is finished. This arrangement gives buffer operations priority over program steps in requests for storage time. If no action request is detected on the four channels, a storage reference may be made by a program step and no auxiliary requests may be serviced until storage is released $(6.4 \, \mu \text{sec})$

INTERRUPT

In each external equipment and in certain computer control circuits conditions may arise which require immediate action by the computer. The signals which notify the computer of these conditions are called interrupts. Interrupts are controlled by the computer program. If an interrupt is desired when a particular condition exists, an external function instruction (74.0) must be used to select the external equipment to interrupt on that condition. Unless such a selection is made, no interrupt is produced when the condition arises. 1604-A interrupts are divided into two classes: (1) interrupts which indicate a fault within the computer (Internal) and (2) interrupts which indicate a fault in external equipment (External).

Internal Interrupts

Any one of six arithmetic faults may cause an internal (arithmetic) interrupt. These conditions are controlled collectively by the select instruction: Allow (or Disallow)* Interrupt on Internal (Arithmetic) Faults (see page 29 of appendix). Internal interrupts have priority over external interrupts. When an internal interrupt occurs the computer jumps to address 00007 and executes the lower instruction at that location.

External Interrupts

There are eight external interrupt signals for the 1604-A (one for each of the six buffer channels and two for the high-speed transfer channel). Each of these interrupts may be allowed or disallowed* by its own select code (see page 29 of appendix). In addition, all external interrupts may be controlled by the instructions:

74 0 04000 Allow Selected External Interrupts from to under olice (Set Master Interrupt Mask)

74 0 04001 Disallow (Mask) All External Interrupts (Clear Master Interrupt Mask)

When an external interrupt occurs the computer automatically jumps to one of the addresses 00010 - 00017 (see table 3-1) and executes the lower instruction.

^{*} Even though an interrupt is disallowed, it may be sensed with a 74.7 instruction.

Channel 4	00014
Channel 5	00015
Channel 6	00016
Channel 7 (Input Transfer)	00017

INTERRUPT SUBROUTINE

An interrupt address (0007-00017) normally contains two jump instructions:

75 0 XXXXX

75 0 YYYYY

When an interrupt occurs, the content of the P register is stored in the upper address portion (XXXXX) of the interrupt address. This provides for return to the main program after the interrupt has been processed. The lower instruction at the interrupt address is a jump to the beginning address (YYYYY) of an interrupt routine. An interrupt routine (table 3-2) senses for possible cause of the interrupt. When the cause of the interrupt is determined, a jump is made to that portion of the routine which corrects the fault (or notifies the operator). The interrupt routine must contain an instruction to remove the interrupt indication.

TABLE 3-2. TYPICAL INTERRUPT SUBROUTINE

00007	75 0 XXXXX	75 0 YYYYY	Exi	it/Entrance

ovf01				
au red tomor	Market The Company of	74 0 00070 {	Clear Arithmetic	Process Overflow
		75 0 00007 {	Jump to Interrupt Addres	s

After an interrupt has been processed the interrupt routine must provide a jump to its interrupt address (00007-00017). The upper instruction at the interrupt address is a jump back to the main program. At least one instruction of the main program must be executed before another interrupt can occur.

REAL TIME CLOCK

Address 00000 in core storage may be selected to provide a continuously operating record of elapsed time. When the real time clock is running, the 48-bit quantity stored at 00000 is advanced by one every 1/60 of a second (accuracy is maintained by the 60-cycle power source). The content of address 00000, which may be sampled at any time, gives an indication of elapsed time from the start of the real-time clock operation. The clock may be started by the EXF instruction 74 0 01000 and stopped by 74 0 02000. Starting the clock does not alter the information already in address 00000.

As shown in figure 3-1, a clock request (generated every 1/60 of a second) has priority over interrupt requests and can break in between any two instructions.

INTERNAL SELECT INSTRUCTIONS

		INTERTINAL SELECT INSTRUCTIONS
74 0	C0000	Clear All Channel C Selections Clears all previous selections made on the designated channel C except interrupt on channel C inactive.
	000C0	Allow Interrupt on Channel C Inactive Selects interrupt when channel C becomes inactive. C = 1 - 6 An interrupt signal is generated whenever the channel becomes inactive. More than one interrupt can be selected. The interrupt remains selected until cleared.
	000C1	Disallow Interrupt on Channel C Inactive Interrupt on channel C inactive selection cleared,
	00100	Allow Interrupt on Internal (Arithmetic) Faults and Clock Overflow Selects interrupt on occurrence of any arithmetic fault or clock overflow.
	00101	Disallow Interrupt on Internal (Arithmetic) Faults and Clock over-flow
		Prevents arithmetic faults and clock overflow from interrupting program.
	00070	Clear Arithmetic Faults and Clock Overflow Removes all arithmetic and clock overflow fault indications and turns off fault background lights on console.

		INTERNAL SELECT INSTRUCTIONS (Cont'd)
74 0	01000	Start Real-Time Clock
		Begins process of adding one to contents of address 00000 each
		16.6 ms; address 00000 is not cleared by starting the clock.
	02000	Stop Real-Time Clock
		Halts process of increasing address 00000. The contents of
		00000 remain unchanged.
		INTERNAL SENSE INSTRUCTIONS
74 7	000C0	Exit on Channel C Active
		Full exit if channel C is active

74 7	00200	Exit if Next Main Program Instruction is Upper
74 7	00201	Exit if Next Main Program Instruction is Lower
74 7	00300	Exit on Clock Overflow
74 7	00301	Exit on No Clock Overflow

CONSOLE INPUT/OUTPUT EQUIPMENT

Three input/output devices mounted on the console are standard equipment with the 1604-A computer. A Teletype BRPE 11 punch and a CONTROL DATA 350 reader provide for the processing of perforated paper tape. An electric typewriter provides for direct keyboard entry of data and for printed copy output. The console input/output units communicate with the central computer via buffer channels 1 (input) and 2 (output). Other input/output units may share these channels but console input/output units use only these channels.

Data may be transmitted between the computer and the console equipments in either the character or assembly mode. Keyboard input from the typewriter is in the character mode only.

In the character mode one character is buffered at a time. The typewriter uses 6-bit characters. The reader and punch use 8-bit characters. When characters of less than eight bits are desired for the punch and reader the upper bits of the 8-bit character are "0's". A character occupies the lowest bit positions of a 48-bit composite word; the upper bits are "0's".

In the assembly mode the 48-bit word, consisting of eight 6-bit characters, is buffered. During an input buffer in the assembly mode eight successive characters are assembled into a 48-bit word and sent to the computer. The first character occupies the upper 6 bits of the word; the last character occupies the lower order 6 bits.

For an output buffer in the assembly mode a 48-bit word from the computer is disassembled into eight characters, the upper 6 bits first.

TYPEWRITER

The typewriter may be used as a keyboard input device (character mode only) or as an output device (either character or assembly mode) for producing printed copy; during output it types approximately 10 characters per second.

All of the typewriter characters and functions are represented by unique combinations of 6 bits. (Codes are in appendix X.) During a keyboard input operation, striking a character key causes the coder to produce the code which is sent to the computer. Space is the only coded typewriter control function which is sent to the computer. For typewriter output, a 6-bit character code sent to the decoder causes the typewriter to print the selected character or perform the designated control function.

If the keyboard is selected by code 11140, the interrupt signal occurs for each carriage return (CR).

If an illegal code (unlisted) is sent to the typewriter from the computer, the typewriter hangs up. Striking the carriage return, backspace or shift keys will allow operation to be resumed.

A zero code (all "0" bits) which constitutes a do-nothing code is used to fill out a 48-bit word in the assembly mode.

TYPEWRITER CODES

INPUT SELECT	
74 0 00200	Clear Carriage Return or Tab FF
11100	Select the Typewriter for Input and No Interrupt on Carriage Return Selects keyboard (character mode only) Interrupt selection cleared, Carriage Return indicator cleared
11140	Select the Typewriter for Input and Interrupt on Carriage Return Selects keyboard (character mode only) Interrupt selection set, Carriage Return indicator cleared. The next carriage return, which is not output, will set the Carriage Return FF and cause an interrupt. The interrupt selection can be cleared by the external master clear or the 74 0 11100 select only.
OUTPUT SELECT	
74 0 21100	Select the Typewriter for Output in the Assembly Mode Selects keyboard to print*
21110	Select the Typewriter for Output in the Character Mode Selects keyboard to print*

^{*} Will not change the Carriage Return FF nor the interrupt selection on channel 1. The code "00" will be ignored; all other illegal codes will cause the typewriter to hang up. It is released by manually performing a function, usually spacing.

TYPEWRITER CODES (Cont'd)

SENSE	(Input	Channel	Only)
-------	--------	---------	-------

74 7	11100	Full Exit if Carriage Return Performed on Input
		If a carriage return (which was not the result of an output)
		has been performed since the last input select, a full exit
		is executed; if not, a half exit.
	11101	Full Exit if No Carriage Return Typed on Input
		If the Carriage Return indicator is not set, a full exit is
		executed; if set, a half exit.
	11140	Full Exit Lower Case
		If the typewriter keyboard is in the lower case a full exit is
		performed.
	11141	Full Exit Upper Case
		If the typewriter keyboard is in the upper case a full exit is
		performed.

PAPER TAPE READER

The CONTROL DATA 350 Paper Tape Reader enters information into the computer from punched paper tape. The reader, which is always connected to channel 1, operates at a maximum rate of approximately 350 frames per second. A frame, which is across the width of the tape, can store up to 8 bits of information (figure 3-2 shows a seven-level tape). The sprocket or feed holes between levels 3 and 4 generate signals to time the reading of the tape. In the character mode a tape character may be 5, 6, 7, or 8 bits.

In the assembly mode a character is six bits and level seven is used as a control bit (the eighth level is not used in assembly mode). The first of the eight characters in a word is indicated by a hole in the control level (figure 3-2).

Manual controls for the reader are on the punch and reader control panel of the console (figure 4-4). When the Reader Mode switch is raised to ASSEMBLY, the tape is positioned at the first frame in which the seventh level is punched (load point). When the mode switch is depressed to CHARACTER, the tape moves ahead one frame.

