OP=CF sets or clears flags in the CSU map or MSF catalog. The FL and ON or OF parameters indicate the flag type and the action to be taken. The appropriate FCT or CSU map entry is determined from the FO, V, or XI and YI parameters. For FCT stream detail flags (FL=SF, FC, or SC), the user can specify either a single stream via the ST parameter or a range of streams via the SL and SU parameters.

#### **Parameters for the ASDEBUG Directives**

The descriptions of the parameters to the ASDEBUG directives follow. Not all parameters are valid with all directives, as indicated.

| <sup>p</sup> i | Description                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------|
| CS=id          | CSU identifier of the CSU to be used by ASDEBUG; id is a letter from A to M.                       |
| CS             | Same as CS=A.                                                                                      |
| CS omitted     | Same as CS=A.                                                                                      |
| D=d            | Input drawer slot to be used; $0 \le d \le 7$ . Not valid for OP=RS if V=vsn or XI=x is specified. |
| D              | First available input drawer slot is to be used.                                                   |
| D omitted      | V=vsn or XI=x and YI=y must be specified for OP=RS.                                                |

# Description

Name of flag in CSU map or MSF catalog to be set or cleared. Valid

Description

EW Excessive write parity error flag.

ME Linkage error flag (in CSU map).

FE Linkage error flag (in MSF catalog FCT).

FC Frozen chain flag.

IB Inhibit allocation flag.

LC Lost cartridge flag.

SC Stream conflict flag.

SF Start of fragment flag.

FL=flag must be specified for OP=CF.

FM=familyname Family to be processed. FM Same as FM=system default family. FM omitted Same as FM=system default family. F0=ord MSF catalog ordinal indicating the file to be read or the chain whose space is to be released. Not valid for OP=CF if V=vsn or XI=x is specified. FO=ord must be specified for OP=RF, OP=RP, and OP=RL. V=vsn or XI=x FO omitted and YI=y must be specified for OP=CF. OF Flag specified by FL=flag is to be cleared. Valid only with OP=CF. Flag specified by FL=flag is to be set. Valid only with OP=CF. ON PF=filename File to which the MSF image (streams or file) is to be copied. Each stream copied is separated by an end-of-record. This file is defined under the user's current family and user index. PF Same as PF=ZZZZBUG. PF omitted Same as PF=ZZZZBUG. SB=subfamily Subfamily to be used;  $0 \leq \text{subfamily} \leq 7$ . SB Same as SB=0. SB omitted Same as SB=0. SL=i Stream where OP=RS begins copying or OP=CF begins changing flags;  $0 \leq i \leq 15$ ;  $i \leq j$  (refer to SU=j).

p<u>i</u> FL=flag

FL omitted

only for OP=CF.

flag

| <sup>p</sup> i | Description                                                                                                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SL             | Same as SL=0.                                                                                                                                                                                                                                    |
| SL omitted     | Same as SL=0.                                                                                                                                                                                                                                    |
| ST=s           | Stream where OP=RF begins reading or OP=RP begins releasing. If<br>specified with OP=CF, ST=s indicates a single stream detail to be<br>changed and takes precedence over the SL and SU parameters.                                              |
| ST omitted     | ST=s must be specified for OP=RF and OP=RP.                                                                                                                                                                                                      |
| SU=j           | Stream where OP=RS ends copying or OP=CF ends changing flags; $0 \le j \le 15$ ; $i \le j$ (refer to SL=i).                                                                                                                                      |
| SU             | Same as SU=15.                                                                                                                                                                                                                                   |
| SU omitted     | Same as SU=15.                                                                                                                                                                                                                                   |
| V=vsn          | Volume serial number of the cartridge to be used; not valid for OP=RS if D=d, D, XI=x, or YI=y is specified; and not valid for OP=CF if FO=ord, XI=x, or YI=y is specified.                                                                      |
| V omitted      | D=d or D, or XI=x and YI=y must be specified for OP=RS. FO=ord or XI=x and YI=y must be specified for OP=CF.                                                                                                                                     |
| XI=x           | x coordinate of the cubicle where the cartridge to be read resides;<br>$0 \le x \le 57$ and $x \ne 30$ . YI=y must also be specified. D=d, D, or V=vsn<br>must not be specified with OP=RS. FO=ord or V=vsn must not be<br>specified with OP=CF. |
| XI omitted     | D=d, D, or V=vsn must be specified for OP=RS. FO=ord or V=vsn must<br>be specified for OP=CF. XI=x and YI=y must be specified for OP=RC.                                                                                                         |
| YI=y           | y coordinate of the cubicle where the cartidge to be read resides;<br>$0 \le y \le 36$ and y $\ne 18$ . XI=x must also be specified. D=d, D, or V=vsn<br>must not be specified with OP=RS. FO=ord or V=vsn must not be<br>specified with OP=CF.  |
| YI omitted     | D=d, D, or V=vsn must be specified for OP=RS. FO=ord or V=vsn must<br>be specified for OP=CF. XI=x and YI=y must be specified for OP=RC.                                                                                                         |

# **Restrictions to ASDEBUG**

The following restrictions apply to the ASDEBUG utility.

- MSSEXEC must be running when ASDEBUG is run.
- Only one copy of ASDEBUG can be run at one time.
- ASDEBUG, ASVAL, and ASLABEL cannot be run at the same time.

# **MSS OPERATIONAL PROCEDURES**

The operational procedures used in an MSS environment are summarized next. These include modifications to existing procedures and also new MSS procedures, especially in the areas of permanent file backup and reloading and disk space management. Refer to the descriptions of the appropriate utilities for details about these operational procedures.

# INITIALIZATION

MSS processing is initiated when the ASDEF utility is run to create the system files necessary to allow storage of files on MSF. ASDEF creates both a CSU map for each CSU that is to store file data on cartridges and eight MSF catalogs (one for each subfamily) for each family that is to have MSF-resident files. Once these system files have been created, the ASLABEL utility can then be run to allocate portions of the CSU to each subfamily and to initialize cartridges for use by files belonging to these subfamilies. When permanent files are defined, they reside on disk until the ASMOVE utility is run. Depending on the parameters specified, ASMOVE can destage files to MSF and release the disk space assigned to files so that it is available for general use.

#### DISK SPACE MANAGEMENT

The availability of disk space must be managed more frequently in an MSS environment than in a non-MSS environment. This is necessary because MSF-resident files must be staged to disk before a user can access them, and their disk space is not immediately released upon completion of the jobs that attached the files. Consequently, disks are apt to approach a disk full condition unless the ASMOVE utility is used periodically to release disk space.

The ASMOVE utility destages selected files to MSF and, optionally, releases their disk space. It is recommended that the site analyst use ASMOVE as part of a periodic disk space management procedure and also just prior to a full dump to reduce the amount of data dumped to tape. (Refer to Dump Tape Management, under File Dumping, later in this section.)

The E,M display can be used to monitor the tracks on a device or set of devices. When too few tracks (as defined by the installation) are available on the direct access devices for a family or subfamily, the ASMOVE utility with the RD and RT parameters specified should be run. ASMOVE reads the PFC entries for the specified family, selects certain files to reside on MSF, and decides which files should be released from disk.

Files can be destaged to MSF without their disk space being released. This destage-only feature can be used prior to a routine backup dump to create MSF images for files with the BR=MD attribute and thereby eliminate the need to include them on a backup dump tape. (Refer to Dump Tape Management, under File Dumping, later in this section.) Having an MSF image also provides backup for the file in special cases where the permanent file is being updated at the same time PFDUMP is being run.

The destage-only feature can also be used to allow disk space to become available immediately when ASMOVE is run again. That is, ASMOVE can directly release disk space of files that have both disk and MSF images but are to reside on MSF only. However, for files that have no MSF image, there is a delay before the disk space can be released because these files must first be destaged to MSF.

#### **MSF SPACE MANAGEMENT**

The availability of MSF space must be managed because MSF space is not automatically released when a permanent file is purged. This allows you to perform a permanent file recovery to a time prior to the purging of the file. On a typical dump tape, the entry for an MSF-resident file includes the PFC and permit entries, but not the file data. A subsequent reload operation recovers only what was dumped; the PFC and permit information, but not the file data. Thus, MSF space for a purged permanent file cannot be released until you no longer need to recover the file data, because the file data resides on MSF only and typically not on any dump tape.

An MSF-resident file is stored only on the cartridges within the cubicles of CSUs assigned to a subfamily. When destaging a file to MSF, MSSEXEC selects the CSU with the most space available. If no CSU has enough free space to store the file being destaged, MSSEXEC abandons that destage request, issues a message to the dayfile, and continues to destage other files that fit on the available MSF space. To avoid this problem, use the ASVAL utility periodically to release MSF space for purged files, thereby making it available for reuse.

When you want to reuse MSF space currently allocated to files that have been purged, run ASVAL with the RF and RL parameters specified. The RF parameter specifies an RDF, which is an auxiliary file produced by the permanent file utility PFDUMP and which contains versions of the MSF catalogs and PFC entries that were current at the time of the dump. ASVAL examines the RDF to identify unneeded MSF files (those without PFC entries) and their MSF space is released. Choose which RDF to use based on the date and time of the dump that produced it. That is, a particular RDF is used only if there is no need for a permanent file recovery to a time prior to the dump that produced the RDF.

Once an RDF is used by ASVAL to release MSF space, you should discard it and any other RDFs for the same set of devices. These RDFs cannot be used as input to ASVAL in any future run. The MSS software does not permit an RDF to be specified by the RF parameter on an ASVAL call, unless it was produced by PFDUMP after the last ASVAL run that released MSF space was completed. This prevents the inadvertent release of MSF space that was previously released and reassigned to a file.

#### Example 1:

Assume that two PFDUMPs were run a week apart producing two release data files, RDF1 and RDF2. Assume, also, that according to both RDF1 and RDF2, file AFILE is an orphan (it has been purged but still resides on MSF). If the following call to ASVAL is made, the MSF space assigned to AFILE is released and made available for reuse, if no errors were encountered.

#### ASVAL, RF=RDF1, RL.

Now, suppose that a new file, BFILE, which did not exist when RDF1 and RDF2 were produced, is assigned to the MSF space on which AFILE has resided. If ASVAL were to accept either RDF1 or RDF2 on a subsequent ASVAL call, the MSF space allocated to file AFILE (which is now the space where BFILE resides) is released. However, any RDF created after the ASVAL run that purged AFILE would not have an entry for AFILE and, hence, ASVAL would not inadvertently release the MSF space presently allocated to BFILE.

After ASVAL uses a release data file to release MSF space, the corresponding backup tape from PFDUMP is the oldest tape that should be used for the first reel of a future incremental load. The first reel determines which files are to be reloaded according to the CIR on the tape (refer to PFLOAD in section 17, Permanent File Utilities). Use of an older tape as the first reel can allow the PFC entry for a purged file to be restored even though its MSF space may have been reassigned. The MSS software does not prevent loading from the wrong dump tape, but does detect as an error an attempt to stage a file whose data was overwritten (see Example 2).

#### Example 2:

Assume that RDF1 and RDF2 are as in the previous example, and that file CFILE is an orphan according to RDF2, but not according to RDF1. The following ASVAL call releases MSF space allocated to CFILE.

ASVAL, RF=RDF2, RL.

Now assume that the dump tape created by the PFDUMP run that produced RDF1 is used as the first reel of an incremental PFLOAD. Then the PFC and permit entries for file CFILE are reloaded, but, in fact, file CFILE does not exist on MSF. This will be detected as an error when a user attempts to attach CFILE.

## BACKUP AND RECOVERY

Permanent file backup and recovery methods in an MSS environment are similar to those in a non-MSS environment. It is assumed that most sites with disk-resident permanent files have a file backup procedure consisting of a full dump followed by a series of incremental dumps. The assumed reload procedure is to load from tapes starting with the most recent incremental dump tape and continuing through older incremental dump tapes until the most recent full dump tape is processed. These procedures can be modified as follows to accommodate MSF-resident files.

#### File Dumping

The normal backup dump procedure is to dump files based on the modification date field in the PFC entries for the files. New parameters to PFDUMP provide the capability to dump files that have been modified during a certain interval, which is useful in recycling old dump tapes (refer to Dump Tape Management later in this section). For files that reside only on MSF, you can either stage the file to disk and thereby include it in the dump, or suppress staging and include only the file's PFC and permit information on the dump tape. If the device or family being dumped has MSF-resident files, the following procedures should be included with the normal dumping procedures.

# Full Dumps

Full dumps should be performed as usual, but OP=S should be specified on the call to PFDUMP to suppress staging. Thus, all files on disk are dumped but only the PFC and permit entries for MSF files without disk images are included in the dump. It is unnecessary and not feasible to dump the files that reside only on MSF. Specify OP=S and SD on the call to PFDUMP; use the RD=filename parameter at your own discretion.

| Parameter   | Description                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP=S        | Selects no staging. If the SD option was inadvertently used on any previous nonincremental dump, an incremental dump should be taken prior to the full dump.                                                                              |
| SD          | Updates the dump date/time field on each master device dumped to<br>permit files created or modified prior to this dump to be released<br>when ASMOVE is run again. Refer to Release Algorithm, under ASMOVE,<br>earlier in this section. |
| RD=filename | Specifies that PFDUMP is to write a release data file to be used<br>later by ASVAL. RD=filename is included or excluded on a call to<br>PFDUMP depending on how often you want to purge unneeded MSF files.                               |

# Incremental Dumps

Incremental dumps should be performed as usual. No staging should occur because any files that were created or modified since the last dump will still be on disk if a tape backup is required. The following parameters should be specified on the call to PFDUMP.

| Parameter     | Description                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------|
| OP <b>=</b> M | Selects incremental dumps.                                                                        |
| SD            | Updates the date/time field on each master device dumped, as previously described for full dumps. |
| AD=yymmdd     | Selects the date and time just prior to the previous incremental or                               |
| and           | full dump of the device. Hence, all files not included in the last dump are dumped.               |
| AT=hhmmss     |                                                                                                   |

The following parameters should be used with caution.

| Parameter   | Description                                                                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP=S        | Selects no staging. If the SD option was inadvertently used on any<br>recent partial dump, OP=S should not be specified so that any file<br>with a BR=Y attribute that had its disk space inadvertently released<br>will be in the dump. |
| RD=filename | Specifies that PFDUMP is to write a release data file to be used later by ASVAL, as previously described for full dumps.                                                                                                                 |

#### Dump Tape Management

In a non-MSS environment, it is possible to make all previous dump tapes available for use after a full dump is completed. However, in an MSS environment, such dump tape recycling cannot occur because files that have resided only on MSF for some time are probably not included on any recent dump tape. When a low percentage of files on a tape are active files, it is possible to redump any remaining files in order to recycle the tape by running PFDUMP and specifying the OP=M, BD, and BT parameters, but not specifying the OP=S parameter. † This performs a dump of all files that were last dumped before the date and time specified on the PFDUMP call. If necessary, files will be staged in from MSF; after the dump is completed, the disk space for these staged files is released. Thus, files that might not be on any dump tape made after the date specified by the BD parameter are dumped and tapes created before this date can be recycled.

The number of dump tapes created can be reduced by using ASMOVE to reduce the amount of data written on these dump tapes. If ASMOVE is run prior to an incremental dump, files with the BR=MD attribute can be destaged to MSF and excluded from the dump. That is, the incremental dump will exclude the files with a BR=MD attribute that are on both MSF and disk. If ASMOVE is run prior to a full dump, disk space for files that do not have to be on disk can be released and these files are not written on the dump tape. The following procedure involving dumps and ASMOVE runs can be used for efficiency.

- 1. Run ASMOVE to destage files with the BR=MD attribute.
- 2. Take an incremental dump to back up files with the BR=Y attribute.
- 3. Run ASMOVE to release the disk images of files backed up in step 2.
- 4. Take a full dump to reduce the number of dump tapes involved if a reload is required.

#### CSU Map/MSF Catalog Backup

A CSU map is created for each CSU in an MSS environment and is updated by the ASLABEL, ASVAL, and ASDEBUG utilities. (Refer to the definition of CSU map earlier in this section.) It is recommended that the CSU map be copied on tape or on another device or family immediately after every update of the CSU map. If the device containing subfamily 0 of the default family is reloaded, the latest CSU maps should be recovered from the backup copies. After recovering the CSU maps, run the ASVAL utility with the AM and FM parameters specified to ensure that the CSU map and MSF catalog entries match. If they do not, corrective action should be taken as described under Error Conditions and Corrective Actions later in this section. Failure to retain or recover the latest CSU maps can cause problems with future ASLABEL runs (refer to the definition of CSU map earlier in this section).

An MSF catalog is created for each subfamily of a family that can have MSF-resident files and is updated by the ASLABEL, ASMOVE, ASVAL, and ASDEBUG utilities. When PFDUMP copies permanent files to tape for a master device or all devices in a family, it ensures that corresponding MSF catalogs are also dumped. (If MSSEXEC has an MSF catalog attached in modify mode, PFDUMP interfaces with MSSEXEC so that the MSF catalog is included on the dump tape. While PFDUMP is accessing the MSF catalog, any file destage requests for that subfamily are delayed.) Consequently, if PFLOAD is used to reload all files, the MSF catalogs are automatically recovered and entries for all MSF-resident files reflected in recovered PFC entries will exist in the recovered MSF catalog.

<sup>†</sup> It is possible to specify the AD and AT parameters also, thereby dumping files that were dumped during an interval after the date and time specified by AD and AT and before the date and time specified by BD and BT (refer back to the parameters for PFDUMP). This performs a dump of all files last dumped during the interval specified (including MSF-resident files) and allows your site to recycle all dump tapes created during this interval.

If PFLOAD is run after the ASLABEL utility has updated the MSF catalog and CSU map but before the MSF catalog has been backed up, the recovered MSF catalog will not match exactly the corresponding CSU map. In this case, recovery procedures (as described in MSF Catalog/CSU Map Mismatch later in this section) must be taken to bring the CSU map, MSF catalog, and cartridge label information into agreement.

#### **File Reloading**

PFLOAD runs should be made as usual. PFLOAD reads the CIR records from the most recent incremental dump tape to control loading of file data and PFC and permit information. For MSF-resident only files, PFLOAD reloads only the PFC and permit information (if PFDUMP dumped only this information). The following situations involve PFLOAD in an MSS environment.

- If one device needs to be reloaded, the DN or TD parameter specifies the device. The OP=Z and UD parameters should not be specified.
- If PFLOAD is used for other than a device recovery, both OP=Z and UD should be specified. The OP=Z parameter ensures that the PFC entry does not link to an MSF file that may no longer exist, and UD ensures that the file is included in the next incremental or full dump.
- If a file has a nonzero as avalue in its PFC entry (indicating that the file has an MSF image), the ASCVER flag in the PFC entry will be set when the PFC and permit information are reloaded. If the file is successfully staged to disk when it is attached, this flag is cleared. Otherwise, the flag remains set. This can be used to indicate the possibility of an operational error, such as omitting OP=Z when a file or set of files is reloaded from an obsolete dump tape.
- If any unscheduled device reload that includes recovery of an MSF catalog and/or CSU map is made, ASVAL should be run with the AM and FM parameters specified. ASVAL examines the PFC entries for MSF-resident files, the MSF catalog, and the CSU map to detect any error conditions that exist.

#### ERROR CONDITIONS AND CORRECTIVE ACTIONS

It is possible for operational, hardware, or software malfunctions to cause a variety of error conditions to exist or appear to exist in the MSF catalogs, CSU maps, PFC entries, or cartridge labels. The ASVAL utility can analyze the MSF catalogs, CSU maps, and PFC entries to detect these errors, and the ASLABEL utility can identify problems with cartridge labels. The following paragraphs describe some specific error conditions and the actions that should be taken to correct them. Most of the errors are caused either by incorrect operational procedures that result in the recovery of the wrong version of an MSS system file, or by abnormal termination of MSSEXEC or MSS utility processing, which can interrupt the updating of an MSS system file.

#### **Clearing Permanent File Error Flags**

The permanent file error flags that have been set by MSSEXEC in the PFC can be cleared by the CE parameter of the CHANGE command. The job must be of system origin.

#### **Permanent File Recovery**

If a permanent file cannot be accessed or is included by ASVAL on the validation report, try the following procedures to recover a copy of the file:

- 1. Attach the file. If the file has a disk image or can be staged in from MSF, the file data will be available on disk and can be copied to another file. ASVAL should then be run as described in step 2.
- 2. If the file cannot be attached, reload the file from a dump tape. To identify the PFDUMP run that saved a backup copy of the file, check the output from ASVAL or PFCAT, which includes date and time fields from the PFC entry for the file. Depending on the BR attribute (backup requirement) of the file, a backup copy on a dump tape may not exist.

If the file can be reloaded to disk, ASVAL should be run as follows:

ASVAL, FM=familyname, SB=subfamily, FX=n, AM.

familyname and subfamily identify the family and subfamily of the recovered file and n is sufficiently large that the fixing/flagging will be done. ASVAL sets the obsolete flag in the PFC entry because the file now has a disk image; thus the file is disassociated from the error condition. The error condition may still exist in the MSF catalog or CSU map, but you can analyze and then correct the error by using the ASDEBUG utility. Before using ASDEBUG to correct the error, you should take an incremental dump so the old PFC entry with an asa value pointing to a problem MSF-resident file will not be reloaded if a device reload occurs before the next scheduled backup dump.

- 3. If steps 1 and 2 fail, try to regenerate the file. Depending on the particular problem and status of the cartridges to which the file was destaged, the OP=RF or OP=RS directive to ASDEBUG might recover the file data.
- 4. If the file cannot be recovered, purge it so there is no PFC entry pointing to a problem MSF-resident file.

#### Cartridge Restoration and Reuse

If a cartridge is unexpectedly found anywhere outside its assigned cubicle, follow these steps to restore the cartridge so it can be used again:

- 1. Put the cartridge in the input drawer of the CSU to which it is assumed to belong, and run ASLABEL with the OP=RS directive. If the cartridge label information agrees with the CSU map entry for the cubicle with the coordinates (x,y) written on the cartridge label, the cartridge will be restored to that cubicle and the MSF catalog entry for the cartridge is updated to clear the lost flag. Otherwise, the cartridge is put in the output drawer and the cartridge label information is included in the output from ASLABEL.
- 2. If the cartridge was not restored to its CSU cubicle, examine the label information reported by ASLABEL. If the cartridge is assigned to a different CSU, repeat step 1 using the correct CSU. If the family name is blank, the cartridge has a scratch label and can be assigned normally with the OP=AM directive to ASLABEL.

- 3. If steps 1 and 2 fail, examine the CSU map entry for the cubicle with the coordinates (x,y) written on the cartridge label to see how the cubicle is assigned. Examine the cartridge, if any, in this cubicle. Also, it might be useful to run ASVAL to ensure the CSU map and MSF catalog entries for the cartridge match or to identify affected permanent files, if any, if they do not match.
- 4. If step 3 does not produce any useful information and the cartridge cannot be restored, use the OP=FX directive to ASLABEL to rewrite the cartridge label and thereby make a scratch cartridge. It might be useful to first run ASDEBUG with the OP=RS directive to preserve the data on the cartridge.

#### **Removal of Faulty or Missing Cartridges**

The following steps should be taken to remove a cartridge that has unrecoverable errors, or to release the CSU map entry for a cartridge that is missing.

For unallocated cartridges:

- 1. Attempt to remove the cartridge with the ASLABEL OP=RM directive.
- 2. If CARTRIDGE NOT FOUND is reported, repeat step 1 specifying the LT parameter.
- 3. If CARTRIDGE NOT EMPTY is reported, at least one AU on the cartridge is still allocated.

#### For allocated cartridges:

- 1. Use the ASLABEL OP=IB directive to inhibit further allocation of the cartridge.
- 2. Run ASVAL specifying the AM parameter. Examine the report for possible discrepancies between the CSU map, MSF catalog, and PFC entries related to this cartridge.
- 3. If no MSF catalog entry corresponds to the CSU map entry, use the OP=RC directive to ASDEBUG to remove the map entry.
- 4. If no discrepancy is reported by ASVAL, the affected files should be attached in write mode (if possible), reloaded using PFLOAD with the OP=Z parameter, or purged. Then ASVAL release processing should be done to release the MSF space on the cartridge, and the cartridge can be removed with the ASLABEL OP=RM directive.

#### MSF Catalog/CSU Map/PFC Problems

If error conditions exist in the MSF catalogs or CSU maps, the recovery procedure is to correct the appropriate entry rather than reload the entire file. Reloading other than the latest copy of the CSU map is not feasible because it can contain entries for several families and these entries would not be up to date. Reloading an old copy of the MSF catalog is not desirable because any permanent file that was destaged and released from disk since the last incremental dump will be lost. The following paragraphs describe corrective action for specific problems with MSF catalogs, CSU maps, or PFC entries.

#### MSF Catalog/CSU Map Mismatch

The following examples of MSF catalog/CSU map mismatches can appear as error type 1 or 2 on the ASVAL output report, which identifies the mismatch and the permanent files or orphans affected. Before taking any corrective action, the analyst should ensure that operational errors did not result in loading the wrong version of the CSU map or MSF catalog.

- If a cartridge has an MSF catalog entry indicating that all AUs on the cartridge are available for allocation but is not identified in any CSU map entry (type l mismatch), use the OP=RL directive to ASDEBUG to remove the MSF catalog entry for the cartridge.
- If a cartridge is identified in a CSU map entry but has no MSF catalog entry (type 2 mismatch), use the OP=RC directive to ASDEBUG to update the CSU map entry to unassigned and empty status. This directive will write a scratch label for the . cartridge, if any, and place the cartridge in the output drawer.
- If a cartridge has an MSF catalog entry indicating that at least one AU on the cartridge is allocated, recover the disk space for the affected permanent file, if any, or purge the file. Run ASVAL to purge unneeded MSF files and thereby make the cartridge unallocated. Use the OP=RL directive to ASDEBUG to remove the MSF catalog entry for the cartridge.

# NOTE

It sometimes takes two ASVAL/ASDEBUG runs to completely clear up type 1 or type 2 errors. Therefore, it is recommended that ASVAL be rerun with the AM parameter after an ASDEBUG run using OP=RC or OP=RL.

#### MSF Catalog Chain Problems

AUs that are allocated to an MSF-resident file are chained together in the MSF catalog to identify the sequence of AUs that contain the file. (Refer to the definition of cartridge earlier in this section.) For most files, the AUs in the chain reside on the same cartridge. Hence, one disk access is sufficient to update information for the entire chain at one time. However, an MSF-resident file can reside on several cartridges, and several disk accesses may be necessary to update its chain. If MSSEXEC is interrupted during such an update, the resultant chain will be incomplete. ASVAL identifies incomplete chains as error type 4, 5, or 6 on the validation report. The following are types of incomplete chains.

- If an incomplete chain is produced while an MSF-resident file is being purged, it is a chain fragment (one without an HOC entry).
- If an incomplete chain is produced while a file is being destaged to MSF, it is an ill-formed chain (one without an EOC entry).
- If an ill-formed chain is not corrected, the AU that should have been linked to it may be reused and become part of a good chain. Although the ill-formed chain may appear to be complete, the ill-formed chain and the good chain are intersecting.

The corrective action procedure for any of these bad chain conditions follows.

- 1. Run ASVAL with the FM parameter specified and use a sufficiently large FX=n value so that ASVAL updates the MSF catalog entries affected by the problem chains.
- Recover the permanent files, if any, that have MSF images potentially affected by these error conditions. (The ASVAL report identifies these files.) Use the procedure described under Permanent File Recovery earlier in this section.
- 3. Take an incremental or full backup dump. This prevents PFC entries with inaccurate as avalues or problem MSF chains from being recovered if a device reload is necessary.
- 4. Run ASDEBUG with the OP=RP directive to make each AU on the problem chain available for allocation. Thus, the AUs can be included in a new chain without any problems. In the case of intersecting chains, all chains that have an AU in common with another chain should be released before any further destage attempts; otherwise, errors will occur when a user tries to attach a file that is contained on an intersecting chain.

#### PFC/MSF Catalog Mismatch

It is possible that an old version of an MSF catalog can be reloaded because of incorrect operational procedures. If so, the asa value in the PFC entry for a file can be invalid according to the obsolete MSF catalog or can point to a problem chain. If the correct version of the MSF catalog is available on tape, it should be reloaded. If it is not available, the following action is appropriate. If the file also has a disk image, ASVAL should be run to clear the asa field in the PFC entry. If there is no disk image, the analyst should reload the file from tape, if possible, and then run ASVAL to clear the asa value.

#### PSEUDORELEASE

The pseudorelease capability allows the site analyst to experiment with MSS operational procedures in order to determine which procedures should be used normally, and to become adept at recognizing error conditions and performing appropriate recovery procedures. While employing the pseudorelease feature, the analyst runs no risk of losing any permanent files used in this checkout phase, as explained in the following paragraphs.

Pseudorelease mode is initiated by an ASMOVE run with TM=Y specified. ASMOVE selects files to be destaged and/or released from disk by using the destage and release algorithms as usual. The destage to MSF process is the same whether or not pseudorelease mode is in effect (refer to the description of ASMOVE earlier in this section for details on destaging). However, the procedures for disk space release vary depending on whether or not pseudorelease mode is enabled. Disk space is not actually released in pseudorelease mode. Rather, the AFPDR flag is set in the PFC entry for a file that has been selected for disk space release. This flag indicates that PFM should ignore the disk image for this file. Therefore, if the user attaches such a file, the disk image is ignored and the file is staged to disk from MSF. The normal staging process is followed except that the disk image is created on a scratch device instead of a permanent file device. Thus, in actuality, two disk images of the file exist. However, once the file is staged to disk, whether or not staging errors are detected and reported by MSSEXEC, the AFPDR flag is cleared so that the user accesses the original disk image. Also, the file staged to the scratch disk is released so the scratch space is available for reuse. If MSS processing becomes disabled, the original disk image can still be accessed using an ATTACH request.

There are two methods for terminating pseudorelease mode. One is to perform a full dump followed by a reload with OP=Z specified on the PFLOAD call. This clears the asa field in the PFC entry for each file, thereby indicating that no MSF images exist and that the files reside on disk only. The other method is to run ASMOVE with TM=N specified. This causes the disk images for pseudoreleased files to be really released from disk, thereby leaving the file with only the MSF image.

You can use the following examples after pseudorelease mode is enabled to force different error conditions to occur. You can implement these incorrect operational procedures and then perform error recovery action without endangering any of the permanent files involved. These examples assume that ASDEF has been run to create a CSU map and the MSF catalogs for the CSU and family being tested.

#### Example 1:

- 1. Run ASLABEL to add cartridges (for example, A, B, C) to a subfamily.
- 2. Dump the CSU map file to tape.
- 3. Run ASLABEL to remove cartridge A and add another cartridge (for example, D).
- 4. Reload the CSU map file dumped in step 2. This creates a mismatch between the CSU map and MSF catalog, because the MSF catalog indicates that cartridge D resides in the CSU but cartridge A does not.
- 5. Run ASVAL to detect the mismatch.
- 6. Run ASDEBUG to correct the mismatch. The resultant CSU map and MSF catalog should contain entries for cartridges B and C, but not A or D.

#### Example 2:

- 1. Run ASLABEL to add several cartridges to a subfamily.
- 2. Create some permanent files with different backup requirements and preferred residence requirements.
- 3. Run ASMOVE to destage and/or release the files created in step 2.
- 4. Physically remove one of the cartridges from the CSU; do not use ASLABEL to remove it.
- 5. Attach the files whose disk space was released in step 3.
- 6. Run ASVAL to verify that only files resident on the removed cartridge are affected.
- 7. Run ASLABEL to restore the cartridge removed in step 4.
- 8. Attach the files reported in step 6. There should be no problems reported.

Example 3:

- 1. Run ASLABEL to add several cartridges to a subfamily. Make a backup copy of the CSU map and MSF catalog files.
- 2. Create several files with the BR=Y or BR=MD attribute. Run ASMOVE to destage all of them and release those with the BR=MD requirement.
- 3. Take a backup dump of the family.
- 4. Reload the CSU map and MSF catalog backed up in step 1.
- 5. Create several new files with the BR=MD attribute. Run ASMOVE to destage them and to release the disk space of the files with the BR=Y attribute in step 2.
- Attach the files created in step 2. They should have been overwritten by the files destaged in step 5.
- 7. Recover the files with the BR=Y attribute from the dump tape made in step 3.

## Example 4:

Try to interrupt MSSEXEC while it is destaging new files or releasing unused MSF files to create incomplete chains. ASVAL reports such errors and ASDEBUG fixes them.

# INTRODUCTION

Multimainframe operation provides mechanisms by which more than one computer can share mass storage devices. Each mainframe in a multimainframe configuration has access to the shared mass storage devices and their preserved files. Preserved files are those files that are retained across a level 0 deadstart (nonsystem recovery). Types of preserved files are permanent files, queued files, and system dayfiles.

There are two types of multimainframe configurations: linked shared device multimainframe (SDM), and independent SDM. The main difference between the two SDM configurations is their method of maintaining the critical device tables necessary to control shared mass storage and intermainframe communications. Linked SDM configurations maintain the critical device tables in extended memory, while independent SDM configurations maintain the tables on each shared mass storage device. Because the independent SDM configurations maintain the tables on the shared devices, it causes some performance degradation.

Each mainframe in a multimainframe configuration can operate in multimainframe mode or in standalone mode; however, two machines may not access the same device unless both are in multimainframe mode. A device is considered shared if it can be accessed by more than one of the mainframes; it need not be accessible to all mainframes in the complex.

The fact that a computer is operating as part of a multimainframe complex is not apparent to the user, except for some degrading of performance for the independent SDM. However, there are operational changes and additions that the operator should note. These include deadstart commands, displays, online commands necessary in the event of an interruption on one of the sharing mainframes, and the UNLOAD/MOUNT process for removable devices.

Recovery allows a machine to either join other machines operational in a multimainframe complex or to operate in a standalone mode. The standalone system is not allowed to use the same mass storage devices as other machines. In the event of a system interruption to one machine, it is possible to operate the remaining machines in a multimainframe environment.

Automatic detection of extended memory is not provided, because it is not possible to determine its absence and continue to run on all machine types. For example, a 6600 will hang if an attempt is made to execute an extended memory instruction without extended memory. Extended memory status is checked during deadstart when processing an extended memory entry in the EQPDECK.

Except where explicitly specified that controllers and/or equipment can be shared between mainframes, assume they cannot be shared. For example, NOS does not support sharing a two-channel tape controller between mainframes; nor does it support sharing mass storage controllers except as specified in this section.

13

# LINKED SDM OPERATION

In a linked SDM complex, up to four computers can access mass storage devices. Any combination of 1 to 4 model 71, 72, 73, 74, 171, 172, 173, 174, 175, 720, 730, 740, 750, 760, 865, 875 mainframes or 6000 Computer Systems mainframes can be used. Each mainframe requires one CPU port connected to extended memory. The presence of a DDP on a CPU port decreases by one the total number of mainframes that can run together. Shared mass storage devices supported are: 844 (single and double density), 885-11/12, and extended memory.

Extended memory is the means for controlling shared mass storage and intermainframe communications. Each mainframe has a CPU port into extended memory through which system activity is controlled. In order to control shared mass storage devices, several extended memory resident tables are required. The device access table (DAT) contains the logical description (family name/pack name and device number) of each mass storage device (shared or nonshared) that is accessible by any machine in the linked SDM complex. For each device in the DAT that is to be accessed by more than one machine, a corresponding MST (image of central memory resident MST) and TRT also reside in extended memory. In addition, a machine recovery table (MRT) exists in extended memory for each machine and device (that is, there are as many MRTs for each shared device as there are mainframes in the complex).

If MSS is used, one mainframe in the linked SDM complex is physically connected to MSF and is called the master mainframe; all other mainframes in the complex can access MSF files and are called slave mainframes. MSSEXEC runs on the master mainframe and is the main processing program that controls MSS activity. MSSSLV runs on each slave mainframe and communicates with MSSEXEC to retrieve files from MSF in response to ATTACH requests by jobs running on the slave mainframes.

If MSAS is used, one mainframe in the linked SDM complex is physically connected to 7990 and is called the master mainframe; all other mainframes in the complex can access 7990 files and are called slave mainframes. SSEXEC runs on the master mainframe and is the main processing program that controls MSAS activity. SSSLV runs on each slave mainframe and communicates with SSEXEC to retrieve files from 7990 in response to ATTACH requests by jobs running on the slave mainframes.

#### DEADSTART

A linked SDM environment is defined at deadstart by CMRDECK and EQPDECK entries in each machine. Use the following entries to do this.

#### CMRDECK Entry

#### Description

MID=id.

The 2-character machine identification. This identification is used to associate a specific machine with its access to a shared device. It is required, however, even if no devices are shared during system operation. This id must be unique for each machine in the complex. If id is omitted, the default value is MID=AA.

#### EQPDECK Entry

#### Description

 $SHARE=est_1, est_2, \dots, est_n$ . est\_i are the EST ordinals of the mass storage devices that will be shared with other machines in the linked SDM complex. The MST/TRT for each device resides in extended memory.

PRESET, n.

You can specify this entry only at the system console. n is the total number of devices to be shared by all mainframes in the complex. You must specify the PRESET entry on a level 0 deadstart on the first machine to be deadstarted in the linked SDM complex. This entry initializes the flag register and extended memory resident tables. If n is omitted, the default value is the number of shared devices defined for the particular machine.

These entries are also described in section 3, Deadstart Decks.

Because in a linked SDM complex two or more machines can utilize the same mass storage devices, the device assignments and EQPDECKs of all machines are interrelated. Care must be taken to ensure proper EQPDECK settings for each machine to obtain the desired device configuration. The following items are important in obtaining this proper device configuration.

- Each machine must specify a unique machine identification (using the MID entry in the CMRDECK). This identification associates a particular machine with its files on a shared device. There are no external characteristics associated with this identification. However, if the machine identification specified on a machine deadstarting into a multimainframe complex is identical to a machine identification on a machine already operating, the deadstart process halts and an appropriate message is displayed.
- The assignment of shared mass storage devices should be made properly to ensure the recoverability of the device and the proper operation of the system (refer to Shared Mass Storage later in this section).
- If SHARE EQPDECK entries are present, an extended memory entry (DE or DP equipment type) must also be present in the EQPDECK. If none is found, an error message is given to the operator indicating that no link device has been defined.

- The first machine deadstarted (level 0 only) must specify the PRESET EQPDECK entry. This command causes tables to be preset in extended memory, and in so doing, assures that no other machine has arrived at the same point in the deadstart sequence and is attempting the same thing. These other machines should not have the PRESET entry specified during deadstart. All other machines that arrive at that point in the deadstart process display a message indicating that they are waiting for deadstart on the preset machine. A machine that does not preset extended memory has no means of detecting whether extended memory has been preset previously by another machine. Therefore, the operator must ensure that extended memory has been preset by a prior deadstart before deadstarting another machine that is to be in the multimainframe complex.
- If extended memory is initially placed in maintenance mode (half of extended memory used for online diagnostics), the first machine deadstarted in a complex must have the INITIALIZE and PRESET EQPDECK entries specified when deadstarting (level 0 only). The remaining machines must have the extended memory size correspondingly reduced in their EQPDECKs.

When a mainframe joins a linked SDM complex, it is associated with an identification that it utilizes during system operation but which is independent of the machine identification. This association is done during deadstart, when the machine investigates the multimainframe tables residing on the link device and places its machine identification in an empty slot of the four that are available. Associated with each slot is a unique machine index and a unique machine mask, which the machine uses either to index itself into various MMF tables or to identify itself in these tables. The indices are 1, 2, 3, and 4. The masks are 1, 2, 4, and 8.

When performing a level 0 recovery deadstart on one of the machines, the MREC utility should be run on some or all of the remaining machines before the deadstart proceeds. The purpose of this utility is to clear interlocks held by the machine to be deadstarted that have not been cleared by CPUMTR. It can also recover mass storage space on a shared device that is currently not accessible because of a machine interruption (necessitating a level 0 deadstart). MREC may have to be run from more than one machine since it affects only shared devices (that is, devices specified on the SHARE EQPDECK entry) of the machine on which MREC is run. If the interrupted machine shares different devices with different machines, MREC must be run from enough machines to account for all devices shared with the interrupted machine. The interface to the MREC utility is described in section 8, K-Display Utilities.

If a level 3 recovery deadstart will be performed, extended memory must be intact as well as CMR. For a level 1 or 2 recovery in a linked SDM environment, extended memory must be intact.

Figure 13-1 illustrates the steps generally needed to deadstart a machine in a multimainframe complex.

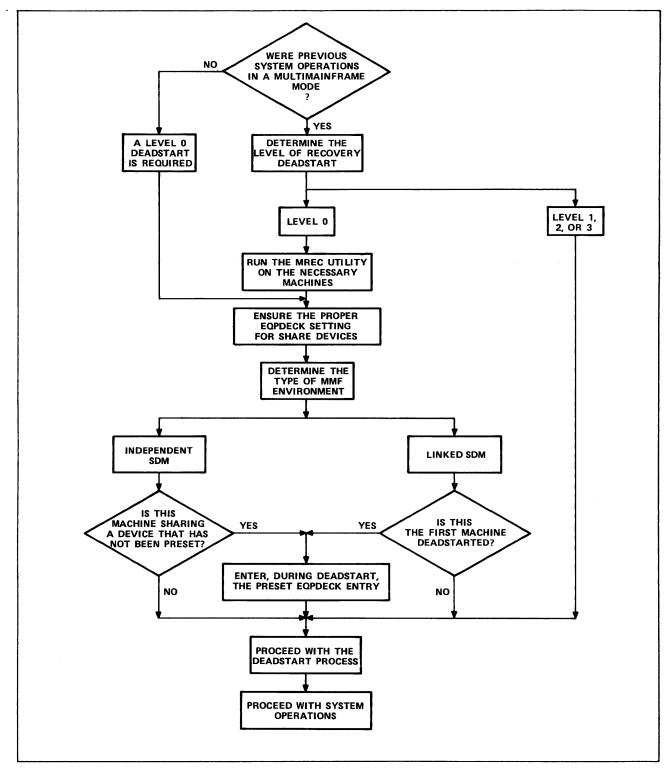

Figure 13-1. Deadstarting a Machine in a Multimainframe Complex

#### SHARED MASS STORAGE

A major reason for operating a multimainframe complex is to be able to share mass storage devices between machines. Thus, the users of two systems may be able to utilize the same files if these files reside on a shared mass storage device. Having the ability to share files between systems also means that several additional procedures are required when operating a multimainframe complex. Additional consideration must also be given when configuring mass storage devices. This material, which is unique to multimainframe operation, is discussed in the following paragraphs.

#### **CONFIGURING SHARED MASS STORAGE DEVICES**

Some consideration should be given as to which devices should be made shared devices and which ones should not. Since a shared device contains preserved files that can be accessed by more than one machine, it must be physically connected to and logically defined (as shared) by each machine sharing the device. If one device of a family is defined as shared, then normally all devices in the family should be defined as shared for accessibility. If a removable device will be treated as shared, it must be defined as removable in each machine sharing it. If a shared device is not removable, additional use of the device (beyond preserved files) is defined by each machine, independently of any other machine definition (that is, each machine specifies whether the device is to contain such things as a copy of the system or temporary files).

There is no real advantage to having nonpreserved files on a shared device, unless spreading them across shared devices outweighs having them on a dedicated device. A key factor is drive and controller contention. Another factor is whether or not enough drives and accesses to those drives are available to warrant spreading temporary files across several devices from all systems. Also, additional overhead is incurred by the system for each shared device. This includes additional CMR space for each device (100<sub>8</sub> CM words) and additional time that is required to maintain the device-related tables (such as the MST or the TRT) on the link device. These factors must be weighed to determine how best to configure shared devices.

#### **DEVICE ACCESS TABLES**

In a linked SDM complex, mainframes use DATs to determine device usage. The DATs identify the status of all shared and nonshared devices for the mainframes in the complex. One DAT for each machine resides in extended memory.

In order to minimize configuration problems, shared removable equipment should be configured the same way on all machines in the complex. For example, if one system defines three shared units as three single-unit devices and another system defines the same units as one three-unit device, the first system can accommodate a two-unit device on these units, whereas the second system would consider it an error. Unless the configurations are the same on all machines, any devices mounted on those drives may not necessarily be recoverable on all machines.

# NOTE

RESEX considers only the configuration of the machine on which it is executing in its overcommitment algorithm.

# MASS STORAGE RECOVERY TABLES

One problem that is created by having more than one machine sharing a mass storage device is that of recovering the mass storage space and interlocks of a machine, if it requires recovery processing. This problem is solved by defining a table that provides the information needed to recover the mass storage space of a machine and by having a machine recovery utility that performs the recovery. The table is called the mass storage recovery table (MRT). There is one MRT for each mainframe per device. It tells which tracks are interlocked and which tracks are first tracks of files local to a particular machine. The MRT is utilized by CPUMTR on another machine to clear track interlocks and by the MREC utility on another machine to recover the mass storage space of the interrupted machine. For specific information on the MRT, refer to the NOS 2 Systems Programmer's Instant.

#### **DEVICE INITIALIZATION**

To initialize a mass storage device, it is necessary first to prevent any new activity from starting up on the device, then to wait until all current activity has completed, and finally to interlock the device and proceed with initialization. To accomplish this on shared mass storage devices in a linked SDM environment, follow these steps:

- 1. Enter the DSD UNLOAD command. All machines sharing the device must unload it to prevent any new activity. (This command can be used for both removable and nonremovable shared devices.)
- 2. Enter the DSD INITIALIZE command on the machine from which the initialization is to take place. If you enter the INITIALIZE command from another machine, an error message is displayed. Refer to the NOS 2 Operations Handbook for error messages.
- 3. The machine from which the INITIALIZE command was entered monitors the status of the other machines that are sharing the device. Once they have unloaded the device and user activity has ceased, the device tables are updated and the device is checkpointed.
- 4. To activate the device on the other machines, enter the DSD MOUNT command from each machine. This command clears the UNLOAD status. If initialization is still in progress on another machine when you enter a MOUNT command, the MOUNT process is terminated with an error. Refer to the NOS 2 Operations Handbook for error messages.

#### **DEVICE UNLOAD**

In a linked SDM environment, unloading a device involves more than it does under a onemachine system. A device can be unloaded from a machine (referred to as a local unload), or it can be unloaded from the entire multimainframe complex (referred to as a global unload). A device can be physically removed from the complex only after a global unload has been accomplished. This is the general procedure to complete a global unload:

- 1. Enter the UNLOAD command from each machine. This is an indication to the machine that no new accesses should be initiated. You must enter this command from each machine sharing the device.
- 2. When all local unloads are set and user access has ceased, global unload status is set if the device is a removable device. This global unload status is displayed on all machines, indicating that there is no activity on the device from any machine and that the device may be physically unloaded.
- 3. You can then switch packs and enter the MOUNT command at the console to initiate recovery of the device. The MOUNT command clears the global unload status and the local unload status on the machine from which it was entered and indicates that this machine is now accessing the device. All other machines continue to ignore the device until you enter the MOUNT command on each machine. The MOUNT command does nothing if local unload status is not set on the machine.

# **DEVICE RECOVERY**

Deadstart and online recovery methods are similar in logic for recovering mass storage devices.

When a device is recovered in a linked SDM complex, the DAT in extended memory is interlocked while a check is made to see if an entry exists for this device. The presence of an entry indicates that another machine is also accessing the device. If an entry is found and the machine recovering the device has not been instructed to share it, an error is indicated and recovery halts with an appropriate message displayed. If the machine already accessing the device is not allowing it to be shared, the same error condition occurs. Therefore, if a device is being accessed, another machine can recover that device only if the recovering machine and the accessing machine use the device in a multimainframe mode.

NOTE

If two devices recovered on separate machines have the same family name/device number or pack name, there is no method of determining whether or not they are the same device if both are shared. If they are different devices, they are both destroyed when used.

#### **DEVICE CHECKPOINT**

Local MST information for each machine that shares a mass storage device is maintained on the device. MST information for other machines may also be present on the device. The information for each machine is kept in one sector on the label track following the TRT sectors. Entries for up to 31 unique machine identifiers can exist.

During checkpoint, only the local MST information of the machine performing the checkpoint is updated. Since local MST information for many machines is kept on the device, updating of all these areas by one machine could cause a loss of information needed if the device were to be used with another system.

For shared devices in a linked SDM complex, duplication of checkpointing by more than one machine is prevented. If a machine attempts to checkpoint a shared device and determines that a second machine is performing the checkpoint (a checkpoint request bit is set in the local MST area of the second machine), no action is taken. Only one checkpoint bit is set at any given time for a device.

#### **MSS PROCESSING**

Unlike most other mass storage devices, the MSF is not shared by mainframes. Rather, MSF is physically connected to and driven by one mainframe called the master mainframe. All other mainframes that share permanent files with the master mainframe are called slave mainframes. The disks to which MSF-resident files are staged must be shared devices and accessible by all mainframes.

MSSEXEC runs on the master mainframe and is the main program that controls MSS processing activities. You can activate MSSEXEC by entering the following DSD commands at the system console.

L.SUBSYST. ENABLE,MASTER MSS. L.END. MSSffff.

MSSSLV runs on each slave mainframe and is the program that supports file retrieval from MSF for jobs running on a slave mainframe. You can activate MSSSLV by entering the following DSD commands at the system console.

L.SUBSYST. DISABLE,MASTER MSS. L.END. MSSffff.

When a job running on a slave mainframe attaches an MSF-resident file that has no disk image, MSSSLV is requested to stage the file to disk. However, MSSSLV cannot access MSF directly. MSSSLV must communicate with MSSEXEC, which stages the file to shared disk and then notifies MSSSLV when the file is available. MSSSLV then causes the requesting job to be resumed so that the file ATTACH can complete.

The permanent files used for communication between MSSEXEC and MSSSLV are initialized and recovered automatically and require no backup or recovery processing. The name of the permanent file used by MSSSLV running on mainframe i (i=1, 2, 3, 4) to send requests to MSSEXEC is STOMNOI. The name of the permanent file used by MSSEXEC to respond to all requests by all MSSSLVs is MTOSPFN. These files belong to the family that contains extended memory and are saved under the user index  $377760_8$ .

## **MSAS PROCESSING**

Unlike most other mass storage devices, the 7990 is not shared by mainframes. Rather, 7990 is physically connected to and driven by one mainframe called the master mainframe. All other mainframes that share permanent files with the master mainframe are called slave mainframes. The disks to which 7990-resident files are staged must be shared devices and accessible by all mainframes.

SSEXEC runs on the master mainframe and is the main program that controls MSAS processing activities. You can activate SSEXEC by entering the following DSD commands at the system console.

L.SUBSYST. ENABLE,MASTER MAS. L.END. MASffff.

SSSLV runs on each slave mainframe and is the program that supports file retrieval from a 7990 for jobs running on a slave mainframe. You can activate SSSLV by entering the following DSD commands at the system console.

L.SUBSYST. DISABLE,MASTER MAS. L.END. MASffff.

When a job running on a slave mainframe attaches a 7990-resident file that has no disk image, SSSLV is requested to stage the file to disk. However, SSSLV cannot access 7990 directly. SSSLV must communicate with SSEXEC, which stages the file to a shared disk and then notifies SSSLV when the file is available. SSSLV then causes the requesting job to be resumed so that the file ATTACH can complete.

The permanent files used for communication between SSEXEC and SSSLV are initialized and recovered automatically and require no backup or recovery processing. The name of the permanent file used by SSSLV running on mainframe i (i=1, 2, 3, 4) to send requests to SSEXEC is STBMNOi. The name of the permanent file used by SSEXEC to respond to all requests by all SSSLVs is MTBSPFN. These files belong to the family that contains extended memory and are saved under the user index  $377760_8$ .

# INDEPENDENT SDM OPERATION

In an independent SDM complex, up to 16 computers can access shared mass storage devices. Any combination of from 1 to 16 model 71, 72, 73, 74, 171, 172, 173, 174, 175, 176, 720, 730, 740, 750, 760, 865, 875, CYBER 180-class machines, or 6000 Computer Systems mainframes can be used. Shared mass storage devices supported are 844 (single and double density) and 885-11/12 (single and double density).

Each shared device contains in its label track all of the tables necessary to control multimainframe access. These tables include the MST, TRT, device index table (DIT), and MRT for each mainframe sharing the device. Whenever a mainframe needs to access a shared device, it is necessary for the mainframe to ensure its copies of these tables are up-to-date.

One or more of the mainframes can have extended memory, but each mainframe's extended memory must be used as a nonshared device.

If MSS or MSAS is used, one mainframe in the independent SDM complex is physically connected to MSF or 7990 and only that mainframe can assess it.

## DEADSTART

MID=id.

An independent SDM environment is defined at deadstart by CMRDECK and EQPDECK entries in each machine. Use the following entries to do this.

#### CMRDECK Entry

\_\_\_\_\_

Description

The 2-character machine identification. This identification is used to associate a specific machine with its access to a shared device. It is required, however, even if no devices are shared during system operation. This id must be unique for each machine in the complex. If id is omitted, the default value is MID=AA.

EQPDECK Entry

## Description

ISHARE=est1,est2,...,estn. esti are the EST ordinals of the mass storage devices that will be independently shared with other machines in the multimainframe complex. The ISHARE entry must precede the PRESET entry. The MST/TRT resides on each shared device.

PRESET=est1,est2,...,estn.
You can specify this entry only at the system console.
esti is the EST ordinal of the shared mass storage
device to be preset. Several machines at level 0
deadstart may need the PRESET entry. The PRESET entry is
specified only on a level 0 deadstart by the first machine
accessing the device and must follow the ISHARE entry.
PRESET initializes the tables residing on the label track
of the shared devices.

These entries are also described in section 3, Deadstart Decks.

Since in an independent SDM complex two or more machines can utilize the same mass storage devices, the device assignments and EQPDECKs of all machines are interrelated. Care must be taken to ensure proper EQPDECK settings for each machine to obtain the desired device configuration. The following items are important in obtaining this proper device configuration.

- Each machine must specify a unique machine identification (using the MID entry in the CMRDECK). This identification associates a particular machine with its files on a shared device. There are no external characteristics associated with this identification. However, if the machine identification specified on a machine deadstarting into a multimainframe complex is identical to a machine identification on a machine already operating, the deadstart process halts and an appropriate message is displayed.
- The assignment of shared mass storage devices should be made properly to ensure the recoverability of the device and the proper operation of the system (refer to Shared Mass Storage, next).
- Each machine must specify the ISHARE=est EQPDECK entry to inform the system that devices will be shared in the independent shared device mode.
- On a level 0 deadstart, any shared device that has not been shared prior to this deadstart must include the PRESET entry in its definition.

- On a level 0 deadstart, if a device was previously shared by the deadstarting machine, the MRT and DIT device resident tables must be zeroed out.
  - If the machines that share the device are not currently running, the device must be preset or initialized to zero out the tables.
  - If any machine that shares the device is running, the machine recovery utility (MREC) must be run from a running machine to remove the machine identification of any machines that are not currently running and to clear all interlocks held by these machines.
- On a level 0 deadstart, if a device was previously shared by a machine other than the deadstarting machine, the MRT and DIT device resident tables may or may not have to be zeroed out.
  - If another machine that is sharing the device is running, the device must not be preset.
  - If no machines that will be sharing the device are running and one or more of them will be deadstarted at a level 1, 2, or 3, the device must not be preset.
  - If all machines that will be sharing the device are not currently running and all will be deadstarted at level 0, the device can be preset or initialized.

When performing a level 0 recovery deadstart on one of the machines, the MREC utility should be run on some or all of the remaining machines before the deadstart proceeds. The purpose of this utility is to clear interlocks held by the machine to be deadstarted that have not been cleared by CPUMTR. It can also recover mass storage space on a shared device that is currently not accessible because of a machine interruption (necessitating a level 0 deadstart). MREC may have to be run from more than one machine since it affects only shared devices (that is, devices specified on the ISHARE EQPDECK entry) of the machine on which MREC is run. If the interrupted machine shares different devices with different machines, MREC must be run from enough machines to account for all devices shared with the interrupted machine. The interface to the MREC utility is described in section 8, K-Display Utilities.

