NOS VERSION 2 ANALYSIS HANDBOOK

CDC[®] COMPUTER SYSTEMS: CYBER 180 CYBER 170 CYBER 70 MODELS 71, 72, 73, 74 6000

REVISION RECORD

REVISION	DESCRIPTION
A (04-26-82)	Manual released at NOS 2.0, PSR level 562. NOS Version 2 is the successor product to NOS Version 1. The file name table reorganization and support of models 825, 835, and 855 is documented. In addition, parameter changes and enhancements are included for the permanent file utilities, queue file utilities, mass storage subsystem utilities, data gathering utilities, memory dump directives, and system accounting information. The ASTIM, NSTIM, and VALNET commands have been deleted and a glossary has been added.
B (01-27-83)	Manual released at NOS 2.1, PSR level 580. New features include support of the Remote Host Facility, Remote Diagnostic Facility, Multi Host, and models 815, 865, and 875. Section 4 has been revised to include the NAMI and COLLECT utilities. Also the LFG and NDA utility descriptions have been revised and the Network Products Stimulator and NETUVSN utility have been deleted. New CMR dump directives have been added to section 10. The Controlware Loading utility described in section 14 has been expanded and rewritten. Section 16 has been added to describe the new RHF utilities. New diagnostic messages and glossary terms have also been added. Due to extensive changes, change bars and dots are not used, and all pages reflect the latest revision level. This edition obsoletes all previous editions.
C (10-11-83)	Manual released at NOS 2.2, PSR level 596. New features include support of project prologues and epilogues, enhanced system security, service class assignment by users, expanded equipment status table, reformatted TRACER output, network enhancements, and support of model 845. Also the K displays have been revised for permanent file utilities, queue file utilities, MODVAL, and PROFILE. Due to extensive changes, change bars and dots are not used, and all pages reflect the latest revision level. This edition obsoletes all previous editions.
D (10-05-84)	Manual released at NOS 2.3, PSR level 617. New features include support of the 721 console, CYBER 180 Computer Systems, 834 Disk Storage Subsystem, 639 Magnetic Tape Units, and Mass Storage Archival Subsystem.
	The NOS 2 Analysis Handbook, formerly the System Maintenance Reference Manual, no longer contains user validation and system accounting information (that information is now included in the NOS 2 Administration Handbook). All error messages have been moved to the NOS 2 Operations Handbook. New to this manual is the analysis information from part II of the Operator/Analyst Handbook, such as the DSD commands, DIS operations, K-display and L-display utilities, and network operations. Also incorporated in this manual are the deadstart decks (CMRDECKs, EQPDECKs, APRDECKs, IPRDECKs, and LIBDECKs), which were in the Installation Handbook. Due to extensive changes, change bars and dots are not used, and all pages reflect the latest revision level. This edition obsoletes all previous editions.
Publication No. 60459300	

REVISION LETTERS I, O, Q, S, X AND Z ARE NOT USED.

# PREFACE

This manual describes the CONTROL DATA® Network Operating System (NOS) Version 2. NOS 2 operates on these computer systems:

- CDC® CYBER 180 Computer Systems Models 810, 830, 835, 845, and 855
- CDC CYBER 170 Computer Systems Models 171, 172, 173, 174, 175, 176, 720, 730, 740, 750, 760, 815, 825, 835, 845, 855, 865, and 875
- CDC CYBER 70 Computer Systems Models 71, 72, 73, and 74
- CDC 6000 Computer Systems

# AUDIENCE

This manual assumes you are a site analyst. It assumes you are familiar with the hardware of your computer system(s) and that you understand the functions of the various components of NOS.

# ORGANIZATION

This manual includes information required for the day-to-day maintenance of the operating system and for troubleshooting. Topics discussed include the mass storage subsystems, network operations, the K and L utilities, backing up and reloading files, deadstart, and DIS operations.

Since the sections of the manual are self-contained in that they do not build on each other, the sections are ordered alphabetically by title. The appendixes include character set tables; a glossary; and descriptions of the SCOPE 2 Station Facility, the status/control register simulator, programmable format control for 580 printers, and disk pack reformatting for 881/883 units.

# CONVENTIONS

Models 815, 825, 835, 845, and 855 of the CYBER 170 Computer Systems share many of the functional and architectural attributes of the CYBER 180 Computer Systems. This manual uses the term CYBER 180-class machines when describing these similar models collectively.