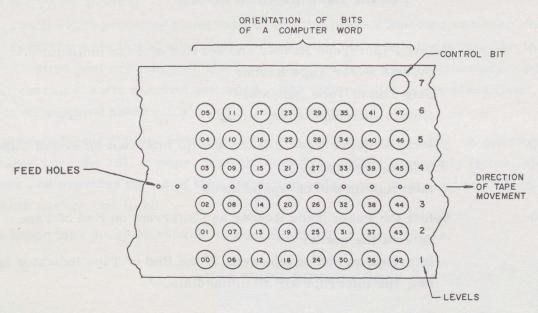

Figure 3-2. Seven-Level Punched Paper Tape (Assembly Mode)

Reader tape motion stops on any one of three conditions:

- 1) When buffer operation terminates (assembly or character mode).
- 2) When the load point in assembly mode is reached.
- 3) Absence of a 7th level every 8th character in the assembly mode. *

The reader End of Tape indicator is set on any of three conditions:

- 1) On a computer master clear.
- 2) Absence of a 7th level every 8th character in the assembly mode.*
- 3) By a 74 0 11210 instruction. This instruction is used to indicate the end of information in the character mode.

After reading all information on the tape in the assembly mode, tape motion stops and the End of Tape indicator is set because the 7th level control bit is missing. In the character mode, however, motion stops when the buffer operation is satisfied but the End of Tape indicator remains cleared. A 74 0 11210 instruction may be programmed to set the End of Tape indicator after the buffer terminates. The state of the End of Tape indicator, regardless of the mode of operation, may be used to determine if all information on the paper tape has been read.

^{*} Only after at least one seventh level bit has been read.

PAPER TAPE READER CODES

SELECT

SELECT	
74 0 11210	Select Paper Tape Reader and Set End of Tape Indicator Selects Paper Tape Reader Sets End of Tape indicator* Clears interrupt on end of tape
11200	Select the Paper Tape Reader and No Interrupt on End of Tape Selects the reader Interrupt on end of tape cleared
11220	Select the Paper Tape Reader and Interrupt on End of Tape Selects the reader Interrupt on end of tape set. If the End of Tape indicator is set, the interrupt will be immediate.
SENSE	
74 7 11200	Full Exit on End of Tape Indicator Set If the End of Tape indicator is set a full exit is performed; if not, a half exit.
11201	Full Exit on No End of Tape Indicator Set If the End of Tape indicator is not set a full exit is performed; if set, a half exit.
11210	Full Exit on Assembly Mode If the paper tape reader is in the assembly mode a full exit is performed; if not, a half exit.
11211	Full Exit on Character Mode If the paper tape reader is in the character mode a full exit is performed; if not, a half exit.

^{*} This select is usually used in character mode operation only. The End of Tape indicates the logical end of tape, and can be cleared externally only by moving the switch (on the reader control) to the CHARACTER or ASSEMBLY position. Master clear selects the paper tape reader and sets the End of Tape indicator. When the End of Tape indicator has been set the reader is "not ready".

PAPER TAPE PUNCH

The punch which prepares paper tape output is always connected to buffer channel 2. The operating rate is 110 characters per second. In character mode, the lower 8 bits of each word sent are punched; the upper bits are ignored. In assembly mode, eight 6-bit characters are punched per word. The upper 6 bits are punched first, with the 7th level supplied automatically every eighth frame.

On the punch, the feedout lever provides for punching out leader. A microswitch is mounted near the roll of paper tape in the punch. When the supply is low, the switch closes and provides an out of tape indication which may be sensed and which lights a console background light.

The paper tape punch is capable of punching 5, 6, 7, or 8 levels.

PAPER TAPE PUNCH CODES

SELECT	
74 0 '21200	Select the Paper Tape Punch, Assembly Mode
	Selects the punch, sets mode to assembly
	Turns the punch motor on
21210	Select the Paper Tape Punch, Character Mode
	Selects the punch, sets mode to character
	Turns the punch motor on
21240	Turn the Punch Motor Off
SENSE	
74 7 21200	Full Exit on Out of Tape
	If the paper tape punch is out of tape, a full exit is performed;
	if not, a half exit.
21201	Full Exit on Not Out of Tape
	If the paper tape punch is not out of tape, a full exit is
	performed; if out of tape, a half exit.

CHAPTER 4 OPERATION

DESCRIPTION OF INDICATORS AND CONTROL SWITCHES

All main computer controls and indicators are on the console. Functional significance of console background lights is listed in table 4-1; computer controls are described in table 4-2.

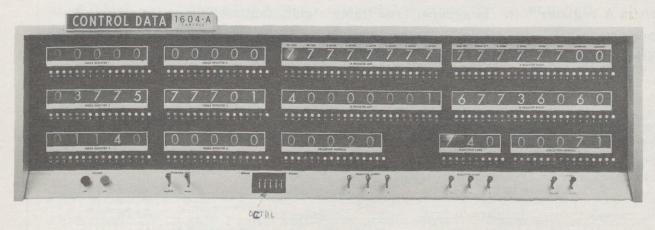

Figure 4-1. Center Panel of Console

The indicators are lamp modules, each of which displays a single octal digit. The lamps, in response to signals from the computer, display the contents of the operational registers in octal form only when the computer is stopped; the display is blank when the computer is running. Each indicator has three push buttons which are numbered in the powers of two, from right to left, starting with zero. Pressing a push button forces that particular stage of the register to the SET state. Each group of three buttons represents an octal digit. To aid in distinguishing between octal digits, the buttons for adjacent octal digits are different shades of blue.

At the right end of each register is a Clear push button (white). This button will clear all the FFs within that register. Set and Clear push buttons should be used only when the computer is stopped; otherwise errors may result.

Conditions which stop the computer are listed below. When these conditions exist register contents may be altered by setting or clearing.

- 1) Illegal function codes 00 and 77
- 2) Selective Stops (instruction 76)
- 3) Breakpoint Stop
- 4) Pressing Start/Step switch
- 5) Pressing Clear switch (internal master clear)*

At some of the modules there are colored background lights which indicate certain internal conditions (figure 4-2, table 4-1). A light is identified by the register in which it is located and its position in the register. For example, AL-4 is fourth from the left in A register left. In general, red lights signify faults and blue lights signify special operating conditions. The background lights may be illuminated when the computer is running as well as when it is stopped.

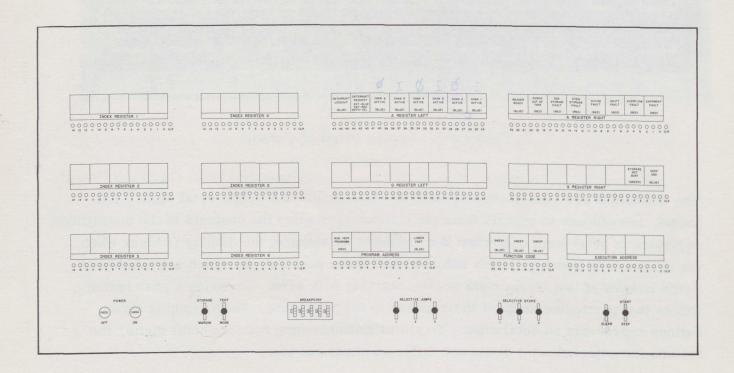

Figure 4-2. Console Display

^{*} Pressing the Clear switch while the computer is running may destroy the contents of the storage location being referenced

TABLE 4-1. CONDITIONS INDICATED BY CONSOLE BACKGROUND LIGHTS

Light	Condition		
AL-1 (blue)	Interrupt Lockout - Computer is in interrupt routine.		
AL-2 (red)* AL-2 (blue)	Internal Interrupt Request External Interrupt Request Interrupt request signal is being received from interrupt circuit.		
AL-3 (blue)	Channel 6 Active - Channel 6 is in use for output buffer.		
AL-4 (blue)	Channel 5 Active - Channel 5 is in use for input buffer.		
AL-5 (blue)	Channel 4 Active - Channel 4 is in use for output buffer.		
AL-6 (blue)	Channel 3 Active - Channel 3 is in use for input buffer.		
AL-7 (blue)	Channel 2 Active - Channel 2 is in use for output buffer.		
AL-8 (blue)	Channel 1 Active - Channel 1 is in use for input buffer.		
AR-1 (blue)	Reader Ready - (1) Paper tape is at load point, ready for an input buffer; or (2) input buffer paper tape is in progress.		
AR-2 (red)	Punch Out of Tape - Punch tape reel is nearly empty.		
AR-3 (red)	Odd Storage Fault - Fault in sequence chain of odd storage unit; storage unit is inoperative until master cleared.		
AR-4 (red)	Even Storage Fault - Fault in sequence chain of even storage unit; storage unit is inoperative until master cleared.		
AR-5 (red)	Divide Fault - Improper divide instruction executed.		
AR-6 (red)	Shift Fault - Shift count greater than 127 (decimal).		
AR-7 (red)	Overflow Fault - Required sum or difference exceeds capacity of A register.		
AR-8 (red)	Exponent Fault - In a floating-point instruction, exponent of result is 2 ¹⁰ or greater.		
QR-7 (green)	Storage Not Busy - Indicates when storage is not in use.		
QR-8 (blue)	Deep End - Computer fails to complete operation in step mode.		
PA-1 (red)	1604/1604-A Switch in 1604 position.		
PA-5 (blue)	Lower Instruction - Lower instruction is indicated.		
FUNCTION CODE (blue) (3 lights)	Sweep - Computer is in sweep mode (Mode switch is down).		

^{*} On both internal and external interrupt requests the light is yellow.

MAIN COMPUTER CONTROLS

TABLE 4-2. MAIN COMPUTER CONTROLS

Control	Function	
Power ON - green push button	Applies a-c and d-c power to computer by energizing contactor in primary power lines of motor generator.	
OFF - red	Removes d-c and a-c power from computer by de-energizing contactor in primary power lines of motor generator.	
Storage MARGIN Test	Varies the bias applied to storage sense amplifiers. Used for maintenance purposes only; should be in neutral position at all other times.	
Lever switch MODE locks in up, down and neutral positions.	Up: an instruction is executed repeatedly in either the step or start mode. Down: contents of consecutive storage locations may be manually examined by pressing Step. Consecutive half-words are displayed in function code and execution address registers but are not executed.	
Breakpoint Five 8-position switches can be set to octal address 00000 through 77777.	Provides for selection of any storage address as a breakpoint address. Computer stops when program address and breakpoint address are equal, just prior to performing the upper instruction at the breakpoint address.	
Selective Jumps 1, 2, 3 Three lever switches lock in upper positions, momentary in down positions.	Provide manual conditions for instruction 75, normal jumps, b = 1, 2 or 3, return jumps, b = 5, 6 or 7.	
Selective Stops 1, 2, 3 Three lever switches lock in upper position, momentary in down positions.	Provide manual conditions for stopping the computer on instruction 76, b = 1, 2, 3, 5, 6 or 7.	
Clear Lever switch, momentary in up and down positions.	Up: master clears external equipment, causing most of the registers and control FFs of the external equipment to be cleared and the paper tape reader to be selected.	
	Down: master clears the computer, clears all operational registers and most control FFs. Magdestroy content of one storage location if pressed while computer is operating.	