In an independent SDM complex, as in a standalone system, critical tables that reside on the device must be intact for a level 1, 2, or 3 deadstart recovery.

Figure 13-1 illustrates the steps generally needed to deadstart a machine in a multimainframe complex.

#### SHARED MASS STORAGE

A major reason for operating a multimainframe complex is to be able to share mass storage devices between machines. Thus, the users of two systems may be able to utilize the same files if these files reside on a shared mass storage device. Having the ability to share files between systems also means that several additional procedures are required when operating a multimainframe complex. Additional consideration must also be given when configuring mass storage devices. This material, which is unique to multimainframe operation, is discussed next.

#### CONFIGURING SHARED MASS STORAGE DEVICES

Some consideration should be given as to which devices should be made shared devices and which ones should not. Since a shared device contains preserved files that can be accessed by more than one machine, it must be physically connected to and logically defined (as shared) by each machine sharing the device. If one device of a family is defined as shared, then normally all devices in the family should be defined as shared for accessibility. If a removable device will be treated as shared, it must be defined as removable in each machine sharing it. If a shared device is not removable, additional use of the device (beyond preserved files) is defined by each machine, independently of any other machine definition (that is, each machine specifies whether the device is to contain such things as a copy of the system or temporary files).

There is no real advantage to having nonpreserved files on a shared device, unless spreading them across shared devices outweighs having them on a dedicated device. A key factor is drive and controller contention. Another factor is whether or not enough drives and accesses to those drives are available to warrant spreading temporary files across several devices from all systems. Also, additional overhead is incurred by the system for each shared device. This includes additional CMR space for each device (1008 CM words) and additional time that is required to maintain the device-related tables (such as the MST or the TRT) on the link device. These factors must be weighed to determine how best to configure shared devices.

In an independent SDM complex, where device-related tables are maintained on the device itself, system performance degradation can occur if the shared devices are not properly configured. Since the device must be accessed every time its tables in CMR are not up to date, drive and controller contention is increased and system performance is affected. To reduce the impact on system performance you can:

- Put the system and temporary files on nonshared devices.
- Put only those fast-attach files that must be global on shared devices.
- Use multiple channels and multiple controllers to improve performance and provide additional paths to shared devices.

#### **DEVICE INDEX TABLES**

In an independent SDM complex, mainframes use DITs to determine device usage. The DITs contain the MIDs of the mainframes that can access the shared device. The shared device maintains a DIT for each mainframe that shares it. The DITs reside on each shared device within the MST on the device's label track.

#### MASS STORAGE RECOVERY TABLES

One problem that is created by having more than one machine sharing a mass storage device is that of recovering the mass storage space and interlocks of a machine, if it requires recovery processing. This problem is solved by defining a table that provides the information needed to recover the mass storage space of a machine and by having a machine recovery utility that performs the recovery. The table is called the MRT. There is one MRT for each mainframe per device. It tells which tracks are interlocked and which tracks are first tracks of files local to a particular machine. The MRT is utilized by CPUMTR on another machine to clear track interlocks and by the MREC utility on another machine to recover the mass storage space of the interrupted machine. For specific information on the MRT, refer to the NOS 2 Systems Programmer's Instant.

## **DEVICE INITIALIZATION**

To initialize a mass storage device, it is necessary first to prevent any new activity from starting up on the device, then to wait until all current activity has completed, and finally to interlock the device and proceed with initialization. To accomplish this on shared mass storage devices in an independent SDM environment, follow these steps:

- Enter the DSD UNLOAD command. All machines sharing the device must unload it to prevent any new activity. (This command can be used for both removable and nonremovable shared devices.)
- 2. Enter the DSD INITIALIZE command on the machine from which the initialization is to take place. Each entry of the INITIALIZE command toggles INITIALIZE on and off. If two machines in the complex enter the INITIALIZE command, the INITIALIZE command is toggled off and no error message is displayed.
- 3. The machine from which the INITIALIZE command was entered monitors the status of the other machines that are sharing the device. Once they have unloaded the device and user activity has ceased, the device tables are updated.
- 4. To activate the device on the other machines, enter the DSD MOUNT command from each machine. This command clears the UNLOAD status. If initialization is still in progress on another machine when you enter a MOUNT command, the machine waits for INITIALIZE to finish and then continues with the MOUNT process.

### **DEVICE UNLOAD**

In an independent SDM environment, unloading a device involves more than it does under a one-machine system. A device can be unloaded from a machine (referred to as a local unload), or it can be unloaded from the entire multimainframe complex (referred to as a global unload). A device can be physically removed from the complex only after a global unload has been accomplished. This is the general procedure to complete a global unload:

- 1. Enter the UNLOAD command from each machine. This is an indication to the machine that no new accesses should be initiated. You must enter this command from each machine sharing the device.
- 2. When all local unloads are set and user access has ceased, global unload status is set if the device is a removable device. This global unload status is displayed on all machines, indicating that there is no activity on the device from any machine and that the device may be physically unloaded.
- 3. You can then switch packs and enter the MOUNT command at the console to initiate recovery of the device. The MOUNT command clears the global unload status and the local unload status on the machine from which it was entered and indicates that this machine is now accessing the device. All other machines continue to ignore the device until you enter the MOUNT command on each machine. The MOUNT command does nothing if local unload status is not set on the machine.
- 4. A pack that has not been previously mounted in this system must be preset with a MOUNT,est,P command.

#### **DEVICE RECOVERY**

Deadstart and online recovery methods are similar in logic for recovering mass storage devices.

For a machine to recover a device in an independent SDM complex, the MID of the machine must be in the device's DIT. If the MID is not in the DIT, an error message is issued and recovery is impossible. When recovering a device in a standalone environment, the device is not checked if it is/was an independent shared device.

#### **DEVICE CHECKPOINT**

Local MST information for each machine that shares a mass storage device is maintained on the device. MST information for other machines may also be present on the device. The information for each machine is kept in one sector on the label track following the TRT sectors. Entries for up to 31 unique machine identifiers can exist.

During checkpoint, only the local MST information of the machine performing the checkpoint is updated. Since local MST information for many machines is kept on the device, updating of all these areas by one machine could cause a loss of information needed if the device were to be used with another system.

In an independent SDM complex, the MST and TRT information is maintained on the device. If the MST and/or TRT information changes during a device access, the system updates the MST and/or TRT information making it unnecessary for the system to periodically checkpoint the device.

#### MSS PROCESSING

Unlike most other mass storage devices, the MSF is not shared by mainframes. Rather, MSF is physically connected to and driven by one mainframe. The only machine that can access the MSF-resident files is the physically connected independent SDM. MSS processing is the same in an independent SDM environment as it is in a single mainframe environment. Refer to section 12, Mass Storage Subsystem.

#### **MSAS PROCESSING**

Unlike most other mass storage devices, the 7990 is not shared by mainframes. Rather, 7990 is physically connected to and driven by one mainframe. The only machine that can access the 7990-resident files is the physically connected independent SDM. MSAS processing is the same in an independent SDM environment as it is in a single mainframe environment. Refer to section 11, Mass Storage Archival Subsystem.

.

Maintenance Logging Transfer Facility (MLTF) Dump NAD Memory (DMPNAD) 14-1

14-1

This section describes utilities that are used to maintain network access devices (NADs).

# MAINTENANCE LOGGING TRANSFER FACILITY (MLTF)

MLTF is a utility program that controls logging NAD error logs into the binary maintenance log. At regular intervals MLTF maintains the network description file on disk, calls the NETLOG program, and rolls out after execution. The time interval is determined by an input parameter to MLTF (refer to the NOS 2 Installation Handbook).

NETLOG uses the network configuration file to determine which remote NADs should be logged. Each time NETLOG runs it receives a copy of the network configuration file from RHF and saves the file on disk. If RHF is not active, NETLOG uses the saved copy of the network configuration file from disk to determine which NADs to log. Local NADs are always logged. For each NAD that is logged, NETLOG enters the NAD error log into the binary maintenance log.

The MLTF utility is started automatically by RHF when RHF is initialized. The mainframe identified as the maintenance host must have the MLTF utility running periodically even if RHF is not active.

# DUMP NAD MEMORY (DMPNAD)

DMPNAD is a utility program that reads the NAD memory and formats the data into an output file. The dump is formatted so that each NAD word is printed in both hexadecimal and 7-bit ASCII code representations.

The format of the command is:

DMPNAD,  $p_1$ ,  $p_2$ , ...,  $p_n$ .

| <u>p1</u> | Description                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AC=aaaa   | The 4-digit hexadecimal number specifying the remote NAD's access code (refer to the RHF K display in section 8, K-Display Utilities). The default is AC=0000. |
| B=binfile | The 1- to 7-character name of the file on which the binary output is to be written. The default is no binary output file.                                      |
| В         | Same as B=BINOUT.                                                                                                                                              |
| СН=сс     | The 1- or 2-digit octal number specifying the channel number of the local NAD defined in the EST entry associated with the NAD.                                |
| I=infile  | The 1- to 7-character name of the file on which the binary input is written. The default is no binary input file.                                              |

| Des | scr | ip | ti | on |
|-----|-----|----|----|----|
|     |     |    |    |    |

ISame as I=BININ.L=outfileThe 1- to 7-character name of the file on which the list output is<br/>to be written. The default is L=OUTPUT.LT=tot1t2t3The 4-digit binary bit pattern specifying the TCUs that connect a<br/>local NAD to a remote NAD. tn=1 enables TCUn. For example,<br/>LT=1100 indicates that local TCUs 0 and 1 are enabled.

The DMPNAD utility can be called from the console or a batch job. The calling job must be of system origin or you must be validated for system origin privileges. You normally include the channel number on the DMPNAD command to specify which online NAD is to be dumped. The dump can also be saved as a binary output file (B parameter) which can later be formatted for printing by using the file as a binary input file (I parameter) and no access to the NAD is required. No special privileges are required when using the I parameter.

For a local NAD dump, DMPNAD can dump either a local NAD (380-170 NAD connected to the host mainframe using a channel and configured in the EST) or a remote NAD (any 380 NAD accessible to a local NAD using a loosely-coupled network trunk), The EST entry associated with the local NAD's channel number must be OFF or the controlware-not-loaded flag must be set. Since the local NAD dumping process stops all NAD activity, the NAD controlware must be reloaded using LOADBC (refer to section 1, Controlware Loading Utility) before the local NAD can be used by the operating system.

Remote NAD dumping is selected by specifying the remote NAD to be dumped (AC and ND parameters), the local NAD's channel number used to access the remote NAD (CH parameter), and the TCU used to connect the local NAD to the remote NAD (LT parameter). For remote NAD dumping, the local NAD must be loaded and running and its EST entry must be ON.

Remote NAD dumping operations can occur concurrently with RHF use of the local NAD. However, extreme care should be exercised when performing a remote NAD dump to ensure that the correct remote NAD is being dumped and that the remote NAD is not being used by the mainframe to which it is connected. After the remote NAD dumping operation, the NAD controlware must be reloaded into the remote NAD before it can be used by the remote mainframe.

Pi

ND=nn The 2-digit hexadecimal number specifying the remote NAD's address (refer to the RHF K display in section 8, K-Display Utilities).

# **NETWORK OPERATIONS**

| Network Organization                         | 15-1  |
|----------------------------------------------|-------|
| NAM Startup                                  | 15-3  |
| Initiating NAM Without Operator Intervention | 15-3  |
| Altering the Memory File                     | 15-4  |
| NAM Shutdown                                 | 15-5  |
| Network Control by HOP                       | 15-6  |
| Disabling and Enabling of Couplers           | 15-6  |
| Status Message Formats for HOP               | 15-6  |
| Unsolicited Status Reports for HOP           | 15-0  |
| HOP Commands                                 | 15-7  |
| NS Control Commands                          | 15-7  |
| Cancel Alternate NPU Load File Command       | 15-8  |
| Change NPU Load File Command                 | 15-8  |
| NPU Load Status Command                      | 15-8  |
| NS Recent History Command                    | 15-11 |
| NVF Control Commands                         | 15-11 |
| Disable Host Element Command                 | 15-11 |
| Enable Application Command                   | 15-12 |
| Idle Host Element Command                    | 15-12 |

# **NETWORK OPERATIONS**

The commands described in this section are used when the network access method (NAM) is being initialized or is active. They initialize and control the network processing units (NPUs), trunks, lines, terminals, and application programs under network supervision.

# **NETWORK ORGANIZATION**

Initiating NAM (refer to the DSD NAM command in section 5, DSD Commands) causes NAM, and the communications supervisor (CS), network supervisor (NS), network validation facility (NVF), and terminal verification facility (TVF) to be loaded and initiated at control points. Refer to the NAM/CCP 3 Terminal Interfaces Reference Manual for more information on TVF. CS provides control and status of the NPUs and all of their communication lines and terminals. NS loads and dumps all of the NPUs in the communication network. NVF validates terminal users and applications as they attempt to access the network.

Multiple hosts may belong to the network. Hosts may assume one or more supervisory roles in the network. Each host will have a copy of NVF that will validate users connecting to and applications executing in that host. The supervisors CS and NS may execute in any or all of the CYBER hosts. Whenever an NPU needs to be loaded, it may request any copy of NS to perform the load (not always the same copy). Once an NPU is running, it may request any copy of CS to supervise it. Each NPU will have a preferred copy of CS, but it may request supervision from an alternate copy of CS if its preferred CS is not available. In any case, the network is always capable of functioning without any one or more of its hosts.

The network consists of channels, couplers, lines, logical links, NPUs, terminals, and trunks (refer to figure 15-1) connected to the host computer.

- A channel is a data path on which a peripheral device controller can be accessed.
- A coupler is a hardware element that links an NPU to a channel.
- A line is the circuit that connects a terminal to an NPU.
- A logical link is a logical path connecting a coupler and an NPU or two couplers.
- An NPU is the communications controller that transmits data between terminals and a host computer or between two host computers.
- A public data network is an X.25 packet switching network (PSN). Terminals, NPUs, and foreign hosts can be connected to a PSN to exchange data.
- A terminal is a device by which a user supplies input messages to, and accepts output messages from, an application program.
- A trunk is the communication line connecting two NPUs.

RBF IAF TAF TVF TERMINALS NETWORK APPLICATIONS TERMINAL TERMINAL TERMINAL 00705

Figure 15-1. Sample Network

The network recognizes three types of network operators: the host operator, the NPU operator, and the diagnostic operator. A host operator (HOP) resides at the system console, initiates NAM, and can control network elements being supervised by this host. An NPU operator (NOP) resides at a terminal and controls communication network elements (such as lines, logical links, NPUs, terminals, and trunks). A diagnostic operator (DOP) resides at a terminal and control lines.

The HOP can always perform NOP and DOP functions regardless of the existence of NOPs and DOPs. NOPs can perform all DOP functions regardless of the existence of DOPs. CS supports up to 10 concurrent NOP and DOP connections in addition to one HOP connection. NS and NVF support only the HOP connection.

The HOP can communicate with NAM and any of the supervisors (CS, NS, or NVF) executing in its host. NOPs and DOPs can communicate with any CS executing in any host to which the operator has access. However, a NOP or DOP can communicate with only one CS at a time. A NOP or DOP can monitor and control only those elements owned by NPUs being supervised by their CS.

Each NPU in the network is controlled by the HOP and, optionally, one NOP connected to its supervising CS. A HOP controls all NPUs supervised by CS. Each NOP connected to CS can control one or more NPUs.

# NAM STARTUP

If the NPUs in the network were running version 3.5 or earlier Communications Control Program (CCP), you must master clear all local NPUs before initiating NAM. If the NPUs were running version 3.6 or 3.7 of CCP, then master clear NPUs only if the running version is not the desired version.

You initiate NAM by entering:

NAM.†

or

NAMNOGO.

NAM and NAMNOGO are names of procedure files that are called when the HOP initiates NAM.

The first time the network is initiated the NAMNOGO procedure must be used to create a memory file (refer to the NOS 2 Installation Handbook). The memory file contains the name of the master file, the last parameter record, and the network invocation number (NIN) used. The NIN is incremented by 1 every time NAM is started. The NIN is displayed in the NAM K display. If the network has been previously initiated, a memory file exists and the NAM procedure file may be used.

#### INITIATING NAM WITHOUT OPERATOR INTERVENTION

If you initiate NAM by entering

NAM.†

NAM is brought up without further operator action. This results in starting the network using the previously specified master file and the parameter record RESTRT.

<sup>†</sup>Any procedure file of the form NAMffff is allowed.

# ALTERING THE MEMORY FILE

If you initiate NAM by entering

NAMNOGO.

NAM displays the message:

ENTER DESIRED OPTION

You reply to this message with a CFO command in this format:

 $\tt CFO, \tt NAM.keyword_1=param_1, \tt keyword_2=param_2, \ldots, \tt keyword_n=param_n.$ 

The following keyword and parameter combinations are allowed on the CFO command.

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MFN=filename    | Permanent file name of the master file to be used. The master file<br>contains all the information needed to initiate the network. Once<br>this parameter is specified all subsequent network initiations use<br>this master file until a new master file is specified. The master<br>file resides in the system default family and must be permitted to<br>SYSTEMX. If this parameter is not specified, NAMSTRT is assumed. |
| UN=username     | User name for the master file. If this parameter is not specified, NETOPS is assumed.                                                                                                                                                                                                                                                                                                                                        |
| PW=password     | Password associated with the master file user name.                                                                                                                                                                                                                                                                                                                                                                          |
| RN=recordname † | Name of the parameter record on the master file that is used for<br>this network initiation. If this parameter is not specified, the<br>previously specified parameter record is used. The parameter<br>record specifies the characteristics of any particular network<br>initiation.                                                                                                                                        |
|                 | You can select one of the parameter record names listed in table 15-1 to obtain the given combination of features.                                                                                                                                                                                                                                                                                                           |
| OIN=xx          | Previous network invocation number from which dumps/traces are collected. If this parameter is not specified, the current network invocation number minus 1 is used.                                                                                                                                                                                                                                                         |

*<sup>†</sup>* Specifying a record name changes recordname only for this initiation.

| Feature Descriptions                                                              | Parameter Record Name |        |        |       |       |        |

## Table 15-1. Parameter Record Feature Descriptions

You can enter all desired parameters with a single entry or enter several CFO commands. In this way you add (if the file is empty) or replace entries in the NAM memory file.

When you have finished adding or replacing data, enter the command:

CFO,NAM.GO.

After entering this command, you cannot add or replace additional parameters during this NAM initiation.

# NAM SHUTDOWN

NAM is idled by assigning the K display to the application NVF, followed by entering the DISABLE, HOST or IDLE, HOST command.

The sequence of commands is:

K.AP=NVF.

K.DISABLE,HOST.

or

K.IDLE,HOST.

Use the IDLE command for a graceful shutdown, and the DISABLE command for an immediate shutdown.

# NETWORK CONTROL BY HOP

The commands described next are available only to the HOP. The HOP can perform all functions of the the NPU operator and diagnostic operator as well as those unique to the HOP. The commands unique to the HOP are processed by NS and NVF.

#### **DISABLING AND ENABLING OF COUPLERS**

The HOP enables a coupler using the DSD ON command and disables the coupler using the DSD OFF command. You can examine the NP equipment entry on the E,A display to determine the EST ordinal. When an active coupler is turned OFF, NAM stops communicating with that coupler. The coupler is not used again until it is turned ON while NAM is executing. When a coupler is turned ON, NAM automatically begins to communicate with the NPU connected across the coupler.

## STATUS MESSAGE FORMATS FOR HOP

The HOP commands cause various status messages to be displayed at the system console. The normal response to a STATUS command consists of a single status line for each referenced element.

Following are the general formats for these status messages.

- Application status line

APPL: name, status, conncount, mxcopies, jsn, restart.

- Terminal status line

TERM: name, username, hh.mm.ss, applname/acn, ah.am.as, dt.

- User status line

USER: name,termname,hh.mm.ss,applname/acn,ah.am.as,dt.

In the preceding status message general formats the following variables are used.

| Variable  | Description                                                                   |
|-----------|-------------------------------------------------------------------------------|
| acn       | Connection number for the connected application.                              |
| ah.am.as  | Time of the connection to the application (hours, minutes, and seconds).      |
| applname  | Name of the connected application.                                            |
| conncount | Count of the active connections to this application.                          |
| dt        | Device type.                                                                  |
| hh.mm.ss  | Time of the system or host login (hours, minutes, and seconds).               |
| jsn       | Job sequence name of the application.                                         |
| mxcopies  | Maximum number of copies of this application that can be running at one time. |

| Variable | Description                                                                                                                                                                                                                               |    |  |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|--|
| name     | Name of the specified element.                                                                                                                                                                                                            |    |  |
| restart  | If the characters RS are present, they indicate that NVF will<br>automatically start up a copy of this application to complete a<br>connection request for it.                                                                            |    |  |
| status   | tatus of the application. The application program is initially set to<br>ither an enabled or disabled state. Enabled application programs<br>ecome active when they start executing. The application program is in<br>ne of these states: |    |  |
|          | status Description                                                                                                                                                                                                                        |    |  |
|          | AC Application is active (you can establish a connection to th application).                                                                                                                                                              | ıe |  |
|          | DI Application is disabled.                                                                                                                                                                                                               |    |  |
|          | DN Application is down (the application failed; NAM tables are being cleared up).                                                                                                                                                         | :  |  |
|          | EN Application is enabled.                                                                                                                                                                                                                |    |  |
| termname | ame of the terminal at which the user resides.                                                                                                                                                                                            |    |  |
| username | ogin user name of the terminal user.                                                                                                                                                                                                      |    |  |

## UNSOLICITED STATUS REPORTS FOR HOP

Each time a significant event occurs, CS, NS, or NVF updates its recent history buffer (refer to Recent History Command later in this section) and logs the event in the NAM dayfile. CS, NS, or NVF then sends a report about the event, called the unsolicited status report, to the HOP. The HOP can get unsolicited status reports from CS, NS, or NVF by assigning the NAM K display to that particular application. Refer to section 8, K-Display Utilities, for information on how to assign the NAM K display. Unsolicited status reports are time-stamped whereas solicited status reports are not time-stamped.

## HOP COMMANDS

The HOP must assign the NAM K display to a supervisory application (CS, NS, or NVF) before entering any of the following commands. Refer to section 8, K-Display Utilities, for information on how to assign the NAM K display.

All HOP commands consist of a command verb and, sometimes, one or more parameters. The commands must begin in the first character position after K. and contain no blanks. The terminator (.) is optional. Some command verbs and parameters can be shortened to a 2- or 3-character abbreviation. You can mix abbreviated and unabbreviated command verbs and parameters in all network commands. Parameters are order independent except where noted.

## NS CONTROL COMMANDS

The HOP assigns the NAM K display to NS to enter the following commands.

#### **Cancel Alternate NPU Load File Command**

After using a FILE command, the HOP can instruct NS to return to the use of the default NPU load file for loading all NPUs by specifying the NOFILE command.

The command format is:

NOFILE.

or

NO.

#### **Change NPU Load File Command**

The HOP can assign an alternate load file to NS for loading a specific NPU with the FILE command.

The command format is:

FILE,NPU=npuname,NLF=loadfile,UN=username,PW=password.

or

FI,NP=npuname,NL=loadfile,UN=username,PW=password.

| Parameter | Description                                          |
|-----------|------------------------------------------------------|
| npuname   | Name of the NPU.                                     |
| loadfile  | Name of the alternate load file loadfile.            |
| username  | Username of the user to which file loadfile belongs. |
| password  | Password for the specified username.                 |

The next load of the specified NPU will be from the alternate load file. You can return to the default NPU load file by using the NOFILE command.

## **NPU Load Status Command**

The HOP can request the current load/dump status of a specific NPU or all NPUs using the STATUS command.

There are two forms of the STATUS command.

The first form requests the current load/dump status of a specific NPU.

The command format is:

STATUS, NPU=npuname.

or

ST,NP=npuname.

The second form requests the current load/dump status of all NPUs.

The command format is:

STATUS, NPUS.

or

ST,NPS.

The normal status response consists of four lines of information for each NPU, as shown below.

| npuname     | NN=nid<br>dflag<br>message | NBS=nid,nid,nid,nid,nid EC=errcnt<br>LDS=ldcnt LD=yy/mm/dd LT=hh.mm.ss<br>dmpfile HALT ffff DD=yy/mm/dd DT=hh.mm.ss        |  |  |
|-------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------|--|--|
| Status      |                            | Description                                                                                                                |  |  |
| npuname     |                            | Name of the network processing unit.                                                                                       |  |  |
| NN=nid      |                            | Node number of the NPU identified by npuname.                                                                              |  |  |
| NBS=nid,    | ,nid                       | Node numbers of up to six neighboring NPUs or couplers.                                                                    |  |  |
| EC=errcnt   |                            | Protocol error count. Number of dump/load service messages received from the NPU that violated the NPU dump/load protocol. |  |  |
| LDS=1dcnt   |                            | Number of attempted loads of this NPU.                                                                                     |  |  |
| LD=yy/mm/dd |                            | Date in year, month, and day when the most recent load attempt of this NPU occurred.                                       |  |  |
| LT=hh.mm.ss | 3                          | Time in hours, minutes, and seconds when the most recent load attempt of this NPU occurred.                                |  |  |
| dflag       |                            | NPU memory dump indicator; one of the following:                                                                           |  |  |
|             |                            | dflag Description                                                                                                          |  |  |
|             |                            | DUMP Dump NPU before a load.                                                                                               |  |  |
|             |                            | NODUMP No NPU dump before a load.                                                                                          |  |  |
|             |                            | blank NPU is not currently being loaded.                                                                                   |  |  |
| dmpfile     |                            | Name of the most recent NPU dump file.                                                                                     |  |  |
| ffff        |                            | Halt code (halt codes are described in the CCP 3 Diagnostic<br>Handbook).                                                  |  |  |
| DD=yy/mm/dd | 1                          | Date in year, month, and day when the most recent dump of this NPU occurred.                                               |  |  |
| DT=hh/mm/ss | 3                          | Time in hours, minutes, and seconds when the most recent dump of this NPU occurred.                                        |  |  |

Description

<u>Status</u> message

Message is the NS activity and its associated status.

| Activity          | Status                                             |                            |                                                                                                                                           |

|                   |                                                    | error                      | Description                                                                                                                               |
|                   |                                                    | TIMEOUT                    | No response was<br>received from the<br>NPU during a preset<br>time-out period.                                                           |
|                   |                                                    | RETRY TIMEOUT              | Only abnormal<br>responses were<br>received from the<br>NPU during a preset<br>time-out period.                                           |
|                   |                                                    | FILE ERRORS                | Irrecoverable I/O<br>error occurred on<br>the network con-<br>figuration file or<br>network load file.                                    |
|                   |                                                    | PREEMPTED                  | An incomplete SAM<br>load or dump/load<br>sequence was<br>interrupted by a<br>request from the<br>same NPU to initiate<br>a new SAM load. |

## **NS Recent History Command**

The HISTORY command requests a display of recent unsolicited status reports from NS (refer to Recent History Command later in this section for further information).

#### **NVF CONTROL COMMANDS**

The HOP assigns the NAM K display to the network validation facility (NVF) to enter the following commands.

## **Disable Host Element Command**

The HOP uses the DISABLE command to force immediate termination of a particular application or all host network operations.

The command format is:

DISABLE, operation.

or

DI, operation.

| Parameter | Description           |                                                                                                                                                                                                              |
|-----------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| operation | One of the following: |                                                                                                                                                                                                              |
|           | operation             | Keyword Abbreviation                                                                                                                                                                                         |
|           | APPL=applicationname  | AP                                                                                                                                                                                                           |
|           | HOST                  | НО                                                                                                                                                                                                           |
|           | applicationname       | Name of the application to be<br>disabled. If more than one copy of<br>an application is allowed, then<br>applicationname can be a 1- to<br>5-character root name specifying<br>that all copies of the named |

Results of using the DISABLE, APPL command:

• The status of the named application is changed from enabled (EN), active (AC), or down (DN) to disabled (DI), thereby prohibiting the application from accessing the network.

application are affected.

• If the application is active at the time the command is entered, NAM requests the application to immediately terminate access to the network. If the application remains active for an undue period of time after entering this command, the HOP can resort to the DSD DROP or STOP command (refer to section 5, DSD Commands).

Results of using the DISABLE, HOST command:

- NAM requests that all active applications in the host immediately terminate their access to the network.
- When all applications (including CS and NS) terminate their access to the network, NAM and NVF also terminate.
- If NAM or NVF do not terminate, enter the STATUS, APPL command to determine which application has not terminated. You can then use the DSD DROP or STOP command to drop the application.

#### **Enable Application Command**

The HOP uses the ENABLE command to change the status of a network application from disabled (DI) to enabled (EN). The application status becomes active (AC) when the application begins to access the network.

The command format is:

ENABLE, APPL=applicationname.

or

EN, AP=applicationname.

Parameter

Description

applicationname Name of the application to be enabled. If more than one copy of an application is allowed, then applicationname can be a 1- to 5-character root name specifying that all copies of the named application are affected.

## Idle Host Element Command

The IDLE command terminates execution of an individual application or all host network operations.

The command format is:

IDLE, operation.

or

ID, operation.

Parameter

Description

operation

One of the following:

# operation

APPL=applicationname

HOST

Keyword Abbreviation

AP

HO

applicationname

Name of the application to be idled. If more than one copy of an application is allowed, then applicationname can be a 1- to 5-character root name specifying that all copies of the named application are affected.

Results of using the IDLE, APPL command:

- The application is warned of an imminent shutdown.
- The application completes any operations in progress but does not allow any new connections.
- When all users are disconnected, the application terminates normally.

Results of using the IDLE, HOST command:

- Applications are warned of an imminent shutdown.
- New application requests to access the network are rejected.
- New application to application connections are rejected.
- New terminal connections to the host are rejected by NAM.
- CS warns all connected NOPs and DOPs that shutdown of the network is imminent. CS terminates when all NOPs and DOPs end their connections to CS.
- NS ignores any new dump or load requests from NPUs. Any ongoing dump and load processes are completed normally before NS terminates.
- When all applications (including NS and CS) terminate their access to the network, NAM and NVF also terminate. If an application does not terminate, use the DISABLE command to request immediate termination of network activity in the host.

#### **NVF Recent History Command**

The HISTORY command requests a display of recent unsolicited status reports from NVF (refer to Recent History Command later in this section for further information).

#### **Status Host Element Command**

Host elements are the applications associated with the host, terminals currently connected to the host, and users currently logged in to the host. With the STATUS command a HOP can status a single application, terminal device, or user name; or all applications, terminal devices, or users connected to a given application.

There are five forms of the STATUS command. Refer to Status Message Formats for HOP, earlier in this section, for the format of the status line returned.

The first form requests the status of a particular host element.

The command format is:

STATUS, element.

or

ST,element.

Parameter Description

element One of the following:

| element           | Keyword Abbreviation                                                                                                                                                                                                                                                                         |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APPL=elementname  | AP                                                                                                                                                                                                                                                                                           |
| TERM=elementname  | TE                                                                                                                                                                                                                                                                                           |
| UNAME=elementname | UN                                                                                                                                                                                                                                                                                           |
| elementname       | Name of the element whose status is<br>desired. If elementname is the name<br>of an application and more than one<br>copy of the application is allowed,<br>then elementname can be a 1- to<br>5-character root name specifying<br>that all copies of the named<br>application are affected. |

The second form requests the status of all network applications in the host.

The command format is:

.

STATUS, APPLS.

or

ST,APS.

The third form requests the status of all active network applications in the host.

The command format is:

STATUS, APPLS, AC.

or

ST, APS, AC.

The fourth form requests the status of all terminal devices connected to the specified application or logged in under the specified user name.

The command format is:

STATUS, TERMS, termelement.

or

ST, TES, termelement.

| Parameter   | Description           |                                          |
|-------------|-----------------------|------------------------------------------|
| termelement | One of the following: |                                          |
|             | termelement           | Keyword Abbreviation                     |
|             | APPL=elementname      | AP                                       |
|             | UNAME=elementname     | UN                                       |
|             | elementname           | Name of the desired application or user. |

The fifth form requests the status of all users connected to the specified application. The command format is:

STATUS, UNAMES, APPL=applicationname.

or

ST, UNS, AP=applicationname.

## Parameter

Description

applicationname

Name of the desired application.

# **NETWORK CONTROL BY NOP**

The commands described later in this section are available to both HOPs and NOPs. The NOPs can perform all functions of the diagnostic operators as well as those unique to NOPs.

The controlling NOP (refer to CONTROL command later in this section) is responsible for controlling one or more NPUs and its associated couplers, lines, logical links, terminal devices, and trunks.

A controlling NOP can control any of the NPUs supervised by a CS and shares that responsibility with the HOP. The controlling NOP and HOP must, therefore, coordinate their activities.

#### **BECOMING A NOP**

To become a NOP, you must be authorized by site personnel to access the CS application and to become a controlling NOP.

After initiation of the network, you become a NOP as follows:

- 1. Log in as described in the NOS 2 Reference Set, Volume 2.
- 2. In response to the APPLICATION: prompt, enter:

CS

3. The system responds:

HELLO, YOU ARE NOW AN NPU OPERATOR

This message is followed by the prompt:

READY ..

You can now enter the NOP commands described later in this section.

You can cancel a command that results in a large volume of output by entering the interruption or termination sequence (refer to the NOS 2 Reference Set, Volume 3).

## NOTE

Use caution when cancelling output because unsolicited status messages could also be discarded.

When you cancel output, the message

OUTPUT DISCARDED READY..

or

**OUTPUT DISCARDED..** 

appears at the terminal at the point from which the data was discarded.

If the terminal is in page wait mode, † you must press CR after every page of output before more output can be sent to the terminal.

To relinquish NOP status, enter one of the following.

To log out and end the terminal connection to the host, enter:

GOODBYE or

BYE

or

LOGOUT

To initiate a new login dialog, enter:

HELLO

or

LOGIN

To remain logged in and be prompted for another application, enter:

END

To remain logged in and be switched automatically to the application named applname, enter:

END, applname

<sup>†</sup> It is suggested that a hardcopy device be used for NOP terminals; this prevents the paging problem and provides a permanent log of network events.

#### STATUS MESSAGE FORMATS FOR NOP

Some of the NOP commands cause various status messages to be displayed on your terminal. The normal response to a STATUS command is one line of text returned when status is requested for a coupler, line, NPU, or terminal device. Two text lines can be returned when status is requested for logical links or trunks (if the CS to which you are connected is supervising NPUs at each end of the element, a line of text is returned for each end of the logical link or trunk). For multiple element status commands, a response is generated for all elements expressed or implied in the command. For example, a status request for all terminals on an NPU begins with a status report (text line) for the NPU. This is followed by a status report for the first active (AC) line on the NPU. A status report for each terminal device configured on the line follows. This is followed by a status report of the next active line and so on.

The response to the ENABLE or DISABLE command is a status report for each element affected by that command.

Following are the general formats for these status messages.

- Coupler status line

CPLER: name, status, nodenum, npuname1/cplnum.

- Line status line

LINE: name, status, linetype, npunamel/port.

- Logical link status line

LLINK: name, status, RL=n, loglinktype, npunamel/nodenum, npuname2/nodenum.

- NPU status line

NPU: name, status, nodenum, gostatus, dump.

- Archetype switched virtual circuit (SVC) status line
  - SVC: atname, EN=ennum, DI=dinum, AC=acnum, stip.
- Terminal device status line

TERM: name, status, dt/cc, /hostnid, linename/al/a2.

- Trunk status line

TRUNK: name, status, linetype, npuname1/port, npuname2/port.

In the preceding status message general formats the following variables are used.

Variable

# Description

| acnum  | Number of SVCs of the element that are in an active state (from 0 to $255$ ).  |
|--------|--------------------------------------------------------------------------------|
| atname | Name of the archetype SVC element.                                             |
| al     | First level address (cluster address, configuration ordinal).                  |
| a2     | Second level address (terminal address, stream number).                        |
| cplnum | Coupler number for the indicated NPU.                                          |
| dinum  | Number of SVCs of the element that are in a disabled state (from 0 to $255$ ). |

| Variable    | Description                                                                                                      |                                                                                                                                                                                                                                                |  |
|-------------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| dt          | Device type (CON, CR, LP, CP, PL).                                                                               |                                                                                                                                                                                                                                                |  |
| dump        | NPU dump flag                                                                                                    | g (ON or OFF).                                                                                                                                                                                                                                 |  |
| ennum       | Number of SV(<br>255).                                                                                           | Cs of the element that are in an enabled state (from 0 to                                                                                                                                                                                      |  |
| gostatus    | Go status of                                                                                                     | the NPU (if waiting for GO, NEEDGO appears).                                                                                                                                                                                                   |  |
| hostnid     | Host (couple<br>currently co                                                                                     | r) node number of the host to which the terminal is<br>nnected.                                                                                                                                                                                |  |
| linename    | Name of the                                                                                                      | line to which the terminal device is connected.                                                                                                                                                                                                |  |
| linetype    | Line type (r                                                                                                     | efer to the NDL Reference Manual).                                                                                                                                                                                                             |  |
| loglinktype | Logical link                                                                                                     | type (H-N for host to NPU, H-H for host to host).                                                                                                                                                                                              |  |
| name        | Name of the                                                                                                      | element.                                                                                                                                                                                                                                       |  |
| nodenum     | Node number                                                                                                      | of a coupler or NPU.                                                                                                                                                                                                                           |  |
| npunamel    | Name of an NPU that supports or is connected to the element (also the name of the NPU that reported the status). |                                                                                                                                                                                                                                                |  |
| npuname2    | Name of the NPU at the other end of the logical link or trunk.                                                   |                                                                                                                                                                                                                                                |  |
| port        | Port number of the line or trunk on the indicated NPU.                                                           |                                                                                                                                                                                                                                                |  |
| RL=n        | Regulation level currently in effect.                                                                            |                                                                                                                                                                                                                                                |  |
| status      | state. Init<br>the course o                                                                                      | ents are initially set to either a disabled or enabled<br>ially enabled elements automatically become active during<br>f normal network operation. Every network element (such as<br>l link, NPU, or trunk) is in one of the following states. |  |
|             | status                                                                                                           | Description                                                                                                                                                                                                                                    |  |
|             | AC                                                                                                               | Network element is active. An element becomes active when it is enabled and is handling network data traffic.                                                                                                                                  |  |
|             | DI                                                                                                               | Network element is disabled. The element cannot become active unless enabled by an operator command.                                                                                                                                           |  |
|             | DN                                                                                                               | Network element is down. A failure was detected that<br>terminated data traffic for the element. If the failure<br>condition ceases, the element returns to an enabled status.                                                                 |  |
|             | EN                                                                                                               | Network element is enabled. It was enabled by the operator<br>and is in a physically operative condition.                                                                                                                                      |  |
|             | NC                                                                                                               | Network element is not configured. The NPU does not recognize the element.                                                                                                                                                                     |  |
| stip        | SubTIP type                                                                                                      | (PAD or APPL).                                                                                                                                                                                                                                 |  |
| tc          | Terminal cla                                                                                                     | SS.                                                                                                                                                                                                                                            |  |

#### UNSOLICITED STATUS REPORTS FOR NOP

Each time a significant event occurs, CS updates its recent history buffer (refer to Recent History Command later in this section) and logs the event in the NAM dayfile. CS then sends a report about the event, called the unsolicited status report, to all NOPs who have selected to receive unsolicited status reports from the NPU (refer to Report Unsolicited Status Command later in this section). Unsolicited status reports are time-stamped whereas solicited status reports are not time-stamped.

A single unsolicited status report occurs as a result of an element recovery or failure. An unsolicited status message is sent when an NPU joins the network. Batches of unsolicited status reports can occur as a result of an operator command to enable all elements of a given type (refer to Enable Network Element Command later in this section).

#### NOP COMMANDS

All NOP commands consist of a command verb and, sometimes, one or more parameters. The commands must begin in the first character position and contain no blanks. The terminator (.) is optional. Some command verbs and parameters can be shortened to a 2- or 3-character abbreviation. You can mix abbreviated and unabbreviated command verbs and parameters in all network commands. Parameters are order independent except where noted. You can enter commands pertaining only to the NPUs supervised by the CS to which you are connected.

To enter the following commands you must control the NPU (refer to CONTROL Command later in this section).

#### **ALERT** Command

The ALERT command changes the threshold that CS uses for alerting the HOP and the controlling NOP of NPU saturation.

The command format is:

ALERT, CP=cpuse, BU=buff, element.

or

AL,CP=cpuse,BU=buff,element.

| Parameter | Description                      |                                                 |  |  |
|-----------|----------------------------------|-------------------------------------------------|--|--|
| cpuse     | Percent of the NPU cen percent). | tral processor currently in use (from 50 to 100 |  |  |
| buff      | Number of available NP           | U data buffers (from 0 to 500).                 |  |  |
| element   | One of the following:            |                                                 |  |  |
|           | element                          | Keyword Abbreviation                            |  |  |
|           | NPU=npuname                      | NP                                              |  |  |
|           | NPUS                             | NPS                                             |  |  |
|           | npuname                          | Name of the NPU supervised by your CS.          |  |  |

If the CPU usage reported to CS by the NPU is greater than cpuse, the HOP and the controlling NOP are alerted. If the buffer availability reported to CS by the NPU is less than buff, the HOP and the controlling NOP are alerted. To turn off all messages, set CP=100 and BU=0.

## **CONTROL** Command

After establishing communication with a CS, you can gain or lose control of one or more NPUs supervised by your CS with the CONTROL command.

The command format is:

CONTROL, option, status.

or

CO, option, status.

Parameter

option

Description One of the following:

| option      | Keyword Abbreviation |
|-------------|----------------------|
| NPU=npuname | NP                   |
| NPUS        | NP S                 |
| AUTO        | AU                   |
| npuname     | Name of the NPU.     |

status ON or OFF.

The NPU=npuname option allows you to gain control of a specific NPU. The NPUS option allows you to gain control over all uncontrolled NPUs currently supervised by your CS. The AUTO option allows you to gain control over all uncontrolled NPUs currently supervised by your CS and all other uncontrolled NPUs that may later come under the supervision of your CS. The AUTO option can be cancelled by entering any valid CONTROL command with the OFF status specified.

## Example:

Suppose there are four NPUs (1, 2, 3, and 4) available to be controlled in the network. The first NOP logs in to CS and controls NPU 1. The second NOP establishes a connection to CS and enters the CONTROL, AUTO, ON command. The second NOP becomes the controlling NOP and controls all of the uncontrolled NPUs (in this example 2, 3, and 4). When the first NOP relinquishes control of NPU 1, that NPU is then controlled by the second NOP. The second NOP also controls all of the new NPUs joining the network automatically.

If no other NOP exists for the NPUs specified, the response to a request for control consists of a list of the NPUs you now control followed by a READY.. prompt; otherwise, you receive a diagnostic messsage.

Since a HOP automatically controls all NPUs being supervised by a CS, the CONTROL commands are not used by the HOP. Whenever a NOP loses control of an NPU for any reason (including ending the connection to CS or the failure of some network element that was supporting the connection to CS), CS informs the HOP and all other connected NOPs by sending an unsolicited status report.

If any NOP has AUTO control status, the operators are informed of the identity of the controlling NOP. Whenever a CS gains supervision of a new NPU, the HOP, all NOPs, and all DOPs are informed that the NPU is being supervised.

#### **Disable Network Element Command**

The controlling NOP changes the status of a network element from enabled (EN), active (AC), or down (DN), to disabled (DI) by the DISABLE command.

There are two forms of the DISABLE command. Refer to Status Message Formats for NOP, earlier in this section, for the format of the status line returned.

The first form disables a single element in a network.

The command format is:

DISABLE, element.

or

DI,element.

Parameter

#### Description

One of the following:

element

| element           | Keyword Abbreviation                |
|-------------------|-------------------------------------|
| LINE=elementname  | LI                                  |
| LLINK=elementname | LL                                  |
| TERM=elementname  | TE                                  |
| TRUNK=elementname | TR                                  |
| elementname       | Name of the element to be disabled. |

For a logical link or trunk, if the element is active when the command is entered, all data traffic through the element is terminated and the affected host application programs and terminal users are notified. For a line or terminal, if the element is active when the command is entered, all data traffic through the element is terminated and only the affected host application programs are notified.

The second form disables archetype switched virtual circuits (SVCs) that are in an enabled state.

The command format is:

DISABLE, SVC=atname, NCIR=numcir.

or

DI,SV=atname,NC=numcir.

 Parameter
 Description

 atname
 Archetype SVC name.

 numcir
 Number of SVCs to change from an enabled state to a disabled state.

The second form of the DISABLE command allows you to decrease the number of enabled SVCs for a particular X.25 subTIP type. If the number of enabled SVCs is greater than or equal to numcir, then the number of disabled SVCs is increased by numcir and the number of enabled SVCs is decreased by numcir. If the number of enabled SVCs is less than numcir, then the number of disabled SVCs is increased by the number of available enabled SVCs and the number of enabled SVCs is set to zero. Disabling SVCs has no effect on active SVCs. If, for a particular SVC element, the command could not be executed, an unsolicited status report is sent to you giving the reason the command was not executed.

## NOTE

No attempt is made to protect you from disabling network elements that support your connection to CS. You may lose contact with CS as a result of such a command. When this happens, you may need to use another terminal or the host console to enable the disabled network element.

The NPUs affected by the command send an unsolicited status report indicating the new status for the element.

Trunks and logical links can have two owning NPUs (one at each end of the trunk or logical link). When two NPUs are involved and both are supervised by your CS, the DISABLE,TRUNK and DISABLE,LLINK commands are processed as follows:

- If one of the NPUs is local and one is remote, the command is forwarded to the local NPU.
- If both of the NPUs are local or both are remote, the command is forwarded to the NPU with the lower node number.
- If your CS supervises only one of the NPUs, the command is forwarded to that NPU.

In either case, the trunk or logical link enters the disabled (DI) state at the owning NPU that receives the DISABLE command and is detected as being down (DN) by the other NPU. Both of these changes are reported to CS, which informs all operators of the changes by sending unsolicited status reports.

If a single NPU owns both ends of the link, the command is forwarded to that NPU. This status change is also reported by sending unsolicited status reports.

Disabling a trunk can cause one or more logical links to go down. The owning NPUs report the failure of these links by sending unsolicited status reports.

#### **Enable Network Element Command**

The controlling NOP changes the status of one or more network elements from disabled (DI) to enabled (EN), allowing the element(s) to become active for data traffic by the ENABLE command.

There are five forms of the ENABLE command. Refer to the Status Message Formats for NOP, earlier in this section, for the format of the status line returned.

The first form enables a single element in the network.

The command format is:

ENABLE, element.

or

EN,element.

#### Parameter Description

element One of the following:

| element           | Keyword Abbreviation |
|-------------------|----------------------|
| LINE=elementname  | LI                   |
| LLINK=elementname | LL                   |
| TERM=elementname  | TE                   |
| TRUNK=elementname | TR                   |
|                   |                      |

elementname

Name of the element to be enabled.

The second form enables all disabled elements of the specified type on an NPU.

The command format is:

ENABLE, element, NPU=npuname.

or

EN,element,NP=npuname.

## Parameter Description

element One of the following:

| element | Keyword Abbreviation |
|---------|----------------------|
| LINES   | LIS                  |
| LLINKS  | LLS                  |
| TERMS   | TES                  |
| TRUNKS  | TRS                  |
| •       |                      |

npuname Name of an NPU.

The third form enables all disabled elements of the specified type on all NPUs.

The command format is:

ENABLE, element, NPUS.

or

EN,element,NPS.

Parameter

operation

Description One of the following:

| element | Keyword Abbreviation |
|---------|----------------------|
| LINES   | LIS                  |
| LLINKS  | LLS                  |
| TERMS   | TES                  |
|         |                      |

The fourth form enables all disabled terminals on a line.

TRUNKS

The command format is:

ENABLE, TERMS, LINE=termline.

or

EN, TES, LI=termline.

Parameter

## Description

TRS

termline Name of the line to which terminals are connected.

The fifth form enables SVCs that are in a disabled state.

The command format is:

ENABLE, SVC=atname, NCIR=numcir.

or

EN,SV=atname,NC=numcir.

#### Parameter

## Description

atname Archetype SVC name.

numcir Number of SVCs to change from a disabled state to an enabled state.

The ENABLE, TRUNK and ENABLE, LLINK commands are forwarded to both of the owning NPUs (one at each end of the trunk or logical link) if both are supervised by your CS. Enabling a trunk can cause one or more logical links with a down status to become enabled or active. Status changes resulting from enabling a trunk or logical link are reported by the owning NPUs by sending unsolicited status reports.

Enabling a trunk can cause CS to become available to an NPU and, therefore, allow CS to gain control of an NPU.

The ENABLE command allows you to enable all lines or terminal devices on an NPU. When you enable all lines or terminal devices of a given type on an NPU or all terminals on a line, the NPU or line affected by the command sends an unsolicited status report telling you how many elements of the given type are curently disabled. The NPU then sends unsolicited status reports telling the new status of each element for which the command was executed. If, for a particular element, the command could not be executed, an unsolicited status report is sent to you giving the reason the command was not executed.

The ENABLE,SVC command allows you to increase the number of enabled SVCs for a particular X.25 subTIP type. If the number of disabled SVCs is greater than or equal to numcir, then the number of enabled SVCs is increased by numcir. If the number of disabled SVCs is less than numcir, then the number of enabled SVCs is increased by the number of disabled SVCs and the number of disabled SVCs is set to zero. Enabling SVCs has no effect on active SVCs. If, for a particular SVC element, the command could not be executed, an unsolicited status report is sent to you giving the reason the command was not executed.

#### NPU Go Command

After establishing a connection with CS, the newly supervised NPU may ask for a GO command from the controlling NOP.

The GO command format is:

GO,NPU=npuname.

or

GO,NP=npuname.

Parameter Description

npuname Network defined name of the NPU.

If there is a controlling NOP for the NPU when CS receives a GO request, the GO request is relayed to the controlling NOP and to the HOP. If there is no controlling NOP, the GO request is relayed to the HOP and to all currently connected NOPs. The HOP or controlling NOP (if there is one) can, as needed, request status information or enable/disable network elements. Thus, the controlling NOP can control the initial status or the network elements connected to or supported by a given NPU prior to that NPU beginning terminal operations.

The GO request message is repeated periodically until an operator takes control of the NPU and enters the GO command.

Upon entry of the GO command the NPU proceeds to activate lines and accept terminal connections.

## NPU Load Command

The LOAD command causes an active (AC) NPU or all active NPUS to be stopped, reloaded, and reactivated.

There are two forms of the LOAD command.

The first form causes the specified NPU to be stopped, reloaded, and reactivated.

The command format is:

LOAD, NPU=npuname, dumpoption.

or

LO,NP=npuname,dumpoption.

#### Parameter

#### Description

npuname

dumpoption Optional dump parameter; one of the following:

Name of the NPU.

| dumpoption | Keyword Abbreviation |
|------------|----------------------|
| DUMP       | DU                   |
| NDUMP      | ND                   |

If the DUMP option is specified, a memory dump of the NPU is taken prior to reloading. If the NDUMP option is specified, the NPU is reloaded without taking a memory dump. If the dump status is not specified, taking a memory dump depends upon the setting of the dump flag. Refer to NPU Memory Dump Command, next, for more information. The DUMP or NDUMP option is in effect only for the immediate load. It has no permanent effect on the NPU memory dump flag.

When an NPU executes a LOAD command, the CS connection to that NPU is lost during the dump/load process. The trunks and logical links supported by the NPU are detected as down (DN) by the NPUs at the other ends of the trunks and logical links. All of the appropriate operators receive corresponding unsolicited status reports.

The second form causes all active NPUs to be stopped, reloaded, and reactivated.

The command format is:

LOAD, NPUS, dumpoption.

or

LO,NPS, dumpoption.

Parameter

#### Description

dumpoption

Optional parameter; one of the following:

| dumpoption | Keyword Abbreviation |
|------------|----------------------|
| DUMP       | DU                   |
| NDUMP      | ND                   |

If the DUMP option is specified, a memory dump of all active NPUs (supervised by this host) is taken prior to reloading. If the NDUMP option is specified, the NPUs are reloaded without taking a memory dump. If the dump status is not specified, taking a memory dump depends upon the setting of the dump flag. Refer to NPU Memory Dump Command, next, for more information. The DUMP or NDUMP option is in effect only for the immediate load. It has no permanent effect on the NPUs memory dump flag.

When all of the NPUs execute LOAD commands, the corresponding CS connections to the NPUs are lost during the dump/load process. The trunks and logical links supported by the NPUs are detected as down (DN) by the NPUs at the other ends of the trunks and the logical links. The appropriate operators receive corresponding unsolicited status reports.

#### NPU Memory Dump Command

The DUMP command causes the memory dump flag to be reset for the specified NPU or NPUs. Initially, this reset condition is set independently for every NPU in the network and is specified on the NPU statement (refer to the NDL Reference Manual for more information on the NPU statements).

There are two forms of the DUMP command.

The first form causes a memory dump of the specified NPU to be taken.

The command format is:

DUMP, NPU=npuname, status.

or

DU, NP=npuname, status.

Parameter Description

npuname Name of the NPU.

status ON or OFF.

The second form causes a memory dump of all NPUs to be taken.

The command format is:

DUMP, NPUS, status.

or

DU, NPS, status.

ParameterDescriptionstatusON or OFF.

If status is ON, a memory dump will be taken the next time the NPU is reloaded (unless overridden by the LOAD command). If status is OFF, a memory dump will not be taken the next time the NPU is reloaded (unless overridden by the LOAD command).

## Send Message Command

A controlling NOP can send a message to the HOP or any terminal device user or group of terminal device users using the SEND command. The NOP can address the message to a single user or to all users on the specified line, logical link, NPU, or all NPUs under the supervision of the CS.

The HOP cannot use the HOST element to send a message.

The command format is:

SEND, element, MSG=message.

or

SE, element, MS=message.

#### Parameter Description

element

One of the following:

## element Keyword Abbreviation LINE=elementname LI LLINK=elementname LL NPU=elementname NP TERM=elementname TE HOST HO NPUS NPS elementname

Name of the element to which the message is addressed.

Text message of no more than 50 characters. If more than 50 characters message are entered, a diagnostic message is issued. The MSG=message parameter is order dependent and must appear as the last parameter of the command.

CS, upon accepting a SEND command, does not issue the READY.. prompt until processing of the SEND command has completed, in order to prevent an NPU from being flooded with operator messages. CS sends a message to you as each NPU receives the SEND command. When processing is complete, CS sends the READY.. message.

If a terminal is specified as the network element, it must be an interactive terminal device. Otherwise, an error message is issued to the sender.

If the element referenced by a SEND command is not currently active or enabled, you receive an error message. This error message is followed by a status line for the element; the operator is thus informed why the message could not be delivered. The status text line is followed by the READY .. prompt.

# NETWORK CONTROL BY DOP

The commands described next are available to the HOPs, NOPs, and DOPs. All DOPs can obtain unsolicited status reports and use status and diagnostic commands.

## **BECOMING A DOP**

To become a DOP you must be authorized by site personnel to access CS.

After initiation of the network, you become a DOP as follows:

1. Log in as described in the NOS 2 Reference Set, Volume 2.

2. In response to the APPLICATION: prompt, enter:

CS-

3. The system responds:

HELLO, YOU ARE NOW A DIAGNOSTIC OPERATOR

This message is followed by the prompt:

READY..

You can now enter the DOP commands described later in this section.

You can cancel a command that results in a large volume of output by entering the interruption or termination sequence (refer to the NOS 2 Reference Set, Volume 3).

# NOTE

Use caution when cancelling output because unsolicited status messages could also be discarded.

When you cancel output, the message

OUTPUT DISCARDED READY..

or

OUTPUT DISCARDED ..

appears at the terminal at the point from which the data was discarded.

If the terminal is in page wait mode, † you must press CR after every page of output before more output can be sent to the terminal.