Extended memory for model 176 is large central memory extended (LCME). Extended memory for models 865 and 875 and CYBER 180-class machines is unified extended memory (UEM). Extended memory for models 865 and 875 may also include either extended core storage (ECS) or extended semiconductor memory (ESM). Extended memory for all other NOS computer systems is either ECS or ESM. ECS and ESM are the only forms of extended memory that can be shared in a linked shared device multimainframe complex and can be accessed by a distributive data path (DDP).

In this manual, ECS refers to both ECS and ESM, and extended memory refers to all forms of extended memory unless otherwise noted. However, when referencing extended memory in the context of a linked shared device multimainframe complex or DDP access, UEM and LCME are excluded.

(Manuals dealing with the various form of extended memory are listed next, under Related Publications.)

# **RELATED PUBLICATIONS**

All of the manuals listed next are available through Control Data sales offices or through:

Control Data Corporation Literature Distribution Services 308 North Dale Street St. Paul, Minnesota 55103

,

The following is a list of NOS operating system manuals.

The reader should be thoroughly familiar with the material in the following publications.

•

<sup>&</sup>lt;sup>†</sup>The NOS Manual Abstracts is a pocket-sized manual containing brief descriptions of the contents and intended audience of all NOS and NOS product manuals. The abstracts can be useful in determining which manuals are of greatest interest to a particular user.

<sup>&</sup>lt;sup>††</sup>The Software Publications Release History lists all of the software manuals and revision packets Control Data has issued. The history specifies the revision level of a particular manual that corresponds to the level of software installed at the site.

.

By using the LOADBC command, you can download control module controlware, disk controlware, or network access device (NAD) controlware to the associated controller.

# CONTROL MODULE CONTROLWARE

You can use the LOADBC command to load controlware into a control module for the 834 Disk Storage Subsystem. The calling job must be of system origin or you must be validated for system origin privileges, and the system must be in engineering mode (refer to the DSD ENABLE command in section 5). LOADBC will issue appropriate messages to indicate the success or failure of the attempt to load controlware.

The format of the command is:

LOADBC,EQ=est,F=loadfile.

Parameter

Description

- EQ=est est is the EST ordinal of the control module in which to load the controlware.
- F=loadfile Name of the local file from which control module controlware is to be loaded. If F=loadfile is specified, local file loadfile must contain the control module controlware in binary format and an appropriate header (refer to the NOS 2 Installation Handbook). If F=loadfile is omitted, controlware is read from the system library SYSTEM.

## DISK CONTROLWARE

You initiate downloading of disk controlware only by entering a console command. Also, you can load the disk controlware from a channel only if it is either active or down and unassigned. The calling job must be of system origin or you must be validated for system origin privileges. The system must be in engineering mode (refer to the DSD ENABLE command in section 5). LOADBC will issue appropriate messages to indicate the success or failure of the disk controlware load attempt.

The format of the command is:

LOADBC,C=cc,F=loadfile,D=dumpfile.

Parameter

Description

C=cc

cc is a 2-digit octal number of the channel from which the disk controlware is to be loaded. The controlware can be loaded only if the channel status is UP, or if the channel status is DOWN and not assigned to a maintenance user.

1

# Parameter Description F=loadfile Name of the local file from which disk controlware is to be loaded. If F=loadfile is specified, local file loadfile must contain the disk controlware in binary format and an appropriate header (refer to the NOS 2 Installation Handbook). If F=loadfile is omitted, controlware is read from the system library SYSTEM. D=dumpfile Name of the local file to which 7155/7255 disk controlware is to be dumped before reloading. This parameter is ignored for other types of controllers and an informative message is issued. LOADBC performs a binary comparison between the old and new controlware and writes this data to a file that can be processed by DSDI by using the DMB parameter

# NETWORK ACCESS DEVICE (NAD) CONTROLWARE

The LOADBC command can be used to load NAD controlware into local NADs (380-170) and remote NADs (380-170, 380-200, 380-370, and 380-110). Since the NAD controlware is not automatically loaded at deadstart, LOADBC must be used before a local NAD can be used by the operating system. NAD controlware may be automatically loaded by the Remote Host Facility (RHF) when RHF is initiated. Refer to the RHF K display in section 8.

(refer to section 6 for information on DSDI).