TABLE 4-2. MAIN COMPUTER CONTROLS (Cont'd)

Control	Function		
Start/Step Lever switch, momentary in up and down positions.	START (up) selects high-speed mode in which a program of instructions and auxiliary operations proceeds until completed or stopped.		
in up and down positions.	STEP (down) selects step mode. Each time switch is pressed a single instruction is executed and computer stops (all buffer requests are completed before operation stops). Step selection overrides any previous selection of start.		
Volume Control	Controls volume of signal from console loud-		
Black knob under console desk	speaker.		
*The Set push buttons, numbered in the powers of 2, beginning with zero. Each group of three is an octal digit.	Allow for manual entry of a quantity into a given register. Forces that particular stage of register to the set state.		
*The Clear push buttons	Clear all FFs within that register.		
1604/1604-A Switch Mounted near console speaker	Enables 1604-A to run 1604 programs.		

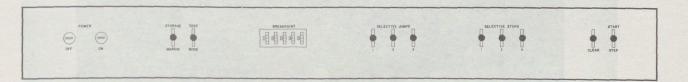

Figure 4-3. Manual Controls

^{*} Should be used only when the computer is stopped.

READER AND PUNCH CONTROLS

TABLE 4-3. READER AND PUNCH CONTROLS

Switch	Function Turns punch motor on or off. (Motor may also be turned on under program control.)		
Punch Motor			
Select/Tape Feed	Select enables use of the punch.		
	Tape Feed causes leader to be punched.		
Reader Motor	Turns reader motor on or off. (Motor cannot be turned on by any other means.)		
Character/Assembly	In character mode each character is sent to computer separately.		
	In assembly mode eight consecutive characters are assembled into a word to be sent to computer.		

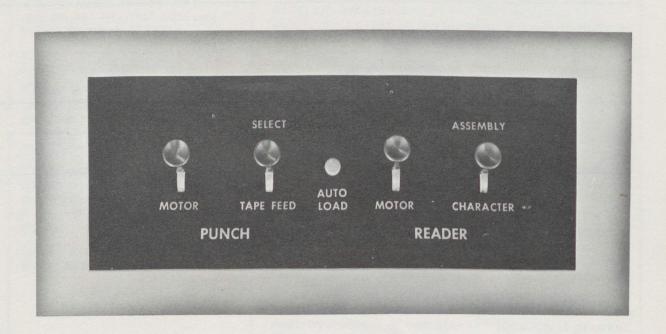

Figure 4-4. Reader, Punch, and Auto Load Controls

AUTO LOAD CONTROL

The Auto Load button initiates a bootstrap routine to read into memory (via channel 3) the first record from magnetic tape #1, on 1615 or 1607 equipment #2.

Pressing the Auto Load button selects the tape and loads the bootstrap routine into memory locations 00000 and 00001, and puts an address of 32000 (arbitrary and > 00004) in the lower address of 00003.

The program appears as:

(00000)	74 0 32005	Rewind the tape
1.	74 7 32000	Wait for ready
(00001)	74 3 00002	Activate, FWA = 00002
**************************************	74 7 32000	Wait for ready
(00002)	XX X XXXXX	Will be the first
	XX X XXXXX	word read from tape
(00003)	74 3 00002	
	74 7, 32000	

The routine will be executed unless Breakpoint is set to 00000 or 00001. The first word read from tape will be read into location 00002 and be executed as soon as the tape is ready again. The second word will be read into the control word address (00003). The lower address of the second word sets the buffer terminating address; the upper address must be 00004 (control word address plus one).

OPERATION

The 1604-A is a stored-program computer. To load a program in the computer a load program (basic service library) is needed. The load program is entered manually. A paper tape reader, a paper tape punch, an electric typewriter, and a set of magnetic tapes are some of the important external devices used for communicating with the 1604-A. The programmer, before operating any of these devices, should make himself familiar with instructions for these devices and they should be followed in the order recommended.

LOAD PROGRAM ENTERING

A load program to be entered in storage is usually on bi-octal paper tape. The following procedure enters the load program:

- 1) Turn on power.
- 2) Master clear, both internal and external.
- 3) Press Start/Step switch once.
- 4) Clear function code and set to 200.
- 5) Clear execution address and set to 00001.
- 6) Set terminal address of buffer in lowest five octal digits of A register right.
- 7) Press Start/Step switch once.
- 8) Load tape into reader.
- 9) Turn on reader motor (wait 10 seconds).
- 10) Raise reader Mode switch to ASSEMBLY position.
- 11) Clear function code and set to 741.
- 12) Clear execution address and set to initial address of buffer.
- 13) Press Start/Step switch once. Wait until tape loads (console lights come on).
- 14) Press Clear switch.
- 15) Perform steps 2 through 8 of operation with pre-stored program.

STARTING OPERATION WITH PRE-STORED LOAD PROGRAM

When a general loading program which provides for loading other programs is held in storage, the starting procedure is as follows:

- 1) Turn on power (Power On, figure 4-3).
- 2) Make required manual selections:

Selective Jumps Selective Stops Breakpoint

- 3) Set in operation the external device or devices selected to communicate with the computer. (Follow the instructions for the devices given in this chapter.)
- 4) Master clear, both internal and external (press clear, then raise it).
- 5) Set Program Address register to address of first instruction of program.
- 6) Begin computer operation (raise Start switch).
- 7) To shut down the equipment after the operation has stopped, follow the instructions as given for each external device.
- 8) Press Power Off button, which disconnects power from all equipments.

READER

The reader is a CONTROL DATA 350 paper tape reader (figure 4-5). It can read either a 5-, a 7-, or an 8-level tape. For a bi-octal tape with the 7th level control holes, assembly mode is selected; for a flex or other code, character mode is selected.

- 1) Check if tape basket is at the proper place. Do not allow the tape to fall on the floor.
- 2) Turn tape release lever clockwise to raise tape guide plate.
- 3) Select the desired tape level by means of the tape level switch.

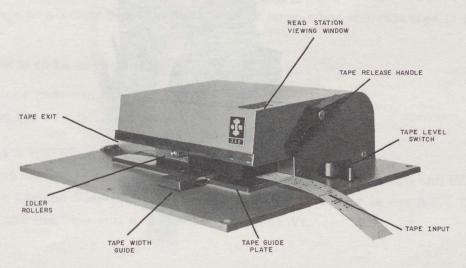

Figure 4-5. Paper Tape Reader

- 4) Holding the tape guide down, slide it so that the marker rests above the proper etched mark on the tape deck surface. The outer position is for 8-level tape, the center for 7-level, and the inner for 5-level.
- 5) Insert tape as shown in figure 4-5. Make sure that the tape is properly aligned.
- 6) Turn Tape Release lever counterclockwise to lower the tape guide.
- 7) Select the desired mode of operation by the Mode switch (figure 4-4) on the control panel.
- 8) Turn on Reader switch on control panel (figure 4-4).
- 9) After the reader has read the tape, remove paper tape from reader and basket; rewind tapes.
- 10) Turn off reader motor.

PUNCH

The paper tape punch (figure 4-6) is mounted on a hinged rack at the rear of the right wing of the console. Punch tape feeds out of a slot in the compartment door; the chad box is just inside the door.

- 1) To ensure proper performance of the punch, always keep the chad box clean.
- 2) Set Punch switch to SELECT (control panel) and check for sufficient paper in reel.

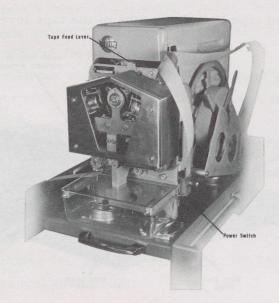

Figure 4-6. Paper Tape Punch

- 3) If you have used the punch, generate a foot of leader by pressing tape feed; remove feed; remove tape and wind it up.
- 4) Perform the following steps to replace a tape roll at punch.
 - a) Remove the tape reel from cradle at side of punch.
 - b) Unscrew tape hold-down assembly, remove old roll, and place new roll on reel. Replace hold-down assembly and mount reel in cradle.
 - c) Thread tape as shown in figure 4-6. Bring tape around lower roller and into guides leading to punch block.
 - d) Turn on punch motor and advance tape through the punch block by pressing the tape feed-out lever (top of punch block).
 - e) Bring leader out through slot in door. Swing punch back into compartment.

TYPEWRITER

The typewriter has all of the characters and functions of a standard electric machine. As a keyboard entry device the typewriter is used only in the character mode. After the program selects keyboard and initiates an input buffer, each striking of a key causes a 6-bit coded character to be entered into the lower six positions of a computer word. The remaining bits of the word are all "0". If the keyboard is selected along with an interrupt feature, each carriage return or tab sends an interrupt signal to the computer. This notifies the program of the entry of data from the keyboard.

When the typewriter is used as an output device certain conditions cause it to hang up until the space bar is struck: receipt of an illegal typewriter code, a code to shift up when the carriage is already up, or a code to shift down when the carriage is already down.

If the typewriter is to be used:

- a) Place paper in it.
- b) Set the switch beneath the righthand corner to ON.

MAGNETIC TAPE UNITS

The tape units which can be used with 1604-A are CONTROL DATA 606 and CONTROL DATA 1607. To use the 606, the CONTROL DATA 1615 Adapter is needed. The codes for the adapter and the tape unit are given in appendix VI.

606 TAPE UNIT

Controls and Indicators

The manual controls and indicators for operating each tape unit are mounted on a panel located below the front door of the unit (figure 4-7). The functions of the controls are described in table 4-4.