To relinquish DOP status, enter one of the following:

To logout and end the terminal connection to the host, enter:

GOODBYE

or

BYE

or

LOGOUT

To initiate a new login dialog, enter:

HELLO

or

LOGIN

To remain logged in and be prompted for another application, enter:

END

To remain logged in and be switched automatically to the application named applname, enter:

END, applname

## STATUS MESSAGE FORMATS FOR DOP

Some of the DOP commands cause various status messages to be displayed on your terminal. The normal response to a STATUS command is one line of text returned when status is requested for a coupler, line, NPU, or terminal device. Two text lines can be returned when status is requested for logical links or trunks (if the CS to which you are connected is supervising NPUs at each end of the element, a line of text is returned for each end of the logical link or trunk). For multiple element status commands, a response is generated for all elements expressed or implied in the command. For example, a status request for all terminals on an NPU begins with a status report (text line) for the NPU. This is followed by a status report for the first active (AC) line on the NPU. A status report for each terminal device configured on the line follows. This is followed by a status report of the next active line and so on.

<sup>†</sup> It is suggested that a hardcopy device be used for DOP terminals; this prevents the paging problem and provides a permanent log of network events.

The following are the general formats for these status messages.

- Coupler status line

CPLER: name, status, nodenum, npunamel/cplnum.

- Line status line

LINE: name, status, linetype, npunamel/port.

- Logical link status line

LLINK: name, status, RL=n, loglinktype, npunamel/nodenum, npuname2/nodenum.

- NPU status line

NPU: name, status, nodenum, gostatus, dump.

- Archetype switched virtual circuit (SVC) status line

SVC: atname, EN=ennum, DI=dinum, AC=acnum, stip.

- Terminal device status line

TERM: name, status, dt/cc, / hostnid, linename/al/a2.

- Trunk status line

TRUNK: name, status, linetype, npunamel/port, npuname2/port.

In the preceding status message general formats the following variables are used.

Variable

| acnum    | Number of SVCs of the element that are in an active state (from 0 to $255$ ).        |
|----------|--------------------------------------------------------------------------------------|
| atname   | Name of the archetype SVC element.                                                   |
| al       | First level address (cluster address, configuration ordinal).                        |
| a2       | Second level address (terminal address, stream number).                              |
| cplnum   | Coupler number for the indicated NPU.                                                |
| dinum    | Number of SVCs of the element that are in a disabled state (from $0$ to 255).        |
| dt       | Device type (CON, CR, LP, CP, PL).                                                   |
| dump     | NPU dump flag (ON or OFF).                                                           |
| ennum    | Number of SVCs of the element that are in an enabled state (from 0 to $255$ ).       |
| gostatus | Go status of the NPU (if waiting for GO, NEEDGO appears).                            |
| hostnid  | Host (coupler) node number of the host to which the terminal is currently connected. |

Description

| Variable    |                                                                                                                                                                                                                                                                                               | Description                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linename    | Name of the lin                                                                                                                                                                                                                                                                               | ne to which the terminal device is connected.                                                                                                                                     |
| linetype    | Line type (refer to the NDL Reference Manual).                                                                                                                                                                                                                                                |                                                                                                                                                                                   |
| loglinktype | Logical link ty                                                                                                                                                                                                                                                                               | ype (H-N for host to NPU, H-H for host to host).                                                                                                                                  |
| name        | Name of the element.                                                                                                                                                                                                                                                                          |                                                                                                                                                                                   |
| nodenum     | Node number of a coupler or NPU.                                                                                                                                                                                                                                                              |                                                                                                                                                                                   |
| npuname l   | Name of an NPU that supports or is connected to the element (also the name of the NPU that reported the status).                                                                                                                                                                              |                                                                                                                                                                                   |
| npuname2    | Name of the NPU at the other end of the logical link or trunk.                                                                                                                                                                                                                                |                                                                                                                                                                                   |
| port        | Port number of the line or trunk on the indicated NPU.                                                                                                                                                                                                                                        |                                                                                                                                                                                   |
| RL=n        | Regulation level currently in effect.                                                                                                                                                                                                                                                         |                                                                                                                                                                                   |
| status      | Network elements are initially set to either a disabled or enabled<br>state. Initially enabled elements automatically become active during<br>the course of normal network operation. Every network element (such as<br>line, logical link, NPU, or trunk) is in one of the following states. |                                                                                                                                                                                   |
|             | status                                                                                                                                                                                                                                                                                        | Description                                                                                                                                                                       |
|             | AC                                                                                                                                                                                                                                                                                            | Network element is active. An element becomes active when it is enabled and is handling network data traffic.                                                                     |
|             | DI                                                                                                                                                                                                                                                                                            | Network element is disabled. The element cannot become active unless enabled by an operator command.                                                                              |
|             | DN                                                                                                                                                                                                                                                                                            | Network element is down. A failure was detected that<br>terminated data traffic for the element. If the failure<br>condition ceases, the element returns to an enabled<br>status. |
|             | EN                                                                                                                                                                                                                                                                                            | Network element is enabled. It was enabled by the operator and is in a physically operative condition.                                                                            |
|             | NC                                                                                                                                                                                                                                                                                            | Network element is not configured. The NPU does not recognize the element.                                                                                                        |
| stip        | SubTIP type (PA                                                                                                                                                                                                                                                                               | AD or APPL).                                                                                                                                                                      |

tc

Terminal class.

# UNSOLICITED STATUS REPORTS FOR DOP

Each time a significant event occurs, CS updates its recent history buffer (refer to Recent History Command later in this section) and logs the event in the NAM dayfile. CS then sends a report about the event, called the unsolicited status report, to all DOPs who have selected to receive unsolicited status reports from the NPU (refer to Report Unsolicited Status Command later in this section). Unsolicited status reports are time-stamped whereas solicited status reports are not time-stamped.

#### DOP COMMANDS

All DOP commands consist of a command verb and, sometimes, one or more parameters. The command must begin in the first character position and contain no blanks. The terminator (.) is optional. Some command verbs and parameters can be shortened to a 2- or 3-character abbreviation. You can mix abbreviated and unabbreviated command verbs and parameters in all network commands. Parameters are order independent except where noted. You can enter commands pertaining only to the NPUs supervised by the CS to which you are connected.

## **CS INFORMATION COMMAND**

You can access information about all operators and NPUs connected to and supervised by your CS with the INFO command.

The command format is:

INFO.

or

IN.

The response lines are an operator information line and an NPU information line for each operator (DOP and NOP) and for each NPU supervised by a CS, respectively.

The format of the operator information line is:

DOP: termname, username, acn.

NOP: termname, username, acn, auto.

The format of the NPU information line is:

NPU: npuname, status, nodenum, go-status, nopname.

In the preceding information line formats the following variables are used.

#### Variable

#### acn CS application connection number. auto Control status of the NOP (if the NOP is an auto control NOP, AUTO appears). Refer to the NOP CONTROL commands described earlier in this section. nodenum Node number of the NPU. Terminal name of the NOP that is controlling the NPU. If the NPU has no nopname controlling NOP, the field is blank. npuname Name of the supervised NPU. status Status of the NPU. (AC if the NPU is active, MI if the NPU is in a mismatch condition). termname Name of the terminal at which the DOP or NOP resides. username User name of the DOP or NOP. go-status If the NPU is waiting for GO, NEEDGO is displayed.

Description

## NPU DIAGNOSTIC TEST COMMAND

The TST command allows any operator to request, interact with, or terminate the diagnostic program within any NPU supervised by a CS.

The command format is:

TST,NPU=npuname,option.

or

TS,NP=npuname,option.

Parameter

Description

npuname

Name of the NPU containing the diagnostic program with which the operator wants to communicate.

option

One of the following:

| option      | Keyword Abbreviation                                                      |
|-------------|---------------------------------------------------------------------------|
| DROP        | DR                                                                        |
| MSG=message | MS                                                                        |
| REQUEST     | RE                                                                        |
| message     | Command that controls the execution of the diagnostic program in the NPU. |

CS keeps track of which NPUs are currently running diagnostic tests and which operators are using them. A single operator is permitted to perform diagnostic tests in several different NPUs simultaneously. All operators can interact with the diagnostics in a single NPU, but only one operator can run the diagnostics.

## **TST Drop Option**

The DROP parameter cancels your diagnostic program reservation in the specified NPU. All diagnostics currently being performed by you in the specified NPU are terminated. If the diagnostic program is not executing, the TST command is ignored and an error message is returned.

#### **TST Msg Option**

The MSG=message parameter allows you to interact with an NPU diagnostic program. It allows you to send a command message in the form of a text string to the diagnostic program in the specified NPU. A typical use of the message option is to initiate and terminate diagnostic tests. The option is accepted only if you previously entered and confirmed a REQUEST option; otherwise, an error message is received. Refer to the CCP 3 Diagnostic Handbook for more information. The diagnostic program sends text messages through CS to you. The message is an unsolicited status report with this format:

FROM npuname/DIAGNOSTIC: TO termname: messagetext

| npuname     | Name of the NPU.                     |
|-------------|--------------------------------------|
| termname    | Name of your terminal.               |
| messagetext | Message from the diagnostic program. |

#### **TST Request Option**

The REQUEST parameter allows you to initiate interaction with an NPU diagnostic program. An NPU diagnostic program is assigned to you until one of these events occurs:

- You drop the diagnostic program (by sending a TST command with the DROP option).
- The connection between you and CS is terminated for any reason.
- Supervision of the NPU is lost by CS.

# **RECENT HISTORY COMMAND**

The HISTORY command requests a display of the recent unsolicited status reports from a CS.

The command format is:

HISTORY,ALL.

or

HI,ALL.

If the ALL option is not used, only the last (most recent) page (based on your terminal's page size) of the unsolicited status reports is displayed.

Any DOP or NOP can enter the HISTORY command to obtain reports from CS.

A HOP can enter the HISTORY command to obtain reports from CS, NS, or NVF after assigning the NAM K display to the desired application (refer to section 8, K-Display Utilities, for more information on the NAM K display).

Each application maintains a separate record of the most recent significant NPU load, DOP, NOP, or HOP events. The occurrence of these various significant events prompts the sending of an unsolicited status report to all appropriate operators. All reports are temporarily available through the HISTORY command and are permanently recorded in the NAM dayfile.

# **REPORT UNSOLICITED STATUS COMMAND**

The REPORT command requests a CS to report all unsolicited status messages from an NPU.

The command format is:

REPORT, element, option

or

RE,element,option

Parameter

Description

element

One of the following:

| element     | Keyword Abbreviation |
|-------------|----------------------|
| NPU=npuname | NP                   |
| NPUS        | NPS                  |
| npuname     | Name of the NPU.     |

option ON or OFF. If option is not specified, ON is assumed. If option is ON, CS reports all unsolicited status messages until you turn reporting off.

By default, HOPs receive reports for all NPUs supervised by a CS, and controlling NOPs receive reports for the NPUs they control. Other NOPs and DOPs do not receive any reports. However, any operator can use this command to request unsolicited status reports from any NPU supervised by a CS.

# SEND MESSAGE COMMAND

A DOP can send a message to any of the other operators (HOP, NOPs, and other DOPs) connected to the same CS using the SEND command.

The command format is:

SEND, element, MSG=message

or

SE,element,MS=message

Parameter Description

element One of the following:

Keyword Abbreviation

ΤE

HO

TERM=termname

element

HOST

termname

Name of the terminal to which the message is addressed.

message Text message of no more than 50 characters. If more than 50 characters are entered, an error message is issued. The MSG=message parameter is order dependent and must appear as the last parameter of the command.

If a terminal device is specified as the network element, it must be an interactive terminal device currently connected to your CS. Otherwise, an error message is issued to the sender.

If you specify HOST, the message is sent to the HOP of the host to which you are connected.

If the element referenced by a SEND command is not currently connected to a CS, you receive a diagnostic message. The diagnostic message is followed by the READY.. prompt.

# STATUS NETWORK ELEMENT COMMAND

You request a CS to display status information on the various network elements (such as couplers, NPUs, and trunks) with the STATUS command.

There are five forms of the STATUS command. Refer to the Status Message Formats for DOP, earlier in this section, for the format of the status line returned.

The first form requests the status of a particular element in the network.

The command format is:

STATUS, element.

or

ST,element.

## Parameter

## Description

element

One of the following:

| element           | Keyword Abbreviation                         |
|-------------------|----------------------------------------------|
| CPLER=elementname | CP                                           |
| LINE=elementname  | LI                                           |
| LLINK=elementname | LL                                           |
| NPU=elementname   | NP                                           |
| SVC=elementname   | SV                                           |
| TERM=elementname  | TE                                           |
| TRUNK=elementname | TR                                           |
| elementname       | Name of the element whose status is desired. |

60459300 D

The second form requests the status of all of the elements of a particular type on one or all NPUS.

The command format is:

STATUS, linkelement npuelement, statuscode.

or

ST,linkelement,npuelement,statuscode.

|--|

linkelement

Description

One of the following:

| linkelement | Keyword Abbreviation |
|-------------|----------------------|
| CPLERS      | CPS                  |
| LINES       | LIS                  |
| LLINKS      | LLS                  |
| SVCS        | SVS                  |
| TERMS       | TES                  |
| TRUNKS      | TRS                  |

npuelement

One of the following:

| npuelement  | Keyword Abbreviation |
|-------------|----------------------|
| NPU=npuname | NP                   |
| NPUS        | NPS                  |
| npuname     | Name of the NPU.     |

statuscode

Optional. If specified, only the elements with that status are reported.

| statuscode | Description |
|------------|-------------|
| AC         | Active      |
| DN         | Down        |
| DI         | Disabled    |
| EN         | Enabled     |

The third form requests the status of all terminal devices on a line or a logical link. The command format is:

STATUS, TERMS, mode, statuscode.

or

ST, TES, mode, statuscode.

| section of the sectio |             |

mode

One of the following:

| LINE=elementname LI<br>LLINK=elementname LL                                                                      | mode             | Keyword Abbreviation |
|------------------------------------------------------------------------------------------------------------------|------------------|----------------------|
| LLINK=elementname LL                                                                                             | LINE=elementname | LI                   |
| and the second |                  | LL                   |

elementname

Name of the specified element.

statuscode

Optional. If specified only the elements with that status are reported.

| statuscode | Description |
|------------|-------------|
| AC         | Active      |
| DN         | Down        |
| DI         | Disabled    |
| EN         | Enabled     |

The fourth form requests the status of all NPUs supervised by the CS.

The command format is:

STATUS, NPUS.

or

ST, NPUS.

The fifth form requests the status of all archetype SVCs on a line.

The command format is:

STATUS, SVCS, LINE=line.

or

ST, SVS, LI=line.

Parameter

### Description

line Name of the specified line.

A CS does not keep track of the status of the various network elements. NPUs supply the information required to satisfy the STATUS commands by sending messages to CS. In the case of a multiple-element status request, the number of messages sent can become significant. You cannot enter another command until all the messages are delivered and a READY.. prompt is displayed. A controlling NOP, other NOPs, or the DOPs can cancel a STATUS command by enter-ing the interruption or termination sequence (refer to the NOS 2 Reference Set, Volume 3 for details). A HOP can cancel a STATUS command by using the slant (/) key.

When status is requested for a coupler, line, NPU, or terminal the normal response to the STATUS command is one line of text. When status is requested for logical links or trunks, two text lines may be returned (if the CS to which you are connected is supervising NPUs at each end of the element, a line of text is returned for each end of the logical link or trunk). When status is requested for archetype SVCs on a line, a text line with the line status is returned and a text line for each active archetype SVC is returned.

# SUMMARY OF NETWORK OPERATION COMMANDS

Following is a summary of the network operation commands.

#### CONTROL COMMANDS FOR HOP

The following commands are available only to the HOP.

# NAM K Display

Assign the NAM K display by using one of the following (refer to section 8, K-Display Utilities, for additional information):

| Command   | Description                                                                              |
|-----------|------------------------------------------------------------------------------------------|
| K.AP=CS.  | Assigns the NAM K display to the communication supervisor (CS).                          |
| K.AP=NS.  | Assigns the NAM K display to the network supervisor (NS).                                |
| K.AP=NVF. | Assigns the NAM K display to the network validation facility (NVF).                      |
| K•*       | Assigns the NAM K display back to NAM mode after it has been assigned to CS, NS, or NVF. |

## **NAM Startup**

Initiate NAM by entering NAM.

# NAM Shutdown

The sequence of commands used to shutdown NAM is:

K.AP=NVF.

K.DISABLE,HOST.

or

K.IDLE,HOST.

# NAM Mode Commands

The HOP assigns the NAM K display to NAM mode before entering any of the following commands.

| Command | Description                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------|
| DB      | Activates the inline debug code.                                                                                         |
| DE      | Deactivates the inline debug code.                                                                                       |
| DU      | Activates field length dump.                                                                                             |
| END     | Clears the NAM K display.                                                                                                |
| FL      | Changes NAM's maximum field length.                                                                                      |
| HELP    | Displays information about the NAM mode commands on the right K-display screen.                                          |
| IG      | Causes NAM to ignore alert requests.                                                                                     |
| LB      | Begins logging of the network traffic on the debug log file.                                                             |
| LE      | Ends logging of the network traffic on the debug log file.                                                               |
| LR      | Releases the debug log file.                                                                                             |
| RS      | Dumps the statistics data to the statistics file, resets the counters to $0$ (zero), and continues gathering statistics. |
| SEND    | Sends a message to another HOP.                                                                                          |
| ST      | Causes the NAM status display to appear on the left K-display screen.                                                    |

### **NS Control Commands**

The HOP assigns the NAM K display to NS before entering any of the following commands.

| Command † | Description                                                         |
|-----------|---------------------------------------------------------------------|
| FILE      | Assigns an alternate load file to NS for loading the specified NPU. |
| HISTORY   | Requests a display of the recent unsolicited status reports.        |
| NOFILE    | Instructs NS to use the default NPU load file for loading all NPUs. |
| STATUS    | Requests the current load/dump status of NPUs.                      |

### **NVF** Control Commands

The HOP assigns the NAM K display to NVF before entering any of the following commands.

| Command † | Description                                                  |
|-----------|--------------------------------------------------------------|
| DISABLE   | Disables an application or all host network operations.      |
| ENABLE    | Enables an application.                                      |
| IDLE      | Terminates an application or all host network operations.    |
| HISTORY   | Requests a display of the recent unsolicited status reports. |
| STATUS    | Requests the status of network elements.                     |

### CONTROL COMMANDS FOR HOP AND NOP

The HOP assigns the NAM K display to CS before entering any of the following commands. The NOP can enter these commands by logging into CS.

| Command † | Description                                                                        |
|-----------|------------------------------------------------------------------------------------|
| ALERT     | Changes the threshold that CS uses for alerting the NOP and HOP of NPU saturation. |
| CONTROL   | Allows you to gain or give up control of NPUs.                                     |
| DISABLE   | Changes the status of the specified elements to disabled.                          |
| DUMP      | Causes the memory dump flag to be reset for the specified NPU.                     |
| ENABLE    | Changes the status of the specified elements to enabled.                           |
| GO        | Activates the lines and accepts terminal device connections on an NPU.             |
| LOAD      | Causes active NPUs to stop, reload, and reactivate.                                |
| SEND      | Sends a message of no more than 50 characters to users.                            |

<sup>†</sup> To use the abbreviated form of commands, you can type the first two letters of the command. For example, FI for FILE.

# CONTROL COMMANDS FOR HOP, NOP, AND DOP

The HOP assigns the NAM K display to CS before entering any of the following commands. The DOP and NOP can enter these commands by logging into CS.

| Command <sup>†</sup> | Description                                                                            |
|----------------------|----------------------------------------------------------------------------------------|
| INFO                 | Accesses information about all operators and NPUs connected to CS.                     |
| HISTORY              | Requests a display of the recent unsolicited status reports.                           |
| REPORT               | Requests CS to report all unsolicited status messages from NPUs.                       |
| SEND                 | Sends a message of no more than 50 characters to the HOP or another NOP or DOP.        |
| STATUS               | Requests the status of network elements.                                               |
| TST                  | Allows you to control interaction with an NPU diagnostic program in the specified NPU. |

<sup>&</sup>lt;sup>†</sup>To use the abbreviated form of commands, you can type the first two letters of the command. For example, IN for INFO.

# **NETWORK UTILITIES**

This section describes the following utilities and files involved in the operation of the network and interactive subsystems of NOS.

- NAM Initialization (NAMI). This utility controls the network software startup process.
- Network Dump Collector (COLLECT). This utility produces permanent files from the various NPU and host dump, trace, statistics, and list files resulting from any abnormal termination of the network.
- Load File Generator (LFG). This utility produces a direct access file used by the Network Access Method (NAM) to perform the downline load of network processing units (NPUs).
- NPU Dump Analyzer (NDA). This utility produces readable listings from dump files produced when NAM dumps NPUs.
- PIP Dump Analyzer (LISTPPM). This utility program converts binary records from the peripheral interface package (PIP) memory dump file into a report listed in byte format.
- Application Interface Program (AIP) Trace. This utility produces a trace file of the messages transferred between an application program and NAM. The information contained in this trace can be useful in tracking network problems and in debugging application programs.
- Network description files. Network description files are used by the Transaction Facility (TAF) to describe user access characteristics defined by terminal definition directives.
- Stimulator. A stimulator is a collection of programs that artificially loads the system to analyze the effects of such a load on system performance and reliability.

# NAM INITIALIZATION (NAMI)

The NAMI utility controls the network software startup process. The network software consists of the NAM Subsystem and several rollable jobs (NS, CS, NVF, TVF, COLLECT) and network applications (IAF, TAF, RBF, MCS, PTF, QTF, ITF). The NAMI utility starts NAM and the programs NS, CS, NVF, TVF, COLLECT, and other applications desired at the site such as RBF, QTF, and ITF by submitting jobs to the input queue. The skeletons of these jobs are contained on a master startup file along with parameter records containing directives telling the NAMI utility what parameters to substitute in the job skeletons and what jobs to start. Refer to the NOS 2 Installation Handbook for descriptions of the master startup file, parameter records, and job skeleton records.

The advantage of having the NAMI utility start up the network software is that parameters that are common to more than one job or that change from one network startup to the next can be changed easily.

The console operator enters the procedure call NAM or NAMNOGO to call procedure file NAM or NAMNOGO respectively (refer to the NOS 2 Operations Handbook). These procedure files (saved under the SYSTEMX user name) contain the NAMI command, which calls the NAMI utility. The format of the NAMI command is:

NAMI, p1, p2,..., pn.

 $\mathsf{P}_1$  is a parameter consisting of a keyword or a keyword equated to a value. All parameters are order independent.

| P <sub>i</sub> |                                                                                                                                                                                                                                                                                                                                  | Description                                                                                                                                                                                                                                                                              |  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| GO             | This parameter initiates the network startup process without operator intervention.                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                          |  |
| MFN=filename † | The permanent file name of the master file to be used. Once this<br>parameter is specified, subsequent network startups use this master<br>file until a new master file is specified. If this parameter is<br>omitted, the previously selected master file is used. The master<br>file must reside on the system default family. |                                                                                                                                                                                                                                                                                          |  |
| 0IN=nnn        | dumps/traces with                                                                                                                                                                                                                                                                                                                | The previous network invocation number (nnn) for which the<br>dumps/traces will be collected during this run. If this parameter<br>is omitted, the current network invocation number minus l is used.                                                                                    |  |
| PW=password †  | The password assigned to the user name where the master file is<br>stored. If this parameter is omitted, the previously selected<br>password is used. This parameter is not required if UN=NETOPS is<br>specified.                                                                                                               |                                                                                                                                                                                                                                                                                          |  |
| RN=recordname† | The name of the parameter record on the master file that is used for<br>this network initiation. Once this parameter is specified,<br>subsequent network startups use this same parameter record until a<br>new parameter record is specified. The following recordnames can be<br>specified.                                    |                                                                                                                                                                                                                                                                                          |  |
|                | recordname                                                                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                              |  |
|                | INIT                                                                                                                                                                                                                                                                                                                             | Purge existing dumps/traces, stop but do not dump<br>local NPUs at network startup, take host dumps when<br>an NPU fails, and stop local NPUs at host<br>termination. Use INIT for the initial startup of<br>single host networks.                                                       |  |
|                | MINIT                                                                                                                                                                                                                                                                                                                            | Purge existing dumps/traces, stop local NPUs at<br>network startup, do not take NPU dumps before<br>initial loading of NPUs, do not stop local NPUs at<br>host termination, and do not take host dumps when an<br>NPU fails. Use MINIT for the initial startup of<br>multihost networks. |  |
|                | MRECOV                                                                                                                                                                                                                                                                                                                           | Purge existing dumps/traces, do not take NPU dumps<br>before initial loading of NPUs, do not stop local<br>NPUs at network startup or host termination, and do<br>not take host dumps when an NPU fails. Use MRECOV<br>for recovery startup of multihost networks after a<br>failure.    |  |

<sup>&</sup>lt;sup>†</sup>This parameter must be specified for the initial network software startup. It can be specified either on a NAMI command or by an operator entry using the NAMNOGO procedure.

#### Description

recordname

# Description

- MULTI Collect dumps/traces on tape before network startup, take NPU dumps before initial loading of NPUs, do not stop local NPUs at network startup or host termination, and do not take host dumps when an NPU fails. Use MULTI for the normal restart of multihost networks.
- RECOVR Purge existing dumps/traces, take host dumps when an NPU fails, do not stop NPUs at network startup or termination, and do not dump NPUs before initial load. Use RECOVR for recovery startup of single host networks after a failure.
- RESTRT Collect dumps/traces on tape before network startup, take NPU dumps before initial loading of NPUs, take host dumps when an NPU fails, stop local NPUs at host termination, and do not stop local NPUs before network startup. Use RESTRT for the normal restart of single host networks.
- RS=applname The name of the application to start up. This parameter allows a specified application to be started when the network is already operational. It is not valid at network initiation. The application's startup job skeleton must reside on the parameter record/master file specified for this network initiation.

UN=username†

Pi

The user name where the master file is stored. If this parameter is omitted, the previously selected user name is used.

The first time the network startup process is executed, a permanent file is created using a network invocation number of 1 and parameters from the NAMI command. The initial call to NAMI must specify the filename, password, and username of the master file and parameter record to be used or the console operator must enter them using NAMNOGO.

On subsequent network startup operations, a permanent file exists and contains the names of the last used master file, parameter record, and network invocation number. Parameters from this permanent file will be used to start up the network unless overridden by parameters from the NAMI command or parameters entered by the console operator using NAMNOGO. The NAMI command parameters take precedence over the permanent file parameters, and operator entries take precedence over parameters from either the NAMI command or the permanent file.

16-3

<sup>†</sup> This parameter must be specified for the initial network software startup. It can be specified either on a NAMI command or by an operator entry using the NAMNOGO procedure.

# NETWORK DUMP COLLECTOR (COLLECT)

The COLLECT utility is a program that produces two permanent files: one of the various host dump, trace, statistics, and list files that result from any abnormal termination of the network, and one of any NPU dump files. The collected local files may be copied to the two permanent files and then purged, or copied and not purged. The permanent files can then be copied to tapes. There is also an option to purge the local files without copying them to the permanent files. The format of the COLLECT command is:

COLLECT, NIN=nnn, NOPURGE, NOSAVE.

#### Parameter

### Description

NIN=nnn The 1- to 3-character network invocation number that indicates the upper limit of the invocation numbers to be collected. All files with an NIN value from 1 to nnn are copied to the permanent file. If NIN=nnn is omitted, the default value is 1.

### NOTE

NPUs that stop when the host network software terminates are dumped during the subsequent network invocation. Therefore, the network invocation number of these dumps is 1 greater than the dumps of the host programs taken at the time of the termination.

- NOPURGE Specifies that no purging activity will take place after the collected files are copied to the permanent files. If NOPURGE is omitted, the collected files are purged after they are copied to the permanent files. NOPURGE should not be specified if NOSAVE is specified.
- NOSAVE Specifies that the collection process is not performed and the files indicated by NIN=nnn are purged. NOSAVE should not be specified if NOPURGE is used.

The COLLECT utility is automatically initiated by the network startup job (NAMI) upon each invocation of the network. (COLLECT may not be automatically initiated if the master file has been modified.) The utility receives an NIN value of the last network invocation number. The current network will be initiated with an incremented value of NIN. For example, on the fifth initiation of the network the COLLECT utility has a command call of

COLLECT, NIN=004.

and the network is initiated with an NIN of 005.

The COLLECT utility processes all dump, trace, statistics, and list files whose file names are in the form:

pptsnnn

pp is a 2-character product prefix.

Description pp CS Communication Supervisor IA Interactive Facility NI Network Interface Package NΡ Network Processing Unit NS Network Supervisor NV Network Validation Facility RB Remote Batch Facility TV Terminal Verification Facility

t is the type of file.

| <u>t</u> | Description     |
|----------|-----------------|
| D        | Dump file       |
| L        | List file       |
| S        | Statistics file |
| т        | Trace file      |
|          |                 |

s is the subtype 0, 1, 2, or 3 for the file.

nnn is the network invocation number in the range 000 through 999.

In the case of NPU dumps (pp=NP), ts is a unique hexadecimal number identifying the dump.

The permanent files produced by the COLLECT utility each have one file with many records. Each dump, trace, statistics, or list file is copied to a permanent file as one or more records, where the first record copied is preceded by a 2-word record containing the original file name. This format enables an ITEMIZE or CATALOG of a COLLECT utility permanent file to show which collected files were copied to the permanent file.

The COLLECT utility assigns each permanent file a file name of the form:

DUMPnnn for host dump, trace, statistics, or list files.

or

DUNPnnn for NPU dump files.

nnn is the network invocation number from the COLLECT command.

The permanent files DUMPnnn and DUNPnnn are attached and copied to magnetic tape (or other operator-assigned equipment) if the RESTRT or MULTI startup procedure is selected. Once the files are successfully copied, they are purged.

The COLLECT utility purges all dump and trace files without collecting them on a permanent file if the INIT, MINIT, MRECOV, or RECOVR startup procedure is selected.

# LOAD FILE GENERATOR (LFG)

LFG is a utility program that reformats Communications Control Program (CCP) files for subsequent use by the network supervisor of NAM to load NPUs. LFG accepts one or more input files in single or multifile format and produces a single network load file (NLF) for use by the network supervisor.

LFG is invoked with this command:

LFG, p<sub>1</sub>, p<sub>2</sub>,..., p<sub>n</sub>.

 $P_i$  is a parameter consisting of a keyword or a keyword equated to a value. All parameters are optional and order independent.

°i

Description

BC=nn

This parameter specifies the maximum number of load service messages in a network load file record. It is used to optimize NPU loads. l  $\leq$  nn  $\leq$  64.

BC omitted Same as BC=64.

I=infile The 1- to 7-character name of the file on which the input directives are written.

I omitted Same as I=INPUT.

L=outfile The 1- to 7-character name of the file on which the summary listing is to be written.

L=O Suppress the summary listing. If an error is detected an error message is written to file OUTPUT.

L omitted Same as L=OUTPUT.

NLF=loadfile The 1- to 7-character name of the network load file.

NLF omitted Same as NLF=NLF.

An input directive is contained on the command after the terminator. The I parameter is ignored. This eliminates the need to use a separate input directive file when there are only a few input directives.

When the input directive appears on the LFG command, the first character following the command terminator is the separator  $cha^{ra}cter$ . Any character that is not used in the input directive can be used as the separator character. The input directive must be preceded by a separator and terminated by a blank, period, or the end of the input line (column 72).

For example, (slant used for separator):

LFG,Z./\*FILE,PFILE1,PFILE2.

Z omitted Input directives are not contained on the command. The system uses the I parameter.

Z

### **INPUT DIRECTIVES**

Input directives have this format:

\*FILE,filename1,filename2,...,filenamen.

An input directive begins with an asterisk followed by the directive identifier FILE and a string of file names. The directive identifier and file names are separated by commas. If a specified file is empty, LFG ignores it. LFG scans a directive until it detects a terminator or the end of the directive line (column 72). A directive is terminated by a blank, period, or the end of the line. If an asterisk is not specified, LFG assumes \*FILE and proceeds to read file names. LFG continues to read input directives until the end of the record.

Each file specified by filename contains a load partition or a program initiation control block (PICB) for LFG to reformat. These files are created by the CCP installation process (refer to the NOS 2 Installation Handbook). A load partition is any loadable software module that can be loaded into an NPU during one operation. For example, all of the software for CCP can be loaded into an NPU as one load partition. A PICB consists of a sequence of commands that controls the load or dump operations. For each step in a PICB that specifies a load operation there is a corresponding load partition.

The names of the input files can be specified on the LFG command (Z parameter) or in a separate file (I=infile parameter). In either case, these files must be local to the job that runs LFG. LFG does not rewind the input files.

If the input directives are written on a separate record in a batch job (I=INPUT), the job format is:

ujn. USER,username,password,familyname. LFG,I=INPUT. --EOR--\*FILE,AFILE1,...,AFILEn. \*FILE,BFILE1,...,BFILEn. \*FILE,CFILE1,...,CFILEn. --EOI--

### NETWORK LOAD FILE

The network load file produced by LFG is a random access file with the local file name specified by the NLF parameter of the LFG command. The default network load file name is NLF.

### SUMMARY LISTING

The summary listing produced by LFG is a summary of the network load file contents. The summary is written on the file specified by the L parameter of the LFG command. The default summary file name is OUTPUT. Error messages produced by LFG are also written on this file. The summary listing format is:

| NO. | PARTITION NAME | INPUT FILE | RECORDS |
|-----|----------------|------------|---------|
| 1   | PN 1           | AFILE1     | 3       |
| 2   | PN2            | AFILE2     | 7       |
| 3   | PN3            | AFILE3     | 2       |

| Field          | Description                                                         |
|----------------|---------------------------------------------------------------------|
| NO.            | Line number of the summary listing.                                 |
| PARTITION NAME | Name of the load partition or PICB for LFG to reformat.             |
| INPUT FILE     | Name of the input file on which the load partition or PICB resides. |
| RECORDS        | Number of records in the load partition or PICB.                    |

# NPU DUMP ANALYZER (NDA)

NDA is a utility program that produces a readable printout from the NPU dump file. The NPU dump file may contain one or more dump records, which are created by the network supervisor during the initiation or reloading of a failed NPU. NDA reports depict the state of an NPU at the time a dump is generated. NDA uses the following local scratch files during its processing: NEUFILE, ZZZZINP, and FDMP.

NDA is accessed by a command that allows selection of:

- Dumps from/to specific NPU macromemory addresses.
- Listing options.
- The input directive file.
- The output file.

The format of the command for the NPU Dump Analyzer is:

NDA,  $p_1, p_2, \ldots, p_n$ .

Each parameter is a keyword or a keyword equated to a value. All parameters are optional and order independent. If a parameter is not specified, a default value is assumed. If the same keyword is specified more than once, the last (rightmost) occurrence of the keyword overrides all previous ones. Invalid or undefined parameters cause the run to terminate.

| P <sub>i</sub> |                                                                                                                                                                                                            | Description                                                                                                                                                                                       |  |  |  |  |  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
| BA=addr        | which the dump r<br>beginning of the                                                                                                                                                                       | t hexadecimal address within the NPU macromemory at<br>report begins. Default is BA=address of the actual<br>e dump. This parameter is valid only if parameter LO=M,<br>lirective 9 is specified. |  |  |  |  |  |
| EA=addr        | which the dump r                                                                                                                                                                                           | t hexadecimal address within the NPU macromemory at<br>report ends. Default is EA=address of the actual end of<br>parameter is valid only if parameter LO=M, LO=E, or<br>9 is specified.          |  |  |  |  |  |
| I=infile       |                                                                                                                                                                                                            | cacter name of the input directive file. If there is no file, I=O (zero) must be specified. Default is I=INPUT.                                                                                   |  |  |  |  |  |
| L=outfile      | The $l-$ to 7-character name of the output file. Default is L=OUTPUT.                                                                                                                                      |                                                                                                                                                                                                   |  |  |  |  |  |
| LO=opt         | The 1- to 3-character listing option. Each character specifies a portion of the NPU dump to be listed; any unspecified portions are not listed. Default is LO=MR, if no input directive file is specified. |                                                                                                                                                                                                   |  |  |  |  |  |
|                | opt                                                                                                                                                                                                        | Description                                                                                                                                                                                       |  |  |  |  |  |
|                | E                                                                                                                                                                                                          | All NPU words in the NPU dump record (all of<br>macromemory, file l registers, and page registers).<br>Redundant lines are not suppressed.                                                        |  |  |  |  |  |
|                | м                                                                                                                                                                                                          | Macromemory only. Redundant lines are suppressed.                                                                                                                                                 |  |  |  |  |  |
|                | R                                                                                                                                                                                                          | File 1 registers and page registers only.                                                                                                                                                         |  |  |  |  |  |
| NDF=npudump    | Local file name of the NPU dump file. The NPU dump file may contain<br>multiple NPU dump records. Each record causes a separate NPU dump<br>output to be generated. Default is NDF=NDF.                    |                                                                                                                                                                                                   |  |  |  |  |  |

### INPUT DIRECTIVES

Input directives must be contained in a single logical record on the input directive file. Each directive is in 80-column format. Column 1 is reserved for a 1-character keyword that indicates a change in the processing rules and defines the new rule to be used for the following directives. Each directive containing a keyword in column 1 causes NDA to begin a new listing page. Any comments contained in that directive are printed as the first line of the new page. Columns 71 through 80 are ignored on all directives. Comments are allowed in columns 11 through 70 on directives that contain a 1-character keyword.

Directive parameters are in fixed formats. The number of parameters and their respective columns within the directive varies with the 1-character keyword specified. Each parameter is a 5-digit hexadecimal value (leading zeros are required). Parameters are separated by either a comma or a blank. The remaining space between the last parameter and column 70 of a directive may contain optional comments; such comments appear on the line of the output file preceding the information produced by the directive.

### 0 — Comments

The O directive specifies that comments can be entered in columns 11 through 70 of this directive and succeeding directives until a different keyword is specified.

#### 1 — File 1 Register

The 1 directive causes the contents of a specific file 1 register to be listed. Each file 1 register is specified by its 5-digit hexadecimal address in columns 2 through 6 of the next directive and succeeding directives until a different keyword is specified.

#### 2 — Macromemory Word

The 2 directive causes the contents of a specific macromemory word to be listed. Each macromemory word is specified by its 5-digit hexadecimal address in columns 2 through 6 of the next directive and succeeding directives until a different keyword is specified.

#### 3 — Contiguous Block Data Structure

The 3 directive causes identical data structures that are contiguously addressed in macromemory to be listed. Each directive contains five parameters in 5-digit hexadecimal format. Each parameter has a field name that is used in diagnostic messages.

| Columns | Field Name | Description                                                                                                                          |
|---------|------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 2-6     | PNTR       | Macromemory location that contains the pointer to the first identical data structure.                                                |
| 8-12    | SIZE       | Size of the data structure in NPU words.                                                                                             |
| 14-18   | INDX       | Index value of the first data structure to be listed. The first identical data structure has an index value of l.                    |
| 20-24   | FIRST      | Number assigned to the first data structure to be listed.<br>The next data structure listing is assigned the next<br>highest number. |
| 26-30   | LAST       | Number assigned to the last data structure to be listed.<br>The data structure listing terminates when it reaches<br>this number.    |

### 4 — Circular Buffer Data Structure

The 4 directive causes circular buffers to be listed in chronological order. Two types of buffers can be listed; fixed-length data structures and variable-length data structures. Each directive contains seven parameters in 5-digit hexadecimal format. Each parameter has a field name that is used in diagnostic messages.

| Columns | Field Name | Description                                                                                                                                                      |
|---------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-6     | FWA        | File l register location that contains the first word address of the circular buffer.                                                                            |
| 8-12    | OLDEST     | File l register location that contains the address of the oldest item in the circular buffer.                                                                    |
| 14-18   | LWA        | File l register location that contains the last word address of the circular buffer.                                                                             |
| 20-24   | FLAG       | File l register location used as a flag to indicate<br>whether the buffer contains meaningful data. The buffer<br>is not listed if this location contains zeros. |
| 26-30   | PTRN       | Bit pattern that delimits a variable-length data structure.                                                                                                      |
| 32-36   | MASK       | Mask for isolating the appropriate bits to identify the delimiter.                                                                                               |
| 38-42   | SIZE       | Data structure size. Nonzero indicates a fixed-length<br>data structure. Zero indicates a variable-length data<br>structure.                                     |

For variable-length data structures, the next occurrence of a data structure is determined by first masking each word to isolate the bit pattern and then comparing this pattern with the specified bit pattern until a match is found. Listing begins at the first match and ends at the second match or at the oldest item found. For fixed-length data structures, the mask and bit pattern are not used.

The circular buffer format starts by listing the oldest item in the buffer (specified in columns 8 through 12), then proceeds to the last word address (specified in columns 14 through 18), then goes to the first word address (specified in columns 2 through 6), and continues to the oldest item in the buffer.

#### 7 — Page Registers

The 7 directive causes the contents of the page registers to be listed. The 7 directive does not have parameters.

### 8 — File 1 Registers

The 8 directive causes file 1 registers to be listed in lines of 16 consecutively addressed registers in hexadecimal format. The 8 directive does not have parameters. However, if the parameter LO=E is specified on the NDA command, the selected option will be in effect.

### 9 — Macromemory Words

The 9 directive causes NPU macromemory words to be listed in lines of 16 consecutively addressed words in hexadecimal format. Repetitive lines are suppressed and addressing continues with the next nonrepetitive line. This line is flagged with double asterisks to indicate the suppression. The 9 directive does not have parameters. However, if parameters BA=addr, EA=addr, or LO=E are specified on the NDA command, the selected options will be in effect.

### A — LCB and TCB/CCB

- -

The A directive causes line control blocks (LCB) to be listed with their associated terminal control blocks (TCB) or cluster control blocks (CCB). Each directive contains seven parameters in 5-digit hexadecimal format. Each parameter has a field name that is used in diagnostic messages.

| Columns | Field Name | Description                                                                                                                                      |
|---------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-6     | LCBP       | Macromemory location that contains the pointer to the first LCB.                                                                                 |
| 8-12    | LCBL       | Size of the LCB in NPU words.                                                                                                                    |
| 14-18   | FTCB       | Index value of the LCB word that contains the pointer to<br>the first TCB/CCB. The first word in an LCB has an index<br>value of 0 (zero).       |
| 20-24   | TCBL       | Size of the TCB/CCB in NPU words.                                                                                                                |
| 26-30   | NTCB       | Index value of the TCB/CCB word that contains the pointer<br>to the next TCB/CCB. The first word in a TCB/CCB has an<br>index value of 0 (zero). |
| 32-36   | NLCB       | File 1 register location that contains the number of LCBs to be listed. If set to 0 (zero), only one LCB is listed.                              |
| 38-42   | LCBX       | Index value of the first LCB to be listed. The first LCB has an index value of $0$ (zero).                                                       |

The LCBs and their associated TCB/CCBs are listed vertically in columns such that any line of the report represents an LCB and its associated TCB/CCBs. In this format, an LCB and 15 TCB/CCBs can be listed in one line. If more than 15 TCB/CCBs are associated with the LCB, the next page lists the next 15 TCB/CCBs with the LCB column blank to indicate the association of these TCB/CCBs with the previous LCB.

#### B — Port Tables and MUXLCB

The B directive causes port tables to be listed with their associated multiplex line control blocks (MUXLCBs). Only one MUXLCB can be associated with each port table. Each directive contains eight parameters in 5-digit hexadecimal format. Each parameter has a field name that is used in diagnostic messages.

| Columns | Field Name | Description                                                                                                                                           |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-6     | PTTP       | File l register location that contains the pointer to the first port table.                                                                           |
| 8-12    | PTTL       | Size of the port table in NPU words.                                                                                                                  |
| 14-18   | MUXP       | Index value of the port table word that contains the pointer to the associated MUXLCB. The first word in a port table has an index value of 0 (zero). |
| 20-24   | MUXL       | Size of the MUXLCB in NPU words.                                                                                                                      |
| 26-30   | PTRN       | Bit pattern that identifies a valid MUXLCB.                                                                                                           |
| 32-36   | MASK       | Mask for isolating the appropriate bits to identify a valid MUXLCB.                                                                                   |
| 38-42   | MUXID      | Index value of the port table word that contains the<br>MUXLCB identifier. The first word in a port table has an<br>index value of O (zero).          |
| 44-48   | NPTT       | File l register location that contains the number of port tables to be listed.                                                                        |

The validity of the pointer to a MUXLCB is determined by first masking the appropriate port table word to isolate the validating bit pattern and then determining if the specific bit pattern is present. If the MUXLCB pointer is invalid, MUXLCB is not listed.

The port tables and their associated MUXLCBs are listed vertically in columns such that any line of the report represents up to eight port tables, each with its associated MUXLCB.

Figure 16-1 is a sample of an NDA output file and its corresponding input directive file.

Figure 16-1. Sample NDA Output File (Sheet 10 of 10)

## NDA OUTPUT FILE CONTENT

The NDA output file (see figure 16-1) begins with a copy of the input directive file, reformatted for printing. The input directive file is followed by the header information, and then the rest of the report is printed in the same order as the input directive file. A description of the header information follows.

| NPU DUMP FILE                                                   | = NPddnnn NDA, command image                                                                                                                                                    |

#### **NPU DUMP FILES**

Each NPU dump file is written as a single-record direct access permanent file when an NPU dump is taken. Individual NPU dump files are named NPddnnn, where dd is a unique hexadecimal dump number consecutively assigned in the range 00 through FF and nnn is the network invocation number assigned at network startup.

#### **Dump Interpretation**

When a halt occurs, halt codes are usually sent to the network operator controlling the NPU. (Halt codes are described in the CCP 3 Diagnostic Handbook.) If a halt occurs after loading but before completion of initialization, or the system becomes trapped in a loop during initialization (before the CCP header prints), dump interpretation may be necessary to determine which halt has occurred, or in which subroutine of the initiation section the program is looping.

When interpreting the NPU dump listing to determine the cause of a halt or loop, first examine the contents of memory location  $30_{16}$ . If the content of that location is nonzero, a halt has occurred; the halt code value is contained in that location.

If memory location  $30_{16}$  equals zero after a halt during initialization, find the address table that begins at fixed memory address  $150_{16}$ . The last nonzero entry in this table is the address of NPINTAB. (This is the table that is displayed at the end of a successful initialization. NPINTAB has a fixed address.) The NPISFL entry in the NPINTAB table contains the flags that mark the initialization subroutines that have completed running when the loop occurred.

## PIP DUMP ANALYZER (LISTPPM)

The peripheral interface package (PIP) Dump Analyzer (LISTPPM) is a utility program that converts all available PIP dump binary records on the PIP memory dump file into a report to be listed in byte format. The PIP PP memory dump file is created as local file ZZZZPP by NAM when the operator drops the network or NAM detects fatal network errors.

The format of the command for the PIP Dump Analyzer is:

LISTPPM, B=pipfile, L=outfile.

The parameters are order independent. Invalid or undefined parameters cause termination of the run.

ParameterDescriptionB=pipfileLocal file name of the PIP PP memory dump file. Default is<br/>B=ZZZZZPP.L=outfileLocal file name of the output file. Default is L=OUTPUT.

# **AIP TRACE WITH IAF**

The AIP trace utility produces a trace file of the messages transferred between IAF and NAM. This file, produced as a local file named ZZZZZDN at IAF's control point, contains information that can be useful in tracking network problems and in debugging application programs. However, the data in this file is in compressed format and hence the debug log file processor (DLFP) must be used to analyze the trace file. Refer to the NAM Version 1/ CCP Version 3 Reference Manual for details about the trace output and the use of DLFP.

Select whether or not to use the AIP trace mode of operation when entering the DSD command, IAFffff, to initialize IAF. This command selects a procedure file that contains the IAFEX command. The T parameter on the IAFEX command determines whether or not AIP trace mode is to be in effect and also the number of messages to be contained on the trace file. The format of the IAFEX command is:

IAFEX, T=count.

Parameter

Description

| T=count | 5000 $\leq$ count $\leq$ 9999999. Message count specifying the number of |
|---------|--------------------------------------------------------------------------|
|         | messages that are to be logged on the trace file before that file is     |
|         | released to the system for processing. If T=* is specified, the          |
|         | trace file is processed only after IAF is terminated.                    |
|         |                                                                          |

T Same as T=16200.

T=0 AIP trace mode is not selected.

T omitted Same as T=0.

Two procedure files are provided for use with the AIP trace, IAFTM and IAFTR. You can create other procedure files using different T parameters on the IAFEX command.

### IAFTM

IAFTM is a procedure file that contains the IAFEX,T=\* command, which causes the trace file ZZZZDN to be processed only after IAF is terminated. The IAFTM procedure file also includes the commands necessary to process the ZZZZDN trace file. Also, all messages logged on the trace file are written to the output file and then sent to a printer.

#### IAFTR

IAFTR is a procedure file that contains the IAFEX,T command, which causes the trace file ZZZZDN to be processed after every 16,200 messages have been transferred between IAF and NAM. A local file called TRACIAF is required by the IAFEX,T command in order to process the trace file. TRACIAF contains a command record, which is copied to the first record of the ZZZZDN trace file by IAF. Trace information is then written to file ZZZZDN, starting at the next record. This makes file ZZZZDN suitable for submission as a batch job. The format of the TRACIAF file should be:

ujn. USER,username,password,familyname. .

DLFP , ... .

NOTE

When system activity is very high, the potential exists for these problems to occur if the AIP trace is used:

- If the system load remains at a very high level for a long period of time, a system hang due to PP saturation could occur.
- If mass storage requirements become great, the ZZZZDN trace file could reach track limit. If so, IAF would stop and wait for resources to become available.

Both of the preceding problems are unlikely to occur in most situations. Also, the risk of reaching track limit can be minimized by selecting a message count on the IAFEX command that causes the trace file to be processed and released after the specified number of messages have been logged. This lowers the mass storage requirements. There are some problems that can only be solved by using the AIP trace. For these problems, do not hesitate to use the AIP trace since any risk involved is minimal.

# **NETWORK DESCRIPTION FILES**

The network description files describe the physical and logical configuration of hardware and software elements that comprise the terminal network. They are important to the proper functioning of the TAF and NAM Subsystems of NOS as well as the QTF/PTF applications if the file transfer capability with NAM is a desired feature. Depending on which subsystems a site has, from one to three such files may be used on a single mainframe. Each file has the following unique function and/or construction.

| File Name   | Description                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LCF and NCF | Local configuration file and network configuration file that must be<br>present if NAM is used. They are created by the network definition<br>language processor (NDLP) from source text prepared according to<br>specifications given in the Network Definition Language Reference<br>Manual. |
| NCTF1†      | Network description file that must be used if the Transaction<br>Facility (TAF) is used. The site analyst prepares this file<br>according to the following specifications.                                                                                                                     |

Under standard operating conditions, the network subsystems expect LCF and NCF to be permanent, direct access public files stored under the NETOPS user index (3777728). LCF and NCF are binary files created by NDLP; NCTFi is a text file composed of terminal definition directives. The text file is interpreted by code in common deck COMCRTN to produce tables used by TAF during system operation. TAF expects NCTFi to be a direct access public file stored under the SYSTEMX user index (3777778).

A terminal definition directive can be up to 90 columns but only columns 1 through 72 are interpreted. Any line containing an asterisk in column 1 is a comment and is ignored.

The following format shows the terminal definition directive. No embedded blanks are allowed.

/terminalname,p<sub>1</sub>,p<sub>2</sub>,...,p<sub>n</sub>.

Parameter

#### Description

The 1- to 7-character alphanumeric name that uniquely identifies the terminal; terminalname must be specified. When NCTFi is created, terminalname must agree with any automatic login user name.

terminalname

| <sup>p</sup> i | Description                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|
| TT=*ID         | Terminal type identified by terminal operator entry.                                                         |
|                | A TAF terminal is defined with the previous parameter,<br>as well as the following, which are unique to TAF. |
| DB=db          | The 2-character data base name to be used by the terminal.                                                   |
| IS=stat        | Initial on/off status of the terminal; stat can be either ON or OFF. Default is ON.                          |

<sup>&</sup>lt;sup>†</sup>i is the network file identifier as specified in the TAF configuration file (refer to the TAF Reference Manual).

#### Parameter

#### Description

| <sup>p</sup> i | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| RS=n           | Data base read security (from 0 to 7). Default is $0$ .                      |
| UA=n           | 24 bits defining the user argument area (from 0 to 777777778). Default is 0. |
| US=n           | Data base update security (from 0 to 7). Default is 0.                       |

To use the permanent file and queued file transfer capability with NAM, you must specify certain NDL statements when creating the local configuration file, as follows:

- Specify application statements with the PRU and NETXFR parameters for applications QTF, QTFS, PTF, and PTFS (QTFS and PTFS require the RS parameter).
- Specify the MXCOPY parameters for these applications depending on expected usage. Suggested values are MXCOPY=4 for QTF, and MXCOPY=14 for QTFS, PTF, and PTFS.
- Specify the INCALL and OUTCALL statements as needed.

Refer to the Network Definition Language Reference Manual for NDL statement formats.

# STIMULATOR

A stimulator is a collection of central memory and peripheral processor programs that enters a hypothetical work load (called a session or script file) into the system to analyze the effects of such a load on response time and system reliability.

The STIMULA stimulator consists of a central memory program (STIMULA) and a peripheral processor program (ITS).

To use the stimulator:

- 1. Create the hypothetical load (refer to Session File Construction later in this section).
- Process these jobs using stimulator commands at the system console (refer to Session File Processing later in this section).

Multiple stimulator sessions are described under Multiple Sessions later in this section. Errors that can occur while the stimulator software is in use are described in the NOS 2 Operations Handbook.

#### STIMULA

STIMULA is an internal stimulator that enters a hypothetical work load into the system through IAF. The stimulator software communicates directly with IAF using a channel. Therefore, 2550s are not used. Only interactive terminals can be analyzed with STIMULA; it does not check out other communication devices or paths. The format of the command is:

STIMULA, I=filename.

 Parameter
 Description

 filename
 Local file to be used as the session file. If not specified, the initial K display (refer to figure 16-5) requests the session file name.

#### SESSION FILE CONSTRUCTION

A session (or script) file is an indirect access permanent file containing the hypothetical job load that is to be analyzed by the stimulator. A session file consists of a group of records; each record is a session and contains a hypothetical job that is composed of the following required entries made in the order shown:

- 1. Begin each internal stimulation session with the entry ANSWERBAC. (Other first lines may be used; however, ANSWERBAC is used in most cases.)
- 2. Enter each session entry on a separate line or card.
- 3. After ANSWERBAC, enter a familyname entry, a username entry, and a password entry.
- 4. Specify the terminal commands and data.
- 5. End each session with the command BYE so that the login of the next session is performed correctly. The HELLO command must not be used unless it is followed by a blank line.

Figures 16-2, 16-3, and 16-4 are examples of session files and figure 16-5 shows the initial K display.

| ANSWERBAC      |                |  |

Figure 16-5. STIMULA K Display (Left Screen)

#### Dynamic Login

If each of the terminals to be analyzed is logged into the system with a unique user name and password, a unique session record for each terminal is stored in central memory at the stimulator control point. Thus, a large amount of central memory could be unavailable to other components of the system. To alleviate this condition, dynamic login is possible, whereby one session record is generated with a unique user name and password that are dynamically translated into unique user names and passwords for each terminal at run time. The generated user names and passwords are then validated via system validation files. The format choices are:

username\$\$\$

or

username\$\$\$,password\$\$\$

Parameter

username

password Password; 1 to 4 alphabetic characters.

\$

Special symbol 12/8/6 (6-bit display code 768), 1 (6-bit display code 348) punch; that is, 12/8/6 punch in one column and 1 punch in next column.

Description

#### NOTE

User name; 1 to 4 alphabetic characters.

The \$ denotes the special symbol previously described, not the character itself. The \$ character is translated into the stimulator terminal numbers at run time.

Example:

P\$\$\$,P\$\$\$ is translated into P000,P000 for the first terminal, into P001,P001 for the second terminal, and so forth.