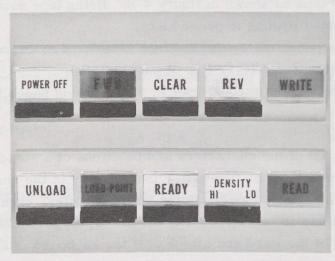

Figure 4-7. Operator Control Panel

TABLE 4-4. 606 CONTROLS AND INDICATORS

NAME		FUNCTION	
POWER OFF	*S	Removes power from all components and power supplies.	
	**I	Power is available to components and power supplies.	
FWD	S	Moves tape forward at 150 ips. Motion stops when end of tape marker is sensed.	
	I	Tape is moving forward at 150 ips.	
CLEAR	S	Master clears all previous settings and conditions. Stops tape motion immediately. New Manual selections are necessary to reselect tape unit and/or operation required.	
	I	606 is cleared	

^{*}Switch **Indicator

TABLE 4-4, 606 CONTROLS AND INDICATORS (CONT'D)

NAME		FUNCTION		
REV	*S	Rewinds tape at 225 ips. Motion stops when load point marker is sensed.		
	**I	Tape is moving in reverse direction at 150 or 225 ips.		
WRITE	I	Write operation is in progress.		
UNLOAD	S	Moves tape at 225 ips to unload position (all tape on supply reel). Tape load procedure must be performed to resume operation.		
	I	Tape is in unload status.		
LOAD POINT	S	Moves tape forward at 150 ips to load point marker. Motion stops when marker is sensed.		
	I	Tape is at load point marker.		
READY	S	Places 606 under external control.		
	I	Unit is under external control.		
DENSITY	S	Changes density mode selection.		
	I (Hi) I (Low)	High density mode selected. Low density mode selected.		
READ	I	Read operation is in progress (not on when reading for horizontal checking during write operation).		
UNIT SELECTION	S	10-position switch; 0-7 provide input designation while two standby positions disconnect unit from external control.		
	I (White) I (Red)	Show selected number. Fault Condition (power failure, tape not in columns, etc.).		
OVERHEAD LIGHTS	I	File protection ring is on reel (unit can write) and tape unit is not in the unload position.		

^{*}Switch **Indicator

Tape Load Procedure

- 1) Make sure that tape unit is properly energized.
- 2) Slide front glass door down to lowest position (figure 4-8).
- 3) Check that supply reel has been file protected as necessary.
- 4) Mount reel on supply reel hub and tighten hub knob. For proper alignment, push reel firmly against hub stop before tightening knob.
- 5) Make sure that tape load arms are in up position.
- 6) Pull sufficient tape from supply reel to reach take-up reel. Thread tape on the outside of the supply tape load arm, over the head assembly, around the outside of the take-up load arm and over the top of the take-up reel hub two or three times.
- 7) Slide tape under head assembly.
- 8) Snap tape load arms down.

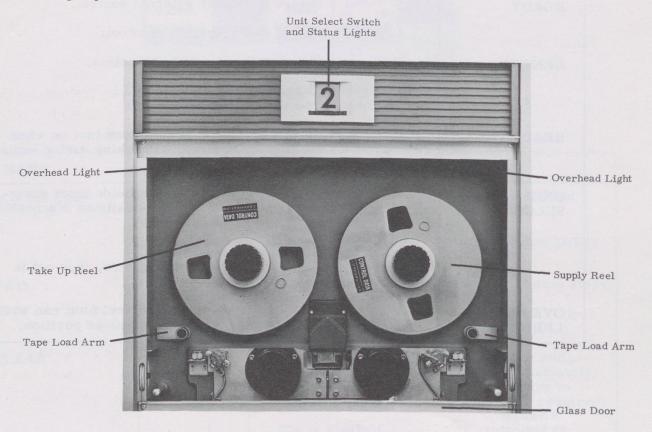

Figure 4-8. 606 Tape Load and Unload Mechanics

- 9) Set Unit Selection switch to one of ten positions (0-7 or standby) to assign a logical program selection number.
- 10) Press Clear switch.
- 11) Press Load Point switch. Tape will drop in columns, move forward, and stop on load point marker. The Load Point light will turn on. (If the light does not turn on, notify maintenance.) If tape continues moving forward for more than 3 or 4 seconds, it indicates either no load point marker was placed on the tape or the operator manually wound the marker onto the take-up reel during step 5.
- 12) If the unit is to be controlled, press the Ready switch. If it is to be manually operated and the Ready switch has been pushed, press the Clear switch.
- 13) Raise the front glass door completely.

If the supply reel contains a file protection ring, the overhead lights should be on, indicating that a write operation may be performed. If the lights are not on, notify maintenance.

Tape Unload Procedure

- 1) Press Clear switch.
- 2) Press Unload switch. All tape will automatically be drawn from the take-up reel and wound on the supply reel. The Unload indicator will light.
- 3) Slide down front door.
- 4) Loosen supply reel hub knob and remove supply reel.
- 5) Check if reel needs to be file protected and if it is labeled adequately prior to storage.

Special Instructions

In order to simulate an unload condition without removing all tape from the take-up reel, simultaneously press the Clear and Unload switches. The unload condition will be simulated but tape will not move. In order to place the unit in operational status, remove all tape from the vacuum columns by revolving the take-up reel clockwise and the supply reel counterclockwise. Snap the tape load arms down and press the Load Point switch. The tape will move forward and stop on the nearest load point marker. The Load Point indicator will turn on.

If all tape is unwound from the supply reel:

- 1) Snap tape load arms up, if necessary.
- 2) Guide tape around the tape load arms, over the head assembly, and wrap approximately ten turns around the supply reel.
- 3) Slide tape under head assembly.
- 4) Press the Load Point switch.
- 5) As soon as the Forward light turns on, press the Clear switch and then the Reverse switch. Tape will rewind on the nearest load point marker.

The following information is applicable when a number of load point or end of tape markers are used on a single tape.

To move forward from a reflective marker and stop at nearest end of tape marker, press the Forward switch.

To move forward off a reflective marker and stop at nearest load point or end of tape marker, press the Forward and then the Load Point switches. Load Point indicator will light if motion stops at load point marker.

To reverse from a reflection marker and stop at nearest load point marker, press the Unload, Clear, and Reverse switches, in that order.

Tape motion may be stopped at any time by pressing the Clear switch. An unload operation may be performed by pressing the Unload switch.

1607 TAPE UNIT

Controls and Indicators

Each tape unit is provided with push buttons for manual operation. These controls are mounted on a panel above the front door (figure 4-9, table 4-5).

Tape Load Procedure

- 1) Open door to handler.
- 2) Check that file reel to be loaded has been file protected as necessary.
- 3) Mount the reel on the file reel hub and tighten the hub knob. To insure proper reel alignment push the reel firmly against the reel hub stop before tightening the knob. If the file protection ring has been removed from the reel, check that the Write Lockout lamp turns on when the reel is loaded. If the lamp does not turn on call maintenance.

TABLE 4-5. 1607 CONTROLS AND INDICATORS

Control		Function
REWIND	*S	Controls manual rewind to load point.
SUSTEEN STATE	**I	Indicates rewind in progress.
CHANGE TAPE	S	Drops any manual selection and places tape unit in automatic or program control mode.
	I	When lighted, indicates tape rewound under program control and interlocked at load point. The interlock prevents operation of the tape unit until the Stop Manual switch is operated.
WRITE LOCKOUT	S	Drops power from unit and removes program designation.
	I	When lighted, indicates that tape unit is loaded with a reel which does not contain a file protection ring. The tape cannot be written as long as the light is on, but may be read.
1, 2, 3 or 4	S	Designates program selection of unit and applies power to unit. Each new unit designation cancels an existing designation.
	I	Indicates unit selection and power-on condition.
REVERSE	S	Initiates reverse tape motion during manual operation.
	I	Indicates reverse tape motion.
STOP MANUAL	S	Drops unit from program control or drops forward or reverse selection and places unit in manual mode.
	I	Indicates manual mode and ready.
FORWARD	S	Initiates forward tape motion during manual mode.
an-H	I	Indicates forward tape motion.

*switch
**indicator

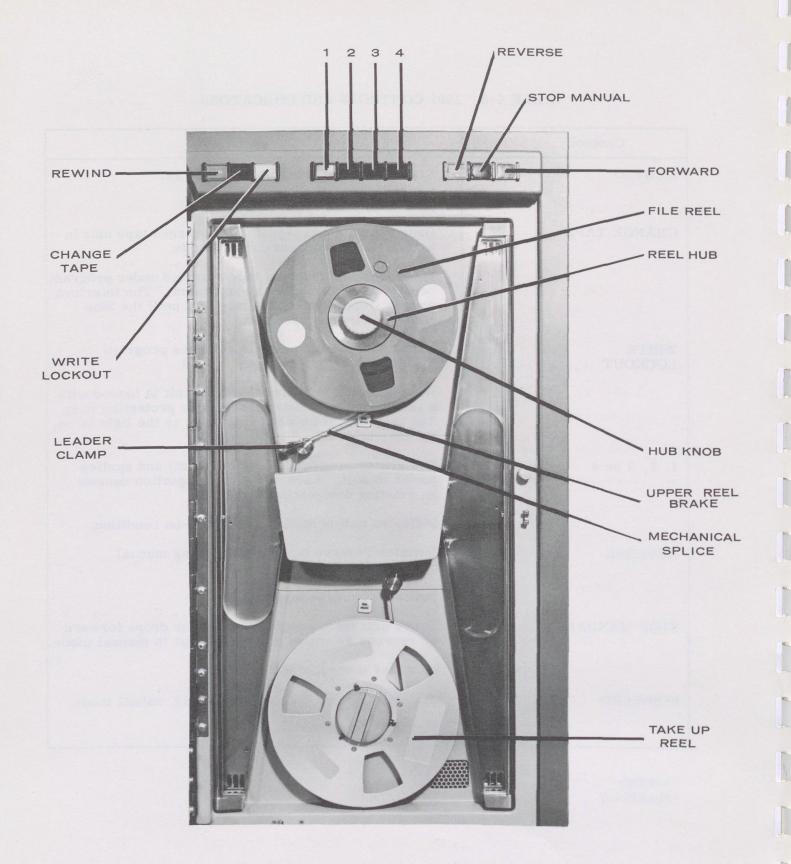

Figure 4-9. 1607 Tape Unit

- 4) Press upper Reel Brake pushbutton to release mechanical brake and check that pulling tape from reel causes it to rotate clockwise. Pull sufficient tape from reel to reach end of permanent machine leader held by leader clamp.
- 5) Connect file tab to permanent machine leader.
- 6) Take up slack by turning file reel while pressing upper Reel Brake push button.
- 7) Lift leader clamp and close door.
- 8) Press one of the unit selection switches (1, 2, 3, 4) to apply power to the unit and assign the unit a logical program selection number. Wait two minutes. The Stop Manual lamp should turn on; if not, call maintenance.
- 9) Press Stop Manual.
- 10) Press Rewind button. Unit is ready when Rewind lamp turns off. If Stop Manual lamp remains on, unit is not ready; call maintenance.

Tape Unload Procedure

- 1) Press Stop Manual button to select manual mode.
- 2) Press Reverse button to move tape backwards to change tape position.
- 3) Open front door of tape unit.
- 4) To secure tape, lower leader clamp.
- 5) Press the upper Reel Brake button to release the mechanical brake and pull tape from file reel to provide slack.
- 6) Unfasten mechanical splice which connects the file tab to the permanent machine leader.
- 7) Loosen file reel hub knob and remove the file reel.
- 8) Check if reel needs to be file protected and also if it is labelled adequately prior to storage.

FILE PROTECTION RING

The back of the file reel has a slot near the hub which accepts a plastic file protection ring (figure 4-10). Writing on a tape is possible only when the reel contains a file protection ring. The ring should be removed from the reel after writing is completed to avoid accidental rewriting. Tape may be read either with the ring in place or without it. On the 606 the overhead lights go on immediately after the tape load procedure is

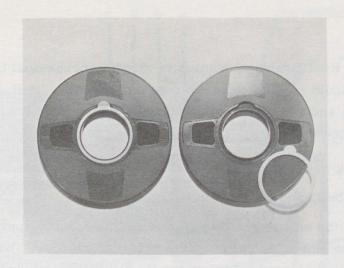

Figure 4-10. File Protection Ring

executed if the file protection ring is in place. The Write Lockout light on the 1607 is off if the file protection ring is in place.

EMERGENCY PROCEDURES

A fault indication, or a warning signal from the buzzer, may call for special procedures on the part of the operator.

TABLE 4-6. EMERGENCY PROCEDURE

Condition	Procedure	
Punch out of tape	Load new roll of tape in punch at end of current operation.	
Odd Storage Fault	Master clear. Restart program.	
Even Storage Fault	Master clear. Restart program.	
Deep End	If all I/O operation has ceased, master clear and restart program. If condition persists, notify maintenance.	
Sweep	Place Mode switch in neutral position.	
Buzzer Signal	Notify maintenance engineer immediately.	

Faults for which the program provides corrective action are: Divide, Shift, Overflow and Exponent Faults. (Refer to appendix.)

GLOSSARY

ABSOLUTE ADDRESS	A specific storage location; contrast with relative address.
ACCESS TIME	The time needed to perform a storage reference, either read or write.
ACCUMULATOR	A register with provisions for the addition of another quantity to its content. It is also the name of the A register.
ADDRESS	A 15-bit quantity which identifies a particular storage location.
ALPHABETIC CODING	A system of abbreviation used in preparing information for input into a computer, e.g., Q Right Shift would be QRS.
AND FUNCTION	A logical function in Boolean algebra that is satisfied (has the value "1") only when all of its terms are "1's". For any other combination of values it is not satisfied and its value is "0".
A REGISTER	Principal arithmetic register; operates as a 48-bit subtractive accumulator (modulus 2 ⁴⁸ -1).
BASE	A quantity which defines some system of representing numbers by positional notation; radix.
BIT	Binary digit, either "1" or "0".
BLOCK	A specified area of storage to which or from which data is to be transmitted.
BOOTSTRAP	The coded instructions at the beginning of an input tape, together with the manually entered instructions.
BORROW	In a subtractive counter or accumulator, a signal indicating that in stage n, a "1" was subtracted from a "0". The signal is sent to stage n+1 which it complements.
BRANCH	A conditional jump.
BREAKPOINT	The address at which a program may be stopped by the Breakpoint switches on the computer console.
B ¹ -B ⁶ REGISTERS	

address.

BUFFER

A device in which data is stored temporarily in the course of transmission from one point to another. To store data temporarily. The operation in which either a word from storage is sent to an external equipment via an output channel (output buffer), or a word is sent from an external equipment to storage via an input channel (input buffer).

BUFFER CONTROL WORD

Each of the six buffer channels is assigned a buffer control word which controls buffer operations on that channel. The lower address holds the terminal address plus one of the buffer; the upper address holds the current or starting address of the buffer.

CAPACITY

The upper and lower limits of the numbers which may be processed in a register or the quantity of information which may be stored in a storage unit. If the capacity of a register is exceeded, an overflow is generated

CARRY

In an additive counter or accumulator, a signal indicating that in stage n, a "1" was added to a "1". The signal is sent to stage n+1, which it complements.

CHANNEL

Transmission path connecting the computer to an external equipment.

CHARACTER

Two types of information handled by the computer:

- 1) A group of 6 bits which represents a digit, letter or symbol. In assembly mode, eight 6-bit characters make up a computer word.
- 2) A group of 5 to 8 bits which represents an item of information. In the character mode, this item is one 5 to 8-bit character with "0's" in the remaining (upper) bits of a 48-bit word.

CLEAR

A command that destroys the quantity in a register by placing every stage of the register in the "0" state.

CLOCK OVERFLOW A clock overflow occurs whenever the capacity of the A register is exceeded during an advance clock instruction. This condition is indicated by a visible display, can be sensed by an EXF code, or may be selected to cause an interrupt.

CLOCK PHASE

One of two outputs from the master clock, "even" or "odd".

COMMAND

A signal that performs a unit operation, such as transmitting the content of one register to another, shifting a register one place to the left or setting a FF.

REGISTER

COMMON CONTROL A 30-bit register used to hold the initial and terminal addresses (CRII and CRI) of the current buffer operation while the comparator samples them. The CCR also has counting logic which is used to advance the address from CRII.

COMPILER

A routine which automatically produces a specific program for a particular problem. The routine determines the meaning for information expressed in a psuedo-code, selects or generates the required subroutine, transforms the subroutine into specific coding, assigns storage registers, and enters the information as an element of the problem program.

COMPLEMENT

Noun: see One's Complement or Two's Complement. Verb: a command which produces the one's complement of a given quantity.

CONTENT

The quantity or word held in a register or storage location.

CONTROL REGISTERS 1-6

30-bit registers used to hold the address portions of the buffer control words. The upper address portion (CR_{II}) is advanced each time a word is buffered and is the current address for a buffer operation.

CORE

A ferromagnetic toroid used as the bistable device for storing a bit in a memory plane.

COUNTER

A register with provisions for increasing or decreasing its content by 1.

EVEN STORAGE

The storage unit which contains the 16,384 even addresses.

EXECUTION ADDRESS

The lower 15 bits of a 24-bit instruction. Most often used to specify the storage address of an operand. Sometimes used as the operand.

EXIT

Initiation of a second control sequence by the first, occurring when the first is near completion; the circuit involved in exiting.

EXTERNAL FUNCTION

- 1) External Function Select (74.0) selects an external equipment or establishes an internal or external condition.
- 2) External Function Sense (74.7) sends a code to an external equipment or internal circuit to sense its condition.

FAULT

Operational difficulty which stops operation or sets an indicator.

FIXED POINT

A notation or system of arithmetic in which all numerical quantities are expressed by a predetermined number of digits with the binary point implicitly located at some predetermined position; contrasted with floating point.

FLIP-FLOP (FF)

A bistable storage device. A "1" input to the set side puts the FF in the "1" state; a "1" input to the clear side puts the FF in the "0" state. The FF remains in a state indicative of its last "1" input. A stage of a register consists of a FF.

FLOATING POINT

A means of expressing a number X by a pair of numbers, Y and Z, such that $X = Yn^{Z}$. Z is an integer, called the exponent or characteristic; n is a base, usually 2 or 10; and Y is called the fraction or mantissa.

FUNCTION CODE

The upper 6 bits of a 24-bit instruction which specify the instruction to be executed.

INDEX CODE

A 3-bit quantity, bits 15, 16, and 17 of an instruction; usually specifies an index register whose contents are added to the execution address; sometimes specifies the conditions for executing the instruction.

INSTRUCTION

A 24-bit quantity consisting of a function code, execution address, and index designator.

INTERRUPT MASKING REGISTER (IMR) Consists of eight FFs which are set or cleared by EXF select codes to apply a mask to the interrupt lines. If one of these FFs is set it disallows the corresponding external interrupt.

INTERRUPT REQUEST A signal received from an external equipment or internal logic that may cause a special sequence of instructions to be executed.

INVERTER

A circuit which provides as an output a signal that is opposite to its input. An inverter output is "1" only if all the separate OR inputs are "0".

JUMP

An instruction which alters the normal sequence control of the computer and, conditionally or unconditionally, specifies the location of the next instruction.

LOAD To place a quantity from storage in a register.

LOCATION A storage position holding one computer word, usually designated by a specific address.

by a specific address

LOGICAL In Boolean algebra, the AND function of several terms. The product is "1" only when all the terms are "1"; otherwise it is "0".

Sometimes referred to as the result of "bit-by-bit" multiplication.

LOGICAL SUM In Boolean algebra, the OR function of several terms. The sum is "1" when any or all of the terms are "1"; it is "0" only when all are "0".

LOOP Repetition of a group of instructions in a routine.

LOWER ADDRESS The execution address portion of a lower instruction; bits 0 through

LOWER See Program Word.

INSTRUCTION

MASK In some instructions, one quantity may determine what part of the other quantity is to be considered. If the first quantity, the mask, contains a "1", the corresponding bit of the second quantity is considered.

MASKED
INTERRUPT
REGISTER (MIR)

A rank of eight FFs through which external interrupt signals enter the 1604-A. The inputs to MIR can be masked (disallowed) by the IMR.

MASTER CLOCK The source of standard signals required for sequencing computer operation. The clock determines the basic frequency of the computer.

MASTER CLEAR
(MC)

A general command produced by placing the Clear switch up
(external MC) or down (computer MC) which clears most of the
crucial registers and control FFs (some FFs are set by MC).

MASTER INTER- A FF for masking all external interrupts. RUPT MASK (MIM)

MNEMONIC CODE A three-letter code which represents the function or purpose of an instruction. Also called Alphabetic Code.

MODULUS

An integer which describes certain arithmetic characteristics of registers, especially counters and accumulators, within a digital computer. The modulus of a device is defined by r^n for an openended device and r^n -1 for a closed (end-around) device, where r is the base of the number system used and n is the number of digit positions (stages) in the device. Generally, devices with modulus r^n use two's complement arithmetic; devices with modulus r^n -1 use one's complement.

NORMALIZE

To adjust the exponent and mantissa of a floating-point result so that the mantissa lies in the prescribed standard (normal) range.

NORMAL JUMP

An instruction that jumps from one sequence of instructions to a second, and makes no preparation for returning to the first sequence.

NUMERIC CODING

A system of abbreviation in which all information is reduced to numerical quantities.

ODD STORAGE

The storage unit which contains the 16,384 odd addresses.

ONE'S COMPLEMENT With reference to a binary number, that number which results from subtracting each bit of the given number from "1". The one's complement of a number is formed by complementing each bit of it individually, that is, changing a "1" to "0" and a "0" to a "1". A negative number is expressed by the one's complement of the corresponding positive number.

ON-LINE OPERATION A type of system application in which the input data to the system is fed directly from the external equipment to the computer.

OPERAND

Usually refers to the quantity specified by the execution address. This quantity is operated upon in the execution of the instruction.