# **Optional Think Time Specification**

Think time is the number of seconds that each line is delayed before it is sent through the interactive system. A random think time can be specified with a session file command. The format of the command is:

≥ xxx

Parameter

Description

xxx Think time (octal):  $xxx \leq 177_8$ .

To return the terminal to the initial think time (refer to figure 16-6), enter this command:

| ENTER STIMUL   | ATION PARAMETERS IN FORM -                                                               |
|----------------|------------------------------------------------------------------------------------------|
| P = VALUE      | (NUMERIC VALUES ARE ASSUMED DECIMAL BASE.)<br>(SEE RIGHT SCREEN FOR SPECIAL PARAMETERS.) |
| NT = 310B      | NUMBER OF TERMINALS TO STIMULATE.                                                        |
|                | (1 – 100B)                                                                               |
| LS = 15        | LINE SPEED IN CHARACTERS/SECOND. (1 - 1000)                                              |

| AD = 10        | ACTIVATION DELAY IN SECONDS. (0 - 127)                                                   |
| RC = 0         | NUMBER OF TIMES TO REPEAT STIMULATION.(0-31)                                             |
| LD = 0         | LOGOUT DELAY.(0 - 4095)                                                                  |
| RO = ON        | OUTPUT RECOVERY. (ON OR OFF)                                                             |
| LF = NO        | LOOP ON SESSION FILE (YES OR NO)                                                         |
| $\overline{\}$ |                                                                                          |

Figure 16-6. STIMULA Session File Parameters

#### **Task Definitions**

A task is a predefined set of interactive commands designated by a task name and a task usage parameter. Tasks can be called throughout a session, and the task usage parameter is used to determine which task is the next most eligible task (that is, the task to be called next).

An  $\dagger$  character (6-bit display code 70<sub>8</sub>) in the session calls the next most eligible task in the session file, which is determined by the following equation.

f<sub>1</sub>= Total initiations of task<sub>1</sub> (Total initiations of all tasks)(Task usage parameter for task<sub>1</sub>)

For each task<sub>i</sub> defined in the session file, the stimulator calculates  $f_i$ , and the task with the smallest f value is the next most eligible task. Multiple  $\dagger$  characters are permitted on one line and are treated as if they occurred on separate lines. For example,  $\dagger \dagger \dagger$  calls the first three most eligible tasks, where eligibility is recalculated after each initiation of a task. If a task is called and the stimulator cannot determine the next most eligible task in the time allotted, the first task defined in the session file is used.

Tasks for the stimulator are defined in the session file as task records following the session records. Tasks are not permitted in the file before session records. The tasks should be defined in descending order according to the task usage parameter. This facilitates use of the first task defined as the default next most eligible task in situations where the stimulator fails to calculate the next most eligible task on time.

The first line in a task record must be:

\$task nnn

Parameter

Description

Denotes the beginning of a new task (character position 1).

\$

task The 1- to 6-character task name.

nnn Task usage percentage;  $0 \le nnn \le 100$  (character positions 8, 9, 10). The task usage percentages of all tasks in the session file must total 100.

The last line in a task record must be a  $\downarrow$  character (6-bit display code 71<sub>8</sub>), which returns control to the calling session. An example of a session file with tasks defined is shown in figure 16-2.

#### SESSION FILE PROCESSING

The stimulator software is used to process the interactive session file following this procedure:

- 1. Ensure that an IAF stimulator entry is present in the EST and that the stimulator has an ON status (refer to the section 3, Deadstart Decks). The stimulator entry must be on a channel that is not used by any other equipment that is currently ON in the EST.
- 2. Use DSD to activate the stimulator.

Enter STMffff, where ffff is 0 to 4 alphanumeric characters. This entry calls a procedure file STMffff, which must be a permanent indirect access file stored under the system user index  $(377777_8)$ . The procedure file STM is called when you enter STM. The stimulator is invoked by a STIMULA command within the STM procedure file. The stimulator requests the K display.

- 3. Enter K,STM. Figure 16-5 appears on the left screen.
- 4. Enter the session file parameters individually as listed in the following format column or as a group on the same line in the format.

K.F=filename,UI=userindex,N=n,GO.

| Format         | Default | Description                                                                                                                          |
|----------------|---------|--------------------------------------------------------------------------------------------------------------------------------------|
| K.F=filename   | None    | filename is the indirect permanent file name of the session file.                                                                    |
| K.UI=userindex | 0       | userindex is the user index of file filename.<br>The default family is assumed.                                                      |
| K.N=n          | 0       | n is the number of files to be skipped on file<br>filename before data is read from the session<br>file; range is from 0 to 3777778. |
| K.GO           | None    | Indicates to the stimulator that all the parameters have been entered or that none are to be entered.                                |

Figure 16-6 appears on the left screen.

- 5. To display the special parameters, enter:
  - KK.

Figure 16-7 appears on the right screen.

TO ENTER MIXED MODE OF PARAMETER ASSIGNMENT -

K.MIXED.

#### Figure 16-7. STIMULA Special Parameters

6. Enter the stimulator parameters individually as listed in the following format column or as a group on the same line in the format.

K.NT=n,LS=s,IS=s,TT=n,TI=i,AC=m,AD=d,RC=n,LD=d,RO=o,GO.

Enter any special parameters (refer to figure 16-9) before the GO. entry.

| Format | Default              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.NT=n | Current EST<br>value | n is the current maximum number of terminals on which<br>the Interactive Subsystem is initialized. It must be<br>less than or equal to the number specified in the EST<br>entry; the range is from 3 to 10008.                                                                                                                                                                                                                                                                                    |
| K.LS=s | 15                   | s is the line speed in characters per second at which<br>you want to run the terminals; the range is from 1 to<br>1000. Any value above 60 characters per second causes<br>a line speed of approximately 60 characters per<br>second. If many terminals (600g, for example) are<br>run, the maximum realizable line speed is determined by<br>the overhead of 1TD and 1TS. The worst case can be<br>determined by checking the 1TD cycle time dayfile<br>message, which is issued IAF is dropped. |
| K.IS=s | 15                   | s is the typing speed in characters per second at which<br>you want to run the terminals; the range is from 1 to<br>1000.                                                                                                                                                                                                                                                                                                                                                                         |
| K.TT=n | 10 seconds           | n is the number of seconds (think time) that each line<br>is to be delayed before it is sent to the IAF; the<br>range is from 0 to 127 seconds.                                                                                                                                                                                                                                                                                                                                                   |
| K.TI=i | 8                    | i is the number of seconds by which the think time will<br>vary; the range is from 0 to 64 and i must be a power<br>of 2. If i is nonzero, the think time varies between n<br>(the value of TT) and n+i.                                                                                                                                                                                                                                                                                          |
| K.AC=m | 4                    | m is the number of terminals that are to be logged in<br>every d seconds (the value of AD); the range is from 1<br>to n (the value of NT). The AC and AD parameters<br>provide a method to stagger the I/O commands and data<br>to the IAF.                                                                                                                                                                                                                                                       |
| K.AD=d | 10 seconds           | d is the number of seconds of delay time until the<br>login of another terminal is allowed; the range is from<br>O to 127 seconds.                                                                                                                                                                                                                                                                                                                                                                |
| K.RC=n | 0                    | n is the number of sessions that will be executed for each terminal; the range is from 0 to $31$ .                                                                                                                                                                                                                                                                                                                                                                                                |
| K.LD=d | 0 seconds            | d is the number of seconds of delay time after a logout<br>is completed until the next login of the terminal is<br>allowed; the range is from 0 to 127 seconds.                                                                                                                                                                                                                                                                                                                                   |

| K.R0=0                                                     | ON                                     | When RO=ON, the output from the IAF is recovered on file STIMOUT. The format of this file is:                                                                                                                                                                                     |  |  |  |  |  |
|------------------------------------------------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
|                                                            | 59                                     |                                                                                                                                                                                                                                                                                   |  |  |  |  |  |
|                                                            |                                        | Terminal Each byte is an ASCII character if less<br>number. than 4000g; otherwise, it is the<br>running-second time.                                                                                                                                                              |  |  |  |  |  |
|                                                            |                                        | When RO=OFF, the output is not recovered.                                                                                                                                                                                                                                         |  |  |  |  |  |
| K.LF=o                                                     | NO                                     | When LF=NO, looping occurs on the session assigned to<br>the terminal. When LF=YES, the subsequent session is<br>the next session in the session file.                                                                                                                            |  |  |  |  |  |
| K.MIXED                                                    | No mixed mode<br>parameters<br>entered | Specifies that special parameter assignments are re-<br>quired for specific input sessions. This command<br>displays the stimulation parameter matrix (refer to<br>figure 16-8) whose values can be changed as described<br>in the right screen K display (refer to figure 16-9). |  |  |  |  |  |
| K.GO                                                       | None                                   | Indicates to the stimulator that the parameters are entered. Stimulation is initiated.                                                                                                                                                                                            |  |  |  |  |  |
| K.MX=<br><sup>s</sup> 1-s2,<br>ttys,ls,<br>is,tt,ld,<br>rc | Current<br>value                       | Mixed mode input. $s_1$ is the number of the first<br>session to be changed, and $s_2$ is the number of the<br>last session to be changed. $s_2$ is optional; the<br>default is $s_1$ . (Refer to figure 16-9 for other<br>parameter descriptions.)                               |  |  |  |  |  |
| K.CF=<br>filename                                          | None                                   | Matrix change file. Indirect access file filename is<br>accessed for mixed mode input directives, and must be<br>saved under the same user index as the session file.                                                                                                             |  |  |  |  |  |

Figure 16-8. Parameter Matrix (Left Screen)

#### DEFINITION OF PARAMETERS

SCRIPT - SCRIPT(S) WHICH THE PARAMS WILL AFFECT (SCRIPT(N) OR SCRIPT(N)-SCRIPT(N+X)) TTYS - NUMBER OF TTYS ASSIGNED TO SCRIPT(S) LS - LINE SPEED ASSIGNED TO SCRIPT(S) IS - INPUT SPEED ASSIGNED TO SCRIPT(S) TT - THINK TIME ASSIGNED TO SCRIPT(S) LD - LOGOUT DELAY ASSIGNED TO SCRIPT(S) RC - REPEAT COUNT ASSIGNED TO SCRIPT(S)

**\*NOTE - NULL PARAMETER WILL KEEP CURRENT VALUE** 

TO MAKE ENTRIES, FOLLOW THE FORMAT -K.MX=SCRIPT,TTYS,LS,IS,TT,LD,RC.

TO CHANGE MATRIX VIA PREDEFINED PARAMETERS-K.CF=XXX WHERE XXX IS PF CONTAINING CHANGE DIRECTIVES IN FOLLOWING FORMAT-MX=SCRIPT,TTYS,LS,IS,TT,LD,RC.

TO ADVANCE DISPLAY ENTER K.+

TO BACKUP DISPLAY ENTER K .-

Figure 16-9. Mixed Mode Parameters (Right Screen)

#### Example:

MX=2-4,3,30,30,,,1.

Three terminals will be assigned to sessions 2, 3, and 4. The line speed and input speed for these terminals will be 30 characters per second. The think time and logout delay will not be changed from the current value. The terminals will have a repeat count of 1.

#### **MULTIPLE SESSIONS**

Each session on the session file is allocated to each terminal line. When each session has been allocated, the stimulator goes to the first session and reallocates the sessions to the next group of terminals. This procedure is repeated until all the terminals are allocated to a session. If a repeat count is not designated (RC parameter), the line is shut off when the session is finished. When the session completes, the repeat count is checked.

The repeat count corresponds to the number of sessions to be executed on a given terminal. The current session is completed, and the LF parameter determines the next session to be executed. If LF=OFF, the session currently assigned to the terminal is repeated. If LF=ON, the next session in the session file is executed. For example, if the repeat count is 4, the session currently assigned to the terminal is repeated four times (LF=OFF), or the next four sessions on the session file (with repetition, if necessary) are executed (LF=ON).

#### PARAMETER OUTPUT FORMAT

The parameter information (shown in figure 16-10) is placed on the output file for printing upon completion of the stimulator run (refer to Session File Processing earlier in this section).

#### POSTPROCESSING

The postprocessing of the interactive stimulator output is accomplished by reading the file STIMOUT and sorting the data according to terminal number. Use the DEMUX command to do this. As DEMUX sorts STIMOUT, it assigns an encounter number (starting at 1) to the output from each terminal session. DEMUX includes this number in the final line of each sorted terminal session output. The data for each terminal is separated by a page eject and an end-of-line indicator. The terminal data appears as it would on a terminal page. If the ASCII character on the STIMOUT file is 4000g or greater, the lower 10 bits are assumed to be time of a carriage return or the first character of output. If STIMOUT will be processed at a later time, you should save it.

Figure 16-10. Output Statistics

An example of output from DEMUX: ANSW ERBAC \*\*\*\*TTT.TTT (Optional output) \*\*\*\*TTT.TTT (Optional output) WELCOME TO THE NOS SOFTWARE SYSTEM. COPYRIGHT CONTROL DATA 1978, 1983. yy/mm/dd.hh.mm.ss. END OF THE LINE -- n (Page Eject) ANSW ERBAC The n in the previous listing is the decimal encounter number. The format of the DEMUX command is: DEMUX, p1, p2, ..., Pn. P; is either a keyword or a keyword equated to a value. Description P<sub>i</sub> I=filename Name of the file containing stimulator data. I omitted Same as I=STIMOUT. NR Specifies that the input and output files are not to be rewound. NT=n Number of terminals to be processed (0 < n < 512). This tells DEMUX how much memory to allocate to process the input file. If no post radix is specified, octal base is assumed. O=filename Name of the file to receive translated session output. 0 omitted Same as O=OUTPUT. SL=terminalnumber Selective terminal number (within the range specified by the NT=n parameter) to be processed. terminal number is the terminal number minus 1 in the T display. If SL is omitted, all terminals within the range specified by the NT=n parameter are processed. т Specifies that the time of each carriage return and first output character is written with the processed data. Subtracting the two time values gives the response time. The time values can also be used to correlate data between each terminal's input and output.

| PFLOAD in an MSS/MSAS Environment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |       |
| PFDUMP/PFLOAD Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 17-52 |

# INTRODUCTION

Five utility processors maintain the NOS permanent file system. They control the processes of dumping and loading permanent files, cataloging permanent files in the system and on backup storage (archive) files, and copying archived files to a job as local files.

The utility processors are overlays under the control of the permanent file supervisor (PFS). PFS processes the parameters in the utility command and loads the correct processing overlay. The overlays interact with the permanent file utility (PFU) routine, which manages the catalogs, permits, data allocation on a device, and the data transfer between the device and the overlay. Figure 17-1 is an overview of this procedure.

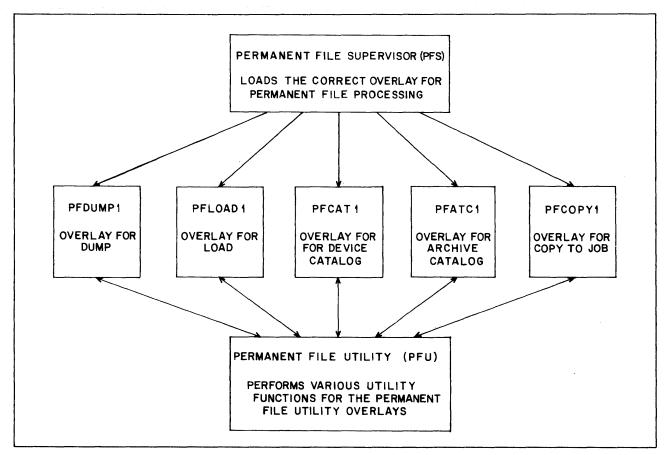

Figure 17-1. Functional Overview of the Permanent File Utility Overlays

17

The names and functions of the permanent file utilities follow. Detailed information about the call and operation of each utility is contained in this section.

| Utility | Description                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------|
| PFATC   | Produces a cataloged directory of file information derived from an archive file.                                               |
| PFCAT   | Produces a cataloged directory of file information derived from catalog tracks on a permanent file device.                     |
| PFCOPY  | Copies files from an archive file to a job as local files.                                                                     |
| PFDUMP  | Dumps files from a permanent file device to an archive file. Files created by this dump can be reloaded by the PFLOAD utility. |
| PFLOAD  | Loads files from an archive file (created by PFDUMP) to a permanent file device.                                               |

#### UTILITY DESCRIPTION TERMINOLOGY

The descriptions of the permanent file utilities in this section include some terms you should be familiar with. These terms are defined next.

#### **Archive File**

All or some of the permanent files accumulated on mass storage can be dumped to a backup tape (or other type of backup medium) to protect the files from loss in case of a device malfunction or to free a device for temporary use during preventive maintenance. Each dump of permanent files is made to a file called an archive file; each permanent file dumped is called an archived file. Each archive file is a multirecord file in which each logical record is an archived file. If two or more dumps are made on one type of backup device, these archive files constitute a multifile archive file (refer to figure 17-2).

The archive file can be loaded back onto the permanent file system as a whole or in part and can also be used to generate reports. The individual archived files can be referenced for selective use. Refer to each utility for more information on how it uses the archive file.

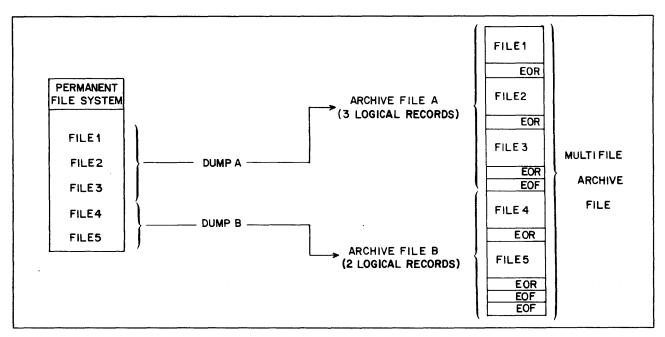

Figure 17-2. Example of Multifile Archive File Structure

#### **User Index**

A 17-bit user index is associated with each user name created on the user validation file. This index is entered through MODVAL (refer to User Validation in the Administration Handbook) with the UI parameter on the user name input directive (/username,UI=userindex) or MODVAL, by default, supplies the next available index.

Whenever you submit a job, the related user index is placed in the control point area along with the user name and other parameters that link hardware, files, and job. The permanent file manager (PFM) identifies the master device and catalog track for you by performing two masking operations that involve the user index and two sets of device parameters (device mask and number of catalog tracks) obtained from the mass storage table in central memory resident (CMR). One operation correlates the rightmost octal digit in the user index (bits 0 through 2) with the bit settings of the device mask for each device in the configuration to determine which device is your master device (refer to the device mask definition next). The other operation performs a logical AND between the remaining portion of the index and the number of catalog tracks on the master device to determine which track contains your catalog (refer to the catalog track definition later in this section).

The lower 3 bits (rightmost octal digit) of the user index are used to group users together into subfamilies. Each permanent file family (refer to the definition of family later in this section) consists of eight subfamilies, subfamily 0 through subfamily 7. Any user whose index ends in 0 belongs to subfamily 0, any user whose index ends in 1 belongs to subfamily 1, and so forth. The concept of subfamily is important in a Mass Storage Subsystem (MSS) environment or a Mass Storage Archival Subsystem (MSAS) environment.

#### **Device Masks**

Two types of device masks exist for each device, the device mask (or primary mask) and the secondary mask.

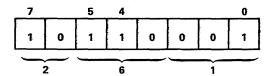

#### Device Mask

The device mask is an 8-bit quantity used to identify the group of users that has the particular device as its master device; that is, it identifies the device that contains the group's file catalogs, all its indirect access files, and possibly some or all of the group's direct access files. (Assigning direct access files to a device is described next, under Secondary Mask.)

If bit i is set in the mask of the device, any user whose index ends in i has this device as a master device.

#### Example:

The device identified by the mask 261g is the master device for any user whose index ends in 0, 4, 5, or 7, because these bits are set in the mask.

When masks are assigned at device initialization time, the following rules must be observed.

- Within a family, the sum of all the device masks must be exactly 3778.
- Each bit position (0 through 7) must be set exactly once for the masks of the devices in one family.

#### Example:

For a family of three devices,  $221_8$ ,  $042_8$ , and  $114_8$  are valid device masks because their sum is  $377_8$  and each bit is accounted for only once.

| 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | = | 2218<br>0428 |  |
|---|---|---|---|---|---|---|---|---|--------------|--|
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | = | 1148         |  |
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | = | 3778         |  |

If the sum of the device masks is less than 3778, then at least 1 bit is not set in any of the device masks. Any user index ending in such a bit-position value does not reference a device. Therefore, if such a user tries to create a permanent file, the system issues an error message.

#### Example:

For a family of four devices,  $142_8$ ,  $020_8$ ,  $010_8$ , and  $204_8$  are not valid device masks because their sum is less than  $377_8$ . Any user whose index ends in 0 would have no master device and could not create a permanent file.

| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | = | 3768 |
|---|---|---|---|---|---|---|---|---|------|
|   |   |   |   |   |   |   |   |   | 2048 |
|   |   |   |   |   |   |   |   |   | 0108 |
|   |   |   |   |   |   |   |   |   | 0208 |
| 0 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | = | 1428 |

If the sum of the device masks is greater than  $377_8$ , then at least 1 bit is set for more than one device mask. Any user index ending in such a bit-position value references more than one master device.

#### Example:

For a family of four devices,  $212_8$ ,  $106_8$ ,  $040_8$ , and  $021_8$  are not valid device masks because their sum is greater than  $377_8$ . Bit 1 is set twice, which indicates that any user whose index ends in 1 would have two master devices, one with mask  $212_8$  and one with mask  $106_8$ .

| 1 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | = | 2128 |
|---|---|---|---|---|---|---|---|---|------|
| 0 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | = | 1068 |
| 0 | 0 |   |   |   |   |   |   |   | 0408 |
|   |   |   |   |   |   |   |   |   | 0218 |
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |   | 4018 |

It is a necessary but not sufficient condition that all masks for one family total  $377_8$ . It is possible, but not allowable, that in one family the device masks total  $377_8$  but some bit is set in more than one device mask.

#### Example:

For a family of three devices, 2618, 1158, and 0018 are not valid device masks because bit 0 is accounted for three times and bit 1 is not set at all. Any user whose index ends in 0 would have three master devices. Any user whose index ends in 1 would have no master device.

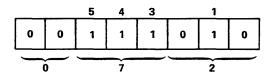

| 1 | 0 | 1 | 1 | 0 | 0 | 0 | 1 | = | 2618 |
|---|---|---|---|---|---|---|---|---|------|
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | = | 1158 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | = | 0018 |
|   |   |   |   |   |   |   |   |   |      |
| 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |   | 3778 |

#### Secondary Mask

The secondary mask of a device is an 8-bit quantity used to identify groups of users who can place direct access files on the particular device. If bit i is set in the secondary mask of the device, any user whose index ends in i can place direct access files on this device.

#### Example:

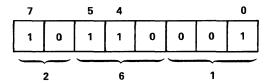

A device whose secondary mask is  $072_8$  can contain direct access files of any user whose index ends in 1, 3, 4, or 5, because these bits are set in the mask.

Direct access files may or may not reside on a master device, depending on the user index and secondary mask. The appropriate bit must be set in the secondary mask of the device on which the user's direct access files are to reside. A direct access file is placed on a valid device with the most space available unless the user specifies a particular device.

#### Example:

The following situations occur for a device whose mask is  $261_8$  and secondary mask is  $072_8$ .

- This device is the master device for, and can contain direct access files of, any user whose index ends in 4 or 5 (bits 4 and 5 are set in both the device mask and the secondary mask).
- This device is the master device for, but cannot contain direct access files of, any user whose index ends in 0 or 7 (bits 0 and 7 are set in the device mask but not in the secondary mask).
- This device is not the master device for, but can contain direct access files of, any user whose index ends in 1 or 3 (bits 1 and 3 are set in the secondary mask but not in the device mask).
- This device is not the master device for, and cannot contain direct access files of, any user whose index ends in 2 or 6 (bits 2 and 6 are not set in either the device mask or the secondary mask).

Existing files can be defined as direct access permanent files, regardless of the secondary mask, for user indexes above  $377700_8$  (AUIMX). However, PFLOAD will enforce the secondary mask check when loading these files. Direct access files for the Mass Storage Facility (MSF/7990) subfamily user indexes (377760 through  $377767_8$ ) are always loaded to their master devices regardless of previous residence or secondary mask values.

There are no restrictions on the number of devices in one family that can have the same bits set in the secondary mask or regarding the sum of the secondary masks for devices in the same family. The secondary mask must be a number between 0 and  $377_8$ .

#### Example:

For a family of three devices, 000,  $131_8$ , and  $326_8$  are possible secondary masks. Any user whose index ends in 0, 3, 4, or 6 can place direct access files on the device whose secondary mask is  $131_8$ . Any user whose index ends in 1, 2, 4, 6, or 7 can place direct access files on the device whose secondary mask is  $326_8$ . No user can place direct access files on the device whose secondary mask is 000. Any user whose index ends in 4 or 6 can place direct access files on two devices, and any user whose index ends in 5 cannot use direct access files.

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | = | 0008 |
|---|---|---|---|---|---|---|---|---|------|
| 0 | 1 | 0 | 1 | 1 | 0 | 0 | 1 | = | 1318 |
|   |   |   |   |   |   |   |   |   | 3268 |
| 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 |   |      |
| - | 1 | - | 1 |   |   |   | - |   |      |

### **Mass Storage Table**

The configuration of mass storage devices currently available to the system is defined by the CMR mass storage table (MST). Each logical device in this configuration has an entry in this table. Refer to the NOS 2 Systems Programmer's Instant for the MST format.

### **Catalog Track**

Your catalog track is a track on your master device containing the catalog entries (definition follows) that define and specify the location of each permanent file you have created. Users are assigned by groups to catalog tracks according to their user index and number of catalog tracks on their master device.

The number of catalog tracks on a device is established when the device is initialized or by default. Default values are:

| Type of Device                   | Default Number of<br>Catalog Tracks |
|----------------------------------|-------------------------------------|
| Extended memory (DE)             | 4                                   |
| 834 (DD)                         | 40 <sub>8</sub>                     |
| 844 (DI, DJ, DK, DL)             | 40 <sub>8</sub>                     |
| 885-11/12 (DM, DQ)               | 108                                 |
| 885-42 (DB)                      | 108                                 |
| 819 (DV, DW)                     | 108                                 |
| DDP path to extended memory (DP) | 4                                   |
| Private device                   | 1                                   |

The number of catalog tracks is always a power of 2; the maximum number is 2008. Therefore, the possible numbers of catalog tracks on a device are:

1, 2, 4, 108, 208, 408, 1008, 2008

Reducing these numbers by 1 produces the following numbers, referred to as track masks.

0, 1, 3, 7, 178, 378, 778, 1778

The track masks in binary form are:

0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

These track masks, except the first one, have all bits set; when bits 3 through 9 of the user index for a particular user are ANDed with the track mask for his/her master device, the user's catalog track number on that device is produced.

Example:

For a family of two devices, the following device masks, number of catalog tracks, and track masks are valid.

| Device | Device Mask                                                  | Number of Catalog<br>Tracks | Corresponding<br>Track Mask |  |  |  |  |
|--------|--------------------------------------------------------------|-----------------------------|-----------------------------|--|--|--|--|
| 1      | 2218 or 10 010 001                                           | 40 <sub>8</sub>             | 408-1=378 or 11 111         |  |  |  |  |
| 2      | $\frac{156_8}{377_8}  or  \frac{01\ 101\ 110}{11\ 111\ 111}$ | 20 <sub>8</sub>             | 208-1=178 or 1 111          |  |  |  |  |

A user whose index is  $14224_8$  is assigned device 1 as his master device because bit 4 (last digit in  $14224_8$ ) is set in the device mask for device 1. Therefore, device 1 contains this user's catalog track.

The binary form of 14224g is 001 100 010 010 100.

Therefore, the catalog track number for this user is 228 (on device 1) because the logical AND of bits 3 through 9 of the user index with the track mask for device 1 is:

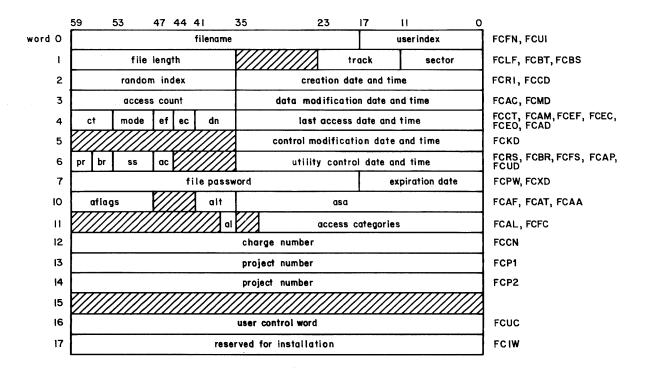

| AND | 1 ( | ) | 0 | - |   | - | 0<br>1 | _ | - |    |                 |
|-----|-----|---|---|---|---|---|--------|---|---|----|-----------------|
|     |     |   |   |   | 1 | 0 | 0      | 1 | 0 | or | 22 <sub>8</sub> |

The end of a catalog track is indicated by an end-of-information (EOI) on the device. All catalog tracks are linked in the track reservation table (TRT) and appear as one logical chain. When catalog entries exceed the logical track, a continuation track is reserved at the end of the catalog track chain in the track reservation table. The disk linkage bytes for the overflowed track point to the continuation track.

#### **Permanent File Catalog Entry**

Files in the permanent file system are referenced by dynamically updated permanent file catalog (PFC) entries on the catalog tracks of master devices. Whenever you create a permanent file, a catalog entry that specifies the characteristics of the file (access information about the file and its location) is entered on a catalog track on your master device. When you modify the file, the PFC entry is updated to reflect the modification.

The format of the PFC entry follows. The 4-character names to the right of each word are symbols used by the system to reference the PFC entry fields. These symbols are defined in common deck COMSPFM.

| Field                  | Word | <u>Bit(s)</u> | Description                                                                                                               |
|------------------------|------|---------------|---------------------------------------------------------------------------------------------------------------------------|
| filename               | 0    | 59-18         | Permanent file name.                                                                                                      |
| userindex              | 0    | 17-0          | User index of file creator.                                                                                               |
| file length            | 1    | 59-36         | Length of the file in PRUs.                                                                                               |
| track                  | 1    | 23-12         | Beginning track of the file.                                                                                              |
| sector                 | 1    | 11-0          | Beginning sector of the file.                                                                                             |
| random index           | 2    | 59-36         | Random disk address of first permit sector.                                                                               |
| creation date and time | 2    | 35-0          | yymmddhhmmss in octal when this file was first<br>entered on the permanent file system. The year<br>(yy) is biased by 70. |
| access count           | 3    | 59-36         | Total number of times this file has been accessed.                                                                        |
|                        |      |               |                                                                                                                           |

| Field                              | Word | <u>Bit(s)</u> | Description                                                                                                                                                                                                |  |  |  |

## Field

#### Word Bit(s)

# Description

# Flag

Bit

- AFTMP 53 Temporary error flag:
  - 0 No temporary error conditions have been detected.
  - A temporary error condition 1 prevented the MSF/7990 image of the file from being staged to disk. After the error condition is detected, this flag is cleared so that the file staging can be retried on the next request for the file.

Description

#### AFVER 52 Verification flag:

- 0 If alternate storage address asa#0, a successful stage/destage operation has occurred and system control errors should not be encountered.
- The PFC entry with  $asa \neq 0$ 1 was reloaded and a stage attempt has not yet been made. If a system control error is detected, the probable cause is that the asa value is obsolete, probably because an obsolete dump tape was used during the reload.
- AFPDR 51 Pseudorelease flag:
  - 0 The file can be attached immediately if it has a disk image.
  - 1 The file has a disk image that cannot be attached until the MSF/7990 image of the file is staged to disk. After the stage attempt (whether or not it is successful), this flag is cleared.

<sup>&</sup>lt;sup>†</sup> The 8 access levels and 32 access categories are referenced by names defined by or in micros in system common deck COMSMLS. The default names are LVLO through LVL7 for access levels and CAT00 through CAT31 for access categories. Each site determines what the access levels and categories mean, and can change the corresponding names to clarify that relationship. For example, access level 3 may be defined as meaning secret, so the name for access level 3 can be changed from LVL3 to SECRET. If any of the COMSMLS micros are changed, all decks calling COMSMLS must be reassembled.

### Track Reservation Table (TRT)

Every device in a permanent file system has a label track (usually track 0) that contains a label sector describing the device (family name, device mask, secondary mask, location of permit information, catalog information, and indirect files) and a number of physical record units (PRUs) containing the track reservation table (TRT). The TRT describes the physical layout of data on the device and is the key to allocating information on the device.

The TRT contains single-word entries that define track linkage and bit-setting controls for those tracks (refer to figure 17-3). Each word has four 12-bit linkage bytes and three sets of 4-bit control settings that match the 4 bytes (refer to figure 17-4). Linkage format is given in figure 17-5.

The numbering of the 12-bit linkage bytes or cells corresponds to the numbering of tracks on the device, with the first track starting at 4000. The entry in a cell references the next cell and its associated track. This next track either continues the information or starts a new sequence depending on the first-track bit setting.

Figures 17-3 and 17-4 show a sequential linkage of tracks (in figure 17-4, from track 4000 to track 4001 to 4002 to 4003). This numerical sequence is purely illustrative. The linkage could just as well have been:

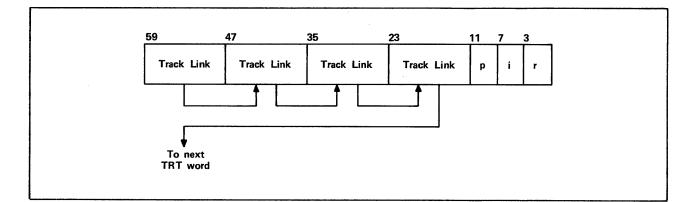

Figure 17-3. Track Reservation Table Word

Each track reservation table word contains the following entries.

| Entry      | Description                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Track Link | Address of the next track that is a logical continuation of this file.<br>(The track links are shown as sequential within a word, but this is not a<br>requirement.) |
| р          | Bit settings for identifying the first track of a preserved file (permanent file chain or queued file).                                                              |
| i          | Bit settings for establishing interlock of a track.                                                                                                                  |
| r          | Bit settings for track reservation.                                                                                                                                  |

The first group of control settings (bits 8 through 11) is used to identify those tracks that begin a sequence of file information. If any one of these bits is set, the associated track is the first track of a chain that may extend across a number of tracks. This chain can be a direct access file, an indirect access file data chain, a catalog chain, a permit chain, a system dayfile, or a queued file.

The second group of control settings (bits 4 through 7) is used to interlock tracks. If any one of these bits is set, the associated track cannot be accessed as long as this bit remains set. Whenever a file is accessed, the system automatically interlocks the catalog track containing the file. The interlocking capability is necessary because PFM may be processing several requests directed at one file simultaneously. Without interlock, these requests could overlap.

The third group of control settings (bits 0 through 3) is used to identify reserved tracks. A track is reserved either because it has data written on it or it is a flawed track. A flawed track is removed from availability by reservation at deadstart, by subsequent initialization, or by reformatting with the FORMAT utility for 844 devices.

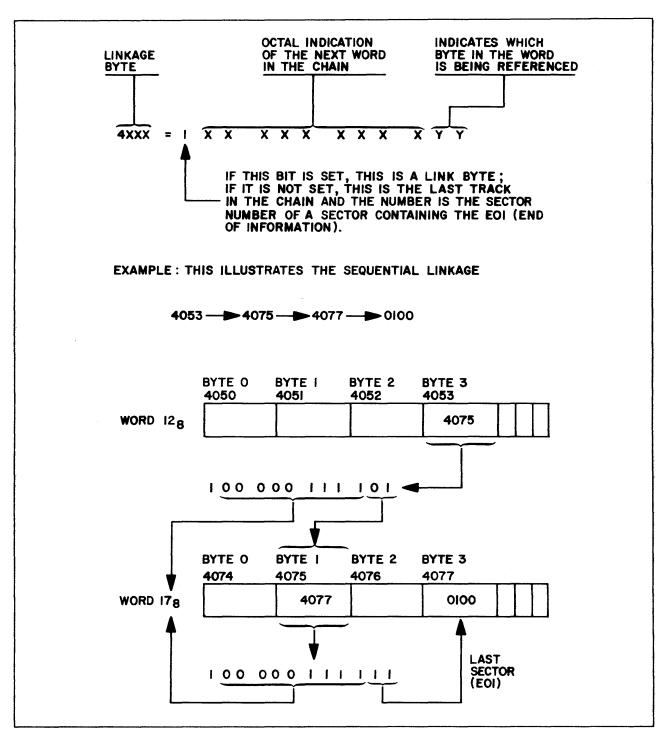

Figure 17-5. Linkage Format With Example

## Family

A family is a collection of from 1 to 63 logical devices identified by a 1- to 7-character family name. Users and their files are grouped together according to the family available to them. Usually, the grouping is within the configuration on which these users normally run jobs. However, a family can be connected to any configuration and still relate to the same users and files.

An auxiliary device, identified by a 1- to 7-character pack name, is a single device that is not included in any family and can be accessed by validated users from any family. An auxiliary device provides users with an alternative to the master devices for storing and accessing permanent files. Use of auxiliary devices enables an analyst to provide special sets of permanent files for selected users or for designated periods. For example, an auxiliary device could be made available from 1200 to 1700 every day for any properly validated user.

A permanent file device is either a member of a family or an auxiliary device. Permanent files on a family device are accessed through user catalogs contained on a master device within the family. The user catalogs that reference permanent files on an auxiliary device are contained on that device; that is, an auxiliary device is a self-contained entity.

Families and auxiliary devices are defined at initialization time by the PF entry in the EQPDECK or by the DSD INITIALIZE command. Normally, a configuration has one family available. Additional families can be defined or introduced (on removable devices) in the same configuration. If more than one family is available in a configuration, you supply the family name at login or on the USER command. The default family is used if no family name is supplied. † Any job can change its associated family name by using the USER command to specify the new family name. †† A system origin job can use the FAMILY command to change the family name associated with the job. If the FAMILY command is included in any nonsystem origin job, the job aborts.

The FAMILY command is valid for unsecured systems only.

The format of the FAMILY command is:

FAMILY, familyname.

Parameter

#### Description

familyname

The 1- to 7-character name of a family of permanent file devices. If omitted, the default family name specified at deadstart is assumed.

<sup>&</sup>lt;sup>†</sup> The default family name is specified at deadstart time with the EQPDECK FAMILY entry and cannot be changed dynamically.

<sup>††</sup> Refer to the IPRDECK entry in section 2, Deadstart Decks, and to the DSD command ENABLE, SECONDARY USER COMMANDS in section 5, DSD Commands; also refer to the USER command in the NOS 2 Reference Set, Volume 3.

If an alternate family of permanent file devices is introduced into the configuration without a user validation file, the job to create the user validation file could include a FAMILY command to identify the alternate family. If the familyname parameter is omitted, the default family name is assumed.

Figure 17-6 is an example of a typical set of configurations.

#### Example:

One configuration with six permanent file devices [equipment status table (EST) ordinals 6 through 13] is identified as system A. Three of the devices are grouped into a family with the name FAMA. They have device numbers 40, 41, and 42. The remaining three EST ordinals have been defined as removable. This means that the system will allow family and auxiliary devices to be introduced on this equipment during system operation.

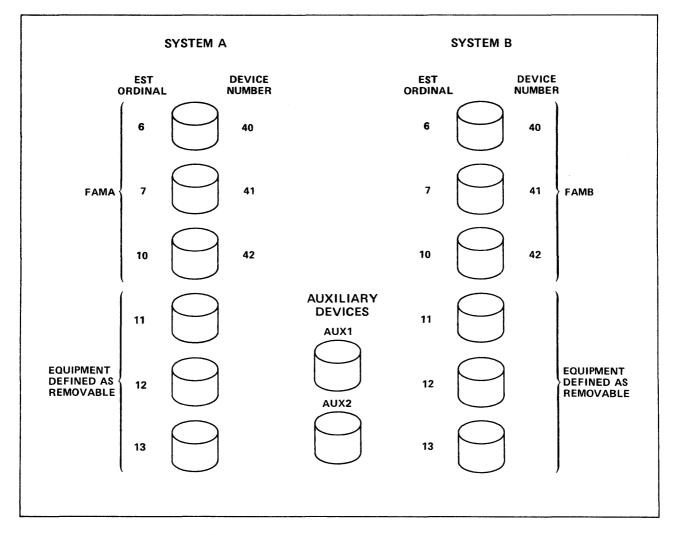

Figure 17-6. Example of Families in Two Configurations

A second configuration with six permanent file devices is identified as system B. Three of the devices have been grouped into a family with the name FAMB. They also have device numbers 40, 41, and 42. The remaining three pieces of equipment have been defined as removable.

Two auxiliary devices are available to both systems. These have the pack names AUX1 and AUX2.

Users of FAMA would normally run jobs on system A. Users of FAMB would normally run jobs on system B.

The removable equipment on system A (EST ordinals 11, 12, and 13) could be used for two purposes:

- To mount auxiliary devices AUX1 and/or AUX2 as required by users of FAMA. If users of FAMB need access to AUX1 and/or AUX2, these auxiliary devices will have to be mounted on some combination of equipment defined by EST ordinals 11, 12, and 13 on system B.
- To mount FAMB devices when they are no longer accessible through system B. In this case, users of FAMB will have to transfer their access to system A. This transfer could involve moving disk packs from equipment defined by EST ordinals 6, 7, and 10 in system B to equipment defined by EST ordinals 11, 12, and 13 in system A, or system A could already have alternate channel connections to equipment defined by EST ordinals 6, 7, and 10 in system B but would define them as EST ordinals 11, 12, and 13 in its own system. If the users of FAMB access their files through system A, they submit their jobs to system A or dial into system A using a different telephone number. (They would dial the same number if communication gear is switched.) The ISF command must be used to make the validation file from FAMB available on system A.

Assuming that access to all of FAMB is transferred from system B to system A, the new array of system A will be as illustrated in figure 17-7. System A now has two families, its original default family FAMA and the newly attached family FAMB whose devices now have the EST ordinals 11, 12, and 13. Its device numbers (40, 41, and 42) remain the same. The device numbers happen to be the same as those used within FAMA but device numbers provide uniqueness only among devices within a family. Accordingly, total uniqueness of a device is provided by the combination of family name and device number.

Users of FAMA will still be able to access their files without specifying the family name since FAMA is still the default for system A. However, users of FAMB will have to specify to system A that they belong to FAMB either at login or on the USER command.

If another equipment (EST ordinal 14) were available on system A, either auxiliary pack AUX1 or AUX2 could be mounted on it and users from either family could access files on this pack.

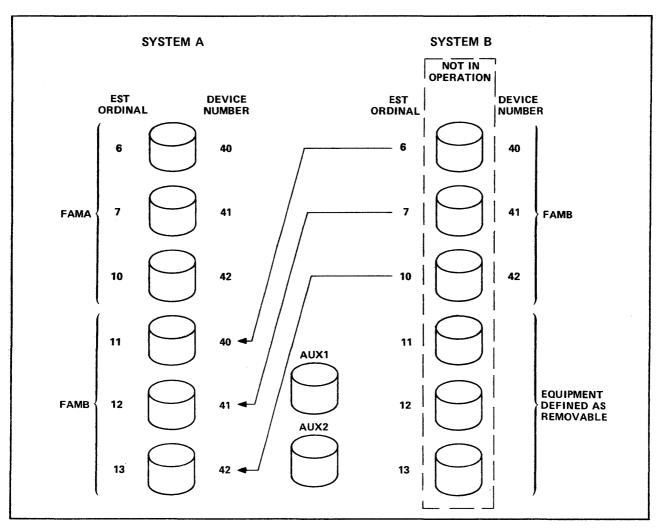

Figure 17-7. Example of Transferring Family Access

## **CALLING THE UTILITIES**

Permanent file utility operations can be initiated through console input or DIS input to a K display, batch input, terminal input, or procedure files. However, for batch or terminal input, the user must be validated for system origin privileges and the system must be in debug mode.

## **CONSOLE INPUT**

It is not possible to preassign an archive file when using the console input sequence. Since a preassigned archive file is usually required, this type of call to the utilities should be avoided in most cases (refer to DIS Input later in this section). However, the console input sequence can be used when an archive file is not required, as with the PFCAT utility.

Input from the console requires the following sequence of entries and responses.

1. Call PFS by entering:

X.PFS.

The B,O display indicates the job sequence name (jsn) of PFS. To the right of the entry appears the message:

REQUEST \*K\* DISPLAY

2. Activate the K display for that control point by entering:

K, jsn. (jsn is the job sequence name of PFS as specified on the B,O display)

The display shown in figure 17-8 appears on the left screen. Instructions at the bottom of the display describe how to select the desired utility.

CURRENT OPTION VALUE

DESCRIPTION

ENTER K.UO. WHERE \*UO\* IS

AT - TAPE CAT CA - DEVICE CAT CP - TAPE COPY DU - DUMP LD - LOAD

Figure 17-8. Initial Permanent File Utilities K Display (Left Screen)

## 3. Activate the right K display by entering:

KK.

The display shown in figure 17-9 appears on the right screen. A description of the permanent file utility options is shown.

| OPTION               | DESCRIPTION                                       |
|----------------------|---------------------------------------------------|
| UT *UTILITY*         | *LD* - PFLOAD                                     |
|                      | *DU* - PFDUMP                                     |
|                      | *CA* - PFCAT                                      |

| ** ONLY ONE ACCESS   | OPTION MAY BE SPECIFIED                           |

Figure 17-9. Permanent File Utilities K Display (Right Screen)

4. Select the desired utility by entering:

K.uo.

uo

uo is one of the following:

#### Description

- AT Catalog archive file.
- CA Catalog permanent files.
- CP Copy archived files to a job as local files.
- DU Dump permanent files.
- LD Load permanent files.

The parameter options available under the chosen utility appear on the left screen. Figure 17-10 shows the left screen after the DU utility has been called (1). The TCE appearing after the LIST OPTIONS VALID (2) indicates that

- T Files processed
- C Catalog image record (CIR) files
- E Errors

are the listings available for the PFDUMP utility. Different combinations of list options are available with the other utilities.

The CAMIDPS (3) appearing after the OPTIONS VALID indicates that

- C Creation
- A Last access
- M Last modification
- I Indirect access files
- D Direct access files
- P Purge after dump
- S Suppress staging of files

are the options available for the dump utility. Different combinations of utility options are available with the other utilities.

5. Select the desired parameter options by entering:

K.opt1=val1,opt2=val2,...,optn=valn.

The opt<sub>i</sub>=val<sub>i</sub> are selected from the parameter option list on the left screen. The selected parameters replace the default values listed on the left screen (refer to Description of Permanent File Utility Parameters later in this section).

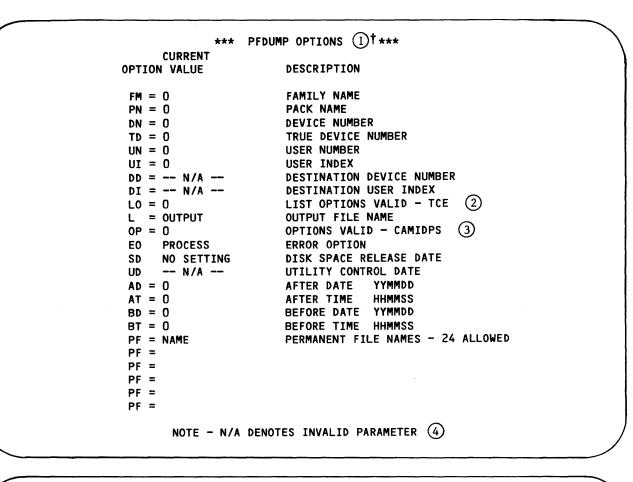

6. Initiate execution by entering:

K.GO.

The lower lines of the left display (4) disappear and are replaced by:

DEVICE MASK DATE TIME

Values appear with these identifiers as processing continues.

PFDUMP OPTIONS \*\*\* \*\*\* CURRENT OPTION VALUE DESCRIPTION ARCHIVE FILE NAME T = TAPESF = 0NUMBER OF FILES TO SKIP NUMBER OF FILES TO PROCESS N = -- N/A --VF = 0VERIFY FILE NAME MF = -- N/A --MASTER FILE NAME RD = ORELEASE DATA FILE NAME LA = 0LOWER ACCESS LEVEL UA = 0UPPER ACCESS LEVEL NOTE - N/A DENOTES INVALID PARAMETER

<sup>†</sup> The circled numbers are identified in the text preceding the figure.

Figure 17-10. PFDUMP Left K Display

## **DIS INPUT**

The following DIS input sequence is recommended for calling PF utilities from the system console. Refer to section 4, DIS Operations.

1. Call DIS by entering:

X.DIS.

- 2. If the utility requires an archive file, it must be preassigned before calling the utility. This can be done with a LABEL or ASSIGN command or by using an existing procedure file.
- 3. Call the utility either by entering

PFS.

which leads to the same sequence of entries and responses previously described under Console Input, or by entering:

 $PFuo, opt_1 = val_1, opt_2 = val_2, \dots, opt_n = val_n$ .

uo is one of the following utility options, and  $opt_i=val_i$  is a desired parameter option and value for the selected utility (refer to Parameters for the Permanent File Utilities later in this section).

| uo   | Description                              |
|------|------------------------------------------|
| ATC  | Catalog archive file.                    |
| CAT  | Catalog permanent files.                 |
| Сору | Copy archive file to job as local files. |
| DUMP | Dump permanent files.                    |
| LOAD | Load permanent files.                    |

If an error in parameters is detected at initiation of a utility, control is returned to PFS and the correct parameters can then be entered using the K display.

## **BATCH INPUT**

To call a utility from a batch job, you must be validated for system origin privileges and the system must be in debug mode. The following sequence of commands is used to call a utility.

ujn. USER,username,password,familyname. PFuo,opt<sub>1</sub>=val<sub>1</sub>,opt<sub>2</sub>=val<sub>2</sub>,...,opt<sub>n</sub>=val<sub>n</sub>.

uo and opt<sub>i</sub>=val<sub>i</sub> are the same as for DIS input.

## **TERMINAL INPUT**

The format of terminal input for calling the permanent file utilities is substantially the same as that for batch input. You must be validated for system origin privileges and the system must be in debug mode. You enter the batch subsystem (or use the X command), call the desired utility, and enter the appropriate parameters with the command:

PFuo,opt1=val1,opt2=val2,...,optn=valn.

uo and  $opt_i = val_i$  are the same as for DIS input.

### **PROCEDURE FILES**

Calling the PF utilities can be made simpler with site-defined procedure files. If these procedures are defined on file PROCFIL under user name SYSTEMX (user index 377778), they can be called from DSD. Since user name SYSTEMX is valid only from system origin jobs, the file PROCFIL should be write-permitted to another user name; this will allow easier maintenance of site-defined procedures.

For example, when called in the following manner, the procedure DUMPIT provides a full dump of device 1 of the system default family on archive tapes with VSNs of PFB11, PFB12, ..., PFB16.

X.BEGIN(DUMPIT,, DEVICE=1, SET=B)

The SETJOB command is used to set the UJN of the job so that the banner page indicates the dump operation performed. In this case it is FULLIB.

.PROC, DUMPIT, DEVICE=0, LISTOP=E, SET=A.

SETJOB, UJN=FULL DEVICE SET.

VSN, TAPE=PF SET DEVICE 1/PF SET DEVICE 2/PF SET DEVICE 3/

PF SET DEVICE 4/PF SET DEVICE 5/PF SET DEVICE 6.

LABEL, TAPE, D=GE, PO=W, W, FI=\$FULL DUMP\$.

PFDUMP, DN=DEVICE, LO=LISTOP.

# PARAMETERS FOR THE PERMANENT FILE UTILITIES

Table 17-1 lists the parameters accepted by each permanent file utility. An X means that the parameter is accepted; a blank means that the parameter is not accepted. Refer to descriptions of parameters following the table for more information.

| rameter | PFATC | PFCAT | PFCOPY | PFDUMP                                | PFLOAD   |
|---------|-------|-------|--------|---------------------------------------|----------|
|         |       |       | +      | · · · · · · · · · · · · · · · · · · · | X        |

## **DESCRIPTION OF PERMANENT FILE UTILITY PARAMETERS**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AD=yymmdd †  | After date in the form year month day. Files with a last access date<br>(if OP=A), a creation date (if OP=C), or a utility control date (if<br>OP=M) more recent than this date are to be processed. If AT=hhmmss<br>is specified, the default is the current date. If neither AD nor AT<br>are specified, after date and time are not used as selection<br>criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| AT=hhmmss †  | After time in the form hour minute second. Files meeting the AD=yymmdd criterion and with a last access time (if OP=A), a creation time (if OP=C), or a utility control time (if OP=M) more recent than this time are to be processed. If AD=yymmdd is specified, the de-fault is 000000 (midnight). If neither AD nor AT are specified, after date and time are not used as selection criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BD=yymmdd †  | Before date in the form year month day. Files with a last access<br>date (if OP=A), a creation date (if OP=C), or a utility control date<br>(if OP=M) prior to this date are to be processed. If BT=hhmmss is<br>specified, the default is the current date. If neither BD nor BT are<br>specified, before date and time are not used as selection criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| BT=hhmmss †  | Before time in the form hour minute second. Files meeting the<br>BD=yymmdd criterion and with a last access time (if OP=A), a<br>creation time (if OP=C), or a utility control time (if OP=M) prior<br>to this time are to be processed. If BD=yymmdd is specified, the<br>default is 000000 (midnight). If neither BD nor BT are specified,<br>before date and time are not used as selection criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DD=dn        | The 1- or 2-digit number that specifies the alternate device to<br>which PFLOAD loads files when the device on which a file is to be<br>loaded cannot be found, is not defined in the system, or cannot<br>accept the file because of secondary mask restrictions. Default is<br>0 (no device is the alternate). This parameter is assumed octal<br>unless the D radix or a nonoctal digit is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DI=userindex | The l- to 6-digit number that specifies the destination user index<br>under which PFLOAD loads all files being processed. Default is 0<br>(the destination user index is the user index from which the file<br>was dumped). This parameter is assumed octal unless the D radix or<br>a nonoctal digit is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DN=dn        | The 1- or 2-digit octal number that specifies the device within the<br>family to be cataloged, dumped, or loaded. For PFLOAD, refer to<br>PFLOAD Selection Process under Load Permanent File (PFLOAD) later in<br>this section for more information. For PFCAT or PFDUMP, the<br>following distinctions are made. If the specified device is a<br>master device, all files cataloged on it (whether or not they reside<br>on the device) are processed if they also meet all other specified<br>selection criteria. However, files that reside on the device that<br>are cataloged elsewhere are not processed. If the specified device<br>is not a master device, all files residing on it are processed if<br>they also meet all other specified selection criteria. (For<br>nonmaster devices the DN and TD parameters have the same effect.)<br>Default is 0 for PFDUMP and PFLOAD (all devices are to be dumped or<br>loaded). DN should always be specified for PFCAT (no default). |

<sup>&</sup>lt;sup>†</sup>When entering dates and times, always enter six characters. For example, 3:30 a.m. should be entered as 033000.

| Parameter     |                                                                                                                                                                                                                                                                                                                                            | Description                                                                                                                                                                                         |  |  |  |  |  |  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|
| EO            | storage err                                                                                                                                                                                                                                                                                                                                | Specifies that PFDUMP or PFLOAD does not process files with mass<br>storage errors. If EO is not specified, PFDUMP dumps files, and<br>PFLOAD loads files, regardless of mass storage errors.       |  |  |  |  |  |  |
| FM=familyname | The 1- to 7-character name of the family of permanent file devices<br>to be cataloged, dumped, or loaded. This parameter option is not<br>required if only one family of devices is active in the system.<br>Default is the default system family name.                                                                                    |                                                                                                                                                                                                     |  |  |  |  |  |  |
| L=filename    |                                                                                                                                                                                                                                                                                                                                            | -character name of the file on which reports are to be<br>Default is OUTPUT.                                                                                                                        |  |  |  |  |  |  |
| LA=level      | The 1- to 7-character name that specifies the lower limit of the<br>range of access levels to process. If this parameter is specified,<br>the UA parameter must also be specified. If neither LA nor UA is<br>specified, the default is that all access levels are selected.<br>Refer to PFDUMP in a Secured System later in this section. |                                                                                                                                                                                                     |  |  |  |  |  |  |
| LO=opt        |                                                                                                                                                                                                                                                                                                                                            | s) specifying the type of information that the permanent<br>y should include in its output report. Default is 0 (no<br>.ected).                                                                     |  |  |  |  |  |  |
|               | opt                                                                                                                                                                                                                                                                                                                                        | Description                                                                                                                                                                                         |  |  |  |  |  |  |
|               | C                                                                                                                                                                                                                                                                                                                                          | List all files in the catalog image record. This option is used only with PFATC, PFDUMP, and PFLOAD.                                                                                                |  |  |  |  |  |  |
|               | Е                                                                                                                                                                                                                                                                                                                                          | List errors.                                                                                                                                                                                        |  |  |  |  |  |  |
|               | S                                                                                                                                                                                                                                                                                                                                          | List cumulative statistics. This option is used only with PFCAT.                                                                                                                                    |  |  |  |  |  |  |
|               | Т                                                                                                                                                                                                                                                                                                                                          | List PFC data for all files processed.                                                                                                                                                              |  |  |  |  |  |  |
| MF=filename   | The 1- to 7-character name of the master file to which PFCOPY copie<br>all the files extracted from a designated archive file. Default is<br>no name; that is, the archived files are copied as individual files<br>retaining their permanent file names.                                                                                  |                                                                                                                                                                                                     |  |  |  |  |  |  |
|               | •                                                                                                                                                                                                                                                                                                                                          | a allows you to extract a file from an archive file and name as a local file.                                                                                                                       |  |  |  |  |  |  |
| N=n           | The 1- or 2-digit number that specifies the number of archive files<br>on a multifile archive file to be processed. If n=0, one file is<br>processed. Default is 1. This parameter is assumed decimal unless<br>the B radix is specified.                                                                                                  |                                                                                                                                                                                                     |  |  |  |  |  |  |
| OP=opt        | control the additional                                                                                                                                                                                                                                                                                                                     | -character string specifying the utility options that<br>processing of files. Many of the options require<br>parameters to complete the definition of the OP<br>Default is 0 (no options selected). |  |  |  |  |  |  |

## Parameter

#### Description

Only one of options A, C, or M can be used at a time. Each of these options requires one of the following to be specified.