OPERATIONAL REGISTERS

Registers which are displayed on the operator's console (B^1-B^6) , A, Q, P, U^1).

OPERATION CODE

The upper 6 bits of a 24-bit instruction which identify the instruction. After the code is translated, it conditions the computer for execution of the specified instruction. This code, which is expressed by two octal digits, is designated by the letter f.

 ${\rm O}^1$ - ${\rm O}^4$ REGISTERS Output registers ${\rm O}^{1,2,3}$ are used for output buffer operations; ${\rm O}^4$ handles all high-speed output transfer operations.

OR FUNCTION A logical function in Boolean algebra that is satisfied (has the value "1") when any of its terms are "1". It is not satisfied when all terms are "0". Often called the 'inclusive' OR function.

OVERFLOW The capacity of a register is exceeded.

PARITY CHECK A summation check in which the binary digits in a character are added and the sum checked against a previously computed parity digit; i.e., a check which tests whether the number of ones is odd or even.

PARTIAL ADD An addition without carries. Accomplished by toggling each bit of the augend where the corresponding bit of the addend is a "1".

P REGISTER The Program Address Counter is a two's complement additive register (modulus 2¹⁵) which generates in sequential order the storage addresses containing the individual program steps.

PROGRAM A precise sequence of instructions that accomplishes a computer routine; a plan for the solution of a problem.

PROGRAM WORD

Two 24-bit instructions contained in one 48-bit storage address; the higher-order 24 bits are the upper instruction, lower-order 24 bits, the lower instruction. A pair of instructions is read from storage, and the upper instruction is executed first. The lower one is then executed, except when the upper one provides for skipping the lower one.

Q REGISTER Auxiliary arithmetic register which assists the A register in the more complicated arithmetic operations (modulus 2⁴⁸-1).

RANDOM ACCESS Access to storage under conditions in which the next position from which information is to be obtained is in no way dependent on the previous one.

R REGISTER Address Buffer register. Two's complement subtractive register (modulus 2 15) which acts as an exchange register for transmissions involving index registers.

READ To obtain a quantity from a storage location.

P	F	Δ	D	Y
TF	_	77	رد	_

- 1) An input/output control signal sent by the computer or an external equipment. The ready signal indicates that a word or character is available for transmission.
- 2) A status response indicating that the external device being addressed is ready for operation.

RELATIVE ADDRESS

Identifies a word in a subroutine or routine with respect to its position. Relative addresses are translated into absolute addresses by the addition of some specific reference address, usually that at which the first word of the routine is stored.

REPLACE

In the title of an instruction, the result of the execution of the instruction is stored in the location from which the initial operand was obtained.

RESUME

The input/output control signal sent by either the computer or an external equipment to indicate that it is prepared to receive another word (48 bits) or character (usually 6 bits). The resume signal is thus a request for data.

RETURN JUMP

An instruction that jumps from a sequence of instructions to initiate a second sequence and prepares for returning to the original sequence after the second is completed.

ROUTINE

The sequence of operations which the computer performs under the direction of a program.

s¹ register

Storage Address register (even storage). Selects the storage address specified by the contents of the P register.

s² register

Storage Address register (odd storage). Selects the storage address specified by the contents of the P register.

SCALE FACTOR

One or more coefficients by which quantities are multiplied or divided so that they lie in a given range of magnitude.

SCANNER

A circuit used to search for one of a number of possible conditions and to initiate action when a condition is detected. The auxiliary scanner scans the six buffer channels for auxiliary requests; the interrupt scanner looks for interrupt requests from external equipments.

SECONDARY	Transie		
REGISTERS	R. X. C		

ent registers not displayed on the console (U^2 , $S^{1,2}$, $Z^{1,2}$, $0^1 - 0^6$).

SHIFT

To move the bits of a quantity right or left.

SIGN BIT

In registers where a quantity is treated as signed by use of one's complement notation, the bit in the highest-order stage of the register. If the bit is "1", the quantity is negative; if the bit is "0", the quantity is positive.

SIGN EXTENSION The duplication of the sign bit in the higher-order stages of a register.

SKIP

To omit the execution of a lower instruction in a program; occurs only if the upper instruction provides for skipping on a specified condition, and the condition is met.

STAGE

The FFs and inverters associated with a bit position of a register.

STORE

To transmit information to a device from which the unaltered

information can later be obtained.

SUBINSTRUCTION The index code specifies one of eight forms of the instruction indicated by the operation code. Such forms are called "subinstructions". Thus, 74.0 is a subinstruction of instruction 74.

TOGGLE

To complement each bit of a quantity as a result of an individual condition.

TRANSFER

High-speed data input/output transmission under direct program control.

TRANSMISSION, FORCED

A transfer of bits into a register which has not been cleared previously.

TRANSMISSION, ONES

A transfer of ones into a register which has been cleared.

TRANSMISSION, ZEROS

A transfer of zeros into a register which has been set.

TWO'S COMPLEMENT Number that results from subtracting each bit of a number from "0". The two's complement may be formed by complementing each bit of the given number and then adding one to the result, performing the required carries.

u ¹ REGISTER	Program Control register. Holds a program step while the two instructions contained in it are executed.
u ² register	Auxiliary Program Control register. A 15-bit subtractive accumulator (modulus 2 ¹⁵ -1) used primarily for modification of the base execution address.
UPPER ADDRESS	The execution address portion of an upper instruction; bit positions 24 through 38 of a 48-bit register or storage address.
UPPER INSTRUCTION	See Program Word.
WORD	A unit of information which has been coded for use in the computer as a series of bits. The normal word length is 48 bits.
WRITE	To enter a quantity into a storage location.
X REGISTER	Exchange register. Most internal transmissions between the arithmetic section and the rest of the computer are made through X.
Z ¹ REGISTER	Storage Restoration register (even storage). Holds the word to be written into a given storage location.
z ² register	Storage Restoration register (odd storage). Holds the word to be written into a given storage location.

APPENDIX SECTION

APPENDIX I NUMBER SYSTEMS

Any number system may be defined by two characteristics, the radix or base and the modulus. The radix or base is the number of unique symbols used in the system. The decimal system has ten symbols, 0 through 9. Modulus is the number of unique quantities or magnitudes a given system can distinguish. For example, an adding machine with ten digits, or counting wheels, would have a modulus of 10^{10} -1. The decimal system has no modulus because an infinite number of digits can be written, but the adding machine has a modulus because the highest number which can be expressed is 9,999,999,999.

Most number systems are positional, that is, the relative position of a symbol determines its magnitude. In the decimal system, a 5 in the units column represents a different quantity than a 5 in the tens column. Quantities equal to or greater than 1 may be represented by using the 10 symbols as coefficients of ascending powers of the base 10. The number 984_{10} is:

$$9 \times 10^{2} = 9 \times 100 = 900$$

+8 \times 10^{1} = 8 \times 10 = 80
+4 \times 10^{0} = 4 \times 1 = 4
 984_{10}

Quantities less than 1 may be represented by using the 10 symbols as coefficients of ascending negative powers of the base 10. The number 0.593_{10} may be represented as:

$$5 \times 10^{-1} = 5 \times .1 = .5$$

+9 × 10⁻² = 9 × .01 = .09
+3 × 10⁻³ = 3 × .001 = .003
0.593₁₀

BINARY NUMBER SYSTEM

Computers operate faster and more efficiently by using the binary number system. There are only two symbols 0 and 1; the base = 2. The following shows the positional value.

The binary number 0 1 1 0 1 0 represents:

$$0 \times 2^{5} = 0 \times 32 = 0$$

$$+1 \times 2^{4} = 1 \times 16 = 16$$

$$+1 \times 2^{3} = 1 \times 8 = 8$$

$$+0 \times 2^{2} = 0 \times 4 = 0$$

$$+1 \times 2^{1} = 1 \times 2 = 2$$

$$+0 \times 2^{0} = 0 \times 1 = 0$$

$$26_{1}$$

Fractional binary numbers may be represented by using the symbols as coefficients of ascending negative powers of the base.

$$2^{-1}$$
 2^{-2} 2^{-3} 2^{-4} 2^{-5} . Binary Point . =1/2 =1/4 =1/8 =1/16 =1/32

The binary number 0.10 110 may be represented as:

$$1 \times 2^{-1} = 1 \times 1/2 = 1/2 = 8/16$$

$$+0 \times 2^{-2} = 0 \times 1/4 = 0 = 0$$

$$+1 \times 2^{-3} = 1 \times 1/8 = 1/8 = 2/16$$

$$+1 \times 2^{-4} = 1 \times 1/16 = 1/16 = 1/16$$

$$11/16_{10} = 0.6875$$

OCTAL NUMBER SYSTEM

The octal number system uses eight discrete symbols, 0 through 7. With the base eight the positional value is:

The octal number 513₈ represents:

$$5 \times 8^{2} = 5 \times 64 = 320$$

+1 \times 8^{1} = 1 \times 8 = 8
+3 \times 8^{0} = 3 \times 1 = 3
\frac{331}{10}

Fractional octal numbers may be represented by using the symbols as coefficients of ascending negative powers of the base.

$$8^{-1}$$
 8^{-2} 8^{-3} 8^{-4} $1/8$ $1/64$ $1/512$ $1/4096$

The octal number 0.4520 represents:

$$4 \times 8^{-1} = 4 \times 1/8 = 4/8 = 256/512$$
 $+5 \times 8^{-2} = 5 \times 1/64 = 5/64 = 40/512$
 $+2 \times 8^{-3} = 2 \times 1/512 = 2/512 = 2/512 = 298/512 = 149/256_{10} = .5811$

ARITHMETIC

ADDITION AND SUBTRACTION

Binary numbers are added according to the following rules:

$$0 + 0 = 0$$

 $0 + 1 = 1$
 $1 + 0 = 1$
 $1 + 1 = 0$ with a carry of 1

The addition of two binary numbers proceeds as follows (the decimal equivalents verify the result):

Augend	0111	(7)
Addend	+0100	+(4)
Sum	1011	(11)

Subtraction may be performed as an addition:

One's Complement

The 1604-A performs all arithmetic operations in the binary one's complement mode. In this system, positive numbers are represented by the binary equivalent and negative numbers in one's complement notation.

The one's complement representation of a number is found by subtracting each bit of the number from 1. For example:

This representation of a negative binary quantity may also be obtained by substituting "1's" for "0's" and "0's" for "1's".

The value zero can be represented in one's complement notation in two ways:

$$0000 \rightarrow 00_2$$
 Positive (+) Zero
 $1111 \rightarrow 11_2$ Negative (-) Zero

The rules regarding the use of these two forms for computation are:

- 1) Both positive and negative zero are acceptable as arithmetic operands.
- 2) If the result of an arithmetic operation is zero, it will be expressed as positive zero. The one exception to this rule is when negative zero is added to negative zero.* In this case, the result is negative zero.

One's complement notation applies not only to arithmetic operations performed in A, but also to the modification of execution addresses in the U^2 register. During address modification, the modified address will equal 77777_8 only if the unmodified execution address equals 77777_8 and b = 0 or (B^b) = 77777_8 .

Two's Complement

The counters in the computer use two's complement arithmetic. A counter is a register with provisions for increasing its contents by one if it is additive (P register) or decreasing its contents by one if it is subtractive (R register). A two's complement counter is open-ended; there is no end-around carry or borrow.

^{*} When a 1604-A instruction calls for subtracting positive zero from negative zero, the computer complements the subtrahend and adds so that the actual operation is the addition of negative zero to negative zero and the result is negative zero.

Positive numbers have the same representation in both systems while negative values differ by one count.

Count	2's comp. rep.	1's comp. rep.
+2	00010	00010
+1	00001	00001
0	00000	00000
-1	11111	11110
-2	11110	11101

The difference in the representation of negative values in these two systems is due to the skipping of the "all one's" count in one's complement notation. In the one's complement system the end-around-carry feature of the register automatically changes a count of all one's to all zeros. (Note exception under one's complement.)

As an example, if the content of a subtractive counter is positive seven (0111) and is to be reduced by one, add the two's complement expression of negative one, (1111), to 0111 as shown below. The result is six.

Note that the two's complement expression for a negative number may also be formed by adding one to the one's complement representation of the number.

MULTIPLICATION

Binary multiplication proceeds according to the following rules:

$$0 \times 0 = 0$$
 $0 \times 1 = 0$
 $1 \times 0 = 0$
 $1 \times 1 = 1$

Multiplication is always performed on a bit-by-bit basis. Carries do not result from multiplication, since the product of any two bits is always a single bit.

Decimal example:

The shift of the second partial product is a shorthand method for writing the true value 140.

Binary example:

multiplicand (14) 1110

multiplier (12)
$$\frac{1100}{0000}$$

partial products $\begin{cases} 0000 & \text{shift to place digits in proper columns} \\ \frac{1110}{10101000} \end{cases}$

The computer determines the running subtotal of the partial products. Rather than shifting the partial product to the left to position it correctly, the computer right shifts the summation of the partial products one place before the next addition is made. When the multiplier bit is "1", the multiplicand is added to the running total and the results are shifted to the right one place. When the multiplier bit is "0", the partial product subtotal is shifted to the right (in effect, the quantity has been multiplied by 10₂).

DIVISION

The following example shows the familiar method of decimal division:

The computer performs division in a similar manner (using binary equivalents):

		1110	quotient (14)
divisor	1101	10111001	dividend
		1101	
		10100	
		1101	
		1110	partial dividends
		1101	
		11	remainder (3)

However, instead of shifting the divisor right to position it for subtraction from the partial dividend (shown above), the computer shifts the partial dividend left, accomplishing the same purpose and permitting the arithmetic to be performed in the A register. The computer counts the number of shifts, which is the number of quotient digits to be obtained; after the correct number of counts, the routine is terminated.

CONVERSIONS

The procedures that may be used when converting from one number system to another are power addition, double dabble, and substitution.

Recommended Conversion Procedures (Integer and Fractional)

Recommended Method				
Power Addition				
Power Addition				
Double Dabble				
Double Dabble				
Substitution				
Substitution				
ULES				
Substitution				
r _i < r _f : use Power Addition, Substitution				
r _i = Radix of initial system				
r _f = Radix of final system				

POWER ADDITION

To convert a number from r_i to r_f (r_i < r_f) write the number in its expanded r_i polynomial form and symplify using r_f arithmetic.

EXAMPLE I Binary to Decimal (Integer)

$$010 \ 111_{2} = 1 \ (2^{4}) + 0 \ (2^{3}) + 1 \ (2^{2}) + 1 \ (2^{1}) + 1 \ (2^{0})$$

$$= 1 \ (16) + 0 \ (8) + 1 \ (4) + 1 \ (2) + 1 \ (1)$$

$$= 16 + 0 + 4 + 2 + 1$$

$$= 23_{10}$$

EXAMPLE 2 Binary to Decimal (Fractional)

$$.0101_{2} = 0 (2^{-1}) + 1 (2^{-2}) + 0 (2^{-3}) + 1 (2^{-4})$$

$$= 0 + 1/4 + 0 + 1/16$$

$$= 5/16_{10} = 0.3125$$

EXAMPLE 3 Octal to Decimal (Integer)

$$324_{8} = 3 (8^{2}) + 2 (8^{1}) + 4 (8^{0})$$

$$= 3 (64) + 2 (8) + 4 (1)$$

$$= 192 + 16 + 4$$

$$= 212_{10}$$

EXAMPLE 4 Octal to Decimal (Fractional)

$$.44_{8} = 4 (8^{-1}) + 4 (8^{-2})$$
$$= 4/8 + 4/64$$
$$= 36/64_{10} = 0.5625$$

DOUBLE DABBLE

To convert a whole number from r_i to r_f ($r_i > r_f$):

- 1) Divide \boldsymbol{r}_i by \boldsymbol{r}_f using \boldsymbol{r}_i arithmetic
- 2) The remainder is the lowest order bit in the new expression
- 3) Divide the integral part from the previous operation by ${\bf r_f}$
- 4) The remainder is the next higher order bit in the new expression
- 5) The process continues until the division produces only a remainder which will be the highest order bit in the ${\bf r}_{\bf f}$ expression.

To convert a fractional number from r; to rf:

- 1) Multiply r; by r; using r; arithmetic
- 2) The integral part is the highest order bit in the new expression
- 3) Multiply the fractional part from the previous operation by r_f
- 4) The integral part is the next lower order bit in the new expression
- 5) The process continues until sufficient precision is achieved or the process terminates.

EXAMPLE | Decimal to Binary (Integer)

$$45 \div 2 = 22 \text{ remainder 1; record}$$
 1
 $22 \div 2 = 11 \text{ remainder 0; record}$ 0
 $11 \div 2 = 5 \text{ remainder 1; record}$ 1
 $5 \div 2 = 2 \text{ remainder 1; record}$ 1
 $2 \div 2 = 1 \text{ remainder 0; record}$ 0
 $1 \div 2 = 0 \text{ remainder 1; record}$ 1
Thus: $45_{10} = 101101_2$

EXAMPLE 2 Decimal to Binary (Fractional)

.25 x 2 = 0.5; record 0
.5 x 2 = 1.0; record 1
.0 x 2 = 0.0; record 0

Thus:
$$.25_{10} = .010_{2}$$

EXAMPLE 3 Decimal to Octal (Integer)

SUBSTITUTION

This method permits easy conversion between octal and binary representations of a number. If a number in binary notation is partitioned into triplets to the right and left of the binary point, each triplet may be converted into an octal digit. Similarly each octal digit may be converted into a triplet of binary digits.

EXAMPLE | Binary to Octal

Binary = 110 000 . 001 010 Octal = 6 0 . 1 2

EXAMPLE 2 Octal to Binary

Octal = 6 5 0 . 2 2 7 Binary = 110 101 000 . 010 010 111

COMMON PURE NOTATIONS

Decimal	Binary	Octal
00	00000	. 00
01	00001	01
02	00010	02
03	00011	03
04	00100	04

28	=	256	88 =	16,777,216		
29	=	512				
2 ¹⁰	=	1,024				

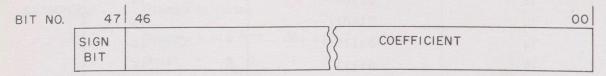

FIXED POINT AND FLOATING POINT NUMBERS

Any number may be expressed in the form kB^n , where k is a coefficient, B a base number, and the exponent n the power to which the base number is raised.

A fixed point number assumes:

- 1) The exponent n = 0 for all fixed point numbers.
- 2) The coefficient, k, occupies the same bit positions within the computer word for all fixed point numbers.
- 3) The radix (binary) point remains fixed with respect to one end of the expression.

A 1604 fixed point number consists of a sign bit and coefficient as shown below. The upper bit of any 1604 fixed point number designates the sign of the coefficient (47 lower order bits). If the bit is "1", the quantity is negative since negative numbers are represented in one's complement notation; a "0" sign bit signifies a positive coefficient.

The coefficient may be an integer or fraction. The radix (binary) point, in the case of an integer, is assumed to be immediately to the right of the lowest order bit (00). In the case of the fraction, the point is just to the right of the sign bit.

In many instances, the values in a fixed point operation may be too large or too small to be expressed by the computer. The programmer must position the numbers within the word format so they can be represented with sufficient precision. The process, called scaling, consists of shifting the values a predetermined number of places. The numbers must be positioned far enough to the right in the register to prevent overflow but far enough to the left to maintain precision. The scale factor (number of places shifted) is expressed as the power of the base. For example, $5,100,000_{10}$ may be expressed as $0.51 \times 10^7, \ 0.051 \times 10^8, \ 0.0051 \times 10^9, \ etc.$ The scale factors are $7, \ 8, \ and \ 9.$

Since only the coefficient is used by the computer, the programmer is responsible for remembering the scale factors. Also, the possibility of an overflow during intermediate operations must be considered. For example, if two fractions in fixed point format are

multiplied, the result is a number < 1. If the same two fractions are added, subtracted, or divided, the result may be greater than one and an overflow will occur. Similarly, if two integers are multiplied, divided, subtracted or added, the likelihood of an overflow is apparent.

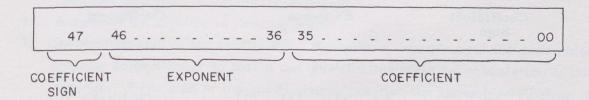

As an alternative to fixed point operation, a method involving a variable radix point, called floating point, is used. This significantly reduces the amount of bookkeeping required on the part of the programmer.

By shifting the radix point and increasing or decreasing the value of the exponent, widely varying quantities which do not exceed the capacity of the machine may be handled.

Floating point numbers within the computer are represented in a form similar to that used in "scientific" notation, that is, a coefficient or fraction multiplied by a number raised to a power. Since the computer uses only binary numbers, the numbers are multiplied by powers of two.

$$F \cdot 2^{E}$$
 where: $F = fraction$
 $E = exponent$

In floating point, different coefficients need not relate to the same power of the base as they do in fixed point format. Therefore, the construction of a floating point number includes not only the coefficient but also the exponent.