- Specify BD/BT to select all files having a last access date/time (if OP=A), a creation date/time (if OP=C), or a utility control date/time (if OP=M) prior to this date/time.
- Specify AD/AT to select all files having a last access date/time (if OP=A), a creation date/time (if OP=C), or a utility control date/time (if OP=M) more recent than this date/time.
- Specify both BD/BT and AD/AT to select all files having a last access date/time (if OP=A), a creation date/time (if OP=C), or a utility control date/time (if OP=M) in the interval defined by these dates/times. The date/time specified by BD/BT must be more recent than the date/time specified by AD/AT to properly define an interval.

See the descriptions of the AD, AT, BD, and BT parameters for more information.

#### opt

## Description

- A Make selection according to time of last access.
- C Make selection according to time of creation.
- M Make selection according to time of last modification.

The following rules apply when OP=M is used. If the utility control date and time field meets the specified date/time criteria, the file is selected. If the date/time criteria are not met, the file can still be selected if the control modification date and time field meets the date/time criteria and is more recent than the utility control date and time field. Refer to Permanent File Catalog Entry earlier in this section for descriptions of the PFC fields.

Only one of the following two options can be used at a time. They can be used in conjunction with the A, C, or M option.

## opt Description

- D Select direct access files only.
- I Select indirect access files only.

### Description

The following options are used only with PFDUMP. Only one of them can be used at a time.

opt

#### Description

- P † Purge after dump. All files for which file data is included in the dump are purged after the dump is completed. If this option is specified, backup requirement parameters are ignored when selecting files to process. Files with no backup requirement (BR=N) are processed, and files with media-dependent backup requirement (BR=MD) are copied to disk and fully dumped.
- S <sup>††</sup> Suppress staging of files. If a file to be dumped resides on MSF/7990 and not on disk, it is not staged to disk and only its PFC and permit entries are copied to the archive file. If OP=S is omitted, the MSF/7990 file is copied to disk and included in the dump. This option should normally be specified for full dumps.
- Y <sup>†</sup> This option causes files with backup requirement BR=MD to be precessed the same as files with backup requirement BR=Y.

The following five options are used only with PFLOAD.

opt

## Description

- R Load with the replace option. If R is specified, PFLOAD loads all selected files from the archive file. If R is not specified, PFLOAD loads only those files selected from the archive file for which no corresponding files (files with identical file names and user indexes) already exist in the permanent file system.
- E Extract only the CIR. Refer to the PFLOAD description for information about the CIR. PFLOAD reads the CIR from the archive file, generates a random file and directory, and requests the next archive file without processing any of the files after the CIR on the first archive file.
- L Load each direct access file on the device with the most available space of those devices where the file is eligible to reside. This option overrides the DD parameter if it is also specified.
- O Do not read the CIR. PFLOAD does not read the CIR for the specified archive file but processes the records in this archive file. PFLOAD then terminates normally without requesting another archive file.
- Z <sup>††</sup> Zero the asa field in the PFC entry when the PFC entry is loaded, if the asa field points to an MSF/7990 image. Also suppresses the loading of PFC only files. Default is to leave the asa field intact and to load PFC only files. OP=Z should normally be omitted if the device has to be recovered and should be specified if data for the file is being reloaded.

<sup>†</sup> Refer to Permanent File Catalog Entry earlier in this section for a description of the backup requirement field.

<sup>&</sup>lt;sup>††</sup>Refer to section 11, MSAS, or to section 12, MSS, for more information.

#### Description

The following option is used only with PFCOPY.

opt

| Description |
|-------------|
|             |

- Q Select leading records. The archived file that is copied to the job as a local file includes two header records, one with the catalog entry for the file and the second with the permit information for the file.
- PF=filename The 1- to 7-character name of a permanent file to be processed. The operator can enter up to 24 permanent file names. The selected file names appear on the bottom of the first page of the left K-display screen (refer to figure 17-10). To delete a permanent file name that has been entered, enter the same file name again. When used from one of the utility commands, up to 10 file names can be entered. The format of the parameter is PF=filename1,PF=filename2,...,PF=filenamen for both the K-display and the utility commands. PF is associated with UI. Default is that permanent file names are not selection criteria.
- PN=packname The 1- to 7-character name of the auxiliary device to be cataloged, dumped, or loaded. The device must be mounted and available. Default is that pack name is not a selection criterion.
- RD=filename<sup>†</sup> The 1- to 7-character name of the release data file (RDF) to be created by PFDUMP, which identifies those MSF/7990-resident files that are pointed to by PFC entries at the time of the dump. The MSS/MSAS utility ASVAL/SSVAL uses this file to identify unneeded MSF/7990-resident files whose space can be released. If RD alone is specified, the release data file created is named ZZZZRDF. Default is that PFDUMP does not create an RDF.
- SD Specifies that PFDUMP is to enter the date and time when the dump was initiated into the inhibit date/time field of the master device. This date/time entry is used by the MSS/MSAS utility ASMOVE/SSMOVE to inhibit the releasing of the disk image of any file with a BR=Y attribute which was last modified after this date/time. The disk space can be released after the next incremental or full dump is taken.
- SF=n The 1- or 2-digit number that specifies the number of archive files on a multifile archive file to be skipped before processing begins. Default is 0. This parameter is assumed decimal unless the B radix is specified.
- T=filename The 1- to 7-character name of the file on which to store or read archive files. Usually, filename is a tape, but it can be a mass storage device. Default is TAPE.
- TD=dn The 1- or 2-digit octal number that specifies the device within the family to be dumped or loaded. For PFLOAD refer to PFLOAD Selection Process under Load Permanent File (PFLOAD) later in this section for more information. For PFDUMP, the following distinctions are made. If the specified device is a master device, all files cataloged and/or residing on it are processed if they meet all other specified selection criteria. If the specified device is not a master device, all files residing on it are processed if they also meet all other specified selection criteria. (For nonmaster devices the DN and TD parameters have the same effect.) Default is 0 (all devices are to be dumped or loaded).

<sup>†</sup>Refer to section 11, MSAS, or to section 12, MSS, for more information.

| Parameter    |                                                                                                                                                                                                                                                                                                                                            | Description                                                                                                                                                                                                                             |  |  |  |  |  |

|              | PFDUMP,T=AA,VF=BB.                                                                                                                                                                                                                                                                                                                         | The dump is written on archive file AA.<br>A duplicate is written on the verify<br>file BB. PFDUMP does not rewind after<br>processing.                                                                                                 |  |  |  |  |  |
|              | PFDUMP,T=AA,VF=BB.                                                                                                                                                                                                                                                                                                                         | A second dump is written after the first<br>on both the archive (AA) and the verify<br>(BB) files. Each dump produces a<br>separate file on the archive and verify<br>files.                                                            |  |  |  |  |  |

† Refer to section 11, MSAS, or to section 12, MSS, for more information.

## Parameter

## Description

## Command

## Description

VERIFY, AA, BB, N=0, A, R.

## A binary comparison of AA and BB is performed. If words do not match, this command lists:

Record number

Word number within the record

Words from both files that do not match

N=O specifies that the verify terminates when the first empty file is encountered. The A parameter specifies an abort if a mismatch is found. R rewinds both files before and after the verify.

## PREASSIGNING THE ARCHIVE FILE

In all permanent file utilities except PFCAT, the archive file must be preassigned. This can be done by using the LABEL or ASSIGN command. For example, file assignment can be made with the following commands.

LABEL, TAPE, VSN=PFDUMP, NT, D=1600.

or

ASSIGN,NT,TAPE.

If no archive file is present, PFDUMP will write on a local mass storage file. The other utilities will attempt to read an empty archive file and terminate. PFLOAD will automatically request the assignment of any incremental or full dump archive tapes needed after the first tape; the request will be for the same track type and density as the first archive tape.

NOTE

The archive file is not rewound or unloaded before or after processing by any of the utilities.

# PERMANENT FILE UTILITY ROUTINES

The parameters available for each of the permanent file utility routines, discussed next, are listed in table 17-1.

The LO parameter allows each permanent file utility to produce a cataloged directory of file information. This catalog information is either derived from the catalog tracks on the permanent file device or from the archive tape. Although the header information may differ from utility to utility, the format of the catalog information remains the same. Following is the general format of the information listed for each file on the directory.

| filename | type    | cat            | length | dn   | cdate | ladate | dmdate | cmdate | ucdate |
|----------|---------|----------------|--------|------|-------|--------|--------|--------|--------|
| password | count   | userindex mode | subsys | stem | time  | time   | time   | time   | time   |
| exp date | level   | pr br rs ac    |        |      |       | flags  |        | at asa | amsg   |
| charge   | project |                |        |      |       |        |        |        |        |

Figure 17-11 illustrates a typical page from a cataloged directory. Although this directory was produced using the command PFATC,LO=T., directories in similar format could be produced using the other utilities. Each of the following fields is shown and cross-referenced on the figure.

| Heade | r Information | Description                                                                                                                                                                                                      |
|-------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | filename      | Permanent file name.                                                                                                                                                                                             |
| 2     | type          | Type of permanent file. This field can be either direct access (DIR) or indirect access (IND).                                                                                                                   |
| 3     | cat           | File category. This field can be either PRIVATE, SPRIV, or PUBLIC.<br>These categories are described in the NOS 2 Reference Set, Volume 3.                                                                       |
| 4     | length        | Length of the file in decimal PRUs.                                                                                                                                                                              |
| 5     | dn            | For direct access files, the device number of the mass storage device<br>on which the file resides if other than the master device. If the<br>file resides on the master device, this field is replaced by an *. |
| 6     | password      | Password associated with the file.                                                                                                                                                                               |
| 7     | count         | Count that specifies the number of times the file has been accessed.                                                                                                                                             |
| 8     | userindex     | User index of the user on whose catalog this file resides.                                                                                                                                                       |
| 9     | mode          | Permission mode. This field can be WRITE, MODIFY, UPDATE, APPEND,<br>READ, READMD, READUP, READAP, or EXECUTE. These modes are explained<br>in detail in the NOS 2 Reference Set, Volume 3.                      |
| 10    | subsystem     | Subsystem under which the file was saved. Possible entries include<br>FORT., FTNTS, BASIC, EXEC., or BATCH. If this field contains no<br>entry, a subsystem is not associated with the file.                     |
| (11)  | cdate time    | Date and time of file creation. The format is:                                                                                                                                                                   |
|       |               | yy/mm/dd.<br>hh.mm.ss.                                                                                                                                                                                           |
| (12)  | ladate time   | Date and time of the last access to the file.                                                                                                                                                                    |
| (13)  | dmdate time   | Date and time of the last data modification to the file.                                                                                                                                                         |

| Header               | r Information | Description                                                                                                                                                                                                                                             |
|----------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14                   | cmdate time   | Date and time of the last control information modification made in the file's PFC entry or permit entries.                                                                                                                                              |
| 15                   | ucdate time   | Utility control date and time set by PFM or a PF utility to ensure that the file will be included in the next incremental (OP=M) dump.                                                                                                                  |
| (16)                 | exp date      | Expiration date associated with the file password.                                                                                                                                                                                                      |
| (16)<br>(17)<br>(18) | level         | Security access level assigned to the file.                                                                                                                                                                                                             |
| (18)                 | pr            | Preferred residence for the file specified by the file owner. This field can be D (disk residence perferred), L (file locked to disk), M (MSF/7990 residence preferred), or N (no preferred residence).                                                 |
| (19)                 | br            | Backup requirement for the file specified by the file owner. This<br>field can be either Y (backup required on dump tape), MD (backup<br>required only if current version of file does not reside on<br>MSF/7990), or N (no backup is to be performed). |
| (20)                 | rs            | Current residence of the file. This field can be D (disk only), A (MSF/7990 only), or B (both disk and MSF/7990).                                                                                                                                       |
| (21)                 | ac            | Alternate user CATLIST permission for the file specified by the file<br>owner. This field can be Y (alternate user can obtain CATLIST<br>information about the file) or N (alternate user cannot obtain<br>CATLIST information about the file).         |
| (22)                 | flags         | Alternate storage flags set for the file (refer to Permanent File<br>Catalog Entry earlier in this section for details). If a flag is<br>not set, a dash is listed. If an undefined flag is set, an asterisk<br>is displayed. This field can be:        |
|                      |               | Field Description                                                                                                                                                                                                                                       |

.

Figure 17-11. Sample Directory Produced by PFATC,LO=T.

.

### CATALOG ARCHIVE FILE (PFATC)

PFATC produces a cataloged directory of file information derived from an archive file previously created by the PFDUMP utility. The format of the directory depends upon the parameters selected.

If LO=T (list all files processed) is specified, the directory produced is similar to that shown in figure 17-11. If LO=C (list all files in catalog image record) is specified and the archive file to be cataloged was produced by an incremental dump (refer to Incremental Permanent File System Dump later in this section), the directory produced is similar to that shown in figure 17-16.

### CATALOG PERMANENT FILE DEVICE (PFCAT)

PFCAT produces a cataloged directory of file information derived from catalog tracks on a master device. The format of the directory depends upon the parameter options selected.

If LO=T (list all files processed) is specified, a directory of file information and a mass storage table report are produced. The directory is similar to that shown in figure 17-12. However, the files are listed according to user index, and totals are given after the files for each user index. The mass storage table report gives information about each mass storage device in the system. Figure 17-13 is an example of a mass storage table report. Messages issued with this report give information concerning the type and status of the device cataloged. The following status messages can be issued.

ACCOUNT INITIALIZE PENDING. CATALOG TRACK OVERFLOW. DAYFILE INITIALIZE PENDING. ERRLOG INITIALIZE PENDING. FORMAT PENDING. I/O QUEUE INITIALIZE PENDING. MAINLOG INITIALIZE PENDING. PF INITIALIZE PENDING. TOTAL INITIALIZE PENDING. UNAVAILABLE FOR PF ACCESS. 8 WORD CATALOG ENTRIES.

The following types of devices can be listed.

ALTERNATE SYSTEM REMOVABLE DEVICE SYSTEM

If LO=S (list cumulative statistics for catalog) is specified, summary reports of file information for each user index and for the entire device are produced. Figure 17-14 lists a page of the information given for each user index. Figure 17-15 lists the general device information.

Figure 17-14. Cumulative Statistics by User Index PFCAT,LO=S,DN=40.

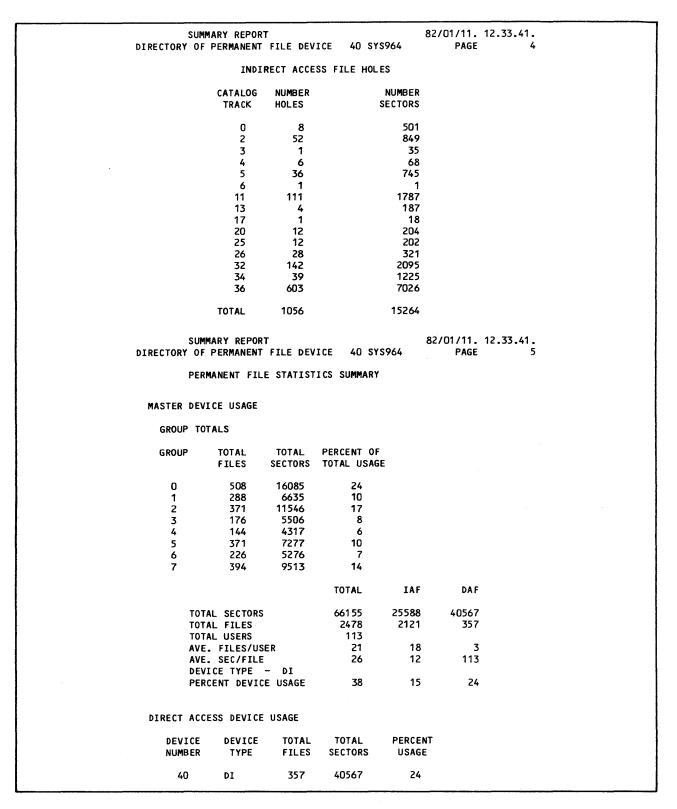

Figure 17-15. Cumulative Statistics for Entire Device PFCAT,LOS=S,DN=40.

## COPY ARCHIVE FILE (PFCOPY)

PFCOPY extracts files from an archive file and copies them to one or more files local to the job. The way the files are copied depends upon the parameter options selected.

If MF=filename is specified, all the files extracted from the archive file are copied to one master file (filename) local to the job and they do not retain their permanent file names.

In a secured system, the access level from the file's PFC entry is used to assign each file to be copied to an appropriate mass storage device. If no device can be found that allows the file to reside there, the PFCOPY utility skips the file and issues a diagnostic message.

#### DUMP PERMANENT FILE (PFDUMP)

PFDUMP copies (dumps) permanent files to backup storage (an archive file). Dumps can be reloaded by the PFLOAD utility and can be accessed by the PFATC and PFCOPY utilities for cataloging and copying. PFDUMP issues messages to the dayfile indicating how many files were dumped and how many files were not dumped due to errors. The type of dump taken depends upon the purpose of the dump and is determined by the parameters selected. The defining characteristics of the three types of dumps follow.

Incremental Dump OP=M is specified and BD=yymmdd and BT=hhmmss are not specified.

Partial Dump Any dump that is not incremental and not full.

Full Dump OP=O is specified or OP is not specified.

If PFDUMP encounters an unrecoverable parity error while writing the archive file, several options are available via the K display. These options are described on the K display. If the option to continue the dump on another reel of tape is selected (K.GO), it may not be possible to recover in such a way as to ensure that the PFLOAD utility can successfully read the archive tape. At least the archived file being written at the time of the error cannot be reloaded correctly.

#### **PFDUMP** in a Secured System

In a secured system, PFDUMP determines the maximum range of access levels that can be dumped. If the LA and UA parameters have been used to select access level limits, these limits will be used. If no access level limits were selected, PFDUMP uses the device limits determined by taking the lowest lower access limit and the highest upper access limit of all the devices to be dumped. The range of possible access levels must be within the system access level limits or PFDUMP aborts the job and issues a diagnostic message. The range of possible access levels must also be within the equipment access level limits for the equipment (tape or mass storage) assigned to the archive file and verify file (if one is being written). If not within the equipment access level limits, PFDUMP aborts the job and issues a diagnostic message. †

<sup>&</sup>lt;sup>†</sup> The system access level limits are displayed as part of the left screen header. The device access level limits (for mass storage) and equipment access level limits (for magnetic tape) are displayed on the E,A display. Refer to the NOS 2 Operations Handbook for display formats.

#### Incremental Permanent File System Dump

An incremental dump copies those permanent files modified after a specified date; that is, the OP=M option is specified together with the date (AD) and time (AT) options but BD=yymmdd and BT=hhmmss are not specified. Other options specified on the PFDUMP call can restrict the dump even further.

For example, the command

PFDUMP, OP=MI, AD=790101, AT=100000.

causes only indirect access files (I parameter) modified after the specified date and time to be dumped. Normal procedure at a site is to follow up this dump with successive incremental dumps (usually with a periodic advancement of date and/or time). This produces a series of archive files containing successive updating of all files in the defined category. (These files can reside on one file: a multifile archive file.) The archive files can then be incrementally loaded (refer to the PFLOAD utility described later in this section) to return the most recently modified versions of the archived files to the permanent file system.

Each incremental dump writes a record (or records) at the beginning of the archive file it creates. The record contains catalog images (refer to Catalog Image Record later in this section) of all files active on the device(s) being dumped when the dump took place. Files with no backup requirement (BR=N) are not included on the catalog image record. This enables a future incremental load of these files on a system or a device basis.

An example of incremental dumping is given under Load Permanent File (PFLOAD) later in this section.

## **Partial Permanent File System Dump**

A partial dump copies permanent files according to any specified option(s), except those defining a full or incremental dump. For example, the command

PFDUMP, OP=D.

is a partial dump of all direct access permanent files. Similarly, a dump of all files created (OP=C) or accessed (OP=A) after a certain date is a partial dump.

A partial dump can dump files from a certain device (DN or TD option) or can dump all files in the system (DN and TD not specified) that meet the criteria of the specified options.

#### **Full Permanent File Dump**

A full dump copies all files in the system or those cataloged on a specified device. That is, the OP option is not specified (or OP=0), and either a particular device is specified (device dump) or no device (DN=0 or TD=0) is specified (system dump).

PFDUMP interlocks a catalog track during the time it takes to dump all files whose PFC entries reside on that catalog track. No files whose PFC entries reside there are accessible until PFDUMP begins processing the next catalog track. For this reason, full permanent file dumps should not be done during heavy system use. An incremental dump provides adequate backup with less interference to the running system.

#### **PFDUMP** in an MSS/MSAS Environment

In an MSS/MSAS environment, the data for a permanent file to be dumped may reside on MSF/7990 and not on disk. However, if the file is to be copied to a dump file, it must have a disk image. The analyst can either stage the file to disk from MSF/7990 in order to include its data on the dump file (OP=S omitted), or copy to the dump file only the PFC and permit entries for the file and not the file data (OP=S specified). Typically, OP=S is specified for full dumps; otherwise, all MSF/7990 files would be included in the dump, which is not feasible because of the time involved to dump such a large permanent file base.

## NOTE

PFDUMP will dump only the PFC and permit entries for a direct access permanent file if that file has an alternate storage copy (MSF/7990 image) and is attached in write mode at dump time. The alternate storage obsolete flag (AFOBS) is cleared in the PFC written to the dump file.

As described in the NOS 2 Reference Set, Volume 3, the file owner can supply a backup requirement for a file using the BR parameter on the DEFINE, CHANGE, or SAVE command. Options include backup on a dump file, backup only if the current version of the file is not on MSF/7990, or no backup on a dump file. This partially determines whether or not a file is included in a particular PFDUMP run. Refer to section 12, MSS, or to section 11, MSAS, for further information on how the PFDUMP utility is used in an MSS/MSAS environment.

#### **PFDUMP** Protected Files

When PFDUMP specifies purging of files (OP=P), files whose user indexes are greater than PGUI (default value is 3000008) are not purged. This is done to prevent files such as critical recovery files, applications, and system utilities from being purged from the system due to lack of use.

## LOAD PERMANENT FILE (PFLOAD)

PFLOAD loads archived files produced by the PFDUMP utility back into the permanent file system. The load can reestablish the permanent file system exactly as it was at the time of the dump, or can load only a desired subset of files on the archive file (as indicated by specified parameters). PFLOAD issues messages to the dayfile indicating how many files were loaded and how many files with errors were encountered.

If LO=T (list all files processed) is specified, the listing produced is similar to that shown in figure 17-11. If LO=C (list all files in the catalog image record) is specified, the listing produced is similar to that shown in figure 17-16.

Figure 17-16. Catalog of Catalog Image Record

The two types of loads available are incremental and nonincremental. An incremental load builds up (increments) an accumulation of the most recently modified versions of the files extracted from the archive files for loading. A series of archive files is read in the reverse order of creation. The CIR created by the most recent incremental dump is read and checked against the archived files on these files. If a file matches an entry on the CIR, that file is a candidate for loading. A nonincremental load does no CIR checking and uses only parameters specified on the PFLOAD call, if any, to select candidates for loading.

#### Catalog Image Record

Each incremental dump (OP=M) writes a CIR at the beginning of the archive file on which the permanent files are dumped. The other types of dumps (full and partial) do not produce a CIR. The CIR is composed of 2-word entries for every permanent file on the device(s) being dumped at the time of the incremental dump (not just files included in the dump).

The format of each entry is:

| 59         |    | 41 | 35 |          | 17   | 0 |
|------------|----|----|----|----------|------|---|
| filename   |    |    | u  | serindex |      |   |
| access cou | nt | dn |    | date     | time |   |

Field Description

| filename     | Name of the permanent file.                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| userindex    | User index under which filename was cataloged.                                                                                                                                                                                               |
| access count | Number of times filename was accessed.                                                                                                                                                                                                       |
| dn           | Device number of the device on which filename resides if it is a<br>direct access file and resides on a device other than your master<br>device. If it resides on the master device, dn=0. If the file is<br>indirect access, dn is ignored. |
| date time    | Date and time filename was last accessed.                                                                                                                                                                                                    |

When a file is loaded, this CIR information is placed in the permanent file catalog of the device being loaded. No other information can be changed over dumps and loads without updating the utility control date and time.

Figure 17-16 contains a partial listing of the CIR. This listing can be obtained after a selective dump if the LO=C option is specified on a PFDUMP, PFLOAD, or PFATC call. A listing similar to the one in figure 17-11 can be obtained after a selective dump if the LO=T option is specified on a PFDUMP, PFLOAD, or PFATC call. In both cases, the headings vary but the format of the information is the same.

## **PFLOAD Selection Process**

Execution of the PFLOAD utility involves the following stages to determine which permanent files (from the archive file) should be loaded and on which devices they should reside.

1. If the DN, TD, or DD parameters are used, the device number specified must exist in the family being loaded or PFLOAD aborts and issues this message:

PFLOAD - DEVICE nn NOT FOUND.

2. If the specified parameters logically imply that no files can be selected (such as OP=I, DN=n where n is not a master device), PFLOAD aborts and issues this message:

PFLOAD - NO FILES SELECTED.

3. The user index mask for selecting files (based on the device mask of the device specified by the DN and DI parameters) must be such that it is possible for some files to be on the archive file. There must be some common bits between the archive file mask (written in the header record by PFDUMP) and the load selection mask. If no common bits exist, PFLOAD aborts and issues this message:

PFLOAD - SELECTED FILES NOT ON ARCHIVE FILE.

4. For nonincremental loads, this stage of checking is bypassed and the entire archive file to be loaded is passed on to the next stage.

The first step is to read the CIR from the most recent selective incremental dump file and place it on a random file. Then the archive files are read in the reverse order in which they were created (the most recently created file is read first).

Each file on an archive file is checked against the CIR on the random file for a match of file name and user index (these fields describe a file uniquely in a family). If a match is found, the file is a candidate for loading and moves to the next stage of checking. Also, the file name and user index are zeroed out in the corresponding CIR entry to prevent subsequent loading of older versions of the same file. If a match is not found, the file is skipped because it has already been accepted (it appeared on a previous archive file and a match with the CIR was found) or has been purged. This process passes on only the latest versions of files obtained from the archive files.

- 5. Only files that satisfy the criteria specified by the parameters on the PFLOAD command are selected (date/time, direct or indirect, user index, file name, and so forth). All other files are skipped.
- 6. The DN and TD parameters are used to select files from the archive file and to determine the device on which the files should be loaded.

Indirect access files, if selected, are always loaded on the appropriate master device (based on user index). Direct access files, if selected, are loaded on the device on which they previously resided. This is the device number contained in the file's PFC entry on the archive file. If the device number is 0, the file previously resided on the master device and will be reloaded there.

It may not be possible to load a direct access file on the device on which it previously resided because the device number may no longer exist or its secondary mask may not allow it. (Refer to Device Masks earlier in this section for additional information.) Either of these situations can occur as a result of a reconfiguration of the permanent file system. In either case, if a direct access file cannot be loaded, the DD parameter is checked. If an alternate device is specified and its secondary mask allows it, the file is loaded on the alternate device. Otherwise, the OP=L option is checked (see step 7). If the OP=L option is not specified, PFLOAD skips the file and issues this message:

PFLOAD - ALTERNATE DEVICE NOT FOUND, FN=filename, UI=userindex.

The DN parameter is used to select files from the archive file in the following manner. If the device specified by DN is a master device, all files (direct and indirect) cataloged on the master device (files with user indexes corresponding to that device's device mask) are selected. If the device specified by DN is not a master device, only direct access files that previously resided on the device (files with a device number of DN in their PFC entry) are selected. Similarly, the TD parameter is used to select files from the archive file in the following manner. If the device specified by TD is a master device, all files that were cataloged on it and all direct access files that previously resided on it are selected. (This corresponds to the way the TD parameter is processed by PFDUMP.) If the device specified by TD is not a master device, only direct access files that previously resided on it are selected.

If neither the DN nor TD parameters are specified, all files meeting other selection criteria are selected. If both the DN and TD parameters are specified, only files that meet the previously described criteria for both parameters are selected.

In all cases, the device masks and master device status for the devices specified by the DN or TD parameters refer to the system in which PFLOAD is running, not the system in which the files were dumped. The user index and device number from the PFC on the archive file reflect the situation that existed at the time the files were dumped.

- 7. If the OP=L option is specified, the device selected in step 6 (or the failure to select a device) for the residence of a direct access file is ignored. PFLOAD determines the device, among those devices where the file may reside (based on the device mask), which has the most available space. The OP=L option is not applicable to indirect access files since they must reside on the appropriate master device.
- 8. When a device has been selected to receive a direct access file, PFLOAD determines if the file will fit on the device. If the file is too large, PFLOAD skips the file and issues this message:

PFLOAD - NO SPACE FOR FILE,FN=filename,UI=userindex.

9. In secured systems, PFLOAD verifies before loading a file that the device where the file is to reside (as selected in steps 7 and 8) is appropriate for the file's access level. If the device is not appropriate, PFLOAD skips the file and issues this message:

PFLOAD - NO DEVICE FOUND FOR FILE, FN=filename, UI=userindex.

If PFLOAD is loading direct access files to the device with the most available space (OP=L), PFLOAD selects the device with the most space that also allows the required access level.

10. PFLOAD determines the catalog track where the files to be loaded are to reside and builds an index file with a 1-word entry for each file on the track. The format of the entry is:

| 59      | 17          | 0 |
|---------|-------------|---|
| filenam | e userindex |   |

PFLOAD checks each candidate file against this entry to determine whether it is in the permanent file system. If it is not, the file is loaded. If it is, loading depends upon the OP=R option. If OP=R was specified on the PFLOAD call, the archive duplicate replaces the one in the permanent file system. If OP=R was not specified, archive duplicates are skipped.

## **Family Reconfiguration**

When reconfiguring a permanent file family by adding or subtracting devices, or changing the device masks, use the PFLOAD OP=L parameter to greatly simplify the procedure. Follow this sequence to reconfigure a permanent file family:

- 1. PFDUMP,FM=familyname.
- 2. Initialize all devices in the family.
- 3. PFLOAD, OP=L, FM=familyname.

#### **PFLOAD** in an MSS/MSAS Environment

In an MSS/MSAS environment, an incremental load as described previously is the typical reload procedure. PFLOAD uses the CIR from the first incremental dump file to control the loading of file data and PFC and permit entries. Files that resided only on MSF/7990 at the time of the dump may or may not have been copied to the dump tape. If OP=S was specified on the PFDUMP call, then only the PFC and permit entries for the MSF/7990 files were included on the dump tape. PFLOAD reloads only what was dumped by PFDUMP. Thus, if the file data was omitted from the dump tape, it will be reloaded to disk. If the file data was omitted from the dump tape, only the PFC and permit information for the files will be reloaded. Refer to section 12, MSS, or to section 11, MSAS, for further information on how the PFLOAD utility is used in an MSS/MSAS environment.

## PFDUMP/PFLOAD EXAMPLE

In this example, permanent files created and modified on three devices are dumped nine times. The action runs from March 1, 1982 (82.3.1) to March 10, 1982 (82.3.10). To keep things simple, the time of day is not shown. Before the last dump, one of the devices becomes inoperable. The example then shows how this device can be loaded from the archive tapes. Following are the three devices.

| Device | Description                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 40     | A master device containing indirect access files only. Users with<br>this master device have their direct access files written on 41 or<br>42. |
| 41     | A master device containing indirect and direct access files. Direct access files cataloged on this device may be written on 42 or this device. |
| 42     | A nonmaster device containing direct access files only. All files written on this device will be cataloged on 40 or 41.                        |

File names consist of a letter and a number. The letter identifies which device contains the catalog entry for this file (A=device 40 and B=device 41). The number is the same as the device on which the file is written.

Each file name is followed by a date in parentheses. This indicates either the day on which the file was created or when it was last modified.

Figure 17-17 outlines the creation, modifications, and dumps that were made. There is one particular action per column. The top of the column identifies the action and the key parameters used by the utility. If an archive tape is produced, it is shown at the bottom of the column. All files in the system are listed in each column. Those files affected by the action are underscored.

60459300 D

Actions during the 10 days in March in which the dumps and modifications were made run as follows:

| Date   | Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 82.3.1 | Five permanent files are created on this date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|        | File A40 (indirect) is written on device 40 and cataloged on device 40.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|        | File A42 (direct) is written on device 42 and cataloged on device $40$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|        | File A41 (direct) is written on device 41 and cataloged on device 40.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|        | File B41 (indirect) is written on device 41 and cataloged on device 41.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|        | File B42 (direct) is written on device 42 and cataloged on device $41.$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 82.3.2 | DUMP 1. A full permanent file system dump. No CIR is written on the archive file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 82.3.3 | Three files (A40, B41, and B42) are modified on this date. This is indicated by the modification date in parentheses following the file name.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 82.3.4 | DUMP 2. This is an incremental dump of device 40 that specifies permanent<br>files modified after 82.3.3. The files for this device are the ones<br>listed on its catalog track. The utility scans this catalog which<br>contains entries for files A40, A42, and A41. File A40 is on device 40<br>and the other two are on the devices indicated by their names. Only file<br>A40, which was modified on 82.3.3, qualifies for this dump. It is written<br>on an archive tape after a CIR for this date (82.3.4). The CIR gives a<br>current description of all five files in the permanent file system. |
| 82.3.4 | DUMP 3. This is an incremental dump of device 41 that specifies all files<br>modified after 82.3.2. The catalog for this device contains entries for<br>files B41 and B42. Both files were modified on 82.3.3 and qualify for<br>this dump. They are written on an archive file after a CIR for this date.                                                                                                                                                                                                                                                                                                |
| 82.3.4 | DUMP 4. This is an incremental dump of device 42 that specifies all files<br>modified after 82.3.2. The PFDUMP utility scans the catalogs on devices<br>40 and 41 to locate the files on 42. One file, B42 (82.3.3), falls in<br>this category.                                                                                                                                                                                                                                                                                                                                                           |
| 82.3.5 | Three files are modified on this date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 82.3.6 | DUMP 5. This is an incremental dump of each of the three devices. All<br>files modified after 82.3.4 are specified by the AD option. Since no DN<br>is specified, all devices are dumped in turn, producing a dump tape with<br>three archive files.                                                                                                                                                                                                                                                                                                                                                      |
| 82.3.7 | DUMP 6. This incremental dump of device 42 specifies all files modified<br>after 82.3.4. Since 42 is nonmaster, the dump routine scans the catalogs<br>of the other two devices.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 82.3.8 | Four files are modified on this date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 82.3.9 | DUMP 7. An incremental dump of device 40 is made with AD=82.3.7. Two files qualify.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# Action

- 82.3.9 DUMP 8. An incremental dump of device 41 is made with AD=82.3.7. The catalog on device 41 contains entries for files B41 and B42. File B41 is an indirect access file located on device 41, and file B42 is a direct access file located on device 42. Both files were modified after 82.3.7 and are dumped.
- 82.3.10 DUMP 9. An incremental dump of devices 40, 41, and 42 is specified, but device 42 becomes inoperable before the dump is made.

To reestablish permanent files on device 42 with the most recent modifications available, the device is first initialized and then incrementally loaded, beginning with the most recent incremental dump tape. Archive dump 8 is the most recent incremental dump tape and accordingly contains the most recent CIR. This reel is assigned first and then the CIR read onto a random file. The dump tapes are read in reverse order with each file on each tape being checked against the CIR. Dump tapes 2 and 3 are omitted since they do not involve device 42.

For each catalog track on device 42 that is to receive file entries, PFLOAD builds and maintains an index file. Before each file can be loaded, PFLOAD checks the index file to see if the file has already been loaded. If it has, the archive duplicate is skipped; if not, the archive file is loaded and another entry goes into the index file.

After initialization of device 42, the loading runs as follows:

#### Archive File

Date

The analyst assigns DUMP8 tape and enters the command:

| DUMP8 tape                 |
|----------------------------|
| CIR(82.3.9)                |
| B41(82.3.8)<br>B42(82.3.8) |

DUMP7 tape

CIR(82.3.9)

A40(82.3.8) A41(82.3.8)

DUMP6 tape

CIR(82.3.7)

B42(82.3.5)

PFLOAD, T=DUMP8, DN=42.

The utility reads the CIR from this tape onto a random file. It then looks for files for device 42 on this tape. B42 qualifies, and its entry in the CIR is removed. The file B42 is loaded on device 42. The catalog of this file on device 41 is created. After loading this file, the utility makes an entry in the index file as follows:

Action

| B42 userindex |     |           |
|---------------|-----|-----------|
|               | B42 | userindex |

The utility then requests the next reel.

The analyst assigns this tape, and the utility reads the archive file and checks it against the CIR loaded from DUMP8 above. No match is found. The next reel is requested.

This tape is assigned and then compared with the CIR. B42 is a file from device 42. However, its entry in the CIR was removed when it was read from DUMP8.

| Archive File                              | Action                                                                                                                                   |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DUMP5 tape                                | This tape is assigned and then compared with the CIR. B42 is from de-                                                                    |
| CIR(82.3.6)                               | vice 42 but it has already been removed from the CIR and the utility skips this version.                                                 |
| A40(82.3.5)<br>B41(82.3.5)<br>B42(82.3.5) |                                                                                                                                          |
| DUMP4 tape                                | This tape is assigned and compared with the CIR originally read from                                                                     |
| CIR(82.3.4)                               | DUMP8 tape. It has been removed from the CIR and this file is skipped.                                                                   |
| B42(82.3.3)                               |                                                                                                                                          |
|                                           |                                                                                                                                          |
| DUMP1 tape                                | This tape, produced by a full dump, contains all the files that were on the permanent file system when the dump was made (82.3.1). These |
| A40(82.3.1)                               | files are checked against CIR (82.3.9). A match is found with A42.<br>This file is loaded.                                               |
| A42(82.3.1)                               | This file is loaded.                                                                                                                     |
| A41(82.3.1)                               | Device 42 now has the same files with the same update status that they                                                                   |
| B41(82.3.1)<br>B42(82.3.1)                | had on 82.3.9 when the last incremental dump was made.                                                                                   |

)

# **QUEUE/DAYFILE UTILITIES**

Several utility programs control queued input and output files and system, account, error log, and binary maintenance log dayfiles. The utility programs are divided into the following two groups, according to the type of selective processing they do.

- The queue file utilities are 10 utilities under the control of the queue file supervisor program QFSP. These utilities select for processing queued files or dayfiles that share certain characteristics you specify such as device residence, file destination, and job sequence name.
- The dayfile dumping utilities are five independent utilities that dump all or selected parts of the active system dayfile, account dayfile, error log, or binary maintenance log. These utilities each process the contents of a single file according to criteria you specify.

# **QUEUE FILE UTILITIES**

The names and functions of the queue file utilities follow. The rest of this section includes detailed information about the call and operation of each utility.

| Utility | Description                                                                                 |
|---------|---------------------------------------------------------------------------------------------|
| DFLIST  | Lists dayfiles that have been made permanent files by the DFTERM utility.                   |
| DFTERM  | Terminates an active or inactive dayfile and retains it as a direct access permanent file.  |
| LDLIST  | Lists queued files present on a QDUMP dump tape.                                            |
| QALTER  | Alters routing information associated with active queued files; purges active queued files. |
| QDUMP   | Dumps queued files to a tape or disk.                                                       |
| QFTLIST | Lists detailed information about active queued files.                                       |
| QLIST   | Lists inactive queued files.                                                                |
| QLOAD   | Loads files dumped by QDUMP as queued files.                                                |
| QMOVE   | Moves queued files from one disk device to another.                                         |
| QREC    | Deactivates or activates selected queued files; purges inactive queued files.               |

### CALLING THE QUEUE FILE UTILITIES

All queue file utility operations, except DFLIST, LDLIST, and QLIST, can be initiated through console input to a K display. All queue utilities except DFLIST, DFTERM, QALTER, and QFTLIST can be initiated through entries made at the system console (under DIS or DSD control, including procedure files), card input (batch), or terminal entries. DFTERM, DFLIST, QALTER, and QFTLIST operation can be initiated only through entries made at the system console. However, in all cases, for batch and terminal input, you must be validated for system origin privileges, the system must be in debug mode, and you must observe certain parameter order dependencies. Since LDLIST, QDUMP, and QLOAD require preassignment of the dump file, only DIS, batch, or terminal input is appropriate for these utilities.

#### **Console Input**

Input from a console through a K display requires the following sequence of entries and responses. These procedures do not apply to DFLIST, QLIST, or LDLIST, because K displays are not available for these utilities.

1. Call QFSP by entering:

X.QFSP.

The B,O display indicates the job sequence name of QFSP. To the right of the entry this message appears:

**REQUEST \*K\* DISPLAY** 

2. Activate the K display for that control point by entering:

K,jsn. (jsn is the job sequence name of QFSP as specified on the B,O display.)

The display shown in figure 18-1 appears on the left screen. Instructions at the bottom of the display describe how to select the desired utility.

\*\*\* QUEUED FILE SUPERVISOR \*\*\*

UTILITY DESCRIPTION QDUMP - QUEUED FILE DUMP PROCESSOR. QLOAD - QUEUED FILE LOAD PROCESSOR. QMOVE - QUEUED FILE MOVE PROCESSOR. QREC - PROCESS QUEUED FILES. DFTERM - TERMINATE DAYFILES. QFTLIST - LIST ACTIVE QUEUED FILES. QALTER - ALTER ACTIVE QUEUED FILES.

SELECT DESIRED UTILITY BY ENTERING K.OPTION WHERE OPTION IS ONE OF THE UILITIES LISTED ABOVE.

Figure 18-1. QFSP K Display (Left Screen)

3. Select the desired utility by entering:

(utility is one of the utilities shown in the K display, figure K.utility. 18 - 1.)

The parameters available under the chosen utility appear on the left screen as the initial K display for the utility. Figures 18-3, 18-9, 18-12, 18-14, and 18-17 exhibit initial K displays for the various utilities. Different parameters are available with the different utilities. (Refer to Description of Queue File Utility Parameters later in this section.)

It is also possible to call each utility directly by substituting the following procedure for steps 1, 2, and 3.

a. Call the desired utility by entering:

X.utility. (utility is one of the utilities shown in figure 18-1.)

The B,O display indicates the job sequence name of the chosen utility. This message also appears:

**REQUEST \*K\* DISPLAY** 

b. Activate the initial K display for the chosen utility by entering:

(jsn is the job sequence name as specified on the B,O display.) K.jsn.

4. Several commands are available to aid in the use of the utilities and direct processing. A right screen display lists and defines each available command. Activate this K display by entering:

KK.

Figure 18-2 shows the resultant display.

Following is a list of the queue file utility commands included on the display and a description of each.

| Command | Description                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GO      | Directs the active utility to proceed with the processing of<br>the entered parameters. When the processing is complete,<br>the left screen K display is reset to the default values.                                        |
| STOP    | Terminates the active utility and ends the K-display interaction.                                                                                                                                                            |
| RESET   | Resets all options displayed on the left screen K display to their default values.                                                                                                                                           |
| LIST    | If the DFTERM utility is active, this command displays a<br>list of all permanent dayfiles (refer to figure 18-4). The<br>list of files displayed is also written on the output file<br>specified by the DFTERM L parameter. |

| Command  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | If the QALTER or QFTLIST utility is active, this command<br>displays a list of active queued files on the right screen K<br>display (refer to figure 18-6). The list of files is also<br>written on the output file specified by the QALTER or<br>QFTLIST L parameter.                                                                                                                                                                                                                 |
|          | If the QREC utility is active, this command displays a list<br>of inactive queued files on the right screen K display<br>(refer to figure 18-18). The list of files displayed is<br>also written on the output file specified by the QREC L<br>parameter.                                                                                                                                                                                                                              |
| LIST=qft | Displays detailed information about the active queued file<br>at QFT ordinal qft on the right screen K display (refer to<br>figure 18-7) and writes the information to the output file<br>specified by the QALTER or QFTLIST L parameter. This form<br>of LIST is accepted only by QALTER and QFTLIST.                                                                                                                                                                                 |
| +        | Used in conjunction with the LIST command; displays<br>succeeding pages (screens) of the information listed. This<br>command applies only to the QREC, QALTER, and QFTLIST<br>utilities.                                                                                                                                                                                                                                                                                               |
| *        | Enables you to page the left screen K display. This command applies only to the QREC, QDUMP, QLOAD, QMOVE, QFTLIST, and QALTER utilities.                                                                                                                                                                                                                                                                                                                                              |
| CLEAR    | Used in conjunction with the LIST command; returns the right<br>screen K display to the list of processing commands<br>initially displayed (refer to figure 18-2) and returns the<br>left screen K display to the first page.                                                                                                                                                                                                                                                          |
| OUT      | Sends the output file specified by the L option of each<br>utility to the print queue for immediate printing. Any<br>information that has been or is currently displayed on the<br>right screen K display via the LIST command is also included<br>with the disposed output. In addition, if the LIST command<br>is currently active, the list displayed on the right screen<br>is disposed, and the initial right screen K display shown in<br>figure 18-2 is returned automatically. |
| FAMILY   | Specifies whether or not files are queued when creation or<br>destination families are not active [not in family ordinal<br>table (FOT)]. Default is not to queue these files. When<br>the FAMILY command is specified, entries are made in the FOT<br>for inactive families and the files are queued. This<br>command applies only to the QLOAD, QMOVE, and QREC utilities.                                                                                                           |
| LID      | Specifies whether or not files are queued when the creation<br>logical identifier (LID) is not in the LID table. Default<br>is not to queue these files. When the LID command is<br>specified, entries are made in the LID table and the files<br>are queued. This command applies only to the QLOAD, QMOVE,<br>and QREC utilities.                                                                                                                                                    |

 $\mathbf{r}$

Figure 18-2. Queue File Utility Commands K Display (Sheet 2 of 2)

5. Select the desired parameters by entering:

 $K \cdot opt_1 = val_1, opt_2 = val_2, \dots, opt_n = val_n$ .

The  $opt_i=val_i$  are selected from the parameter list on the initial K display for the chosen utility.

The option parameter entries are issued to the job dayfile, which is included in the output file specified by the L parameter for each utility (refer to Parameters for the Queue File Utilities later in this section).

If the FM parameter is specified for QDUMP, QMOVE, or QREC (indicating the processing of queue files for only the specified family of devices), the initial left screen display (refer to figures 18-9, 18-14, and 18-17) is replaced by the secondary left screen display (refer to figures 18-10, 18-15, and 18-19). This display closely resembles the initial left screen for the utility but restricts processing to the family of devices specified. Each device in the specified family containing inactive queued files is indicated. In addition, any parameter entered for the utility is reflected in this display. Parameters not entered remain at default values.

If the FM parameter is not specified, the initial K display remains on the left screen. However, the display is modified to reflect the parameters entered. Parameters not entered remain at the default values.

The displays are modified in this manner to provide an opportunity to double-check the entry. If it is necessary to modify the entry, reenter those parameters that are to be changed. Entry of incorrect data causes an error message to appear at the bottom of the left screen K display. In this case, the portion of the entry up to the point where the error was encountered is processed; the remainder of the entry (from left to right) is ignored.

6. Initiate execution by entering:

K.GO.

When processing is complete, the left screen K display is reset to default values, the message

utility COMPLETE (utility is the name of the utility processed)

appears at the bottom of the screen, and the right screen returns to the original display.

7. Terminate use of the chosen utility and end K-display interaction by entering:

K.STOP.

An output file is generated indicating the disposition of queued files or dayfiles processed. Examples of output files generated by each utility are shown in figures 18-4, 18-11, 18-13, 18-16, and 18-20.

It is also possible to call each utility and specify appropriate parameters without using K displays; this is the only way to call DFLIST. You do this using a single keyboard entry in the following format.

X.utility(opt1=val1,opt2=val2,...,optn=valn,I=filename,PO=N)

# ParameterDescriptionutilityAny queue or dayfile utility.opti=valiParameters (refer to Parameters for the Queue File Utilities later in<br/>this section).I=filenameName of alternate input file (optional). This file may contain<br/>K-display utility commands (GO, STOP, RESET, and so on) and parameters.PO=NSpecifies that no K-display input is allowed. The use of the PO=N<br/>parameter and proper parameter selection allows the utility to run<br/>without additional operator intervention. This parameter is not needed<br/>and should not be entered for QLIST, LDLIST, and DFLIST.

The specified utility processes parameters on the command before the alternate input file, if any. If the utility is QLIST, LDLIST, or DFLIST or if PO=N is specified, the requested queue/dayfile processing proceeds after all command and alternate input file parameters have been processed (unless a STOP command is encountered on the alternate input file). If PO=N is omitted from the command and the utility is not one previously mentioned, the utility requests the K display after processing the command and alternate input file (unless a STOP command is encountered on the alternate input file). The K display then reflects the status of all parameters after processing of the command and alternate input file is complete. If the utility encounters an error while processing the command or alternate input file, a request for the K display appears on the DSD B,O display (except for QLIST, LDLIST, and DFLIST). You may then activate the K display, enter the correct parameters, and continue processing. However, if errors are encountered and the utility was invoked by a nonsystem origin job, a message is issued to the dayfile, and utility processing is terminated.

# **Batch Input**

To call the utilities from a batch job, you must be validated for system origin privileges, and the system must be in debug mode. The following sequence of commands is used to call a utility.

ujn. USER,username,password,familyname. utility,opt<sub>1</sub>=val<sub>1</sub>,opt<sub>2</sub>=val<sub>2</sub>,...,opt<sub>n</sub>=val<sub>n</sub>,I=filename,PO=N.

| Parameter                          | Description                                                                                                                                                                                                                                                         |  |  |  |  |  |  |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|
| utility                            | Any of the following utilities: QREC, QDUMP, QLOAD, QMOVE, QLIST, or LDLIST.                                                                                                                                                                                        |  |  |  |  |  |  |
| opt <sub>i</sub> =val <sub>i</sub> | Parameters (refer to Parameters for the Queue File Utilities later in this section).                                                                                                                                                                                |  |  |  |  |  |  |
| I=filename                         | Name of alternate input file (optional). This file may contain<br>K-display utility commands (GO, STOP, RESET, and so on) and<br>parameters.                                                                                                                        |  |  |  |  |  |  |
| PO=N                               | Specifies that no K-display input is allowed. The use of the PO=N<br>parameter and proper parameter selection allows the utility to run<br>without additional operator intervention. This parameter is not<br>needed and should not be entered for QLIST or LDLIST. |  |  |  |  |  |  |

The DFLIST, DFTERM, QALTER, and QFTLIST utilities cannot be called from a batch job. They must be initiated from the system console.

# **Terminal Input**

The format of terminal input for calling the queue utilities is substantially the same as that for batch input. You must be validated for system origin privileges, and the system must be in debug mode. At login, you enter the batch subsystem, call the desired utility, and enter the appropriate parameters with the command:

utility,opt1=val1,opt2=val2,...,optn=valn,I=filename,PO=N

The utility, opt=val, I=filename, and PO=N parameters are the same as described for batch input.

# PARAMETERS FOR THE QUEUE FILE UTILITIES

Table 18-1 specifies the parameters accepted by each queue file utility. (DFLIST is not included because it does not accept any parameters.) An X indicates that a parameter is accepted; a blank indicates that a parameter is not accepted. Refer to the descriptions of parameters following the table for more information.

|           | Utility |       |       |       |        |        |         |        |       |

|               | MAINLOG Binary maintenance log.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|               | This parameter causes the FM and DN parameters to be updated to reflect the current family and device number of the dayfile specified by FT. Default is FT=DAYFILE.                                                                                                                                                                                                                                                                                                                          |
| FU=familyname | Name of family under which the queued files to be processed were<br>created. Queued files created by users of one family can reside on<br>nonremovable devices of another family. The FM parameter specifies<br>the family of devices that will be searched for queued files created<br>by users validated in the family specified by the FU parameter.<br>Default is to process queued files created by users in all families.                                                              |
| ID=id         | The 1- or 2-digit octal number (0 through 678) specifying that<br>only local batch-destined queued files assigned to that identifier<br>are to be processed. This parameter does not deselect remote batch-<br>destined files. If two identifiers, separated by a hyphen, are<br>specified (for example, ID=6-30), any queued file with an identifier<br>in the specified range (including the end points) is processed.<br>Default is to process all queued files regardless of identifier. |
| JSN=jsn .     | The 4-character job sequence name of queued files to be processed,<br>dumped, loaded, or moved. At most, five job sequence names can be<br>specified. If a job sequence name is specified more than once, it<br>is removed from the list. Default is to process all queued files<br>regardless of job sequence name.                                                                                                                                                                         |
| L=outfile     | The 1- to 7-character name of the file to receive output. Default is L=OUTPUT.                                                                                                                                                                                                                                                                                                                                                                                                               |
| LA=level      | The 1- to 7-character name that specifies the lower limit of the<br>range of access levels to process. If this parameter is specified,<br>the UA parameter must also be specified. If neither LA nor UA is<br>specified, the default is that all access levels are selected.                                                                                                                                                                                                                 |

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |   |  |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|--|--|
| LD=lid         | The 3-character logical identifier of the mainframe with which the file is associated. LD=0 means process all files without LIDs. A subsequent LD entry replaces any LD entry previously made. Default is to process all queued files regardless of logical identifier.                                                                                                                                                                                                                                                     |   |  |  |
| LO=opt         | List option associated with the output file specified by the L parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |  |  |
|                | opt Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |   |  |  |
|                | F All routing information for each file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |  |  |
|                | S Condensed listing of each selected queued file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |  |  |
| MI=id          | The 2-character machine identifier indicating the mainframe on which<br>the queued files to be processed currently reside. If MI=ALL is<br>specified, any queued file residing on any mainframe is processed.<br>The MI entry is cleared if previously specified; that is, specifying<br>two identical MI entries is the same as not specifying any at all.<br>If the MI entry is cleared on the K display, the id is not checked.<br>Default is the machine identifier of the mainframe where the utility<br>is being run. | ç |  |  |
| NAL=1evel      | QALTER can change the access level of a queued file. The new access<br>level must be within the origin type limits for the file and within<br>the device limits of the device on which the file resides. This<br>parameter is restricted to users with security administrator<br>privileges.                                                                                                                                                                                                                                |   |  |  |
| NDC=dt         | QALTER can change a print file's disposition type while the file is<br>in the queue. New disposition types that can be selected include<br>the following.                                                                                                                                                                                                                                                                                                                                                                   |   |  |  |
|                | dt Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |  |  |

|           | For plot files:                                                                                                                                                                                                                                                                                                                                                                                                 |  |  |
|           | T6 Transparent 6 bit.<br>T8 Transparent 8 bit.                                                                                                                                                                                                                                                                                                                                                                  |  |  |
| NF=n      | Decimal number of media files to skip. A media file contains all queued files that are dumped by one QDUMP operation. Each of these dumped queued files exists as a record on the media file. If two QDUMP operations are performed, the dumped queued files exist as records on two files. This parameter can be used in conjunction with the SC parameter. Default is $0$ .                                   |  |  |
| NFC=fc    | Two alphanumeric characters or <b>**</b> (null forms code) specifying the<br>new forms code associated with selected output files. The NFC entry<br>is cleared if previously specified; that is, specifying two<br>identical NFC entries is the same as not specifying any at all.<br>Default is no change in forms code.                                                                                       |  |  |
| NID=id    | The 1- or 2-digit number (0 through 678) specifying the new file<br>identifier associated with selected output files. This parameter is<br>meaningful only when altering files routed to or changed to local<br>batch. The NID entry is cleared if previously specified; that is,<br>specifying two identical NID entries is the same as not specifying<br>any at all. Default is no change in file identifier. |  |  |
| NLD=1id   | The 3-character logical identifier specifying the new logical<br>identifier associated with selected files. NLD=0 will remove the<br>LID from selected files. A subsequent NLD entry replaces any NLD<br>entry previously made. Default is no change in logical identifier.                                                                                                                                     |  |  |

| Parameter    |                                           | Description                                                                                                                                                                                                                                                                                                 |  |  |  |  |  |
|--------------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
| NM=filename  | which DFTER<br>2-character<br>(AC, DF, ML | The 1- to 5-character name of the direct access permanent file on<br>which DFTERM writes the terminated dayfile. DFTERM adds a<br>2-character prefix indicating the type of dayfile being terminated<br>(AC, DF, ML, or ER). Default is automatic naming of the file by<br>DFTERM as follows:               |  |  |  |  |  |
|              |                                           | first two characters indicate the type of dayfile being minated (AC, DF, ML, or ER).                                                                                                                                                                                                                        |  |  |  |  |  |
|              | • The                                     | third character is a sequence number (A through 9).                                                                                                                                                                                                                                                         |  |  |  |  |  |

|              | RI                                        | Selected inactive queued files are activated (requeued), and the remaining inactive queued files are ignored.                                                                                                                                                                                               |  |  |  |  |  |
|              | RP                                        | Selected inactive queued files are activated (requeued),<br>and the remaining inactive queued files are purged.                                                                                                                                                                                             |  |  |  |  |  |
|              |                                           |                                                                                                                                                                                                                                                                                                             |  |  |  |  |  |

# Parameter

# Description

With QALTER, opt specifies the destination to which the selected queued files should be changed; it can be one of the following. Default is OP=NC.

- opt Description
- BC Change to local batch.
- NC Do not change file destination.
- PR Purge files.

opt

RB Change to remote batch.

With DFTERM, opt specifies whether active or inactive dayfiles will be terminated. With QLOAD and QMOVE, opt specifies whether the loaded or moved queued files will be active or inactive. With these utilities, opt can be one of the following. Default is OP=A.

# opt Description

- A Active queues/dayfiles are specified.
- I Inactive queues/dayfiles are specified.

Processing option specifying the function to be performed.

P0=opt

#### Description

- N Only command directives are processed. The K display is available to monitor utility progress, but no K-display input is allowed. The N option is implied on all nonsystem origin jobs.
- R The dump or load file is rewound before processing begins.
- E Errored file processing status is toggled. Default conditions for queue utilities include:

| Default           | Utility |
|-------------------|---------|
| Dump file.        | QDUMP   |
| Do not load file. | QLOAD   |
| Do not move file. | QMOVE   |

- F Entries are made in FOT for inactive families and the files are queued.
- L Entries are made in the LID table for inactive LIDs and the files are queued.

| Parameter     |                                                                                                                                                                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                       |  |

| TUI=userindex | The 1- to 6-digit value plus a radix that specifies the destination<br>terminal user index for remote batch destined output files. If one<br>userindex is specified (xxxxxx), only that user index is processed.<br>If a range is specified (xxxxxx-yyyyy), all indexes in the<br>specified range are processed. If TUI=0, no terminal user index is<br>specified. Default is TUI=0. |
| UA=level      | The 1- to 7-character name that specifies the upper limit of the<br>range of access levels to process. If this parameter is specified,<br>the LA parameter must also be specified. If neither LA nor UA is<br>specified, the default is that all access levels are selected.                                                                                                         |
| UI=userindex  | User index under which queued files to be processed were created.<br>If two user indexes, separated by a hyphen, are specified (for<br>example, 75-162), all queued files created by all users having<br>indexes within this range (including the end points) are processed.<br>Default is to process all queued files regardless of user index.                                     |
| UJN=ujn       | The 1- to 7-character user job name specified on Job commands<br>associated with queued files being listed or altered. Only one name<br>can be specified. A subsequent UJN entry replaces any UJN entry<br>previously made. This parameter in conjunction with the JSN<br>parameter uniquely describes which files are to be processed.<br>Default is no UJN specified.              |
| UN=username   | Destination user name within the family specified by the DF option.<br>UN and DF must be specified together. The utility (QALTER or<br>QFTLIST) will process files belonging to the remote terminal<br>identified by these parameters. The UN entry is cleared if<br>previously specified; that is, specifying two identical UN entries<br>is the same as not specifying any at all. |
|               | NOTE                                                                                                                                                                                                                                                                                                                                                                                 |

If the currently displayed value for JSN, NFC, NID, NPR, NRC, NUN, or UN is reentered, the value for the specified parameter is cleared.

.

#### **File Preassignment**

When using the LDLIST, QDUMP, and QLOAD utilities, the dump or load file must be preassigned. This can be done by using a LABEL or an ASSIGN command. For example, the following commands can be used.

LABEL, QFILES, VSN=DMP1, D=HY.

or

ASSIGN, MS, QFILES.

If no dump file is present, QDUMP will write on a local mass storage file; LDLIST and QLOAD will attempt to read an empty file and terminate.

# Active and Inactive Queued Files

A queued file can be active or inactive. All queued files are originally active upon entering a queue. A queued file is deactivated (made inactive) when its entry is removed from the queued file table (QFT) and a corresponding entry is created in the inactive queued file table (IQFT) on the mass storage device where the queued file resides. An inactive queued file is activated when the entry from the IQFT is removed and a corresponding entry is created in the QFT. Inactive queued files are not considered for processing (other than by the queue utilities), nor do they appear on any DSD display.

Three queue file utilities can deactivate or activate queued files (QLOAD, QMOVE, and QREC). QLOAD and QMOVE each transfer queued files from either tape or disk to a disk device. Upon completion of the transfer, the utility leaves the queued files active or inactive according to the parameters you have specified. QREC does not perform any file transfer but only adjusts table entries as described in the preceding paragraph. These three utilities have uses other than deactivation and activation of queued files (refer to the description of the appropriate utility and parameters).

Queued files are also deactivated when they are recovered during a level 0 deadstart. Such files can be activated automatically by an IPRDECK entry that invokes QREC during a level 0 deadstart. Refer to section 3, Deadstart Decks, for further information on IPRDECK.

# QUEUE FILE UTILITY ROUTINES

The queue file utility routines are described next. The parameters available for each of the routines are listed in table 18-1. The K displays (if any) for each utility are shown and contain lists of applicable parameters. The output formats for each utility are also shown.

# DFLIST

DFLIST generates a printer listing of all permanent files created by the DFTERM utility.

DFLIST can be initiated only from the system console directly through this command:

X.DFLIST.

The output generated by DFLIST is the same as that produced by the LIST command available under the DFTERM utility (refer to figure 18-4).

# DFTERM

DFTERM terminates an active or inactive dayfile and retains it as a direct access permanent file on user name SYSTEMX for later interrogation or processing. When an active dayfile (that is, the current system dayfile, account dayfile, error log, or binary maintenance log) is terminated, information in the central memory buffer for that dayfile is written to mass storage to be included with the permanent file, and a new active dayfile is started. The new dayfile can reside on the same device, or a new device can be specified.

Terminating an inactive dayfile has no effect on the currently active dayfiles. Inactive dayfiles are not used by the system. Furthermore, the presence of an inactive dayfile in the system is possible only under unusual conditions. For example, if the system is deadstarted and the device that previously contained the account dayfile is turned off, a new account dayfile is started on another device. Two devices in the system now contain account dayfiles. If both devices are turned on when the system is next deadstarted, two account dayfiles are recovered. The most recent account dayfile is made active and is used by the system. The remaining account dayfile is made inactive.

The DFTERM utility can be initiated only from the system console through a K display or directly through the DFTERM command. No batch or terminal input is allowed.

When DFTERM is selected at the system console, the DFTERM K display appears on the left screen. This display contains a list of all applicable options associated with DFTERM, their default values, and a short description of each (refer to figure 18-3).

A list of the permanent dayfiles is displayed on the right screen when you enter this command:

K.LIST.

When this command is processed, the right screen K display is automatically replaced with the dayfile list K display (refer to figure 18-4). The information presented in this display is the same as that generated by the DFLIST utility.

If there are more files than can be displayed on one screen (page), a message appears at the bottom of the screen indicating that more files exist. When the LIST command is entered, a complete list of permanent dayfiles is written to the output file specified by the DFTERM L parameter; thus, a complete printer listing is provided when the DFTERM utility is terminated. If it is necessary to obtain the output listing immediately, enter this command:

K.OUT.

When this command is processed, the initial right screen K display (a list of the queue file utility commands) is automatically returned. However, if the OUT command is not entered, the original right screen K display can be returned by entering the CLEAR command.

After DFTERM processing is completed, an output file indicating the results of this processing is generated if the LIST command has been entered at any time during DFTERM operations. (Refer to figure 18-4, which shows essentially the same format.) If the LIST command was not entered, no output file is generated.

Figure 18-4. DFTERM Dayfile List

# LDLIST

LDLIST generates a printer listing of queued files present on a QDUMP dump tape.

Since LDLIST requires a QDUMP dump tape to be preassigned, it should be entered from DIS or in a batch or terminal job in the form

LDLIST, opt1=val1, opt2=val2, ..., optn=valn.

opt<sub>i</sub>=val<sub>i</sub> are parameters available for LDLIST.

The output generated by LDLIST is the same as that produced by QLOAD (refer to figure 18-13).

# QALTER

QALTER displays, lists, and/or alters routing and other information about active queued files. The utility selects files for processing according to criteria you specify. QALTER purges selected files from the system when you specify OP=PR.

You may alter the following information associated with the selected files.

- Access level (requires security administrator privileges).
- File destination.
- File identifier (local batch-destined files).
- Destination family (remote batch-destined files).
- Destination user name (remote batch-destined files).
- Forms code.
- Priority of a queued file.
- Repeat count.
- Disposition type.
- External characteristics.
- Destination LID.

When QALTER is selected at the system console, the QALTER K display appears on the left screen. This display contains a list of all applicable parameters associated with QALTER, their default values, and a short description of each (refer to figure 18-5). Follow this procedure to alter active queued files:

- 1. Enter the selection criteria specifying which files are to be altered (parameters FM, DN, JSN, LD, UJN, ID, DF, UN, FC, LA, UA, BC, and RB).
- 2. Ensure that the desired files are selected by inspecting the list of files produced by the K-display commands LIST or OUT (refer to figures 18-6, 18-7, and 18-8). If the file produced by OUT is to be other than OUTPUT or contain a detailed listing of the selected files, specify such with the L and/or LO parameters before entering K.OUT.
- 3. Enter the new information to be associated with the selected files (parameters OP, NDC, NEC, NLD, NDF, NUN, NID, NFC, NPR, NRC, and NAL). QALTER changes only information specified via parameter entry.
- 4. Enter K.GO. QALTER makes the requested changes, issues the message \*QALTER COMPLETE.\*, and resets the K-display parameters to their default values.
- 5. Repeat steps 1 through 4 to alter additional files, or enter K.STOP. to terminate QALTER activity.

Figure 18-8. QALTER Printer Listing

#### Example:

Use the QALTER utility to divert output files from the local printers to a remote terminal. The following command alters the routing of all batch output files with a forms code of AD. These files are routed to a remote terminal with family name FAMI and user name USRNAM. The BC and RB parameters explicitly disable input file selection.

QALTER, PO=N, BC=IN, RB=IN, FC=AD, OP=RB, NDF=FAM1, NUN=USERNAM.

The QFTLIST utility can be used in conjunction with QALTER to ensure that the files were properly altered. The following command generates a list of all active queued files belonging to the remote terminal with family name FAMI and user name USRNAM.

QFTLIST, PO=N, LO=F, DF=FAM1, UN=USRNAM, BC=NONE.

# QDUMP

QDUMP dumps selected queued files from a single device, a family of devices, or all devices on the system. These queued files can be dumped to a tape or disk. When active queued files are dumped, the QFT is searched to obtain the proper file. When inactive queues are dumped, the IQFT is searched. QDUMP also provides a listing of all files dumped with information about each file processed.

For a secured system, QDUMP determines the maximum range of access levels that can be dumped. If the LA and UA parameters have been used to select access level limits, these limits will be used. If no access level limits were selected, QDUMP uses the device limits determined by taking the lowest lower access limit and the highest upper access limit of all the devices to be processed. If this range of access levels is not within the system access level limits, QDUMP issues a diagnostic message.

When QDUMP is selected at the system console, the initial QDUMP K display appears on the left screen. This display contains a list of all applicable options associated with QDUMP, their default values, and a short description of each (refer to figure 18-9).

Figure 18-9. Initial QDUMP Display

If the FM parameter is specified, indicating dumping of queued files from a specified family of devices, the initial QDUMP left screen K display is replaced by the secondary QDUMP K display (refer to figure 18-10). This display closely resembles the initial QDUMP display but restricts QDUMP processing to the family of devices specified. Each device in the specified family containing inactive queued files is indicated. In addition, any parameter entered for the QDUMP utility is reflected in this display. Parameters not entered remain at default values.

Figure 18-11. QDUMP Output File

QDUMP does not purge files upon completion. If you want to purge files, the following sequence of commands is recommended.

| Command      | Description                                                                                                   |  |  |  |  |  |  |  |  |  |
|--------------|---------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|--|--|--|
| QREC, OP=DI. | Dequeues the files.                                                                                           |  |  |  |  |  |  |  |  |  |
| QDUMP,TP=I.  | Dumps the inactive files. The dump file (default name = QFILES) should<br>be preassigned before this command. |  |  |  |  |  |  |  |  |  |
| QREC,OP=PI.  | Purges the files.                                                                                             |  |  |  |  |  |  |  |  |  |

### **QFTLIST**

QFTLIST displays and/or lists routing and other information about active queued files. Its operation is similar to that of QALTER, except file alteration or purging is not allowed. When QFTLIST is selected at the system console, the QFTLIST K display appears on the left screen. This display contains a list of all applicable parameters associated with QFTLIST, their default values, and a short description of each (refer to figure 18-5). The output generated by QFTLIST LIST and OUT K-display commands (both printed and right screen K display) is similar or identical to that produced by QALTER.

## Example 1:

Use the QFTLIST utility to determine what actions are necessary to get queued files processed by the RBF or BIO Subsystems. The following QFTLIST entry generates a detailed list of queued files, from which forms code, id, and other destination routing information can be determined. This information indicates what action must be taken to have the files processed.

X.QFTLIST(PO=N,LO=F)

#### Example 2:

Use the QFTLIST utility to determine what queued files are routed to a particular device. The following QFTLIST entry generates a list of all print files with forms code of AA that are routed to a 580-20 (LT) printer. Input file selection is explicitly disabled.

X.QFTLIST(PO=N,FC=AA,RB=IN,BC=NONE,BC=LT)

# QLIST

QLIST lists inactive queued files, which may include all inactive queued files in the system or a selected subset based on parameters specified when the utility is called.

The QLIST utility is not restricted to use from the system console. However, from the system console, QLIST must be called directly with the following command. No K-display interaction is available.

X.QLIST(opt1=val1,opt2=val2,...,optn=valn)

The applicable parameters associated with QLIST are the same as those used with the QREC utility, except for the OP parameter. The OP parameter is not valid with QLIST.

If all current inactive queued files are to be listed, no parameters need be specified. In this case, the format of the QLIST call is:

X.QLIST.

The output generated by QLIST is the same as that produced by the LIST command available under the QREC utility (refer to figure 18-18).

# QLOAD

QLOAD processes the dump files generated by QDUMP or other utilities using the same format. QLOAD can selectively load the queued files from these dump files. QLOAD can also list the contents of a dump file without loading any files.

For secured systems, the access level for each file selected to be loaded must be within the file's origin type limits and the file must be assigned to an appropriate mass storage device. If a selected file cannot be loaded, QLOAD issues a diagnostic message and skips that file.

When QLOAD is selected at the system console, the QLOAD K display appears on the left screen. This display contains a list of all applicable parameters associated with QLOAD, their default values, and a short description of each (refer to figure 18-12).

After QLOAD processing has been completed and K-display interaction has been terminated by

K.STOP.

an output file is generated, indicating all queued files which were contained on the dump file, and whether they were loaded or not. Figure 18-13 contains an example of this output.

Figure 18-13. QLOAD Output File

#### Example:

Use the QDUMP and QLOAD utilities to dump queued files from one machine and load them onto another. The following commands dump all punch files from machine AA. The QREC utility is used to dequeue the files and then purge them, because QDUMP does not purge files.

QREC, PO=N, I=DIRCTVS, OP=DI. REWIND, DIRCTVS. LABEL, QFILES, VSN=QUEUE, MT. QDUMP, PO=N, I=DIRCTVS, TP=I. REWIND, DIRCTVS. QREC, PO=N, OP=PI, I=DIRCTVS.

File DIRCTVS is the input directive file that contains the following directives.

BC=NONE, BC=PH. RB=NONE, RB=PH.

The following commands load the files dumped by the previous QDUMP onto another machine.

LABEL,QFILES,VSN=QUEUE,MT. QLOAD,PO=N,MI=AA,OP=A,DF=ALL.

# QMOVE

QMOVE moves queued files from one disk device to another. It also produces a listing of all files moved with information about each file processed.

For secured systems, the destination device for each file selected to be moved must have access level limits that are appropriate to accept the file. If the file is being reactivated as well as moved, its access level must be within the file's origin type limits. If a selected file cannot be moved, QMOVE issues a diagnostic message and skips that file.

When QMOVE is selected at the system console, the initial QMOVE K display appears on the left screen. This display contains a list of all applicable parameters associated with QMOVE, their default values, and a short description of each (refer to figure 18-14).

If the FM parameter is specified, indicating the loading of queued files to a specified family of devices, the initial QMOVE left screen K display is replaced by the secondary QMOVE K display (refer to figure 18-15). This display closely resembles the initial QMOVE display but restricts QMOVE processing to the family of devices specified. Each device in the specified family containing inactive queued files is indicated. In addition, any parameter entered for the QMOVE utility is reflected in this display. Parameters not entered remain at default values.

Figure 18-15. Secondary QMOVE Display

-

.

After QMOVE processing has been completed and K-display interaction has been terminated by

K.STOP.

an output file is generated, indicating all files moved. Figure 18-16 contains an example of this output.

Figure 18-16. QMOVE Output File

1

### Example 1:

If there are inactive queued files residing on a removable device, you can activate these files but must first move them to a nonremovable device. This example shows how to use the QMOVE utility to move queued files from the removable device with family name SYSTEM and device number 45 to the nonremovable device with family name FAM1 and device number 5. The following entries are made from DSD.

```
X.QFSP.

K,jsn. (jsn is the job sequence name of QFSP)

K.QMOVE.

K.FM=SYSTEM,DN=45.

K.DF=FAM1,DD=5.

K.OP=A. (the moved files are active)

K.GO,STOP.
```

Example 2:

This example exhibits the relationships among the ID, TF/TUI, and FC parameters. (Refer to the descriptions of these parameters for the types of files affected by them.) The following command moves all local batch-destined output files with ID=6 and all remote batch-destined output files to device 3 in family SYS. The BC and RB parameters explicitly disable input file processing.

QMOVE, PO=N, DF=SYS, DD=3, ID=6, BC=IN, RB=IN.

The following command performs the same function as the previous command except that no remote batch files are moved.

QMOVE, PO=N, DF=SYS, DD=3, ID=6, BC=IN, RB=NONE.

# QREC

QREC deactivates or activates selected queued files and purges selected inactive queued files.

For secured systems, the access level for any file selected to be reactivated must be within the file's origin type limits. If a selected file cannot be processed, QREC issues a diagnostic message and skips that file.

When QREC is selected at the system console, the initial QREC K display appears on the left screen. This display contains a list of all applicable parameters associated with QREC, their default values, and a short description of each (refer to figure 18-17).

A complete list of current inactive queued files is displayed on the right screen when you enter this command:

K.LIST.

When this command is processed, the right screen K display is automatically replaced with the inactive queues K display (refer to figure 18-18). The information presented in this display is the same as that generated by the QLIST utility. The list of files displayed is also written to the output file specified by the QREC L parameter.

Figure 18-18. Inactive Queues List

If the FM parameter is specified, indicating processing of queued files for a specified family of devices, the initial QREC left screen K display is replaced by the secondary QREC K display (refer to figure 18-19). This display closely resembles the initial QREC display but restricts QREC processing to the family of devices specified. Each device in the specified family containing inactive queued files is indicated. In addition, any parameter entered for the QREC utility is reflected in this display. Parameters not entered remain at default values.

After QREC processing has been completed and K-display interaction has been terminated by

K.STOP.

an output file is generated, indicating the disposition of all queued files processed. Figure 18-20 is an example of this output.

Example 1:

If the QFT is becoming full, you can enter QREC from DSD to dequeue active queued files and free up QFT space. This QREC entry dequeues all queued files:

X.QREC(OP=DI,PO=N)

If RBF is not active, you are still able to dequeue remote batch files by using QREC. This QREC entry dequeues all remote batch files:

X.QREC(OP=DI, BC=NONE, PO=N)

If these are queued files that previously had been dequeued, you can activate these files with QREC. This QREC entry requeues all inactive queued files:

X.QREC(OP=RI,PO=N)

Figure 18-20. QREC Output File

Example 2:

Purge all queued files (active and inactive) on a particular device by using QREC either with or without an input directive file. The first method involves two calls to QREC. The first QREC call dequeues (makes inactive) all active files on the device with family name SYSTEM and device number 1, and the second QREC call purges all inactive (and hence all) queued files on that same device.

QREC,PO=N,OP=DI,FM=SYSTEM,DN=1. QREC,PO=N,OP=PI,FM=SYSTEM,DN=1.

The second method involves only one command call to QREC to perform the same function as the first method:

QREC,I=DIR.

File DIR is the input directive file that contains the following directives.

```
OP=DI,FM=SYSTEM,DN=1.
GO.
OP=PI,FM=SYSTEM,DN=1.
GO,STOP.
```

Example 3:

This example exhibits the relationships among the ID, TF/TUI, and FC parameters. It is important to observe the following restrictions regarding these parameters and QREC.

- ID pertains only to local batch-destined output files.
- TF/TUI pertain only to remote batch-destined output files.
- FC pertains to all output files.
- When you specify the OP parameter, all queued files are processed unless the ID, TF/TUI, and FC parameters restrict output file selection or the BC or RB parameter restricts input or output file selection.

The following command activates all local batch-destined output files with ID=6 and FC=AD, all remote batch-destined files with TF=SYSTAA, TUI=3751 and FC=AD, and all input files.

QREC, PO=N, OP=RI, ID=6, TF=SYSTAA, TUI=3751, FC=AD.

The following command performs the same functions as the previous command except that no input files are processed.

QREC, PO=N, OP=RI, ID=6, TF=SYSTAA, TUI=3751, FC=AD, BC=IN, RB=IN.

# **DAYFILE DUMPING UTILITIES**

The dayfile dumping utilities (AFD, DFD, ELD, GETLOG, MAINLOG) write all or selected parts of the account dayfile, system dayfile, error log, or binary maintenance log to a file. AFD, DFD, and ELD produce a listing (output) file. GETLOG writes the error log, binary maintenance log, and an image of the equipment status table to files. GETLOG is used to provide input to the Hardware Performance Analyzer (HPA). MAINLOG produces its output in a binary format. A job using any of these utilities must be of system origin, or you must have system origin privileges and the system must be in debug mode. The following format is used to call the dayfile dumping utilities.

utility,L=listfile,FR=string,OP=op,PD=pd,PL=p1,I=infile,B=binfile,E=estfile.

or

utility, listfile, string, op, pd, pl, infile, binfile, estfile.

# Description

Parameter utility

| Utility called to perform the dayfile dum |
|-------------------------------------------|
|-------------------------------------------|

| <u>Utility</u> | Description                                    |
|----------------|------------------------------------------------|
| AFD            | Dump account dayfile.                          |
| DFD            | Dump system dayfile.                           |
| ELD            | Dump error log.                                |
| GETLOG         | Dump error log, binary maintenance log, image. |
| MAINLOG        | Dump binary maintenance log.                   |

L=listfile Output file containing the dayfile dump produced by AFD, DFD, or ELD. For GETLOG, listfile is the file containing the error log. The utility also places diagnostic messages in this file when various error conditions occur. These messages begin with NOTICE\*\*\* to distinguish them from the lines of the dayfile being processed; they are described in the NOS 2 Operations Handbook.

The default name of listfile is OUTPUT for AFD, DFD, and ELD. The default name is ERR for GETLOG. If L=0 is specified, no file is written. L=listfile is not used with MAINLOG. The utility paginates listfile if it is OUTPUT or if print density and page length are specified.

FR=string Search string for selective dayfile dumping. The utility searches the dayfile for this string in the starting position of the field specified by the OP=op parameter.

OP=op Dump option. If neither FR=string nor the OP dump option is specified, default is OP=F for nonterminal output files. For terminal output files, the default is OP=I. If FR is specified but OP is not, default is OP=M.

### Description

F Full dayfile dump is taken.

<u>op</u>

- I Incremental dump is taken. The dayfile is dumped starting from the point of the last dayfile dump. AFD does not process the I option when executed within a job with system origin privileges that is not system origin.
- J The job sequence name field in the dayfile is searched for the string specified by FR=string. The dump begins from that point.
- M The message field in the dayfile is searched for the string specified by FR=string. The dump begins from that point. OP=M cannot be used with MAINLOG.
- P Incremental dump is taken. The dayfile is dumped starting from the point of the last dayfile dump with this job name.
- T The time field in the dayfile is searched for the string specified by FR=string. The dump begins from that point.

and EST

| PL=pl    |             | in pl lines per page. Default is based on<br>ties. PL cannot be used with MAINLOG.                                                     | n the following |
|----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------|
|          | pd          | Default pl                                                                                                                             |                 |
|          | 3           | 30                                                                                                                                     |                 |
|          | 4           | 40                                                                                                                                     |                 |
|          | 6           | 60                                                                                                                                     |                 |
|          | 8           | 80                                                                                                                                     |                 |
| I=infile | GETLOG, ind | , terminated dayfile is to be used for inpution is an attached terminated binary mainter the utility uses the active dayfile for input | enance log. If  |

PD=6. PD cannot be used with MAINLOG.

Description

Print density in pd lines per inch (3, 4, 6, or 8). Default is

B=binfile File on which GETLOG and MAINLOG write the binary maintenance log. These utilities write binfile with W-type records having C-type blocking (refer to the CYBER Record Manager Basic Access Methods Reference Manual for further information on record types and record blocking). GETLOG and MAINLOG assume B=BML if this parameter is omitted. If B=0 is specified, no file is written.

E=estfile File on which GETLOG writes an image of the equipment status table. GETLOG assumes E=EST if this parameter is omitted. If E=O is specified, no file is written.

Parameter

PD=pd

18-45

# SYSEDIT

After the system is loaded, you can use the SYSEDIT command to modify the system library. A job containing a SYSEDIT command must either be a system origin job, or you must be validated for system origin privileges and the system must be in debug mode. In addition, to prevent unauthorized modification of the operating system on a secured system, SYSEDIT will be allowed only from jobs with security administrator privileges.

# NOTE

Using SYSEDIT in a production environment may cause unpredictable results and is not recommended. The system should be idle to ensure predictable results.

The format of the command is:

SYSEDIT, p<sub>1</sub>, p<sub>2</sub>,..., p<sub>n</sub>. directive<sub>1</sub>, directive<sub>2</sub>,..., directive<sub>n</sub>

Pi is either a keyword or a keyword equated to a value.

| <sup>p</sup> i | Description                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B=repfile      | Replacement records are on file repfile.                                                                                                                                      |
| В              | Same as B=LGO.                                                                                                                                                                |
| B=0            | No replacement file.                                                                                                                                                          |
| B omitted      | Same as B=LGO.                                                                                                                                                                |
| С              | Checkpoint of the system follows SYSEDIT. This parameter is required if changes made to the system library are to be recovered during a level 3 recovery deadstart.           |
| C omitted      | No checkpoint is performed unless the system was generated using the alternate system library residency feature; in that case, the check-point automatically follows SYSEDIT. |
| I=infile       | Directive input is on file infile.                                                                                                                                            |
| I              | Same as I=INPUT.                                                                                                                                                              |
| I=0            | No directive input.                                                                                                                                                           |
| I omitted      | Same as I=INPUT.                                                                                                                                                              |
| L=outfile      | List output is on file outfile.                                                                                                                                               |
| L              | Same as L=OUTPUT.                                                                                                                                                             |

19-1

## Description

L=0 No list output. L omitted Same as L=0. SYSEDIT does not abort if the system file is busy. Execution continues NA when the system file is no longer busy. Restoration is made to copy n of the system. The system copy number is R=n printed on the output listing. R Restoration is made to initial deadstart system. R=0 No system file restoration. R omitted Same as R=0. Z Directive input follows the terminator on the command. The I option is ignored. Z omitted The system uses the I option for directive input.

# NOTE

If the Z option is specified, a terminator must not be placed after the input directives.

# DIRECTIVES

P<sub>i</sub>

Discussed next are input directives to SYSEDIT. The directives \*CM, \*MS, \*AD, \*PROC, \*SC, \*FL, and \*/ can be placed on LIBDECK. A list of valid record types follows the directive descriptions.

# \*CM DIRECTIVE

The \*CM directive specifies the system library routines that are to reside in central memory resident (CMR). These routines will reside in the resident peripheral library (RPL) and resident central library (RCL).

The format of the directive is:

 $CM, ty_1/rec_1, ty_2/rec_2, \dots, ty_n/rec_n$ 

Parameter

## Description

ty<sub>i</sub>/rec<sub>i</sub> Record type and record name of the routine.

60459300 D

Central memory is the most accessible of all storage devices for PP programs. The following programs will automatically reside in CMR.

- Mass storage drivers.
- Programs specified in the internal tables of SLL (SYSEDIT service routine), such as 1DD and ODF.
- Some DSD overlays, such as the 9Cx overlays. A site may make additional DSD overlays reside in CMR.

In addition, it is suggested that high usage PP programs (such as lMT, lMS, and PFM) reside in CMR.

Any addition to central memory allows less space for user jobs.

REL type records cannot reside in CMR.

## \*MS DIRECTIVE

The \*MS directive identifies which system library routines will reside on the system device. It is the default residence for routines; any routine not specified as \*CM will automatically reside on the system device, even if \*MS is not entered in the LIBDECK.

The format of the directive is:

\*MS,ty1/rec1,ty2/rec2,...,tyn/recn

Parameter

#### Description

ty<sub>i</sub>/rec<sub>i</sub> Record type and record name of the routine.

## **\*AD DIRECTIVE**

The \*AD directive places copies of specific system library routines on particular mass storage devices so that they will be accessed from a device other than the system device. For example, it is advantageous to:

- Place frequently used system library routines in extended memory for faster access than is possible from the system device. Notice that CPU programs residing in extended memory can be accessed faster than CPU programs residing in central memory.
- Place PP routines on a mass storage device that has better latency than does the system device.

Once a routine is on an alternate system device, it is accessed from that device instead of from the system device (\*MS LIBDECK entries), except in the following cases of error recovery.

- If there is an unrecoverable error for a PP routine on an alternate system device, all of the PP routines will subsequently be accessed from the system device instead of from any of the alternate system devices.
- If there is an unrecoverable error for a CPU, ABS, or OVL routine on an alternate system device, only that routine will subsequently be accessed from the system device.
- If there is an unrecoverable error for an REL CPU routine, the alternate system device must be turned off by the operator to prevent further access to the routine. In this case, the system copy will be used for backup. The alternate system device is not used for loads.

The devices that are to be used as alternate system devices are specified with the ASR entry in the EQPDECK (refer to section 3, Deadstart Decks); the routines that are to reside on each alternate system device are specified in LIBDECK.

The format of the directive is:

\*AD,xx,ty1/rec1,ty2/rec2,...,tyn/recn

#### Parameter

### Description

xx

The 1- or 2-digit EST ordinal or 2-character equipment type of the equipment to be used as an alternate system device. The equipment can be any nonremovable mass storage device (including extended memory) except for a system device. The EST ordinal specified cannot be larger than  $37_8$ .

If the equipment is not specified in the EQPDECK with the ASR entry, the \*AD entry is ignored without an error indication when the system is loaded.

ty<sub>i</sub>/rec<sub>i</sub>

ty<sub>i</sub> Record type of routine:

Record type and record name of the routine.

| Record |  |
|--------|--|
| Туре   |  |
|        |  |

ABS CPU multiple entry point overlay. OVL CPU overlay.

Description

- PP PP absolute.
- REL Relocatable CPU routine.

If a record type other than ABS, OVL, PP, or REL is specified, the message ILLEGAL CM/AD RESIDENCE. is issued to the output device; the run is aborted.

reci Record name of routine. A routine is allowed on only one
alternate system device.

Additional qualifications:

- Once a routine is placed on an alternate system device, SYSEDIT may be used to prohibit access to the routine; however, the space for that routine is not released until LIBDECK is modified and the system is reloaded.
- If extended memory is an alternate system device, all ABS, OVL, or REL routines residing there will be loaded from extended memory directly to the load address.
- If DDP is available, PP programs residing in extended memory will be loaded using DDP, and CPU programs will be loaded using the CPU access to extended memory.

## \*PROC DIRECTIVE

The \*PROC directive identifies a record as a procedure. It can be treated as any command, with parameters as required by the procedure itself. Further information on procedure creation and execution can be found in the NOS 2 Reference Set, Volumes 2 and 3.

The format of the directive is:

\*PROC, rec1, rec2, ..., recn

Parameter

reci

Description

Record name of routine to be defined as a procedure file.

# **\*SC DIRECTIVE**

The \*SC directive specifies the commands in a certain program that are to be processed in product set format rather than in NOS format (refer to the NOS 2 Reference Set, Volume 3).

The format of the directive is:

```
*SC,ty1/rec1,ty2/rec2,...,tyn/recn
```

Parameter

ty<sub>i</sub>/rec<sub>i</sub> Record type and record name of the routine to be processed in product set format.

Description

## \*FL DIRECTIVE

The \*FL directive specifies the field length that routines to be loaded require to begin execution.

The format of the directive is:

\*FL, $ty_1/rec_1-fl_1$ , $ty_2/rec_2-fl_2$ ,..., $ty_n/rec_n-fl_n$ 

#### Parameter

# Description

ty<sub>i</sub>/rec<sub>i</sub> Record type and record name of the routine.

 $f1_i$ Field length divided by 100g required by the routine.

60459300 D

The actual field length obtained is subject to the rules governing RFL= and MFL= entry points, since the specified  $fl_i$  field is placed in the library directory. The system uses this information to determine field length in the following manner.

- 1. If bit ll is not set, an RFL= entry point is indicated. The field length is set to the value in the entry.
- 2. If bit 11 is set (indicating a value of 4000008), an MFL= entry point is indicated. The field length is determined in one of two ways:
  - If bit 10 is also set, the field length is set to the maximum of the value of the last RFL command and the value in the entry after masking off these upper 2 bits.
  - If bit 10 is not set, the field length is set to the maximum of the existing field length and the value in the entry after masking off these upper 2 bits.

# \*/ DIRECTIVE

The \*/ directive specifies comment lines that are listed on the output file. Other than being listed on the output file, comment lines are ignored. They can occur any place in the directives file or on LIBDECK.

The format of the directive is:

\*/ comment

Parameter

#### Description

comment A comment line can contain any valid characters and be used for any purpose.

# \*DELETE DIRECTIVE

The \*DELETE directive deletes a record from the system. It cannot, however, delete a user library (ULIB type record).

The format of the directive is:

\*DELETE, ty1/rec1, ty2/rec2, ..., tyn/recn

or

**\***D,ty<sub>1</sub>/rec<sub>1</sub>,...,ty<sub>n</sub>/rec<sub>n</sub>

#### Parameter

# Description

ty<sub>i</sub>/rec<sub>i</sub>

Record type and record name to be deleted from the system. ty<sub>1</sub> must not be ULIB.

#### \*FILE DIRECTIVE

The \*FILE directive declares an additional file containing records to be added to the system or to logically replace records on the system.

The format of the directive is:

\*FILE,filename

or

**\*FILE**, filename, NR

Parameter

filename Name of local file containing addition or replacement records to be placed on the system. File filename is rewound before processing if NR is omitted.

Description

NR Optional parameter that inhibits rewinding of file filename before processing.

#### **\*IGNORE DIRECTIVE**

The \*IGNORE directive specifies that records on a replacement file are to be ignored. If no \*FILE directive precedes an \*IGNORE directive, SYSEDIT ignores the records named on this directive on the replacement file specified by the B parameter. If one or more \*FILE directives precede an \*IGNORE directive, SYSEDIT ignores the records on the file specified in the most recent \*FILE directive.

The format of the directive is:

```
*IGNORE,ty1/rec1,ty2/rec2,...,tyn/recn
```

Parameter

Description

ty\_/reci Record type and record name to be ignored on the current replacement
file.

#### \*PPSYN DIRECTIVE

The \*PPSYN directive specifies one or more names to be synonymous with the name of an existing PP routine.

The format of the directive is:

\*PPSYN, name/name1, name2, ..., namen

Parameter

Description

name<sub>i</sub> Additional (synonymous) name for name.

# **RECORD TYPES**

The following record types may be specified in SYSEDIT directives.

| Туре | Description                             |
|------|-----------------------------------------|
| ABS  | Multiple entry point overlay.           |
| CAP  | Fast dynamic load capsule.              |
| OPL  | Modify old program library deck.        |
| OPLC | Modify old program library common deck. |
| OPLD | Modify old program library directory.   |
| OVL  | Central processor overlay.              |
| PP   | Peripheral processor program.           |
| PPU  | Peripheral processor unit program.      |
| PROC | Procedure record.                       |
| REL  | Relocatable central processor program.  |
| TEXT | Unrecognizable as a program.            |
| ULIB | User library.                           |

ISF Deadstart Sequencing 20-1 20-3

# SYSTEM FILE INITIALIZATION

This section describes the system mechanisms used to initialize the fast-attach files used by MODVAL, PROFILE, and RESEX.

ISF

The ISF command initializes the fast-attach system files VALIDUS, PROFILa, RSXDid, and RSXVid.  $\dagger$  A fast-attach file is a special direct-access file under user index 377778 that is initialized with the E parameter on the ISF command and released with the R parameter on the ISF command. However, in order to release a fast-attach file, an idle family situation must be present. That is, the job containing the ISF,R=filename command must be the only job in the family (family count is zero, and the direct-access file count equals the number of fast-attach files). Therefore, the DSD command IDLEFAMILY must be used to clear the system of all other jobs, and when the above conditions have been met [refer to the family status display (E,F) in the NOS 2 Operations Handbook], the IDLEFAMILY command must be used again to allow the ISF command to be entered.

The fast-attach file mechanism should be used by special system jobs for files that are to be retained as permanent files but have a high enough access rate to make permanent file ATTACHs excessively time-consuming. When a permanent file is activated as a fast-attach file, an entry in the system FNT is made that retains the basic data normally kept in the catalog entry and system sector of the file (interlocks and file name). This eliminates the catalog search and system sector read normally necessary to attach a permanent file.

If the file is a shared (global) fast-attach file for a multimainframe network, additional information is also maintained in the fast-attach table (FAT) on the link device. The type of file determines whether it is entered as global fast attach or local fast attach. This criterion is kept internal to ISF. Basically, VALIDUS and PROFILa are entered as global fast-attach files if they reside on a shared device. The resource files are always entered as local fast attach. A limit of 778 exists on the number of files that can be entered as global fast attach in a multimainframe environment.

Because of the special nature of fast-attach files, a job containing an ISF command must be a system origin job. Processing the command causes a search of the system permanent file catalog (UI=3777778) for files with the predefined names previously listed. They are defined in a table internal to ISF. The format of the ISF command is:

ISF, option, FM=familyname, SJ=filename, SP=filename.

<sup>&</sup>lt;sup>†</sup>The resource files are generated and maintained separately for each machine id in a multimainframe or single mainframe system by appending the machine id to the file name (for example, RSXVid becomes RSXVAB on the machine with an id of AB).

| Parameter | Description                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |  |
|-----------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| option    | Specifies whether to initialize or release system files. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |  |
|           | option                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |
|           | E=filename                                               | System file that is initialized. If E=0 or no<br>filename is specified (neither E nor R appear), all<br>files defined in the ISF table are initialized<br>(refer to table 20-1).                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |  |
|           | R=filename                                               | Currently active system file that is released from<br>fast-attach status. If R=0, all of the files in the<br>ISF table for the specified family that are<br>currently active are released. When this parameter<br>is specified, an idle family situation (family count<br>is zero, and the direct-access file count equals the<br>number of fast-attach files) must first be created<br>with the DSD command IDLEFAMILY. When the family is<br>idle, the IDLEFAMILY command must be entered again<br>so that the system will accept the ISF command.<br>To release fast-attach system files, you must use |  |  |  |

this format of the ISF command:

X.ISF(R=filename)

# NOTE

Since initialization and release are mutually exclusive, E and R cannot appear on the same command.

| FM=familyname | Family of devices. If FM is not specified, the calling job's current |
|---------------|----------------------------------------------------------------------|
|               | family is used. The calling job's family will be restored upon exit  |
|               | from ISF.                                                            |

- SJ=filename Job file that ISF submits as a system origin job. The file must be an indirect access permanent file stored under the system user index (3777778). If SJ is specified without =filename, ISF assumes SJ=SYSJOB. If SJ=0 is specified, no job is submitted.
- SP=filename Procedure file that ISF calls with system origin. The file must be an indirect-access permanent file stored under the system user index. If SP is specified without =filename, ISF assumes SP=SYSPROC. If SP=0 is specified, no procedure is called.

ISF is automatically executed at each deadstart (refer to Deadstart Sequencing later in this section). This enables the use of SYSJOB and/or SYSPROC to SYSEDIT local modifications into the system.

ISF can also be entered as a command from the console with the DSD X command or from any system origin job.

The matrix in table 20-1 shows how the initialize (E) and release (R) parameters affect individual fast-attach files.

| Name of                    | Parameter                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                              |  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Fast-Attach<br>System File | Initialize (E)                                                                                                                                                                                                                                                                                                                                                          | Release (R)                                                                                                                                                  |  |
| VALIDUs<br>PROFILa         | Make global fast-attach file.                                                                                                                                                                                                                                                                                                                                           | Return from fast-attach status to normal direct access.                                                                                                      |  |
| RSXDid<br>RSXVid           | Make local fast-attach file. If<br>the file does not exist in the<br>system catalog (UI=3777778),<br>ISF creates the file and makes<br>it a fast-attach file. The file<br>is created with the backup require-<br>ment set to none (BR=N). This pre-<br>vents PFDUMP from dumping the file.<br>If either RSXDid or RSXVid is spec-<br>ified, ISF initializes both files. | Return from fast-attach status to<br>normal direct access. If either<br>RSXDid or RSXVid is specified, ISF<br>returns both files to normal direct<br>access. |  |

Table 20-1. Initialize and Release Parameters of Fast-Attach Files

One use of the R parameter is to release fast-attach files activated on a device to be initialized or unloaded. Device initialization is not initiated as long as any directaccess files are active on the device (an activated fast-attach file is treated the same as an active direct-access file). Until these files are released, the system will reply to an attempted device initialization with the error message:

ACTIVE FILES ON DEVICE

Similarly, a device cannot be unloaded until all its fast-attach files are released.

# DEADSTART SEQUENCING

During a level 0 deadstart, a job is queued for input using the service class DSSC. This job executes the PP routine CMS, whose normal functions include mass storage initialization and recovery. After completing these functions, CMS checks its service class. If the service class is DSSC (indicating a deadstart sequencing call), CMS places one of the following ISF commands in its command buffer and causes the system to execute it.

| ISF,FM=0,SJ.    | (recovery deadstarts) |
|-----------------|-----------------------|
| ISF,FM=0,SJ,SP. | (other deadstarts)    |

The CMS deadstart sequencing job begins execution only after job processing has been enabled by the DSD AUTO or MAINTENANCE command. The job scheduler prohibits scheduling of all other jobs until the CMS job completes, thereby ensuring that all system files in the default family are initialized and that a SYSPROC procedure (if any) is executed before normal job processing begins (refer to ISF earlier in this section).

# **TRACER/PROBE UTILITIES**

The TRACER and PROBE utilities described in this section provide data for statistical analysis of the system. The data is used to determine where problems occur and where improvements in design might be made, and to perform system tuning. The TRACER utility monitors the system's activity and gathers data periodically. The PROBE utility traps and measures particular internal events in the system. Both utilities capture valuable data that may not be obtainable any other way.

# TRACER UTILITY

The TRACER utility monitors these conditions:

- Channel activity by channel.
- Channel reserved.
- Channel requested.
- Requests pending.
- Number of active PPs.
- Buffered input/output list parameters.
- Buffered input/output channel busy.
- CPU use (idle, system, subsystem, system-related activity, or user activity).
- Subsystem CPU use.
- Storage moves pending.
- PP saturation.
- Extended memory transfer in progress.
- MTR cycle time.
- CPUO or CPU1 is or is not in monitor mode.
- Same storage move request is pending.
- Control points in automatic recall (I) status.
- Control points in periodic or automatic recall (X) status.
- Control points in waiting (W) status.
- Amount of available memory.

- Amount of memory at control points by service class.
- Amount of memory in queue by service class.
- Amount of memory at control points by subsystem.
- Number of noninteractive jobs.
- Number of detached interactive jobs.
- Number of online jobs.
- Number of preinitial jobs by service class.
- Number of executing jobs by service class.
- Number of jobs rolled out by job scheduler for each service class.
- Number of jobs rolled in or out by system control point processing for each service class.
- Number of jobs in a timed/event rollout queue by service class.
- Number of jobs rolled out by interactive input/output processing for each service class.
- Number of disabled jobs rolled out by service class.
- Number of suspended jobs rolled out by service class.
- Number of jobs with rollout file errors by service class.
- Number of EST entries in use.
- Number of FNT entries in use.
- Number of EJT entries in use.
- Number of queued files assigned to jobs at control points.
- Number of input files by service class.
- Number of print and punch files by service class.
- Number of other queued files not assigned to jobs at control points.
- Number of QFT entries in use.
- Number of FOT entries in use.
- Number of control points in use.
- Number of IAF active users.
- Number of IAF pots available.
- Number of IAF pots in use.

- Number of tape drives in use.
- Number of tracks available by mass storage device.
- Number of segment table reads.
- Number of missed clock updates.
- Number of extended memory moves.
- Number of central memory moves.
- Number of all rollouts.
- Number of rollouts to secondary rollout devices.
- Number of all sectors rolled.
- Number of sectors rolled out to secondary rollout devices.
- Number of rollouts/user limits.
- Number of time slices.
- Number of PP priority exchanges.
- Number of times communication buffer not available.
- Number of EJT scans.
- Number of schedulable jobs.
- Number of jobs preempted.
- Number of jobs scheduled.
- Number of jobs scheduled with no constraints.
- Number of insufficient CM scans.
- Number of insufficient EM scans.
- Number of no control point scans.

The TRACER utility includes the following programs:

| Program | Description                                                                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ICPD    | A CPU program that initiates system monitoring by CPD.                                                                                                                                                             |
| CPD     | A PP program that monitors any of the system activities just listed.<br>CPD is dedicated to a PP while it is monitoring system activity. Data<br>is written to a direct access permanent file for future analysis. |
| ACPD    | A postprocessor program that generates an output report from the direct access permanent file written by CPD.                                                                                                      |
| ENDCPD  | A CPU program that terminates system monitoring by CPD.                                                                                                                                                            |

## TRACER COMMANDS

TRACER commands are described next.

## ICPD Command

ICPD defines a mass storage file to which CPD will write statistical data and then initiates system monitoring by CPD.

## Format:

| ICPD,p <sub>1</sub> ,p <sub>2</sub> , | p•<br>n                                        |                                                                                                                                                                                          |  |  |  |  |  |  |  |  |  |
|---------------------------------------|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|--|--|--|
| <sup>p</sup> i                        |                                                | Description                                                                                                                                                                              |  |  |  |  |  |  |  |  |  |
| FL=f1                                 |                                                | Fast loop sampling frequency, in milliseconds, during which items such<br>as PPs active and move request pending are sampled. Default is 5<br>milliseconds.                              |  |  |  |  |  |  |  |  |  |
| ML=m1                                 | as control points in                           | edium loop sampling frequency, in milliseconds, during which items such<br>s control points in I, X, and W status and field length available are<br>ampled. Default is 100 milliseconds. |  |  |  |  |  |  |  |  |  |
| SL=s1                                 |                                                | requency, in milliseconds, during which items such<br>e drives in use are sampled. ....

# NOTE

If the sample data file is attached in write mode, the file cannot be accessed until ENDCPD is run. If the sample data file is to be accessed while data is being collected, append or modify mode must be specified. In this situation, the file may be attached in read/allow modify (RM) mode. (Attaching the file in write mode rather than in modify or append mode expends less overhead when interlocking and writing the data file.)

If a loop time is set to 0 (zero), no samples for that loop will be taken. If the data block sample time is set to 0 (zero), the data file will be written only when the sampling interval terminates.

All numeric data should lie within the range 0 through 4095 (0 through  $7777_8$ ).

## ACPD Command

ACPD reads the sample data file produced by CPD and generates reports, in both user-readable and machine-readable formats, for further analysis. The sample data file must be attached before ACPD is called. If ICPD is called with the M=A or M=M parameters, the sample data file can be accessed while CPD is still active.

ACPD assumes a continuity of the sample data file. Therefore, the uncollected information during the time gap separating two consecutive files is assumed to be present, although the information is not reported. As a result, if the consecutive files on the sample data file are not in chronological order, ACPD terminates and issues an error message.

Format:

| <sup>p</sup> i | Description                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FN=datafile    | Name of sample file. Default is SAMPLE. This file is not rewound before or after processing.                                                                                                                                                       |
| L=outfile      | Name of output file generated by ACPD. Default is OUTPUT.                                                                                                                                                                                          |
| S=sumfile      | Name of machine-readable summary file generated by ACPD. If this parameter is omitted, no summary file is generated. If S is specified without sumfile, SUMMARY is assumed.                                                                        |
| IC=nn          | Select the report interval by specifying the number of CPD sample<br>file records. This allows selection of report intervals of less<br>than 1 minute. You can specify the report interval by using eithe<br>the IC or IN parameter, but not both. |

| ₽ <sub>1</sub>     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IN=nn              | Time span of report interval, in minutes. Default value is 6<br>minutes. ACPD generates a report for each report interval. You can<br>specify the report interval by using either the IN or IC parameter,<br>but not both.                                                                                                                                                                                                                                    |
| LO=Z               | Report data items with zero values. Default is to suppress data items with zero values.                                                                                                                                                                                                                                                                                                                                                                       |
| N≕nn               | Number of files on the sample data file to be analyzed and<br>reported. Default is only one file processed. If N is not<br>equivalenced, all files are processed until EOI is reached on the<br>sample data file. The sample data file is not rewound before<br>processing.                                                                                                                                                                                   |
| BT=hhmmss          | Beginning time in the form hour minute second. If BT=hhmmss is<br>specified, only data collected after this time on the date specified<br>by BD=yymmdd is reported. If BT is omitted or no time is specified,<br>BT=0 is assumed.                                                                                                                                                                                                                             |
| ET=hhmmss          | Ending time in the form hour minute second. If ET=hhmmss is<br>specified, only data collected before this time on the date<br>specified by ED=yymmdd is reported. If ET is omitted or no time is<br>specified, ET=0 is assumed.                                                                                                                                                                                                                               |
| BD=y ymmdd         | Beginning date in the form year month day. If BD=yymmdd is<br>specified, only data collected on or after this date is reported.<br>If BD is omitted or no date is specified, the beginning date is the<br>date of the current file on the sample data file.                                                                                                                                                                                                   |
| ED <b>≕</b> yymmdd | Ending date in the form year month day. If ED=yymmdd is specified,<br>only data collected on or before this date is reported. If ED is<br>omitted or no date is specified, but ET=hhmmss is specified, the<br>ending date is the same as the beginning date. If neither ED nor ET<br>is specified, ACPD terminates when the number of files specified by<br>the N parameter are processed, or end-of- information is<br>encountered, whichever happens first. |

ACPD begins by processing the command parameters. If the beginning time (BT) and beginning date (BD) are specified, ACPD first locates the correct file and then processing begins. Processing continues until the ending time (ET) and ending date (ED) are encountered, the number of files specified by the N parameter have been processed, or end-of-information is encountered, whichever happens first.

If the BT and BD parameters are not specified, ACPD starts at the current position of the sample data file. The sample data file is not rewound before processing starts.

## ENDCPD Command

The ENDCPD command terminates all CPD data gathering.

Format:

ENDCPD.

## **OUTPUT FILE FORMAT**

The first three pages of the output report produced by ACPD contain the header block information. Next the data items are reported for fast, medium, and slow loop samples. The report ends with the snapshot data items.

Figure 21-1 is an example showing the format of the output report. The example has been simplified and condensed to reduce the amount of output. Also, supporting text has been added to the example.

Data items monitored at successive time intervals are listed in the same row. For each data item, the average, standard deviation, and percentage are listed in successive rows. Up to 10 intervals can be listed per page in successive vertical columns. If the output file contains more than 10 columns per row, the output report lists the first 10 columns for all rows of data items and then resumes listing subsequent intervals following the snapshot data items.

The SUBTOTAL column contains the values of the data items for the time spanned by the preceding intervals on the current page; that is, the time spanned by the preceding intervals is considered one interval. The TOTAL column appears after the last interval reported and contains the statistical values of the data items for the entire run. The SUBTOTAL column is not listed if the subtotal data and total data are identical and would appear on the same page. In this case, only the TOTAL column is listed. The SUBTOTAL and TOTAL columns are not reported for the snapshot data items. The \*MAX\* and \*MIN\* columns appear at the end of the report and contain the maximum and minimum interval values of the data items for the entire run. The maximum and minimum interval values on each page are indicated by brackets and parentheses, respectively.