Coefficient

The coefficient consists of a 36-bit fraction in the 36 lower-order positions of the floating point word. The coefficient is a normalized fraction; it is equal to or greater than 1/2 but less than 1. The highest order bit position (47) is occupied by the sign bit of the coefficient. If the sign bit is a "0", the coefficient is positive; a "1" bit denotes a negative fraction (negative fractions are represented in one's complement notation).

Exponent

The floating point exponent is expressed as an 11-bit quantity with a value ranging from 0000_8 to 3777_8 . It is formed by adding a true positive exponent and a bias of 2000_8 or a true negative exponent and a bias of 1777_8 . This results in a range of biased exponents as shown below.

True Positive Exponent	Biased Exponent	True Negative Exponent	Biased Exponent
+0	2000	-0	2000*
+1	2001	-1	1776
+2	2002	-2	1775
+1776	3776	-1776	0001
+17778	37778	-17778	00008

The exponent is biased so that floating point operands can be compared with each other in the normal fixed point mode.

As an example, compare the unbiased exponents of $+52_8$ and $+0.02_8$ (Example 1).

EXAMPLE I		Number = +52		
	0	0 0 000	000 110	(36 bits)
	Coefficient Sign	Expon	ent	Coefficient
		Number = +0.02		
	0	1 1 111	111 011	(36 bits)
	Coefficient Sign	Expon		Coefficient

In this case +0.02 appears to be larger than +52 because of the larger exponent. If, however, both exponents are biased, (Example 2) changing the sign of both exponents makes +52 greater than +0.02.

^{*} Minus zero is sensed as positive zero by the computer and is therefore biased by 2000_8 rather than $1777_8.$

EXAMPLE	2	Number = +52 ₈	
	0	1 0 000 000 110	(36 bits)
	Coefficient Sign	Exponent	Coefficient
		Number = +0.02 ₈	
	0	0 1 111 111 011	(36 bits)
	Coefficient Sign	Exponent	Coefficient

When bias is used with the exponent floating-point operation is more versatile since floating-point operands can be compared with each other in the normal fixed point mode.

CONVERSION PROCEDURES

Fixed Point to Floating Point

- 1) Express the number in binary.
- 2) Normalize the number. A normalized number has the most significant 1 positioned immediately to the right of the binary point and is expressed in the range $1/2 \le k \le 1$.
- 3) Inspect the sign of the true exponent. If the sign is positive add 2000₈ (bias) to the true exponent of the normalized number. If the sign is negative add the bias 1777₈ to the true exponent of the normalized number. In either case, the resulting exponent is the biased exponent.
- 4) Assemble the number in floating point.
- 5) Inspect the sign of the coefficient. If negative, complement the assembled floating point number to obtain the true floating point representation of the number. If the sign of the coefficient is positive the assembled floating point number is the true representation.

EXAMPLE | Convert +4.0 to floating point

- 1) The number is expressed in octal.
- 2) Normalize. $4.0 = 4.0 \times 8^0 = 0.100 \times 2^3$.
- 3) Since the sign of the true exponent is positive, add 2000_8 (bias) to the true exponent. Biased exponent = 2000 + 3.

- 4) Assemble number in floating point format.

 Coefficient = 400 000 000 000

 Biased Exponent = 2003

 Assembled word = 2003 400 000 000 000

 Resembled word = 2003 400 000 000 000
- 5) Since the sign of the coefficient is positive, the floating point representation of +4.0 is as shown. If, however, the sign of the coefficient were negative, it would be necessary to complement the entire floating point word.

EXAMPLE 2 Convert -4.0 to floating point

- 1) The number is expressed in octal.
- 2) Normalize. $-4.0 = -4.0 \times 8^0 = -0.100 \times 2^3$
- 3) Since the sign of the true exponent is positive, add 2000_8 (bias) to the true exponent. Biased exponent = 2000 + 3.
- 4) Assemble number in floating point format.

Coefficient = 400 000 000 000₈

Biased Exponent = 2003₈

Assembled word = 2003 400 000 000 000₈

5) Since the sign of the coefficient is negative, the assembled floating point word must be complemented. Therefore, the true floating point representation for -4.0 = 5774 377 777 777 777₈

EXAMPLE 3 Convert 0.5₁₀ to floating point

- 1) Convert to octal. $0.5_{10} = 0.4_{8}$
- 2) Normalize. $0.4 = 0.4 \times 8^0 = 0.100 \times 2^0$
- 3) Since the sign of the true exponent is positive, add 2000_8 (bias) to the true exponent. Biased exponent = 2000 + 0.
- 4) Assemble number in floating point format.

Coefficient = 400 000 000 000₈

Biased Exponent = 2000₈

Assembled word = 2000 400 000 000 000₈

5) Since the sign of the coefficient is positive, the floating point representation of $+0.5_{10}$ is as shown. If, however, the sign of the coefficient were negative, it would be necessary to complement the entire floating point word. This example is a special case of floating point since the exponent of the normalized number is 0 and could be represented as -0. The exponent would then be biased by 1777_8 instead of 2000_8 because of the negative exponent. The 1604, however, recognizes -0 as +0 and biases the exponent by 2000_8 .

EXAMPLE 4 Convert 0.04₈ to floating point

- 1) The number is expressed in octal.
- 2) Normalize. $0.04 = 0.04 \times 8^0 = 0.4 \times 8^{-1} = 0.100 \times 2^{-3}$
- 3) Since the sign of the true exponent is negative, add 1777_8 (bias) to the true exponent. Biased exponent = $1777_8 + (-3) = 1774_8$.
- 4) Assemble number in floating point format.

Coefficient = 400 000 000 000 8 Biased Exponent = 17748

Assembled word = 1774 400 000 000 000_Q

5) Since the sign of the coefficient is positive, the floating point representation of 0.04₈ is as shown. If, however, the sign of the coefficient were negative, it would be necessary to complement the entire floating point word.

Floating Point to Fixed Point Format

- 1) If the floating point number is negative, complement the entire floating point word and record the fact that the quantity is negative. The exponent is now in a true biased form.
- 2) If the biased exponent is equal to or greater than 2000_8 subtract 2000_8 to obtain the true exponent. If less than 2000_8 subtract 1777_8 to obtain true exponent.
- 3) Separate the coefficient and exponent. If the true exponent is negative the binary point should be moved to the left the number of bit positions indicated by the true exponent. If the true exponent is positive, the binary point should be moved to the right the number of bit positions indicated by the true exponent.
- 4) The coefficient has now been converted to fixed binary. The sign of the coefficient will be negative if the floating point number was complemented in step one. (The sign bit must be extended if the quantity is placed in a register.)
- 5) Represent the fixed binary number in fixed octal notation.

EXAMPLE I Convert floating point number 2003 400 000 000 000 8 to fixed octal

- 1) The floating point number is positive and remains uncomplemented.
- 2) The biased exponent $> 2000_8$, therefore subtract 2000_8 from the biased exponent to obtain the true exponent of the number. 2003 2000 = +3
- 3) Coefficient = 400 000 000 000 $_8$ = .100 $_2$. Move binary point to the right 3 places. Coefficient = 100.0 $_2$

- 4) The sign of the coefficient is positive because the floating point number was not complemented in step one.
- 5) Represent in fixed octal notation. $100.0 \times 2^0 = 4.0 \times 8^0$

EXAMPLE 2 Convert floating point number 5774 377 777 777 777 8 to fixed octal

1) The sign of the coefficient is negative, therefore, complement the floating point number.

Complement = 2003 400 000 000 000_Q

- 2) The biased exponent (in complemented form) $> 2000_8$, therefore subtract 2000_8 from the biased exponent to obtain the true exponent of the number. 2003 2000 = +3
- 3) Coefficient = $4000\ 000\ 000\ 000_8$ = 0.100_2 Move binary point to the right 3 places. Coefficient = 100.0_2
- 4) The sign of the coefficient will be negative because the floating point number was originally complemented.
- 5) Convert to fixed octal. $-100.0_2 = -4.0_8$

EXAMPLE 3 Convert floating point number 1774 400 000 000 000 g to fixed octal

- 1) The floating point number is positive and remains uncomplemented.
- 2) The biased exponent $< 2000_8$, therefore subtract 1777₈ from the biased exponent to obtain the true exponent of the number. 1774₈ 1777₈ = -3
- 3) Coefficient = $400\ 000\ 000\ 000_8$ = $.100_2$ Move binary point to the left 3 places. Coefficient = $.000100_2$
- 4) The sign of the coefficient is positive because the floating point number was not complemented in step one.
- 5) Represent in fixed octal notation. $.000100_2 = .04_8$

APPENDIX II

FAULTS

Certain fault conditions may occur in the execution of a computer program which may be sensed by EXF instructions. The occurrence of the fault does not stop operation but sets an indicator that can be sensed. A fault is visually indicated on the console.

SHIFT FAULT

Any attempt to shift a register more than 127_{10} (177₈) places right or left results in a shift fault. If the fault exists, the indicator is set prior to execution of the shift instruction and the shift fault background light on the console display panel is lighted. The shifts will be performed regardless of the status of the fault indicator. If an interrupt has been selected, the main program will be interrupted after executing the shift instruction. The shift fault may be sensed by 47 7 00120, 1.

DIVIDE FAULT

A divide fault occurs in fixed point divide instructions (25 and 27) when the divisor is zero or the required quotient exceeds the 47-bit capacity of the quotient register, Q. The sign bit of Q is examined at the end of the division phase. If it is equal to "1", a divide fault has occurred. If an interrupt has been selected, the main program will be interrupted after the divide instruction is completed. A divide fault is sensed by a 74 0 00110, 1.

OVERFLOW FAULT

An overflow fault results when the capacity of the A register $(2^{47}-1)$ is exceeded. The fault is detected at the time the operation causing the overflow takes place.

If an interrupt on arithmetic faults has been selected, the main program will be halted before another instruction can be executed.

An overflow may be sensed by a 74 7 00130, 1.

CLOCK OVERFLOW

A clock overflow results if the capacity of the A register is exceeded during an advance clock operation. If an interrupt on arithmetic faults has been selected, the interrupt will occur before an instruction can be executed after the advance clock operation. Clock overflow may be sensed by 74 7 00300, 1.

1235 60-

EXPONENT (Floating Point Range) FAULT

The exponent fault occurs during floating point instructions when the exponent of the result, after rounding and normalizing, is $\geq 2^{+10}$ (overflow) or $\leq 2^{-10}$ (underflow). The exponent fault is sensed by a 74 7 00140, 1.

EVEN AND ODD STORAGE FAULTS

These faults indicate a failure in computer storage and turn on background lights on the console display. The indicators may be cleared by an internal master clear. If a storage fault is produced, maintenance should be notified.