The average is not reported for data items that have a weighting factor of 1, and the percentage is not reported for data items that have a weighting factor of 100, since this information is redundant.

The sampling frequency for medium loop items is specified by the ML parameter of the ICPD command. Refer to table 21-1 for all medium loop items that TRACER reports. Medium loop items are described following the table.

.

I.

| 10) SLOW LOOP SAMP | LES         | 119         | 119        | 119              | 119        | 119        | 119         | 119              | 119              | 119              | 1071      |

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 0000 Figure 21-1. Example of TRACER Output (Sheet 10 of 10)

## SUMMARY FILE FORMAT

The machine-readable summary file has two types of records, the header block record and the data block record. An \*EOR\* separates consecutive records.

The header block record contains the header data in an unpacked format.

Each data block record is divided into two equal length parts. The first part contains the average values of the data items. The second part contains the corresponding standard deviations of the data items.

Total and subtotal data and interval percentage data does not appear on the summary file. The loop sample times and snapshot data items have 0 standard deviations to simplify the summary file format.

## DATA ITEMS REPORTED BY TRACER

The data items reported by TRACER are described in the following paragraphs and are summarized in table 21-1. TRACER increments each item's counter when the item is in a given state, and periodically writes the contents of the counters to the data file for future processing by ACPD. When and how the counter for a given item is incremented is also discussed.

Suggestions are given to help you determine system performance. Performance may be affected by several areas within the system; therefore, a full analysis should be done prior to making any changes.

| Fast Loop Items           | Weighting Factor        |
|---------------------------|-------------------------|
| Fast loop samples         | None                    |
| PPs active                | Number of PPs available |
| Move request pending      | 1†                      |

| Other queue files    | Number of QFT entries                                       |
| QFT entries in use   | Number of QFT entries                                       |
| Tape drives in use   | Number of available tape drives                             |
| Tracks available     | Maximum number of tracks for monitored device               |
| Tracks available     |                                                             |

#### **Fast Loop Items**

The following paragraphs describe fast loop items. Fast loop items are continuously changing, so they should be sampled frequently.

#### Fast Loop Samples

TRACER increments the fast loop samples counter each time the fast loop items are sampled.

## PPs Active

TRACER increments the PP active counter for each active PP it finds when scanning the PP communication area. Disabled PPs (those turned off at deadstart time) are not considered active. An active PP is one that has a nonzero input register. MTR (PPO) and DSD (PP1) are always counted as active PPs.

If this counter's percentage exceeds 80 percent and the no PP available counter is greater than 20 percent, you may need more PPs. Check the channel active counters for disks. If the disk channels range from 35 to 40 percent, you may not need additional PPs; instead, look at what is causing your disk channels to be so busy. If you can reduce their activity to below 30 percent, the percentages should also drop for the PPs active counter and the no PP available counter.

Examine which PPs are dedicated. If the percentage of floating PPs is low (about 20 percent of the total PPs configured), you may need more PPs.

#### Move Request Pending

TRACER increments the move request pending counter whenever it determines, from word CMCL of CMR, that a storage move request is outstanding.

If this counter's percentage ranges from 30 to 40 percent, the system is degrading. The following items could cause excessive storage movements.

- Are subsystems at the highest or lowest control points? If not, NOS may be moving them up or down in memory frequently in order to satisfy other user job memory requests. If a subsystem like NAM is being moved, its users may experience slow response time since a subsystem cannot execute while it is moving in memory.
- Try to stabilize the field lengths of your subsystems. For example, if TAF is not built correctly for your site's use, it may roll out and roll in quite often. Depending on your CM constraints, you may want TAF to roll out less frequently. You should evaluate each subsystem and place it at the correct control point.
- Are some user jobs changing their field length excessively? For example, jobs that open and close many files repeatedly cause CMM to adjust the user's field length, which causes other job movement within memory. This may save on field length but takes resources from the sytem, which increases system overhead. This type of job should be changed to be more efficient.

#### No PP Available

TRACER increments the no PP available counter each time it determines, from word PPAL of CMR, that there are no PPs available.

The percentage for this counter should be examined with the percentage for the PP active counter. If the PP active percentage is low (less than 50 percent) but you have counts of no PPs available, it means that you have peaks in your work load and this may be acceptable. However, if the PP active percentage is high (from 80 to 90 percent) and you have counts of no PPs available, you may need more PPs.

#### EM Transfer in Progress

TRACER increments the extended memory transfer in progress counter whenever the S/C register (maintenance register for models 865 and 875) indicates an extended memory transfer is active. This data is available for CYBER 170 Computer Systems except models 176, 815, 825, 835, 845, and 855.

#### MTR Cycle Time

TRACER increments the MTR cycle time counter by the cycle time for the last MTR cycle. This item indicates how fast MTR is completing one complete scan of all PP output registers and processing those functions present.

The MTR cycle time should not exceed 0.5 seconds. If it does, MTR could miss updating the real time clock. Refer to MTR MXN TIME reported in the statistical data area from CMR (figure 21-1) for the worst case.

## Monitor Mode - CPU0/CPU1

TRACER increments the monitor mode counter for CPU0/CPU1 whenever the S/C register (maintenance register for models 865 and 875) indicates that the CPU0/CPU1 is in monitor mode. This data is available for CYBER 170 Computer Systems except models 815, 825, 835, 845, and 855.

During monitor mode, the CPU is executing the code of CPUMTR, which performs NOS overhead. During program mode, CPUMTR is executing to perform a function that a user job requested and only CPUMTR has the capability or security to do.

When the monitor mode counter reaches 20 percent for each CPU on a dual CPU configuration or 30 percent for a single CPU machine, you should examine the data provided by PROBE. PROBE reports each monitor request for both monitor mode and program mode. Examine the requests to determine what functions were called in excess. As a basis of comparison, use a PROBE report for which system performance was good and the monitor mode statistics were normal.

#### Scheduler Active

TRACER increments the scheduler active counter whenever it determines that the job scheduler (1SJ) is active. The job scheduler is considered active when the scheduler active flag in word JSCL is set.

The job scheduler is called to process input queues and rollout queues. The scheduler searches all of the corresponding queues, starting with the last EJT or QFT entry scheduled to a control point. It schedules the highest priority jobs into execution. Queue length and decision processing determines the amount of time the scheduler spends. Limit the size of the queues to the amount shown in the EJT entries in use and the QFT entries in use statistics.

If the scheduler active counter reaches 70 to 90 percent, you may notice problems. The reason is that ISJ is called to process EJT entries or QFT entries, not both. For example, if ISJ spends all of its time processing EJT entries, no input queue jobs are processed. In this case, interactive users entering the system for the first time will never get started. Also, excessive rollin/rollout because of central memory constraints or CM/CP time slice expirations could cause the scheduler to be busy. Examine the SERVICE parameters; you might have to do some tuning.

#### Channel Reserved

TRACER maintains a channel reserved counter for each available channel and increments a counter whenever its channel is logically reserved by the operating system. TRACER samples the channel status table for this data.

A PP program may have a channel reserved without actually using it to transfer data. This can cause a problem only if the channel has a high reserve percentage (from 80 to 100 percent) and the corresponding activity for the channel is low (less than 20 percent). The exceptions are those channels that are dedicated to PPs such as DSD, PIP, and 1HP.

#### Channel Active

TRACER maintains a channel active counter for each available channel and increments a counter whenever it detects that the channel is not inactive, as determined by an IJM PP instruction.

System performance is affected most by disk channel activity. A percentage of from 10 to 30 percent is considered normal. When this percentage reaches 35 to 40 percent, your system may experience performance degradation. High channel activity could be caused by the following factors. If you can scale down these problems, you may decrease channel activity and improve system performance; otherwise, you may need more disk controllers.

• Do all the disk channels show similar activity levels? If not, examine the attributes you have described for each disk unit. For example, what units contain permanent files, rollout files, a copy of the system, and temporary files? You may have to redistribute the work load by changing attributes. Determine which files are busy and the devices on which they reside using the PFCAT utility. You may find that altering device masks and/or moving files will lower the channel activity. You are looking for an even percentage of work performed by each of the disk channels.

The system selects file residency based on several factors. If the file is a permanent file, the system uses the device masks you have set for your family. If it is a temporary file or rollout file, the system looks at the attributes set for each device and selects the best candidate based on the following.

- First, the system looks at the number of tracks available on each potential device. It records which devices have at least 1/8 of their track capacity available for use.
- Second, the system picks the device with the least activity. If all potential devices have less than 1/8 of their tracks available, then the system chooses the least active device.
- Are there an excessive number of rollouts? User jobs may be reaching the CM or CP time slice limits. Check your SERVICE parameters and examine the number of time slices reported in the statistical data area from CMR. The system may be rolling jobs in and out of the control points if your SERVICE limits are too small. By adjusting the limits, you should improve system performance.
- Are large user jobs or subsystems rolling in or out? This can be determined by watching the DSD rollout status display (R). One large job can cause problems if it uses too many resources. Redesigning or rescheduling the job may help.
- Examine the PROBE utility output. PROBE reports the PP programs that were loaded (program name, residency, and number of loads). Any program that is loading more than once per second, should be made central memory resident. If you are short of central memory, place these programs in extended memory.

#### Channel Requested

TRACER maintains a channel requested counter for each available channel and increments a counter whenever there is an outstanding request for that channel. TRACER uses the channel status table to determine the channel requested status.

This counter tells you how often PP programs have requested a channel but were unable to reserve it because another PP program had it reserved. A normal count is from 20 to 50 percent. The exceptions are those channels that are dedicated to PPs such as DSD, PIP, and 1HP.

This can be used for debugging purposes when developong your own PP programs that require channels. Be sure that you follow the rules governing channel dialog.

#### Requests Pending

TRACER maintains a request pending counter for each mass storage device available and increments a counter by the number of outstanding requests on that device when the sampling occurs. The MST provides this information.

Ensure that the number of requests pending is evenly distributed between all units. If not, you may have to redistribute files (permanent, system, temporary, and rollout files) for the devices to obtain a more even distribution. Adding more disk units to a configuration will also aid in reducing the number of requests outstanding.

## Buffered I/O Lists

TRACER maintains a counter for each type of buffered I/O buffer list (Empty, Data Written, Read, Write). The number of buffers assigned to each list is incremented based on the buffered I/O data tables.

An average of 25 percent of the buffers on the Empty and Data Written lists is normal. The Write list should contain from 2 to 3 percent of the buffers, but a higher percentage is acceptable. The Read list is normal at from 65 to 75 percent. If there seems to be a shortage of Empty and Data Written buffers, you can add more extended memory for I/O buffer space.

## Buffered I/O Channel Busy

TRACER maintains a channel busy counter for each buffered I/O channel and increments a counter whenever a data transfer is in progess on that channel. TRACER uses the buffered I/O channel control table to determine the channel busy status.

The normal percentage is from 15 to 20 percent for a model 760 with two channels. This percentage may be higher for machines with slower CPUs.

#### CPU Usage

TRACER maintains a set of CPU usage counters for each CPU. There is a counter for each type of CPU use.

| Counter | CPU Use                                                                                 |
|---------|-----------------------------------------------------------------------------------------|
| IDLE    | CPU is not currently being used.                                                        |
| SYSTEM  | CPU is being used by CPUMTR.                                                            |
| SUB-SYS | CPU is being used by a subsystem.                                                       |
| SYS ORG | CPU is being used by a system origin job (subsystems are not considered system origin). |

CPU is being used by a user program. USER

Each time the CPU status is sampled (in words CPAL and CPAL+1 in CMR), TRACER increments one of the CPU usage counters. It determines which counter to update by investigating the control point area to which the CPU is assigned.

Tune your system to get the most CPU usage for your users. Following are suggestions on how to do this.

If you run a mixture of jobs, such as interactive and batch jobs, set the limit of executing batch jobs to a number that minimally impacts interactive users with respect to central memory and control points. You may have to assign batch jobs a higher queue priority so they essentially will be locked into the control points. Since interactive jobs tend to use the CPU for short durations, the batch jobs will be there using up whatever CPU time is left from the interactive jobs.

- On machines with big memories, it is advantageous to assign most of the memory to the users instead of using UEM as a rollout device. This helps in two ways: 1) rolling jobs to disk takes less CPU overhead than rolling jobs to UEM; 2) with more memory for the users, NOS performs less storage moves.
- If you run site-developed subsystems, examine the possibility of performing more of the work as disk activity rather than manipulating the data in central memory.

## Subsystem CPU Usage

Subsystem CPU usage is a further breakdown of subsystems of the SUB-SYS CPU usage data. TRACER maintains a CPU usage counter for every subsystem. Whenever the SUB-SYS CPU usage counter is incremented, TRACER also increments the appropriate subsystem CPU usage counter.

#### Medium Loop Items

The following paragraphs describe medium loop items.

## Medium Loop Samples

TRACER increments the medium loop samples counter each time the medium loop items are sampled.

#### CPS in W Status

TRACER increments the control points in waiting (W) status counter whenever a control point is found in W status (determined by STSW word of control point area). TRACER scans all control points during each medium loop cycle.

## CPS in X Status

TRACER increments the control points in periodic or automatic recall (X) status counter whenever it finds a control point in X status (determined by STSW word of control point area). TRACER scans all control points during each medium loop cycle.

## CPS in I Status

TRACER increments the control points in automatic recall (I) status counter whenever a control point is found in I status (determined by STSW word of control point area). TRACER scans all control points during each medium loop cycle.

## Same Move Request

TRACER increments the same move request counter every time the move request pending for the current medium loop cycle is the same as the previous medium loop cycle. Word CMCL of CMR is used to determine this status.

Use this counter to determine if NOS is having trouble moving jobs in central memory. A value of from 5 to 10 percent is not unreasonable. A higher percentage indicates that you probably are short of memory. Examine the FL available counter.

## FL Available

TRACER increments the FL available counter by the amount of available FL during the current medium loop cycle. Word ACML of CMR determines the available FL.

Compare this counter with the average FL in the rollout queue (FL in the rollout queue divided by the average number of jobs in the queue). On a busy system, the average amount of FL available should be less than that required for the average job in the rollout queue. You may need to consider any jobs that are in the rollout queue but are not schedulable, such as NAM supervisory applications (CS, NS, and NVF). On a system that is not heavily used, the FL available counter is of little value since there should always be memory available.

#### User EM Available

TRACER increments the user extended memory available counter by the amount of available user extended memory FL during the current medium loop cycle. Word AECL of CMR determines the available user extended memory FL.

Compare this number to the amount of extended memory at control points and rollout queues to determine if you have enough user extended memory.

#### Noninteractive Jobs

TRACER maintains a count of noninteractive jobs by monitoring the number of EJT entries with a connection status of NICS.

#### Detached Jobs

TRACER maintains a count of detached interactive jobs by monitoring the number of EJT entries with a connection status of DTCS.

### Online Jobs

TRACER maintains a count of online jobs by monitoring the number of EJT entries with a connection status of OLCS.

## Preinitial Job Step

TRACER maintains a count of preinitial jobs for each service class by monitoring the number of EJT entries with a job status of PRJS. A job is in this state after it has been assigned to an EJT entry but before it has been assigned to a control point for the first time.

#### Executing

TRACER maintains a count of executing jobs for each service class by monitoring the number of EJT entries with a job status of EXJS.

### Scheduler Rollout

TRACER maintains a count of jobs rolled out by the job scheduler for each service class by monitoring the number of EJT entries with a job status of ROJS.

#### SCP Rollin

TRACER maintains a count of jobs rolled in by system control point processing for each service class by monitoring the number of EJT entries with a job status of SIJS.

#### SCP Rollout

TRACER maintains a count of jobs rolled out by system control point processing for each service class by monitoring the number of EJT entries with a job status of SOJS.

#### Timed/Event Rollout

TRACER maintains a count of jobs in a timed/event rollout queue for each service class by monitoring the number of EJT entries with a job status of TOJS.

#### Interactive Rollout

TRACER maintains a count of jobs rolled out by interactive input/output processing for each service class by monitoring the number of EJT entries with a job status of IOJS.

## Disabled Rollout

TRACER maintains a count of disabled jobs rolled out for each service class by monitoring the number of EJT entries with a job status of DOJS.

#### Suspended Rollout

TRACER maintains a count of suspended jobs rolled out for each service class by monitoring the number of EJT entries with a job status of SUJS.

### Rollout File Error

TRACER maintains a count of jobs with rollout file errors for each service class by monitoring the number of EJT entries with a job status of ERJS.

#### EJT Entries in Use

TRACER maintains a count of the number of EJT entries in use for all jobs during the specified time interval. Each EJT entry is four central memory words long. If you are short of memory, you can gain some memory by decreasing the number of EJT entries.

#### FL at Control Points

TRACER maintains an FL at control point counter for each service class. When an active control point is found, the service class is determined and the appropriate counter is incremented by the amount of FL assigned to that control point (determined by FLSW of control point area). TRACER scans all control points during the medium loop cycle.

Use this count to determine which service class of jobs is using the most memory. For example, if you have poor interactive job response and notice that the batch service class is using the most memory, it may help to restrict batch jobs to a smaller central memory time slice using the CM parameter of the SERVICE entry in the IPRDECK.

## FL in Rollout Queue

TRACER maintains an FL in rollout queue counter for each service class. When a rollout file is found in the queue, and it is not assigned to a control point, the amount of FL it will require (determined from the EJT) when it is rolled into a control point is added to the appropriate counter. TRACER scans all EJT entries during the medium loop cycle.

Use this count in conjunction with the FL available counter to determine if you have a central memory shortage.

#### EM Memory at CP

TRACER maintains an extended memory at control point counter for each service class. When an active control point is found, the service class is determined and the appropriate counter is incremented by the amount of extended memory assigned to that control point (determined by ECSW of control point area). TRACER scans all control points during the medium loop cycle.

Use this count in conjunction with the user EM available counter and the EM in rollout queue counter to determine if you have an extended memory shortage.

## EM in Rollout Queue

TRACER maintains an extended memory in rollout queue counter for each service class. When a rollout file is found in the queue, and it is not assigned to a control point, the amount of extended memory FL it will require when rolled in (determined from the EJT) is added to the appropriate counter. TRACER scans all EJT entries during the medium loop cycle.

Use this count in conjunction with the user EM available counter and the EM memory at CP counter to determine if you have an extended memory shortage.

#### Subsystem FL

TRACER maintains a subsystem FL counter for every possible subsystem. When a subsystem is found at a control point, the amount of FL assigned to that subsystem is added to the appropriate counter. TRACER scans all control points during the medium loop cycle.

## **Slow Loop Items**

The following paragraphs describe slow loop items.

## Slow Loop Samples

TRACER increments the slow loop samples counter each time the slow loop items are sampled.

#### IAF Users

TRACER increments the IAF users counter by the number of users connected to IAF during the slow loop cycle. IAF must be active for this data to be collected. Word VANL of IAF FL determines the number of users.

#### IAF Pots Allocated

TRACER increments the pots allocated counter by the number of pots that are currently available for use, whether they are being used or not. Word VPAL of IAF FL determines the number of pots allocated.

#### IAF Pots in Use

TRACER increments the pots in use counter by the number of pots currently assigned to a connection. Word VPUL of IAF FL determines the number of pots in use.

## Queue Files Assigned

TRACER maintains a count of the number of queued files assigned to control points by monitoring QFT entries.

#### Input Files

TRACER maintains a count of the number of input files for each service class by monitoring QFT entries.

#### **Print Files**

TRACER maintains a count of the number of print files for each service class by monitoring QFT entries.

## Punch Files

TRACER maintains a count of the number of punch files for each service class by monitoring QFT entries.

## Other Queue Files

TRACER maintains a count of the number of other queued files not assigned to control points for each service class by monitoring QFT entries. This includes any queued file that is not an input, print, or punch file.

## QFT Entries in Use

TRACER maintains a count of the number of QFT entries in use for all jobs during the specified time interval. Each QFT entry is four central memory words long. If you are short of memory, you can gain some memory by decreasing the number of QFT entries.

#### Tape Drives in Use

TRACER maintains two tape drives in use counters; one for 7-track and one for 9-track drives. A tape drive is considered to be in use if an EST entry indicates it is logically turned on, and it is assigned to a job. TRACER increments the appropriate counter for each drive found in use.

## Tracks Available

TRACER maintains a tracks available counter for each mass storage equipment and adds the number of available tracks (tracks not currently assigned to a file) for a device to the appropriate counter for each mass storage device found in the EST. TRACER obtains this information from TDGL of the MST.

#### Statistical Summary

The following paragraphs describe various statistics collected by TRACER.

#### MTR Maximum Time

TRACER reports the maximum time, in microseconds, that MTR waits for a CPU exchange to occur after being initiated by a monitor exchange jump (MXN).

#### Worst Case MTR Cycle Time

TRACER reports the maximum time, in milliseconds, that it takes MTR to make a complete cycle; processing all PP output register requests and performing its other system functions.

## Missed Clock Updates

TRACER reports the number of times MTR was not able to update the clock.

## Extended Memory Moves

TRACER reports the number of storage moves of extended memory performed by CPUMTR.

## Central Memory Moves

TRACER reports the number of storage moves of central memory performed by CPUMTR.

## Total Rollouts

TRACER reports the total number of jobs rolled out by the job rollout routine (1R0).

## Secondary Rollouts

TRACER reports the number of jobs rolled out to secondary rollout devices by the job rollout routine (IRO).

#### Total Sectors Rolled

TRACER reports the total number of sectors of mass storage used by the job rollout routine (1RO) for rollouts.

## Secondary Sec Rolled

TRACER reports the number of sectors of mass storage used by the job rollout routine (1RO) for rollouts to secondary rollout devices.

## Rollouts/User Limits

TRACER reports the number of jobs rolled out due to a time limit or SRU limit detected by the job scheduler (ISJ).

## Time Slices

TRACER reports the number of jobs whose scheduling is set to the lower bound for its service class due to an expired CPU or CM time slice.

# PP Priority Exchanges

TRACER reports the number of priority exchange requests issued by PPs. A priority exchange is issued after three unsuccessful attempts to perform a monitor exchange jump (MXN).

#### No Comm Buffer Avail

TRACER reports the number of times CPUMTR could not use a communications buffer because all buffers were full.

## EJT Scans

TRACER reports the number of times the job scheduler (1SJ) scans the executing job table (EJT) to schedule a job to a control point.

## Schedulable Jobs

TRACER reports the total number of schedulable jobs. This is determined by adding the number of schedulable jobs in EJT on each EJT scan.

## Jobs Preempted

TRACER reports the number of jobs rolled out so the job scheduler (1SJ) could schedule a higher priority job.

## Jobs Scheduled

TRACER reports the number of jobs scheduled to a control point.

## Scheduled No Constraints

TRACER reports the number of jobs scheduled with no service class, central memory, or extended memory constraints imposed.

## Insufficient CM Scans

TRACER reports the number of EJT scans for which a schedulable job was found, but could not be scheduled due to insufficient central memory.

#### Insufficient EM Scans

TRACER reports the number of EJT scans for which a schedulable job was found, but could not be scheduled due to insufficient extended memory.

## No Control Point Scans

TRACER reports the number of EJT scans for which a schedulable job was found, but could not be scheduled because all control points were busy.

# **PROBE UTILITY**

The PROBE utility measures the following:

- The number of times a PP routine was loaded.
- The number of CIO RA+1 requests by function number.
- The number of PP requests to CPUMTR by function number.
- The number of MTR requests to CPUMTR by function number.
- The statistical data accumulated in CMR includes items such as number of sectors rolled and number of rollouts.

PROBE data gathering is selectable at deadstart time by an IPRDECK entry. SYSEDIT resets the PROBE data tables to zeros.

The PROBE utility generates a report from the data collected by the system. PROBE analyzes data either from system tables or from a binary file containing data from a previous PROBE run. An IPRDECK entry ENABLE, PROBE must be specified at deadstart time to allow the system to collect the data. (Refer to section 3, Deadstart Decks, for more information.)

#### Format:

| $\frac{p_{\text{ROBE}}, p_1, p_2, \dots, p_n}{\frac{p_i}{2}}$ |                                 | Description                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B=readfile                                                    | Binary file                     | to be read. Default is STATS.                                                                                                                                                                                                                                                                                    |
| L=outfile                                                     | Report file                     | • Default is OUTPUT.                                                                                                                                                                                                                                                                                             |

Figure 21-2. Example of PROBE Output (Sheet 7 of 7)

When looking at the PP program load information reported on the PROBE output, check to see if it meets these suggested performance requirements:

- PP programs called at least once every second should be central memory resident.
- PP programs called at least once every 2 seconds are good candidates for alternate residency using extended memory.
- PP programs called every 3 seconds or less should be disk resident.

You can change a PP program's residency using the SYSEDIT command (refer to section 19, SYSEDIT).

# **CHARACTER SETS**

A character set is composed of graphic and control characters. A code set is a set of codes used to represent each character within a character set.

A graphic character may be displayed at a terminal or printed by a line printer. Examples are the characters A through Z and the digits 0 through 9. A control character initiates, modifies, or stops a control operation. An example is the backspace character that moves the terminal carriage or cursor back one space. Although a control character is not a graphic character, a terminal may produce a graphic representation when it receives a control character.

All references within this manual to the ASCII character set or the ASCII code set refer to the character set and code set defined in the American National Standard Code for Information Interchange (ASCII, ANSI Standard X3.4-1977). References in this manual to the ASCII character set do not necessarily refer to the ASCII code set.

NOS supports the following character sets.

- CDC graphic 64- (or 63-) character set.
- ASCII 128-character set.
- ASCII graphic 64- (or 63-) character set.
- ASCII graphic 95-character set.

Each installation selects either the 64-character set or the 63-character set. The differences between the two are described next, under Character Set Anomalies. Any reference in this appendix to the 64-character set implies either the 63- or 64-character set, unless otherwise stated.

NOS supports the following code sets.

- 6-bit display code.
- 6/12-bit display code.
- 7-bit ASCII code.

Display code is a set of 6-bit codes from 00g to 77g.

The 6/12-bit display code is a combination of 6-bit codes and 12-bit codes. The 6-bit codes are 008 through 778, excluding 748 and 768. (Refer to Character Set Anomalies, next, for the interpretation of the 008 and 638 codes.) The 12-bit codes begin with either 748 or 768 and are followed by a 6-bit code. Thus, 748 and 768 are considered escape codes and are never used as 6-bit codes within the 6/12-bit display code set. The 12-bit codes are 74018, 74028, 74048, 74078, and 76018 through 76778. All other 12-bit codes (74xx8 and 76008) are undefined.

Α

The 7-bit ASCII code (as defined by ANSI Standard X3.4-1977) is right-justified in a 12-bit byte. Assuming that the bits are numbered from the right starting with 0, bits 0 through 6 contain the ASCII code, bits 7 through 10 contain zeros, and bit 11 distinguishes the 0000g code from the end-of-line byte. The 7-bit codes are 0001g through 0177g and 4000g.

# **CHARACTER SET ANOMALIES**

NOS interprets two codes differently when the installation selects the 63-character set rather than the 64-character set. In tables A-1, A-2, and A3, the codes for the colon and percent graphic characters in the 64-character set are unshaded; the codes for the colon and percent graphic characters in the 63-character set are shaded.

If an installation uses the 63-character set, the colon graphic character is always represented by a 638 code, and the 008 code is undefined. However, if the installation uses the 64-character set, output of 6/12-bit display codes 74048 or 6-bit display code 008 produces a colon. In ASCII mode for interactive jobs, a colon can be input only as a 74048 6/12-bit display code.

When using either the 63- or 64-character set, the use of undefined 6/12-bit display codes in output files produces unpredictable results and should be avoided.

On input, NOS recognizes alternate 029 punch codes of 11-0 for the right bracket (]) and 12-0 for the left bracket ([). The alternate codes support the COBOL sign overpunch convention and are not recommended for other uses. Refer to the COBOL 5 Reference Manual.

Also, two  $00_8$  codes may be confused with an end-of-line byte and should be avoided (refer to the NOS 2 Reference Set, Volume 3 for further explanation).

Translation of 7-bit ASCII to 6-bit display code causes character set folding from the 128-character ASCII set to the 63- or 64-character ASCII subset. The following special character substitutions occur:

| 7-B  | Lt ASCII  | 6-Bit | Display Code | 7-в  | it ASCII  |
|------|-----------|-------|--------------|------|-----------|
| Code | Character | Code  | Character    | Code | Character |
| 0140 | •         | 74    | @            | 0100 | 0         |
| 0173 | {         | 61    | [            | 0133 | Ι         |
| 0174 |           |       | \            | 0134 | ١         |
| 0175 | }         | 62    | ]            | 0135 | ]         |
| 0176 | ~         | 76    | ~            | 0136 | ^         |

# **CHARACTER SET TABLES**

This appendix includes character set tables for interactive jobs, batch jobs, and jobs involving magnetic tapes. Table A-1 is for interactive jobs, and table A-2 is for batch jobs. Table A-3 is a conversion table used to cross-reference 7-bit ASCII codes and 6/12-bit display codes and to convert ASCII codes from octal to hexadecimal.

Tables A-4, A-5, and A-6 list the magnetic tape codes and their display code equivalents.

The character set tables are designed so that you can find the character represented by a code (such as in a dump) or find the code that represents a character. To find the character represented by a code, look up the code in the column listing the appropriate code set and then find the character on that line in the column listing the appropriate character set. To find the code that represents a character, you first look up the character and then find the same line in the appropriate column.

# **INTERACTIVE JOBS**

Table A-1 shows the character sets and code sets available to you at an ASCII code terminal. When in NORMAL mode (specified by the NORMAL command), NOS displays the ASCII graphic 64-character set and interprets all input and output as display code. When in ASCII mode (specified by the ASCII command), NOS displays the ASCII 128-character set and interprets all input and output as 6/12-bit display code.

To determine the octal or hexadecimal ASCII code for a character, refer to table A-3. (Certain terminal definition commands require specification of an ASCII code.)

On output, the US code is reserved for network use and defined as an end-of-line. Use of this character, except in transparent mode, causes incorrect formatting and possible loss of output characters.

# **BATCH JOBS**

Table A-2 lists the CDC graphic 64-character set, the ASCII graphic 64-character set, and the ASCII graphic 95-character sets. It also lists the code sets and card punch codes (026 and 029) that represent the characters.

The 64-character sets use display code as their code set; the 95-character set uses 7-bit ASCII code. The 95-character set is composed of all the characters in the ASCII 128-character set that can be printed at a line printer (refer to Jobs Using Line Printers, next). Only 7-bit ASCII code files can be printed using the ASCII graphic 95-character set. To print a 6/12-bit display code file (usually created by an interactive job in ASCII mode), you must convert the file to 7-bit ASCII code. To do this, you enter the FCOPY command (refer to the NOS 2 Reference Set, Volume 3). The 95-character set is represented by 7-bit ASCII codes 0040g through 0176g.

# **JOBS USING LINE PRINTERS**

The batch character set printed depends on the print train used on the line printer to which the file is sent (refer to the ROUTE command in the NOS 2 Reference Set, Volume 3). The following are the print trains corresponding to each of the batch character sets.

| Character Set                  | Print Train | PSU Printer Print Band |
|--------------------------------|-------------|------------------------|
| CDC graphic 64-character set   | 596-1       | -                      |
| ASCII graphic 64-character set | 596-5       | 530-1                  |
| ASCII graphic 95-character set | 596-6       | 530-2                  |

The characters of the default 596-1 print train are listed in the table A-2 column labeled CDC Graphic (64 Character); the 596-5 print train characters are listed in the table A-2 column labeled ASCII Graphic (64 Character); and the 596-6 print train characters are listed in the table A-2 column labeled ASCII Graphic (95 Character).

If a transmission error occurs when printing a line, the system prints the line again. The CDC graphic print train prints a concatenation symbol  $(\sqcap)$  in the first printable column of the repeated listing of the line. The ASCII print trains print an underline (\_) instead of the concatenation symbol.

If an unprintable character exists in a line (that is, a 7-bit ASCII code outside the range 00408 through 01768), the number sign (#) appears in the first printable column of a print line, and a space replaces the unprintable character.

To route and correctly print a 6/12-bit display code file on a line printer with the ASCII graphic 95-character set, you must convert the 6/12-bit display code file to a 7-bit ASCII code file with the FCOPY command (refer to the NOS 2 Reference Set, Volume 3). The resulting 7-bit ASCII file can be routed to a line printer (refer to the ROUTE command in the NOS 2 Reference Set, Volume 3) but cannot be output at an interactive terminal.

# JOBS USING MAGNETIC TAPE

Coded data to be copied from disk to magnetic tape is assumed to be represented in display code. NOS converts the data to external BCD code when writing a coded 7-track tape and to ASCII or EBCDIC code (as specified on the tape assignment command) when writing a coded 9-track tape.

Because only 63 characters can be represented in 7-track even parity, one of the 64 display codes is lost in conversion to and from external BCD code. Figure A-1 shows the differences in conversion depending on the character set (63 or 64) that the system uses. The ASCII character for the specified character code is shown in parentheses. The output arrow shows how the 6-bit display code changes when it is written on tape in external BCD. The input arrow shows how the external BCD code changes when the tape is read and converted to 6-bit display code.

Figure A-1. Conversion Differences

If a lowercase ASCII or EBCDIC code is read from a 9-track coded tape, it is converted to its uppercase 6-bit display code equivalent. To read or write lowercase ASCII or EBCDIC characters, you must assign the tape in binary mode and use FCOPY to read or write the tape.

Tables A-4 and A-5 show the character set conversion for 9-track tapes. Table A-4 lists the conversions to and from the 7-bit ASCII character code and 6-bit display code. Table A-5 lists the conversions between the EBCDIC character code and the 6-bit display code. Table A-6 shows the character set conversions between external BCD and 6-bit display code for 7-track tapes.

# Table A-4. Nine-Track ASCII Coded Tape Conversion

TWhen these characters are copied from/or to a tape, the characters remain the same but the codes change from one code set to the other.

ifom one code set to the other.
ifom one code set to the other.
ifom one code set to the other.
ifom a tape, each 7-bit ASCII character is changed to an alternate 6-bit display code character. The
corresponding codes are also changed. Example: When the system copies a lowercase a, 6116, from tape,
it writes an uppercase A, 018.
if the dealer of the dealer of the dealer of the system copies a lowercase a, 6116, from tape,

tttA 6-bit display code space always translates to a 7-bit ASCII space.

Table A-5. Nine-Track EBCDIC Coded Tape Conversion

Twhen these characters are copied from/or to a tape, the characters remain the same (except EBCDIC codes 4A, 4F, 5A, and 5F) but the codes change from one code set to the other. TThese characters do not exist in 6-bit display code. Therefore, when the characters are copied from a

These characters do not exist in b-bit display code. Inerefore, when the characters are copied from a tape, each EBCDIC character is changed to an alternate 6-bit display code character. The corresponding codes are also changed. Example: When the system copies a lowercase a, 81<sub>16</sub>, from tape, it writes an uppercase A, 018.
 THAIL EBCDIC codes not listed translate to 6-bit display code 558 (space). A 6-bit display code space always translates to an EBCDIC space.

| 37                                                                                                                                          | &                  | 67                                  | 76              | ^                  | 76                                  |  |  |  |
| l                                                                                                                                           |                    |                                     | 77              | ;                  | 77                                  |  |  |  |
| <sup>†</sup> As explained previously in this section, conversion<br>of these codes depends on whether the tape is being<br>read or written. |                    |                                     |                 |                    |                                     |  |  |  |

Table A-6. Seven-Track Coded Tape Conversions

.

# GLOSSARY

Access Category

See File Access Category and System Access Categories.

Access Code

A hardware/software security code assigned to each NAD on the network. A NAD may communicate only with other NADs having matching codes.

# Access Level

A property of each file, job, and equipment on a secured system that is used to indicate the sensitivity of information in the file or job, or the sensitivity of information that can be processed by the equipment. On a secured system, there are up to eight access levels corresponding to increasing levels of sensitivity; you are authorized to access some or all of those levels. Refer also to Equipment Access Levels, File Access Level, Job Access Level, and System Access Levels.

Access Level Limits

See Job Access Level Limits.

Account Dayfile

A dayfile that provides a history of system usage over the life of the account. It provides information necessary for accurate billing and system usage analysis.

#### ACN

See Application Connection Number.

AFD Utility

A dayfile dumping utility that dumps all or selected parts of the account dayfile to produce a listing. AIP Trace Utility

See Application Interface Program Trace Utility.

Allocation Summary Table (AST)

A table that contains information used by the allocation algorithm to select the cartridges on which a file will reside in an MSAS environment.

Allocation Unit (AU)

In an MSS environment, an allocation unit is the name that is given to each of the 16 data streams that make up a cartridge.

In an MSAS environment, an allocation unit is the smallest allocatable portion of a cartridge. Each AU consists of 14 data strips; each cartridge has 1931 AUs.

#### Application

See Application Program.

Application Connection Number (ACN)

A number assigned by the NAM program to identify a particular logical connection within an application.

Application Interface Program (AIP) Trace Utility

A utility that produces a trace file of the messages transferred between IAF and NAM. The information contained in this trace can be useful in tracking network problems and in debugging application programs.

#### Application Program

A program resident in a host computer that provides an information storage, retrieval, and/or processing service to a remote user via the data communication network and the Network Access Method. Application programs use the system control point feature of NOS to communicate with the Network Access Method.

In the context of network software, an application program is not an interactive job, but rather a terminal servicing facility that provides terminal users with a specific processing capability such as remote job entry from batch terminals, transaction processing, entry and execution of interactive jobs, and so forth. For example, the standard CDC Interactive Facility IAF makes terminal input and output appear the same to an executing program as file input and output; IAF is a network application program, but the executing program using IAF is an interactive job.

#### Archive Files

A dump of permanent files accumulated on disk that are dumped as a whole or in part to a backup tape (or other type of backup medium) to protect the files from loss in case of a device malfunction or to free a device for temporary use during preventive maintenance.

### asa

The alternate storage address.

# ASCII

American National Standard Code for Information Interchange. The standard character set and code used for information interchange between systems. It is a 7-bit code representing a prescribed set of 128 characters.

#### ASDEBUG Utility

A utility that allows an analyst to update appropriate entries in the CSU maps and/or MSF catalogs and thereby resolve inconsistencies reported by the ASVAL utility. ASDEBUG can also be used to copy data from selected MSF files or cartridges to disk.

# ASDEF Utility

A utility that creates the system files (CSU maps and MSF catalogs) that are necessary for MSS processing.

#### ASLABEL Utility

A utility that manages cartridge assignment and cubicle allocation in a cartridge storage unit.

# ASMOVE Utility

A utility that manages disk and Mass Storage Facility residence. ASMOVE determines which files to leave on disk, which files to release from disk and move to MSF, and which files should reside both on disk and on MSF.

#### AST

See Allocation Summary Table and Available Stream Table.

#### ASUSE Utility

A utility that reads data in the MSF catalogs and CSU maps and produces reports on the availability of space on MSF cartridges and the allocation of cubicle space within a CSU.

#### ASVAL Utility

A utility that either performs release processing or reports on problems with the current MSS system files.

#### Attach

The process of making a direct access permanent file accessible to a job by specifying the proper permanent file identification and passwords.

#### AU

See Allocation Unit.

# Auto Recall

The act of a program releasing control of the CPU until a requested function is complete. Refer to Recall.

# Auxiliary Device

A disk device that is not part of a permanent file family. Auxiliary devices can contain direct or indirect access permanent files.

# Available Stream Table (AST)

A table that contains information used by the allocation algorithm to select the cartridges on which a file will reside in an MSS environment.

#### Backup Tape

See Archive Files.

# Batch Job

The instructions and data that are submitted as a complete unit without further user intervention. The job can be punched on cards or created and submitted from a terminal.

#### Beginning-of-Information (BOI)

The start of the first programmer record in a file is known as the beginning-of-information. System information, such as tape labels on sequential files or indexes, does not affect the beginning-of-information.

# **Binary File**

A noneditable file that contains a precompiled program.

# BOI

See Beginning-of-Information.

# Breakpoint

A designated location in a program where, if reached during program execution, a break or suspension in execution occurs.

# Buffer

An intermediate storage area used to compensate for a difference in rates of data flow, or times of event occurrences, when transmitting data between central memory and an external device during input/output operations.

# Byte

A group of bits. Unless prefixed (for example, a 6-bit byte), the term means 8-bit groups. When used for encoding character data, a byte represents a single character.

# Cache

A high-speed memory that resides in the central processor.

# Cartridge

A component of the MSF or 7990. The cartridge consists of a plastic housing that encloses a strip of magnetic tape on which data is stored under program control.

Cartridge Storage Unit (CSU)

An MSS device that includes storage cells (cubicles) for 2052 cartridges and a selector that moves cartridges among the mass storage transport, the cubicles, and the input/output drawers of the CSU.

#### Cassette

The magnetic tape device in an NPU used for bootstrap loading of offline diagnostics and (in remote NPUs) the bootstrap load/dump operation. Catalog Image Record (CIR)

A record written at the beginning of the archive file on which the permanent files are dumped for each incremental dump. When a file is loaded, this CIR information is placed in the permanent file catalog of the device being loaded.

#### Catalog Track

A track on a user's master device containing the catalog entries that define and specify the location of each permanent file created by that user. Users are assigned by groups to catalog tracks according to user index and number of catalog tracks on the master device.

#### CCP

See Communications Control Program.

Central Memory Resident (CMR)

The low address area of central memory reserved for tables, pointers, and subroutines necessary for operation of the operating system. It is never accessible to a user's central processor program. The monitor allocates the remainder of central memory to jobs as they are selected on a priority basis for execution.

# Channel Number

The number of the data channel on which a peripheral device controller can be accessed.

### Character

Unless otherwise specified, references to characters in this manual are to 7-bit ASCII code.

# Charge Number

An alphanumeric identifier the installation uses to allocate charges to individual users for system usage.

#### Checkpoint

The process of writing a copy of your job's central memory, the system

information used for job control, and the names and contents of all assigned files that are identified in a CHECKPT request to a magnetic tape or disk.

#### CIO

See Combined Input/Output

# CIR

See Catalog Image Record.

```
CLA
```

See Communications Line Adapter.

CMR

See Central Memory Resident.

# CMRDECK

The central memory resident deck that resides on the deadstart file. It defines central memory, table sizes, and configuration information not oriented to equipment.

Coldstart

Procedure used to deadstart if the tape or disk controller has not yet been loaded with controlware, or the controlware is not running.

Combined Input/Output (CIO)

A system routine that performs NOS I/O.

Common Testing and Initialization (CTI)

Common deadstart process that resides on the deadstart file and the maintenance system library.

Communication Line

A complete communication circuit between a terminal and its network processing unit.

Communications Control Program (CCP)

A portion of the network software that resides in a 255X series network processing unit. This software can include routines such as the terminal interface program. Communications Line Adapter (CLA)

Hardware that provides the interface between NPUs and modems.

Communications Supervisor (CS)

A portion of the network software written as an application program; the CS coordinates the network-oriented activities of the host computer and of the lines and terminals logically linked to it.

# COMPASS

COMPrehensive ASsembly System. The standard assembly language used with CYBER 180, CYBER 170, CYBER 70, and 6000 Computer Systems. Also, the command used to assemble a program written in the COMPASS assembly language.

#### Connection Number

A number assigned to an IAF terminal by the system when the terminal is logged in and an entry is made for the job in the executing job table.

# Connection Status

A job attribute kept in the job's executing job table (EJT) entry. The system uses it to determine the job's relationship with IAF.

#### Control Point

The portion of central memory that is assigned to a job. When a job is allocated a portion of central memory, it becomes eligible for assignment to the central processor for execution.

#### Control Point Number

The number of the control point to which a job is assigned while the job resides in central memory. The actual number of control points is an installation parameter. Before the job can execute, each central processor program must be assigned to a control point.

# Controller

Hardware device that connects channels to peripheral devices. For example, a tape controller might connect up to eight tape units to one channel.

#### Controlling NOP

An NPU operator (NOP) who is allowed to change the status of network elements (lines, logical links, terminals, and trunks) connected to an NPU.

# Controlware

A special type of software that resides in a peripheral controller. The controlware defines the functional characteristics of the controller.

#### Coupler

A component of the MSF. The coupler interfaces between the peripheral processor and the mass storage adapter.

CS

See Communications Supervisor.

CSU

See Cartridge Storage Unit.

CSU Map

A direct access permanent file that contains information indicating how cubicles in a CSU are assigned to a family and identifying the cartridges that reside in the CSU.

CTI

See Common Testing and Initialization.

#### CYBERLOG

A program initiated after deadstart that requests data about the previous service interruption.

#### DAT

See Device Access Table.

Data Channel

One of the 9 to 24 channels (12-bit) by which information passes between the peripheral processors and peripheral devices. Refer to Channel Number.

Data Recording Drive (DRD)

A component of the 7991 Storage Module. The DRD reads data from and writes data to the cartridges.

# Dayfile

A chronological file created during job execution that forms a permanent accounting and job history record. Dayfile messages are generated by operator action or when commands are processed. A copy of the dayfile is printed with the output for each job. The user must explicitly request it in an interactive job.

#### DDP

The distributive data path.

Deadstart

The process of initializing the system by loading the operating system library programs and any of the product set from magnetic tape or disk. Deadstart recovery is reinitialization after system failure.

Deadstart Sequencing

The execution of a selected set of commands before normal system job scheduling is enabled.

Debug Log File Processor (DLFP)

A processor that analyzes trace files produced by the application interface program trace utility.

#### Detached Job

An interactive service class job removed from control of the Interactive Subsystem. It may or may not continue to execute, depending on the presence of commands in the command buffer or an active job step. Control is regained by recovering the EJT entry for the job. Device Access Table (DAT)

A table that contains the logical description (family name/pack name and device number) of each disk device (shared or nonshared) that is accessible by any machine in a linked shared device multimainframe complex.

Device Index Table (DIT)

A table that is used to determine device usage in an independent shared device multimainframe complex.

Device Mask

An 8-bit quantity that identifies the group of users who have the particular device as their master device; that is, it identifies the device that contains their file catalogs, all their indirect access files, and possibly some or all of their direct access files.

DFD Utility

A dayfile dumping utility that dumps all or selected parts of the system dayfile to produce a listing.

DFLIST Utility

A utility that generates a printer listing of all permanent files created by the DFTERM utility.

### DFTERM Utility

A utility that terminates an active or inactive dayfile and retains it as a direct access permanent file for later use.

Diagnostic Operator (DOP)

An NPU operator who resides at a terminal and has permission only to check status and test the network.

Direct Access File

A NOS permanent file that can be attached to the your job. All changes to this file are made on the file itself rather than a temporary copy of the file (compare with Indirect Access File).

#### DIS (Job Display)

A system peripheral processor program similar to the system display (DSD) that provides communication between a job in central memory and the operator at the console, and permits the operator to control execution of the program through the console keyboard.

# Disabled Job

An interactive service class job temporarily rolled out due to user break processing or encountering the end of its command stream. The job scheduler ignores disabled jobs.

#### Display Code

A 6-bit character code set that represents alphanumeric and special characters.

#### Disposition Code

A 2-character mnemonic indicating the destination queue and format for processing a file named on a ROUTE function.

# DIT

See Device Index Table.

# DLFP

See Debug Log File Processor.

#### DMPNAD

See Dump NAD Memory.

#### DOP

See Diagnostic Operator.

#### Downline

The direction of output flow, from host to terminal.

# DRD

See Data Recording Drive.

#### DSD (System Display)

The operating system program that provides communication between the operator and the system by accepting control information typed on the console keyboard and by displaying information pertinent to all jobs known to the system. DSD is permanently assigned to peripheral processor 1.

# DSDI Utility

A deadstart dump interpreter utility that is called by a batch command to convert selected portions of the binary information on an express deadstart dump file into reports to be listed.

Dump NAD Memory (DMPNAD)

A utility that reads the NAD memory and formats the data into an output file.

# ECS

See Extended Core Storage.

EDD File

See Express Deadstart Dump File.

EDD Utility

See Express Deadstart Dump Utility.

# EJT

See Executing Job Table.

# **EJT Ordinal**

An index into the executing job table (EJT). It uniquely identifies an EJT entry. The acceptable range is from 0001 to 4095.

# ELD Utility

A dayfile dumping utility that dumps all or selected parts of the error log dayfile to produce a listing.

#### End-of-Chain Flag (EOC)

In an MSS environment, EOC is a flag in the MSF catalog that identifies the last allocation unit in a chain of allocated data streams.

In an MSAS environment, EOC is a flag in the 7990 catalog that identifies the last volume in a chain of allocated AUs.

#### End-of-File (EOF)

A boundary within a sequential file, but not necessarily the end of a file that can be referenced by name. The actual end of a named file is defined by EOI. For labeled tape, EOF and EOI (denoted by the EOF1 label) are the same. For multifile tape files, EOF and EOI do not correspond. In the product set manuals, an end-of-file is also referred to as an end-of-partition.

#### End-of-Information (EOI)

The end of data on a file. Information appearing after this point is not considered part of file data. In card decks, a card with a 6/7/8/9 multiple punch in column 1. On mass storage devices, the position of the last written data. On labeled tape, it is the EOF1 label. CYBER Record Manager defines end-of-information in terms of file residency and organization.

End-of-Record (EOR)

An indicator that marks the end of a logical record. Also referred to as end-of-section.

# Entry Point

A location within a program or procedure that can be referenced from other programs. Each entry point has a unique name with which it is associated.

#### EOC

See End-of-Chain Flag.

#### EOF

See End-of-File.

# EOI

See End-of-Information.

EOR

```
See End-of-Record.
```

Equipment Access Levels

A range of access levels specified for each equipment on a secured system. In order for a file to be stored or output on a given equipment, the file's access level must be within the equipment access levels for that equipment.

# EQPDECK

The equipment description deck used during deadstart to define the system equipmet configuration.

#### Equipment Number

A number from 0 to 7 that identifies the setting on a peripheral device controller.

Equipment Status Table (EST)

A central memory resident table listing all the defined equipments, parameters affecting their operation, and the status of the equipments.

# EST

See Equipment Status Table.

#### EST Ordinal

The number designating the position of an entry within the equipment status table (EST) established at each installation. Devices are identified in operator commands by EST ordinals. The EST ordinal is sometimes referred to as equipment number.

#### Exchange Package

A table that contains information used during job execution. It is printed as part of the output when a job aborts.

### Executing Job Table (EJT)

A central memory resident table that contains a 4-word entry for all executing jobs including interactive service class jobs. It is used to control jobs that are executing at a control point and jobs that are rolled out. Every executing job in the system has an EJT entry.

#### Execution

An input job is in execution after it is selected by the operating system and assigned to a control point. A job remains in execution until terminated, but it can be temporarily swapped or rolled out by the operating system.

Express Deadstart Dump (EDD) File

A file that is generated on magnetic tape by the express deadstart dump utility. This file contains a dump of memory, executing exchange packages, hardware registers, and controller memory.

Express Deadstart Dump (EDD) Utility

A utility that may be run at deadstart time after a system malfunction has occurred. It generates the express deadstart dump file on magnetic tape.

Extended Core Storage (ECS)

ECS provides optional additional memory. ECS contains 60-bit words; it has a large amount of storage and fast transfer rates. ECS can be used only for program and data storage, not for program execution. Special hardware instructions exist for transferring data between central memory and ECS.

Extended Memory

An extension to central memory that is physically located outside of the machine.

Facility Interface Program (FIP)

A program consisting of routines and buffers that are loaded into each application program's field length. This program is the interface between the application program and RHF.

#### Family Device

A mass storage permanent file device associated with a specific system. A family may consist of from 1 to 63 logical devices. Normally, a system runs with one family of permanent file devices available. However, additional families may be introduced during normal operation. This enables users associated with the additional families to access their permanent files via the alternate family.

Family Name

Name of the permanent file storage device or set of devices on which all of a user's permanent files are stored. When a user requests a permanent file, the system looks for it on this family (group) of devices. Usually a system has only one family of permanent file devices, but it is possible to have alternate families in the system. At login, the user may have to specify which family he/she is using. A user gets a family name from his/her employer, instructor, or computer center personnel.

Family Ordinal Table (FOT)

A table that maintains the relationship between family ordinals and family names.

FCT

See File and Cartridge Table.

FET

See File Environment Table.

Field Length

The area in central memory allocated to a particular job; the only part of central memory that a job can directly access. Also the number of central memory words required to process a job.

# File

A collection of information referred to by a file name (from 1 to 7 alphanumeric characters). You can create a file at the terminal or retrieve a file from permanent file storage for use during a terminal session.

# File Access Category

A property of a permanent file used by the creator of the file on a secured system to restrict access of the file to a particular group of users. A secured system supports up to 32 access categories, and a user is authorized to use some, all, or none of those categories. Refer also to System Access Categories.

#### File Access Level

A property of each file on a secured system used to indicate the sensitivity of information contained on the file. A file is assigned the current job access level by default when it is created or stored; the file creator may specify any access level for that file that is within the set of access levels valid for the job, the system, the file creator, and (for interactive jobs) the communication line to the host mainframe. If a user accesses a file on a secured system, that user must be validated for the access level of the file. Refer also to Access Level, Job Access Level, and Job Access Level Limits.

File and Cartridge Table (FCT)

Table that has an entry for each cubicle assigned to the subfamily from a given CSU or SM.

File Category

Each permanent file is assigned a category of private, semiprivate, or public.

#### File Count

A maximum number of permanent files allowed each user.

File Environment Table (FET)

A table within a program's field length through which the program communicates with operating system input/output routines. One FET exists for each file in use by the program.

#### File Name Table (FNT)

A system-managed table that contains the local file name, the file type, and other job control information. All active files in the system have an FNT entry.

File Status Table (FST)

A system-managed table that contains information pertaining to the file's location in mass storage and other job control information. Each active file in the system has an FST entry. See also File Name Table.

#### FIP

See Facility Interface Program.

First Level Peripheral Processor (FLPP)

The processor that is connected directly to the CYBER 170 Model 176 mainframe and operates synchronously with the mainframe.

# FLPP

See First Level Peripheral Processor.

#### FNT

See File Name Table.

# Forms Code

An attribute of output files and output devices. The user can specify special forms required for output, and then mount the special forms and use the FORM command to let the system process his/her output.

#### FOT

See Family Ordinal Table.

FST

See File Status Table.

### Function Processor

A system CPU or PP program that the user can call by placing a request in location RA+1. Function processors perform input/output, local and permanent file manipulations, and so on.

Hardware Initialization and Verification Software (HIVS)

The software package that assists CTI during deadstart and provides deadstart confidence-level testing (HVS).

Hardware Verification Sequence (HVS)

HVS is a member of HIVS. It tests the ability of memory to hold patterns of data and execute instructions. The user can choose to test central memory, extended memory, PP memory, and central processor memory.

Head-of-Chain Flag (HOC)

Flag that identifies the first allocation unit in a chain of allocated data streams in the MSF catalog.

# Header

A word or set of words at the beginning of a block, record, file, or buffer that contains control information for that unit of data.

# HIVS

See Hardware Initialization and Verification Software.

# HOC

See Head-of-Chain Flag.

#### HOP

See Host Operator.

#### Host

The computer that controls a network, executes the application programs, and processes network messages.

Host Operator (HOP)

The administrative operator who resides at the system console, initiates NAM, and controls NPUs and network related host elements.

HVS

See Hardware Verification Sequence.

IAF

See Interactive Facility.

Inactive Queued File Table (IQFT)

A table of file entries that has been removed from the queued file table. An IQFT file is on each mass storage device on which one or more inactive queued files reside.

# Incremental Dump

An incremental dump copies those permanent files modified after a specified date. Each incremental dump writes a catalog image record at the beginning of the archive file on which the permanent files are dumped.

#### Incremental Load

An incremental load builds up an accumulation of the most recently modified versions of the files extracted from the archive files for loading. A series of archive files is read in reverse order of creation. The CIR is read and checked against the archive files. If a file matches an entry on the CIR, that file is a candidate for loading.

#### Indirect Access File

A NOS permanent file that you access by making a temporary copy of the file (GET or OLD command). You create or alter it by saving or substituting the contents of an existing temporary file (REPLACE or SAVE command).

# Input File

The system-defined file that contains the entire job the user submits for processing. It is also known as the job file.

Input/Output Unit (IOU)

A collection of all PPs, PP channels, and related hardware for models 865 and 875 and CYBER 180-class machines.

#### Interactive Facility (IAF)

An application that provides a terminal operator with interactive processing capability. The Interactive Facility makes terminal input/output and file input/output appear the same to an executing program.

#### Interactive Transfer Facility (ITF)

A network application that allows the user to connect an interactive terminal to a remote CYBER 200 computer system linked to a host mainframe by a loosely coupled network.

#### IOU

See Input/Output Unit.

# IQFT

See Inactive Queued File Table.

# ITF

See Interactive Transfer Facility.

Job Access Level

On a secured system, each job has an access level. This is the default access level that is assigned to files that are created or stored in the job. A job's initial access level is the lower access level limit for the job. The job's access level is automatically raised to the access level of any file from which information is read. The user can also change the job access level. Refer also to Job Access Level Limits.

#### Job Access Level Limits

An upper limit and a lower limit that determine the range of access levels that are valid for a particular job on a secured system. All files used in a given job must have an access level within the job's access level limits.

Job Sequence Name (JSN)

The unique, system-defined name assigned to every executing job or queued file. The JSN is a string of four alphabetic characters.

Job Status

A job attribute kept in the job's executing job table (EJT) entry. It is used by the system to determine if a job is rolled in or rolled out. If the job is rolled out, job status indicates why it was rolled out.

```
JSN
```

See Job Sequence Name.

Large Central Memory Extended (LCME)

A type of extended memory that is an option available for model 176. Refer to Extended Memory.

# LCF

See Local Configuration File.

# LCME

See Large Central Memory Extended.

# LCN

See Loosely Coupled Network.

LDLIST Utility

A utility that generates a printer listing of queued files present on a dump tape produced by the QDUMP utility.

#### LFG

See Load File Generator.

# LID

See Logical Identifier.

# LISTPPM Utility

A PIP dump analyzer program that converts all available PIP dump binary records on th PIP memory dump file into a report to be listed in byte format.

Load File Generator (LFG)

A utility program that reformats communications control program files for subsequent use by the network supervisor of NAM to load network processing units.

# Load Point

Metallic strip marking the beginning of the recordable portion of a magnetic tape. Data, including labels, is written after the load point. A rewind positions a single file volume to the load point.

Load Sequence

A sequence of load operations that encompasses all of the loader's processing from the time that nothing is loaded until the time execution begins. It includes initialization, specification of specified loader requests, and completion of load.

Local Batch Job

A batch job submitted at the central computer site through a card reader or terminal.

Local Configuration File (LCF)

A file in the host computer system containing information on the logical makeup of the communication elements of the host. The file contains a list of the application programs available for execution in the host computer, and the users that can access it. This is a NOS direct access permanent file.

#### Local File

Any file that is currently associated with a job. Local files include all temporary files and attached direct access files. Local File Name

The file name assigned to a file while it is local (assigned) to a job. The name is contained in the local file name table.

Local NAD

A 380-170 NAD connected to the host mainframe using a channel and configured in the EST.

Local NPU

An NPU that is connected to the host via a coupler. A local NPU always contains a host interface program for processing block protocol transfers across the host/local NPU interface.

Logical Identifier (LID)

A 3-character alphanumeric string used to identify a particular mainframe. LIDs are identified by the user's site.

Loosely Coupled Network (LCN)

A network of physically connected computer systems. The LCN environment allows jobs, data files, and messages to be transmitted from one computer system to another.

Machine Identification (MID)

The identifier that associates a specific machine with its access to a shared device.

Machine Recovery Table (MRT)

A table that provides the information needed to recover the mass storage space and interlocks of a machine that shares a mass storage device.

Machine Recovery Utility (MREC)

A utility that clears interlocks held by the machine to be deadstarted that have not been cleared by CPUMTR. It also recovers mass storage space on a shared device that is currently not accessible because of a machine interruption.

### Macro

A sequence of source statements that is saved and then assembled whenever needed through a macro call.

# MAINLOG Utility

A dayfile dumping utility that dumps all or selected parts of the binary maintenance log to produce an output file in binary format.

Maintenance Logging Transfer Utility (MLTF)

A utility that controls logging NAD error logs into the binary maintenance log.

#### Maintenance Register

A hardware register used in error detection, logging, and recovery procedures. Maintenance registers are used on models 865 and 875 instead of status/control registers. Refer to Status/Control (S/C) Register.

### MAP

The Matrix Algorithm Processor.

Mass Storage Adapter (MSA)

A component of the MSF. The adapter interfaces between the coupler and the mass storage transport or the cartridge storage unit. See Mass Storage Facility.

Mass Storage Archival Subsystem (MSAS)

MSAS is the product consisting of the 7990 hardware, the channel interface, the diagnostics, and the operational software. MSAS stores data on the 7990 and moves it to disk upon request for access by an authorized user.

Mass Storage Device

An extended memory or disk unit that has defined logical attributes such as family, file residency, and so on.

# Mass Storage Facility (MSF)

A hardware product that is a large capacity online mass storage device. MSF is a cost-effective extension to the disk file storage system and an alternative to conventional magnetic tape storage.

Mass Storage Facility (MSF) Catalog

A disk-resident direct access permanent file that contains information describing which streams of each cartridge assigned to a particular subfamily are allocated to MSF files and which streams are available for allocation.

Mass Storage Subsystem (MSS)

MSS is the product consisting of the MSF hardware, the CYBER coupler, the diagnostics, and the operational software. MSS stores data on the MSF and moves it to disk upon request for access by an authorized user.

Mass Storage Table (MST)

A table that contains an entry for each logical device in the configuration of mass storage devices currently available to the system.

Mass Storage Transport

A component of the MSF. MST has storage positions for five cartridges: one being read or written, two queued for reading or writing, and two queued for storage by the selector into the CSU.

Master Device

A disk device that contains the user's permanent file catalog entries; all of the user's indirect access files; and all, part, or none of the user's direct access files.

MID

See Machine Identification.

# MLIA

See Multiplex Loop Interface Adapter.

#### Monitor

The system routine that coordinates and controls all activities of the computer system. It occupies peripheral processor 0 and part of central memory. It schedules the use of the central processor and the other peripheral processors.

# MREC

See Machine Recovery Utility.

#### MRT

See Machine Recovery Table.

# MSA

See Mass Storage Adapter.

# MSAS

See Mass Storage Archival Subsystem.

#### MSF

See Mass Storage Facility.

#### MSS

See Mass Storage Subsystem.

## **MSSEXEC** Program

The main processing program that controls MSS activities, such as destaging files from disk to MSF, purging unneeded MSF files, labeling or relabeling cartridges, updating CSU maps, and updating MSF catalogs.

## MSSSLV Program

A program that runs on each slave mainframe and communicates with the MSSEXEC program to retrieve files from MSF in response to ATTACH requests by jobs running on the slave mainframes.

# MST

See Mass Storage Table.

#### Multimainframe Operation

An operation that provides mechanisms by which more than one computer can share mass storage devices. Multiplex Loop Interface Adapter (MLIA)

The hardware portion of the multiplex subsystem that controls the multiplex loops (input and output) as well as the interface between the NPU and the multiplex subsystem.

Multispindle Device

A logical mass storage device that includes from two to eight disk units.

Multiterminal Job

A job that does one specific task for many terminals while being scheduled into the system only once.

#### NAD

See Network Access Device.

#### NAM

See Network Access Method.

#### NCF

See Network Configuration File.

# NCTF

See Network Decription File.

#### NDA

See NPU Dump Analyzer.

#### NDL Processor

See Network Definition Language Processor.

# NDR

See Network Driver.

Negative Field Length (NFL)

Central memory assigned to a control point that physically precedes the job's reference address (RA).

# NETLOG

A program that uses the network configuration file to determine which remote NADs should be logged.

## Network

An interconnected set of network elements consisting of a host and one or more NPUs and terminals.

Network Access Device (NAD)

The primary element in a loosely coupled network. Each NAD connects a computer system to the network.

#### Network Access Method (NAM)

A software package that provides a generalized method of using a communications network for switching, buffering, queuing, and transmitting data. NAM is a set of interface routines used by a terminal servicing facility for shared access to a network of terminals and other applications, so that the facility program does not need to support the physical structures and protocols of a private communication network.

Network Configuration File (NCF)

A network definition file in the host computer containing information on the network elements and permissible linkages between them. The status of the elements described in this file is modified by the NPU operator in the course of managing the network. This is a NOS direct access permanent file.

Network Definition Language (NDL) Processor

The network software module that processes an NDL program as an offline batch job to create the network definition files and other NDL program output.

Network Description File (NCTF)

A file that must be present if the Transaction Facility is used. The file is prepared by the site analyst. Network Driver (NDR)

A program that executes in a dedicated peripheral processor unit. It communicates with the network access devices using a host computer data channel, and is the interface between RHF and the communication network.

Network Invocation Number (NIN)

A 1- to 3-digit decimal number. NIN is incremented by 1 every time NAM is brought up.

Network Load File (NLF)

An output file generated by the load file generator utility for use by the network supervisor.

Network Processing Unit (NPU)

The collection of hardware and software that switches, buffers, and transmits data between terminals and host computers.

Network Supervisor (NS)

A portion of the network software written as a NAM application program. NS dumps and loads NPUs upon request.

Network Terminal

A terminal that communicates with the operating system through the network.

Network Validation Facility (NVF)

A portion of the network software, written as a NAM application program. The network validation facility performs application validation and all connection validation processing and supports login dialog with the terminal user.

#### NFL

See Negative Field Length.

#### NIN

See Network Invocation Number.

NLF

See Network Load File.

Nonincremental Load

A nonincremental load does no CIR checking and uses only parameter options specified on the PFLOAD call, if any, to select candidates for loading.

#### NOP

See NPU Operator.

# NPU

See Network Processing Unit.

NPU Dump Analyzer (NDA)

A utility program that produces a readable printout from the NPU dump files.

NPU Operator (NOP)

The administrative operator who resides at a terminal and controls NPUs.

NS

See Network Supervisor.

# NVF

See Network Validation Facility.

Object Code

The machine language version of a program that has been translated (compiled) from source code written in a higher-level language.

Operating System

The set of system programs that controls the execution of computer programs and provides scheduling, error detection, input/output control, accounting, compilation, storage assignment, and other related services.

#### Origin Type

A job attribute that indicates how a job entered the system. The four origin types are interactive origin, batch origin, remote batch origin, and system origin.

#### Output File

The system-defined file that contains the output from job processing. It is also known as the print or punch file.

# Paging (Screen)

The process of filling a CRT display with data and holding additional data for subsequent displays. Changing the page display is an operator-controlled function if the page-wait option is selected.

## Parity

In writing data, an extra bit is either set or cleared in each byte so that every byte has either an odd number of set bits (odd parity) or an even number of set bits (even parity). Parity is checked on a read for error detection and possible recovery.

#### Partial Dump

A partial dump copies permanent files according to any specified options, except those defining a full or incremental dump.

## Password

A name or word the user enters during login to provide extra security for his/her user name. A unique password ensures that no one else can log into the system with someone else's user name and access that user's files. A user's password is given to him/her by that user's employer, instructor, or computer center personnel. Peripheral Interface Package (PIP)

The interface package between the PPU of the CYBER computer and the network application.

Peripheral Processor (PP)

The hardware unit within the host computer that performs physical input and output through the computer's data channels.

Peripheral Processor Unit (PPU)

First level peripheral processor. A PPU is contained in the mainframe in a multimainframe environment and operates synchronously with the mainframe. Sometimes referred to as FLPP.

## Permanent File

A mass storage file that is cataloged by the system so that its location and identification are always known to the system. Permanent files cannot be destroyed accidentally during normal system operation. They are protected by the system from unauthorized access according to privacy controls specified when they are created.

Permanent File Catalog (PFC)

A 16-word entry that the system maintains and uses to determine attributes of a permanent file.

Permanent File Family

The permanent files that reside on the family devices of a specific system.

Permanent File Manager (PFM)

PFM identifies the master device and catalog track information when a user submits a job.

Permanent File Supervisor (PFS)

The PFS processes parameters in utility commands and loads the correct processing overlays. Permanent File Transfer Facility (PTF)

PTF is an application program initiator started by the user using an MFLINK command. It is responsible for initiating and completing (with the help of its servicing application, PTFS on another host) a permanent file transfer.

Permanent File Transfer Facility Servicer (PTFS)

PTFS is an application program servicer started by RHF or NAM when requested by a PTF on another host. The PTFS application assists the PTF application in completing the file transfer by performing those permanent file functions requested by the user and then transferring the file between PTF and PTFS.

# Permanent File Utility (PFU)

A utility that manages the catalogs, permits, data allocation on a device, and the data transfer between the device and the overlay.

Permission Mode

A mode of operation that a user is allowed for a particular permanent file, such as write, modify, append, read, and so forth.

#### **PFATC Utility**

A utility that produces a cataloged directory of file information derived from an archive file previously created by the PFDUMP utility.

# PFC

See Permanent File Catalog.

# PFCAT Utility

A utility that produces a cataloged directory of file information derived from catalog tracks on a master device.

# **PFCOPY Utility**

A utility that extracts files from an archive file and copies them to one or more files at a control point.

## PFDUMP Utility

A utility that dumps permanent files to an archive file. Dumps can be reloaded by the PFLOAD utility and can be accessed by the PFATC and PFCOPY utilities for cataloging and copying.

PFLOAD Utility

A utility that loads archived files produced by the PFDUMP utility back into the permanent file system. The load can reestablish the permanent file system exactly as it was at the time of the dump, or can load only a desired subset of files on the archive file.

#### PFM

See Permanent File Manager.

#### PFS

See Permanent File Supervisor.

#### PFU

See Permanent File Utility.

Physical Identifier (PID)

The unique 3-character identifier of a specific host.

Physical Record Unit (PRU)

The amount of information transmitted by a single physical operation of a specified device. For mass storage files, a PRU is 64 central memory words (640 characters); for magnetic tape files, the size of the PRU depends upon the tape format. A PRU that is not full of user data is called a short PRU; a PRU that has a level terminator but no user data is called a zero-length PRU.

#### PICB

See Program Initiation Control Block.

# PID

See Physical Identifier.

#### PIP

See Peripheral Interface Package.

# PP

See Peripheral Processor.

# PPS

The Peripheral Processor Subsystem.

PPU

See Peripheral Processor Unit.

#### Primary File

A temporary file created with the OLD, NEW, LIB, (interactive jobs only), or PRIMARY command. The primary file is assumed to be the file on which most system operations are performed unless another file is specified. There can be only one primary file associated with your job.

#### PROBE Utility

A utility that traps and measures particular interval events in the system. PROBE generates a report from the data collected by the system.

#### Procedure

A user-defined set of instructions that can be referenced by name. The instructions consist of procedure directives and system commands.

Program Initiation Control Block (PICB)

A sequence of commands that initiates NPU load and dump operations for a specific NPU variant. Several PICBs may exist on the network load file. Each PICB is a separate record with a unique NPU variant name as its record name.

#### Programmable Format Control

Spacing and format control for 580 line printers provided by the use of software and a microprocessor instead of a carriage control format tape.

#### Project Number

An alphanumeric identifier that may be required at a user's installation for accounting and billing to a specific project. If it is required, the project number is entered during the login procedure. It is given to the user by personnel at his/her installation.

#### PRU

See Physical Record Unit.

Pseudo A Register

A software register used by DSD to function channels and to manipulate peripheral hardware devices from the operator's console.

# PTF

See Permanent File Transfer Facility.

# PTFS

See Permanent File Transfer Facility Servicer.

Public Auxiliary Device

An auxiliary device that is available for access by all validated users knowing the correct pack name. Additional validation is required to create or replace files on an auxiliary device.

#### QALTER Utility

A utility that displays, lists, and/or alters routing and other information about active queued files. It selects files for processing according to specified criteria. QALTER can also purge selected files from the system.

# QDUMP Utility

A utility that dumps selected queued files from a single device, a family of devices, or all devices on the system. These queued files can be dumped either to a tape or disk. QDUMP also provides a listing of all files dumped with information about each file processed.

# QFSP

See Queue File Supervisor Program.

QFT

See Queued File Table.

QFTLIST Utility

A utility that displays and/or lists routing and other information about active queued files. Its operation is similar to that of QALTER, except file alteration or purging is not allowed.

# QLIST Utility

A utility that lists inactive queued files, which may include all inactive queued files in the system or a selected subset based on options specified when the utility is called.

# QLOAD Utility

A utility that processes the dump files generated by QDUMP or other utilities using the same format. QLOAD can selectively load the queued files from these dump files. QLOAD can also list the contents of a dump file without loading any files.

#### QMOVE Utility

A utility that moves queued files from one disk device to another. It also produces a listing of all files moved with information about each file processed.

# QREC Utility

A utility that deactivates or activates selected queued files and purges selected inactive queued files.

# QTF

See Queue File Transfer Facility.

# QTFS

See Queue File Transfer Facility Servicer.

Queue File Supervisor Program (QFSP)

A program that provides control for the queue file utilities.

Queue File Transfer Facility (QTF)

QTF is an applicaton program initiator that periodically scans the I/O queues searching for files to transfer. When it finds a file to transfer, it initiates and completes the queue file transfer with the help of its servicing application, QTFS, on another host.

Queue File Transfer Facility Servicer (QTFS)

QTFS is an application program servicer started by RHF or NAM when requested by a QTF on another host. The QTFS application assists the QTF application in completing the transfer by receiving the queue file and placing it in the I/O queue.

Queue Priority

An attribute associated with input and output files. If all other factors are equal, queue priority is used to select the best file for processing.

Queued File

An input, print, plot, or punch file that has an entry in the QFT, is not assigned to an EJT entry, and is waiting to be selected for processing.

Queued File Table (QFT)

A central memory resident table that contains a 4-word entry for all active input and output queue files.

Random Access

An access method by which any record in a file can be accessed at any time. Random access applies only to mass storage files with an organization other than sequential. Refer to Sequential Access.

# RCFGEN

See RHF Configuration File Generation.

RCL

See Resident Central Library.

RDF

See Release Data File.

Recall

The state of a program when it has released control of the central processor until a fixed time has elapsed (periodic recall) or until a requested function is completed (auto recall). Recall is a system action request as well as an optional parameter of some file action requests.

#### Record

A unit of information. In CYBER Record Manager and its language processors, a record is a unit of information produced by a single read or write request.

Eight different record types exist within CRM. The user defines the structure and characteristics of records within a file by declaring a record format.

#### Regulation Level

A number that indicates to NAM the existence of a logical link and indicates what types of information exchange are possible on that logical link.

Release Data File (RDF)

A file created by PFDUMP that identifies those MSF/7990-resident files that are pointed to by PFC entries at the time of the dump.

Remote Batch Job

A job submitted from a remote batch terminal.

#### Remote Host Facility (RHF)

A central processor program that executes at a system control point. It performs data buffering and switching, and is the intermediary between application programs and the network.

## Remote NAD

Any 380 NAD accessible to a local NAD using a loosely coupled network trunk.

#### Remote NPU

A network processing unit linked to a host computer through other network processing units.

#### Removable Device

A disk storage device that can be physically detached from the disk drive.

Resident Central Library (RCL)

An area in central memory resident that central library routines specified by the \*CM directive reside.

## Resident Peripheral Library (RPL)

An area in central memory resident that peripheral library routines specified by the \*CM directive reside.

RHF

See Remote Host Facility.

RHF Configuration File Generation (RCFGEN)

A utility that reads configuration definition statements to create a permanent file that RHF uses for the network description and access.

# Rollout

The removal of jobs from central memory to mass storage before execution is complete, so the control point and central memory can be assigned to another job. A job is rolled out when it is waiting for an external event, when its control point and/or central memory is needed by a higher priority job, or when it exceeds its central memory time slice.

Rollout File

A file containing a job (and system information) that has been temporarily removed from the main processing area of the system. RPL

See Resident Peripheral Library.

#### SC

See Service Class.

```
S/C Register
```

See Status/Control Register.

Scheduling Priority

An attribute associated with an executing job available for job scheduling. Scheduling priority is used to select the best executing service class job for processing.

## SCOPE 2 Station Facility (SSF)

A NOS subsystem that allows a NOS user to submit jobs (including batch jobs that require interactive I/O) to a linked SCOPE 2 system. The submitted job uses standard SCOPE 2 commands to access NOS files stored on the originating NOS system.

```
SCP
```

See Subcontrol Point.

Screen Management Facility (SMF)

A subsystem that alters the performance characteristics of the Full Screen Editor (FSE). The absence or presence of SMF is not detectable by the FSE user. Performance can be optimized by disabling SMF for small mainframes and interactive work loads, and by enabling SMF for large configurations and heavy work loads.

#### SCRSIM

See Status/Control Register Simulator.

SDF

See System Deadstart File.

# SECDED

See Single Error Correction Double Error Detection.

#### Secondary Mask

An 8-bit quantity used to identify groups of users who can place direct access files on a particular device.

#### Secured System

A system in which a mandatory security mechanism has been enabled during deadstart. A secured system protects information by enforcing restrictions based on access levels and access categories, and restricts many sensitive system functions to security administrators.

# Security Adminstrator

A secured system prevents users and operators from performing certain functions that could result in the unauthorized disclosure or modification of information. These functions can only be performed by someone who is designated a security administrator. A security administrator is always authorized to access the highest level of information stored on the system. This person performs functions in the areas of installation, user validation, system operation, and system maintenance.

# Security Unlock Status

This status of the system console applies only to a secured system and must be set by a security administrator. The console must be in security unlock status in order for the security administrator to perform certain functions that are restricted on a secured system.

# Sequential Access

A method in which only the record located at the current file position can be accessed. Refer to Random Access.

## Sequential (SQ) File

A file in which records are accessed in the order in which they occur. Any file can be accessed sequentially.

#### Service Class (SC)

An attribute associated with a queued file or executing job. The service class determines how the system services the job.

SFS

See Special File Supervisor.

Single Error Correction Double Error Detection (SECDED)

A hardware technique that detects and corrects single bit errors in memory. Double bit errors are detected by not corrected.

SM

See Storage Module.

SM Map

See Storage Module Map.

```
SMF
```

See Screen Management Facility.

#### Source Code

Code input to the computer for later translation into executable machine language instructions (object code).

Special File Supervisor (SFS)

A program that provides routines, table management, data manipulation, and I/O processing for special system jobs.

SQ File

See Sequential File.

# SRU

See System Resource Unit.

#### SSEXEC Program

The main processing program that controls MSAS activities, such as destaging files from disk to the 7990, purging unneeded 7990 files, labeling or relabeling cartridges, updating SM maps, and updating 7990 catalogs.

# SSF

See SCOPE 2 Station Facility.

# SSSLV Program

A program that runs on each slave mainframe and communicates with the SSEXEC program to retrieve files from the 7990 in response to ATTACH requests by jobs running on the slave mainframes.

#### Status

Information relating to the current state of a device, line, and so forth. Service messages are the prncipal carriers of status information. Statistics are a special subclass of status.

Status/Control Register Simulator (SCRSIM)

A program that enables the user to set status/control register bits in order to aid in the testing of error logging and error recovery procedures.

Status/Control (S/C) Register

A hardware register used in error detection, logging, and recovery procedures. This register is present on all CYBER 170 Computer Systems. For models 865 and 875, the S/C register is replaced by a maintenance register. Refer to Maintenance Register.

## Step Mode

A protected or debugging mode for the operating system monitor. The keyboard spacebar must be pressed to process each PP request.

#### Stimulator

A collection of central memory and peripheral processor programs that enters a hypothetical work load into the system to analyze the effects of such a load on response time and system reliability.

## Storage Module (SM)

An MSAS hardware unit that houses up to 312 usable data cartridges, a cartridge accessor unit that picks cartridges from and puts cartridges in their cubicles, and one or two data recording drives. Storage Module (SM) Map

A direct access permanent file that contains information indicating the cartridges that reside in the SM.

## Subcontrol Point (SCP)

A division of a central memory control point. You can set up a control point to contain two or more programs; one of the programs is the executive, and monitors the other programs executing at the subcontrol points.

#### Subfamily

Each permanent file family consists of eight subfamilies, subfamily 0 through subfamily 7. The lower 3 bits of the user index identify the subfamily to which a user belongs.

#### Suspended Job

An interactive job placed in a inactive state. Processing is stopped immediately and recovery information is copied to the rollout file. Processing is resumed as if no interruption took place, if the job's EJT entry is recovered.

#### System Access Categories

On a secured system, a set of access categories are set during level 0 deadstart. This set may consist of some, all, or none of the 32 possible access categories. While the system is running in security mode, you may only use access categories that are within the set of system access categories.

#### System Access Levels

On a secured system, a range of access levels is set during level 0 deadstart. This range may contain some or all of the eight possible access levels. While the system is running, users may only use access levels that are within the range of system access levels.

#### System Deadstart File (SDF)

A file that is a copy of the deadstart tape that resides on a disk storage deadstart device. When the system is deadstarted from disk, this file is read to generate copies of the running system. System Library (SYSTEM)

The collection of tables and object language programs that reside in central memory or on mass storage and are necessary for running the operating system and its product set.

System Origin Job

A job entered at the system console.

System Resource Unit (SRU)

A unit of measurement of system usage. The number of SRUs includes the central processor time, memory usage, and input/output resources used for a given job.

## TAF

See Transaction Facility.

#### TCU

See Trunk Control Unit.

#### Temporary File

A file associated with a job that is not a permanent file. Temporary files no longer exist when the user logs off the system or releases the files.

#### Timed/Event Rollout

A condition in which an executing job has been temporarily removed from central memory but will be rolled back into central memory when a specified event (such as a file is no longer busy) or a specified time period has elapsed.

#### TRACER Utility

A utility that monitors the system's activity and gathers data periodically for statistical analysis of the system.

#### Track Link

An address of the next track that is a logical continuation of a file.

Track Reservation Table (TRT)

A table that describes the physical layout of data on a device and is the key to allocating information on the device.

#### Transaction Facility (TAF)

An application program that provides the transaction terminal with access to a data base. A terminal using TAF can enter, retrieve, and modify information in the data base.

TRT

See Track Reservation Table.

#### Trunk

The communication line connecting two network processing units.

Trunk Control Unit (TCU)

The hardware part of a network access device (NAD) that interfaces with a network trunk.

UDT

See Unit Device Table.

# UEM

See Unified Extended Memory.

Unified Extended Memory (UEM)

A type of extended memory. UEM differs from other types of extended memory in that it is a portion of central memory and not a separate memory unit. See Extended Memory.

Unit Device Table (UDT)

A table that defines the logical mapping of the components within a 7990 configuration.

# Unit Number

The setting of a hardware device. The unit number is used when more than one hardware unit can be connected to a controller.

#### Unsecured System

A system in which the multilevel security mechanism has not been enabled during deadstart. The restrictions based on access levels and access categories are not enforced on an unsecured system.

## Upline

The direction of input flow from terminal to host.

User Break 1 Sequence

The character or sequence of characters that causes an executing program to be interrupted (also called the interruption sequence).

#### User Break 2 Sequence

The character or sequence of characters that causes an executing program to be terminated (also called the termination sequence).

## User Index

A unique 17-bit identifier that is associated with each user name. The user index is used by the permanent file manager to identify the device and catalog track for the user's permanent files.

User Job Name (UJN)

A 1- to 7-character alphanumeric name you specify to replace the system defined JSN for a queued file or executing job.

#### User Name

A name given to the user by his/her employer, instructor, or computer center personnel. A user name has certain resources and privileges assigned to it. When logging in to the system, a user specifies his/her user name as identification, so that it knows that this person is an authorized user and what resources this user is entitled to use. A user name also represents a specific catalog in the permanent file system. All files a user makes permanent are associated with that user's name and this catalog. A file that contains validation information for all users (user names, passwords, resources allowed, and so on).

Volume Serial Number (VSN)

A from 1- to 6-character identifier that identifies the volume of magnetic tape to the system.

VSN

See Volume Serial Number.

# Word

A group of bits (or 6-bit characters) between boundaries imposed by the computer system. A word is 60 bits in length. The bits are numbered 59 through 0 starting from the left. A word is also composed of five 12-bit bytes, numbered 0 through 4 from the left.

#### Write Mode

A mode that allows a user to write, modify, append, read, execute, or purge the file (modify permission applies only to direct access files).

#### Zero-Length PRU

A PRU that contains system information but no user data. Under NOS, a zero-length PRU defines EOF.

## 7**99**0

A hardware product that is a large capacity mass storage device. The 7990 is a cost-effective extension to the disk file storage system and an alternative to conventional magnetic tape storage.

#### 7990 Catalog

A disk-resident direct access permanent file that contains information describing which AUs of each cartridge assigned to a particular subfamily are allocated to 7990 files and which AUs are available for allocation.

# **SCOPE 2 STATION FACILITY**

The SCOPE 2 Station Facility (SSF) is a NOS software subsystem that allows a NOS user to submit jobs and transfer files to a linked SCOPE 2 system residing in a 7000 Computer Systems mainframe. With SSF, a NOS user can route jobs to a linked SCOPE 2 system for processing. While processing the job, the SCOPE 2 system can access permanent files and tape files at the NOS host.

SSF provides these services:

- Provides NOS users with local batch capabilities at a linked SCOPE 2 system.
- Optionally serves as the system operator station for SCOPE 2.
- Provides the NOS user with remote batch capabilities, through RBF, at a linked SCOPE 2 system.
- Allows simultaneous transfer of multiple files.
- Optionally furnishes the deadstart file for SCOPE 2.
- Provides a means of obtaining absolute SCOPE 2 dumps.
- Allows a job executing on a SCOPE 2 system to use SCOPE 2 commands (GETPF, SAVEPF, and PURGE) to access permanent files at a linked NOS system.
- Allows a job executing on a SCOPE 2 system to access magnetic tape files at a linked NOS system.

# EQUIPMENT CONFIGURATION

To establish a NOS-SCOPE 2 link using the SSF Subsystem, the NOS and SCOPE 2 mainframes must be attached to a loosely coupled network (LCN) by a 6683 and 7683 Satellite Coupler, respectively. An equipment status table (EST) device type entry of CC describes the coupler link. The EST table appears on the E,A display.

# SSF FILE TRANSFERS

SSF file transfers between NOS and SCOPE 2 are of two types: staged file transfers and spooled file transfers. Staged file transfers process one file at a time and handle all tape file and permanent file transfers. Spooled file transfers handle multiple I/O file transfers. Normally, operator intervention is not required for either type of transfer.

SSF initiates a special type of job, called a spunoff task (SPOT) job, to perform file transfers. Staged file SPOT jobs differ from spooled file SPOT jobs as described in this appendix. The primary functions of any SPOT job are performing user validation and queuing tasks required to send a file across the link. All SPOT jobs are executed on the NOS system.

Installation parameters or operator commands can be used to limit the number of file transfer activities that can be active concurrently. Independent limits can be set on the following activities:

- Purging NOS files.
- Reading tape files from NOS to SCOPE 2.
- Writing tape files from SCOPE 2 to NOS.
- Reading permanent files from NOS to SCOPE 2.
- Writing permanent files from SCOPE 2 to NOS.
- Reading input files from NOS terminals to SCOPE 2.
- Writing output files from SCOPE 2 to NOS terminals.

The operator commands used to set limits are described in section 8, K-Display Utilities.

# STAGED FILE TRANSFERS

Staged file transfers are essentially the same for both tape and permanent file transfers. In response to an SSF query, SCOPE 2 indicates to SSF that an executing SCOPE 2 job requires access to a NOS file. The SCOPE 2 request can specify either a NOS to SCOPE 2 file transfer, also called a prestaging transfer; or a SCOPE 2 to NOS (poststaging) transfer. In either case, SSF normally responds by creating a SPOT job to perform the file transfer. The SPOT job name is of the form xyyy, where x is the last character of the PID of the SCOPE 2 mainframe, and yyy is the JCB ordinal of the SCOPE 2 job. SSF places the newly created SPOT job into the NOS input queue, and the job executes on NOS in the same manner as any other job.

During execution, the job checks that the user has the appropriate file access permission. If so, the SPOT job initiates the file transfer.

For staged file transfers, each SPOT job terminates upon completion, and the job's dayfile (containing all processing and error messages) is sent to SCOPE 2 to be included in the dayfile of the job that requested the file transfer. SSF initiates a new SPOT job for each staged file transfer request it receives.

SSF periodically queries SCOPE 2 about file staging activities that should be dropped. For example, the SCOPE 2 system operator may have dropped a job for which staging was active. If any file staging activities are to be dropped, SSF requests information to identify the staging activity and then drops the associated SPOT job. No operator intervention is required.

# **SPOOLED FILE TRANSFERS**

Spooled file transfers use a single SPOT job to perform all input/output file transfers between SSF and SCOPE 2. As soon as communications are established between SSF and SCOPE 2, SSF creates a SPOT job to handle input/output file transfers. The job is called xSTA, where x is the PID of the SCOPE 2 mainframe. This SPOT job can be swapped out during periods of low activity, but the job is not terminated until the SSF-SCOPE 2 link is dropped.

An input file transfer begins when the spooling SPOT job selects a file from the NOS input queue that is destined for the SCOPE 2 system. The SPOT job queries SCOPE 2 for a system file table (SFT) entry for the input file to be transferred. When an entry is assigned, the spooling SPOT job transfers the input file to SCOPE 2. Upon completion of the transfer, the SPOT job requests that the input file be removed from the NOS input queue.

For each output file transferred from SCOPE 2, the spooling SPOT job transfers the output file from the SCOPE 2 output queue to a local NOS file. When the transfer is complete, the SPOT job routes the local file to the NOS output queue (with the appropriate disposition code, forms code, or terminal ID). The spooling SPOT job then requests the removal of the output file from the SCOPE 2 output queue.

# **ERROR LOGOUT**

A loss of communications between SSF and SCOPE 2 results in an error logout condition. Error logout occurs as a result of a STOP command entered by the system operator, or a software or hardware error. When SSF detects an interruption in communications, it logs out of the SCOPE 2 system after:

- All partially transmitted files are rewound on the sending end of the link and are deleted at the receiving end.
- All SPOT jobs are dropped.

No files are lost as a result of the communications break. After logging out of the SCOPE 2 system, SSF periodically queries SCOPE 2 to determine if the link has been restored.

Error logging on a CYBER 170 Computer System enables you to detect and log errors identified in the status/control (S/C) register. The status/control register simulator (SCRSIM) allows you to set S/C register bits in order to aid in the testing of error logging and error recovery procedures.

SCRSIM does not run on CYBER 180-class machines. Models 865 and 875 use maintenance registers instead of S/C registers. Throughout this appendix all references to S/C registers also apply to the model 865 and 875 maintenance registers.

SCRSIM runs on CYBER 170 Computer Systems using the S/C register on channel 16 and, if more than 10 PPs are available on the system, the S/C register on channel 36. On CYBER 70 Computer Systems, SCRSIM uses the interlock register on channel 15.

With the aid of a K display, you can specify commands to set and clear bits, set bytes, and set lines and areas in holding registers. This allows both S/C registers to be set up completely. The contents of the holding register can then be transferred to the S/C registers (64 or 128 bits are transferred to the interlock register of a CYBER 70 Computer System).

The bits set through this simulator are logged in the error log if an error bit is set, thus aiding in testing and software checkout. (Refer to the appropriate hardware reference manual for a complete description of the significance of each S/C register bit.) The simulator job dayfile lists all simulator commands entered. This error logging does not occur in a CYBER 70 Computer System, however, unless an ENABLE, SCRSIM IPRDECK entry has been made.

# NOTE

Be careful when using the simulator. Improper use may result in serious system malfunctions.

Refer to the NOS 2 Operations Handbook for descriptions of messages produced by SCRSIM.

# **USING THE SIMULATOR**

Error logging is always enabled on a CYBER 170 Computer System except models 815, 825, 835, 845, and 855. Error logging is enabled on a CYBER 70 Computer System only if the ENABLE, SCRSIM IPRDECK entry is present.

D-1

D

## **CONSOLE OPERATION**

The simulator is called from the console by entering:

X.SCRSIM.

The simulator K display (refer to figure D-1) appears on the left screen after entering:

K,jsn.

jsn The job sequence name of SCRSIM noted on the B,O display.

This K display shows the contents of the temporary holding registers, as well as a central memory buffer. The buffer contains:

- A history of all error status bits since the last level 0 deadstart. If an error status bit has been set in the S/C register, it remains set in the buffer, even though it may have been cleared in the actual S/C register. This history may be useful in diagnosing system malfunctions.
- All other bits in the buffer reflect actual values in the S/C register at the time the last error bit was set. Each time an error bit is set, the entire buffer is updated.

Unless the simulator is running on a CYBER 170 Computer System with more than 10 PPs, the message

CHANNEL 36 NOT AVAILABLE

also appears. This indicates that no channel 36 S/C register is present on the machine, and thus, no simulation need be done for it.

By entering

KK.

the simulator commands K display (refer to figure D-2) appears on the right screen. This display gives a brief description of the commands available.

Commands can be entered on the K display by entering:

K.command.

command One of the commands shown in figure D-2.

# **BATCH INPUT**

The simulator may also be called from batch input by using the SCRSIM command. The input file must have a record containing the commands to be processed, one command per card. The system must be in debug mode and the user must be validated for system origin privileges.

Figure D-2. Simulator Commands K Display (Right Screen)

# SIMULATOR COMMANDS

The simulator commands are described next. You must enter the entire command keyword and only one command may be entered at a time. Each command, except +, must end with a terminator. In all cases, a null argument is assumed to be zero.

# HOLDING REGISTER COMMANDS

The following commands, except GO., affect only the holding register currently displayed on the left screen. These commands are used to set up the entire 204 bits in the holding registers. GO. transfers the holding register contents to the actual S/C register. (On a CYBER 70 Computer System, the channel 16 S/C register is simulated by the interlock register. GO. transfers the first 64 of 128 bits of the holding register to the interlock register.) The current contents of the holding register is displayed in binary and octal on the left screen (refer to figure D-1). The contents of the actual S/C register are also displayed in binary on the left screen.

Command

LINE, x, y.

# Description

Set line x of the holding register to the octal value y. Description

# Parameter

Parameter

- Line number of the holding register shown on х the left display screen (refer to figure D-1); from 0 to 3. Line 0 is positioned at the top and line 3 is positioned at the bottom.
- Value to which line x is to be set. y may У be up to 60 bits of octal value.

Transfer the contents of the actual S/C register to the holding register.

Set bits  $a_1, a_2, \ldots, a_n$  in the holding register. If more than 30 bit numbers are entered, only the first 30 are processed. All others are ignored.

#### Parameter Description

Bit number to be set; from 0 to 203. A ai decimal value is assumed, but a postradix of D or B may be included.

GO .

Transfer the contents of the holding register to the actual S/C register or to the interlock register of a CYBER 70 Computer System. No bits in the holding register are changed by this command.

# **CYCLE COMMANDS**

Command

END.

Set bit x every t periods of time, a total of r times. This command assumes control of the simulator for the total time period specified. During this time, no command is accepted except END. Bit x is set in the holding register by this command.

Description

#### Description

- х Bit number to be set; from 0 to 203.
- t Number of periods of time for each cycle; one period is 16 milliseconds. t=32 is approximately 0.5 second.
- Number of times to set bit x. r may not r exceed 4095.

End CYCLE command processing before r is reached. Control of the simulator is returned to the operator.

READ.

SET, a1, a2, ..., an.

# CYCLE, x, t, r.

# + AND STOP COMMANDS

|---------|---------------------------------------------------------------------------------------------------------------------|
| +       | Toggle the K display between the channel 16 and channel 36 register displays and also change the register currently |
|         | heing worked on, if the simulator is being operated on a                                                            |

CYBER 170 Computer System with two S/C register currently being worked on, if the simulator is being operated on a CYBER 170 Computer System with two S/C registers. If two S/C registers are not present on the machine, no action is taken. The channel 16 register is assumed when the simulator begins. The only holding register that is affected by the holding register and cycle commands is the one currently displayed.

STOP.

End simulator processing.

# **580 PROGRAMMABLE FORMAT CONTROL**

You control the spacing and format on 580 line printers by using carriage control format tapes or programmable format control. The carriage control format tape is punched to indicate particular format channels for each frame. A printer with programmable format control does not use carriage control format tapes; instead, it contains a microprocessor plus memory. Programmable format control arrays are loaded into this memory, performing the same function as the format tape. This appendix describes how to create and load programmable format control arrays. A description of format tapes is included in the NOS 2 Reference Set, Volume 3.

Certain 580 printers are not equipped with a carriage control tape; instead, a microprocessor plus memory called programmable format control is used. Instead of a tape controlling the page format, software is used. This software is called a programmable format control array. A programmable format control array consists of numbers from 0 to 12 and 178. Each nonzero character represents a channel. A 0 (zero) specifies that no channel is selected. An array is similar to a format tape since each number in a programmable format control array corresponds to a line on the print form. As each line of a page is printed, the next number in the programmable format control array buffer is addressed. A carriage control character in column 1 of the output line, indicating a skip to a particular channel, causes the memory in the programmable format control array buffer to be sequentially addressed until the particular number is found. The paper is spaced a similar number of spaces.

A programmable format control array differs from a format tape because only one channel can be specified per line. A number of channels can be specified per line using a format tape. Also, programmable format control arrays are accessed in pairs, one for 6 lines per inch (lpi) printing and one for 8 lpi printing. The 8-lpi array is usually larger, allowing more lines to be printed on the same size page.

# **BUILDING PROGRAMMABLE FORMAT CONTROL ARRAYS**

Observe the following rules when building a programmable format control array.

- Enter only valid numbers (from 0 to 12 and  $17_8$ ) in the programmable format control array.
- A l must be the first number in the programmable format control array, indicating a top-of-form position.
- A 12 should always indicate the last line of the form (bottom of page).
- A 178 should appear as the last number in the array, denoting the end of valid numbers for a given array. This number does not correspond to any particular line on the form.
- Maximum length programmable format control arrays (132 for 6 lpi and 176 or 136 for 8 lpi) must include a 9 only at location 132 for 6 lpi and location 176 or 136 for 8 lpi. Improper paper alignment may occur if a 9 is placed elsewhere.

Ε

To properly load the appropriate programmable format control buffer for a particular form, it is necessary to assemble data that will contain, when transmitted and stored in the programmable format control array buffer, as many numbers as lines on the form. As stored within the programmable format control array buffer, each number is a 4-bit code used to represent channels (1 through 12) or a null code (no channel selected).

# NOTE

Channels 13 and 14 are valid channels but they are not selectable. No programmable format control error occurs when loading these numbers into the programmable format control buffer.

The maximum capacity of the 6-lpi programmable format control buffer is 132 numbers (22-inch form maximum) plus the last line number whereas the 8-lpi programmable format control buffer has a capacity of 176 or 136 numbers (22-inch or 17-inch form maximum) plus the last line number. Fewer than the maximum amount of numbers may be legally loaded into the programmable format control buffer, but an excessive amount of numbers will cause a programmable format control overflow error.

# ADDING PROGRAMMABLE FORMAT CONTROL ARRAYS

Programmable format control arrays must occur in pairs (one 6-lpi array and one 8-lpi array); therefore, when a particular array is specified with the SC option of the ROUTE command, it is possible to switch from 6- to 8-lpi spacing except when using 8.5-inch forms, which are always printed at 8-lpi spacing. Four pairs of arrays are provided with the operating system, two pairs of arrays for 11-inch forms and two pairs of arrays for 8.5-inch forms (refer to table E-1). The numbers are omitted for 6-lpi 8.5-inch forms because this combination is not selectable.

To add additional programmable format control arrays, BIO must be modified to contain these additional arrays as overlays in QAP. The overlay names and corresponding ROUTE command SC parameter options must be added to PFCO, and the programmable format control overlay table in QAP. The first entry in this table specifies the default programmable control format array. This array is used when the SC parameter is not specified. If an added array is to be the default array, the PFCO entry for it should be placed at the beginning of the table. The value that must be specified with the SC parameter is included in this entry. This value can be any 6-bit binary value. The arrays that are also added to QAP must follow the same format, structure, and labeling conventions as the arrays already provided in QAP. To generate the numbers to be loaded into the programmable format control buffer, the DPFC (define programmable format control code) macro is used with the following format. Only the lower 4 bits of each 6 bits are used as programmable format control numbers.

| Location | Operation | Variable |
|----------|-----------|----------|
|          | DPFC      | a,b,c,d  |

# Variable

Description

a, b, c, d Programmable format control numbers for 6 or 8 lpi. These numbers can be any value from 0 to 12 and 178.

# NOTE

In each macro call, all four parameters must be specified (0 denotes no channel is selected). If all four are not required to complete an array (the number of lines on the form is not a multiple of 4), zeros should be used for the remaining parameters.

# 881/883 PACK REFORMATTING UTILITY

Each 881 disk pack used in the 844 disk contains factory-recorded flawing information on cylinder 6328 (410), track 0, sectors 0, 1, and 2. Each 883 pack contains this information on cylinder 14668 (822), track 0, sectors 0, 1, and 2. The following information is included on the cylinders.

- Cylinder 6328 (or 14668 for 883 packs), track 0, sector 0 contains the factory-recorded manufacturing data. This data consists of the pack serial number and the manufacturing date.
- Cylinder 6328 (or 14668), track 0, sector 1 contains the factory map. This map contains a list of all factory-detected flaws, both correctable and uncorrectable.
- Cylinder 6328 (or 14668), track 0, sector 2 contains the utility map. This map originally contains all factory-detected uncorrectable flaws. This map is updated by the reformatting utility.

FORMAT is a CPU program that operates in conjunction with FDP, a PP program, to maintain and reformat 881/883 disk packs. It is used to perform the following functions.

- Factory-recorded manufacturing data, factory-recorded flaw data, and utility flaw data can be retrieved from a factory-formatted disk pack.
- Sector and track flaws can be set or cleared on a factory-formatted disk pack.
- Address fields of a previously factory-formatted disk pack can be restored. (This function is used only in the event that addresses on the pack are lost.)

In order to function, FORMAT requires that the factory-recorded data [sectors 0 and 1 of cylinder 632g (or 1466g)] be correct and readable. The pack cannot be processed if this data is unreadable. If packs are available that do not contain this factory-recorded information, consult a customer engineer to have this information placed on the packs. Also, the correct level of controlware must be present in order for FORMAT to function. To determine the controlware level and for procedures to install this controlware, refer to the NOS 2 Installation Handbook. Since the operating system requires that the utility map contain the physical flaw information in order for automatic logical flawing to be performed, it is important that the utility map be properly maintained.

The operating system automatically sets logical flaws when initializing 844 equipment. This is done by reading the utility map of the 844 units involved, and mapping this physical flaw information into the corresponding logical track addresses. Logical track flaw reservations are then made in the track reservation table (TRT) for the 844 equipment being installed. For example, if the 844 equipment being initialized consists of two physical units (such as a DI-2 configuration), the logical flaws set in the TRT are obtained from the physical flaw information recorded in the utility maps of both units making up the DI-2 configuration. This automatic flawing occurs when an equipment is initialized, regardless of whether the initialization is done during deadstart, online, or is the result of running FORMAT. Automatic flawing also occurs when an X.FLAW request is made from the console.

F

The operating system allows for setting and clearing flaw information. The SLF and CLF APRDECK entries set or clear logical track reservations in the TRT of the equipment. (Refer to section 3, Deadstart Decks, for information concerning these entries.) If the device is then checkpointed, this flaw information is preserved in the TRT portion of the device label. The SLF entry can be made<sup>A</sup>during deadstart, during online initialization, or by using the FLAW utility (as described in section 8, K-Display Utilities). In any case, the flawing done via these entries is only logical; the flaw information remains only in the TRT and is discarded on subsequent deadstart initialization. This information is also lost during online initializations if it was not possible to recover the equipment. Using SLF does not cause any additional information to be recorded in the utility map; only FORMAT is capable of updating the utility map data. Caution should be used if attempts are made to cancel a logical flaw that was made during automatic flawing, since the physical disk sector is still marked as flawed and attempts to access that sector yield error conditions.

The use of the FORMAT utility for maintaining and reformatting 881/883 disk packs is described next.

# FORMAT COMMAND

Processing maintenance operations on an 881/883 type disk pack is initiated by the FORMAT command. This program interfaces with you as required. The format of this command is:

FORMAT,  $p_1, p_2, \ldots, p_n$ .

Each  $p_i$  is a keyword or a keyword equated to a value.

| P <sub>i</sub> |                 | Description                                                                                                                                                                                               |  |  |  |  |

|                | mode            | Description                                                                                                                                                                                               |  |  |  |  |
|                | ALTER           | The input file contains directives to control the set<br>or clear flaw operations (refer to Input Formats<br>later in this appendix).                                                                     |  |  |  |  |
|                | FETCH           | The factory-recorded flawing information contained on<br>cylinder 6328 (or 14668), track 0, sectors 0, 1,<br>and 2 is obtained and copied to the output file (and<br>optional output file, if available). |  |  |  |  |
|                | RESTORE         | The addresses, flawed sectors, and tracks are<br>restored according to information given in the<br>utility flaw map. If the utility flaw map is not<br>intact, the program aborts.                        |  |  |  |  |

I

#### Description

MODE

Same as MODE=FETCH.

0=filename

P<sub>i</sub>

Optional output file to contain the output extracted from the disk pack.

# NOTE

If output files other than OUTPUT or optional output files are specified, they should be created prior to the initiation of FORMAT. If they are not, they are destroyed upon completion of FORMAT processing.

P=serialnumber Pack serial number in decimal of the pack to be processed. If serialnumber does not match the serial number recorded on the disk pack at the factory, processing does not occur. Ρ

Same as P=0.

U=est EST ordinal of the 844 drive on which the disk pack is mounted. The unit is checked to ensure that it is available for formatting (refer to Accessing Disk Devices later in this appendix).

V Specifies that the utility is to verify the addresses recorded on the disk pack. This parameter is valid only if MODE=FETCH or MODE=RESTORE is specified.

If all default values are used, the following call is made.

FORMAT, I=INPUT, L=OUTPUT, MODE=FETCH, P=0.

At least the U and the P parameter must be correctly specified to initiate processing.

# INPUT FORMATS

Input to FORMAT consists of control directives and data statements. Control directives specify the type of operation to be performed. Data statements specify locations on the pack where the operations are to be performed. A number of data statements may follow each control directive. Control directives and data statements are contained on the input file. This file is accessed only when MODE=ALTER has been specified on the FORMAT command. The input file (and therefore, control directives and data statements) has no significance when MODE=FETCH or MODE=RESTORE is specified.

# **CONTROL DIRECTIVES**

Control directives begin in column 1. The format is:

directive

The following are acceptable directives.

| Directive | Description                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------|
| SET       | Declares that the following data statements contain the addresses of flaws to be set and entered in the utility flaw map.       |
| CLEAR     | Declares that the following data statements contain the addresses of flaws to be cleared and deleted from the utility flaw map. |
| FINIS     | Declares the end of the input. No information following this directive is processed. This directive is optional.                |

SET and CLEAR directives may be intermixed in the input file. However, all CLEAR operations are performed before any SET operation. Any attempt to alter the factory map or to set or clear sector flaws in a previously flawed track results in an error.

# DATA STATEMENTS

Data statements begin in column 1. The format is:

x,cccc,tt,ss

Parameter Description Type of flaw to be set or cleared. Acceptable values are: х Description x S Specifies that the SET or CLEAR directive applies to a sector. т Specifies that the SET or CLEAR directive applies to a track. cccc Octal number specifying the cylinder; from 0 to 6328 (or 14668 for 883 packs). Octal number specifying the track; from 0 to 228. tt Octal number specifying the sector; from 0 to 278. This field is ss ignored for track flaws (x=T).

All input data is checked to ensure that the values are within range. Any errors in input result in the termination of the utility before the disk is accessed. Any attempt to alter the factory map, or to set or clear sector flaws in a previously flawed track results in an error.

A maximum of 157 data statements can appear in the input stream.

1

### **OUTPUT FORMATS**

Output generated by FORMAT is placed on the output file (L=filename on the FORMAT command). This file, for all modes of operation (ALTER, FETCH, and RESTORE), contains:

- A listing of the input stream, if any.
- The pack serial number and date of factory formatting on cylinder 6328 (or 14668), track 0, sector 0.
- A listing of the factory flaw map contained on cylinder 6328 (or 14668), track 0, sector 1.
- A listing of the utility flaw map contained on cylinder 6328 (or 14668), track 0, sector 2.
- A listing of the utility flaw map following any changes resulting from SET or CLEAR directives. This listing appears only when MODE=ALTER is specified on the FORMAT command.
- A listing of the flawed sectors and tracks as read from the disk during address verification. This listing appears only when MODE=FETCH or MODE=RESTORE, and the V parameter are specified on the FORMAT command.

The output generated by FORMAT can be directed to an optional output file (O=filename). This file can then be used as input to another program, or it can be punched or printed.

e.

The following three examples of standard output illustrate a series of reformatting operations performed on the same pack.

Example 1:

A RESTORE operation is performed on an 881 pack. A command similar to the following was entered.

FORMAT,U=est,P=819545,MODE=RESTORE.

Figure F-1 illustrates the resulting output.

DISK PACK REFORMATTING UTILITY -VERSION 1.1 - 82/01/25. Figure F-3. FORMAT Output, MODE=FETCH

# **ACCESSING DISK DEVICES**

Special procedures must be used to access the 844 drive used in the reformatting utility. Since certain FORMAT operations (ALTER and RESTORE) can change addresses on the pack, user access to the pack must be restricted.

FORMAT can operate on the pack as follows.

- A read operation (FETCH) obtains formatting information from the pack. The integrity of the pack is maintained.
- Read and write operations (ALTER and RESTORE) can set and clear flaws, and addresses can be rewritten. Users cannot place permanent files on the pack when these operations occur. The integrity of the data on the pack is lost, so a full initialization of the pack must occur before system usage occurs.

#### ACCESS FOR READ OPERATIONS

Accessing the pack for read operations requires that you specify the U parameter on the FORMAT command with the correct EST ordinal of the device containing the pack. In this case, the device must be a single-spindle device unless you also specify the G parameter. You must also specify the P parameter with the correct pack serial number.

In addition, FORMAT must be called from one of the following.

- A system origin job (from the console).
- A system privileged job (in this case, engineering mode must have been selected on the system console).

#### ACCESS FOR READ AND WRITE OPERATIONS

In addition to the information specified for read only operations, the following additional steps must be taken to access a device when write operations (ALTER and RESTORE) are to be performed.

- 1. The pack to be accessed should be mounted on a removable disk device.
- 2. One of the following conditions is required.
  - The device should not be a shared device. (Refer to section 13, Multimainframe Operations.)
  - If the device is shared, a global unload should be set.
- 3. The device must be declared logically off. Use the OFF,est DSD command or the OFF parameter in the EQPDECK EQ entry.
- 4. The disk status display (E,M) must show that the device is not in use.
- 5. One of the following conditions is required.
  - The disk status display (E,M) must show that the device is unavailable for permanent file access.
  - The following conditions are required.
    - The full initialize status and the format pending status must be set. Use the DSD command, INITIALIZE, FP, est.
    - The direct access file user count should be equal to zero. The family status display (E,F) gives this information.

If all the necessary conditions are satisfied, FORMAT is able to access the pack for reformatting purposes. FORMAT repeatedly checks to ensure that these conditions are satisfied throughout the FORMAT operation.

## INDEX

NPU dump analyzer
    Description
                16-1,9
    Dump interpretation
                        16-25
    Input directives
                     16-10
        A - LCB and TCB/CCB
                             16-12
        B - Port tables and MUXLCB
                                    16-13
        0 - Comments
                     16-10
        1 - File 1 register
                             16-10
        2 - Macromemory word
                              16-10
        3 - Contiguous block data
          structure
                    16-10
        4 - Circular buffer data
         structure
                    16-11
                            16-11
        7 - Page registers
        8 - File l registers
                              16 - 11
        9 - Macromemory words
                              16-12
   NPU dump files