LOADBC can be called from the console or a batch job. When loading 380-170 controlware into a local NAD, the EST entry associated with the NAD's channel number must be OFF or the controlware-not-loaded flag must be set.

When loading a remote NAD, a local NAD that is not reserved for maintenance must be defined in the EST. The EST entry must be ON. Controlware must be loaded and running in the local NAD before loading the remote NAD.

Remote NAD loading operations can occur concurrently with RHF use of the local NAD. However, extreme care should be exercised when performing a remote NAD load to ensure that the correct remote NAD is being loaded and that the remote NAD is not being used by the mainframe to which it is connected. LOADBC will issue appropriate messages to indicate the success or failure of the NAD controlware load attempt.

The format of the command is:

 $P_{i}$ 

Description

C=cc

The 2-digit octal number of the channel from which the NAD controlware is to be loaded. This parameter is required.

F=filename Name of the local file from which NAD controlware is to be loaded. If F=filename is specified, local file filename must contain the NAD controlware in binary format and an appropriate header (refer to the NOS 2 Installation Handbook). If F=filename is not specified, the NAD controlware type specified by the TY parameter is read from the system library SYSTEM. The following parameters apply only when loading remote NAD controlware.

| Parameter   | Description                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AC=aaaa     | The 4-digit hexadecimal number specifying the remote NAD's access code (refer to the RHF K display in section 8). The default is AC=0000.                                                             |
| LT=t0t1t2t3 | The 4-digit binary bit pattern specifying the local trunk control units (TCUs) that are enabled. At least one TCU enable must be specified for remote NAD controlware loading. $t_n = 1$ enables TCU. |
|             | For example, LT=1010 indicates that local TCUs 0 and 2 are enabled.                                                                                                                                   |
| ND=nn       | The 2-digit hexadecimal number specifying the remote NAD's address (refer to the RHF K display in section 8). This parameter is required for remote NAD loads.                                        |
| TY=value    | Type of controlware to be loaded.                                                                                                                                                                     |
|             | value Description                                                                                                                                                                                     |
|             | 170 CYBER 170 controlware (380-170)                                                                                                                                                                   |
|             | 200 CYBER 200 controlware (380-200)                                                                                                                                                                   |
|             | IBM IBM controlware (380-370)                                                                                                                                                                         |

- MIN Minicomputer controlware (380-110)

The default value is TY=170.

Under certain conditions, a remote NAD loading operation will fail on the first attempt but a second loading attempt will succeed. This loading problem can be prevented by always preceding a remote NAD loading operation with a remote NAD dumping operation to ensure the remote NAD controlware is halted before loading is attempted.

For example, to load a remote NAD with NAD address 7F and access code FOFO connected to TCU 0 of the local NAD on channel 5, enter the following commands.

X.DMPNAD(CH=05,ND=7F,AC=F0F0,LT=1000) X.LOADBC(C=05,ND=7F,AC=F0F0,LT=1000)

# DEADSTART

Deadstart is the process that makes the system operational and ready to process jobs. After performing the appropriate deadstart procedures described in the CIP User's Handbook, you can continue the deadstart process as shown in figure 2-1 and described in detail following the figure.

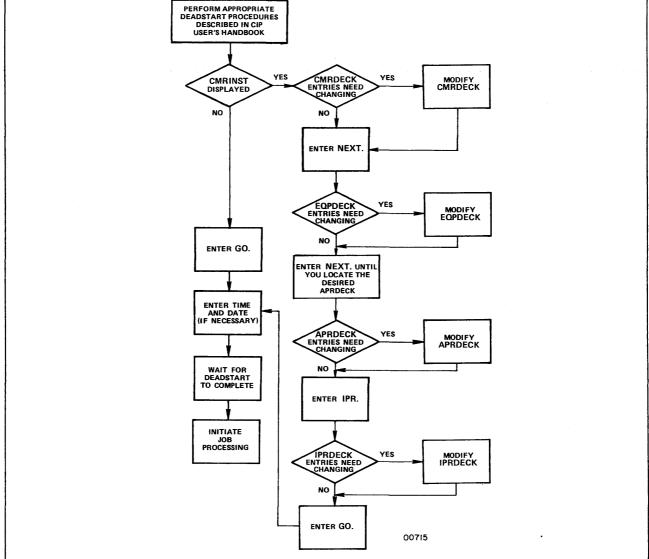

Figure 2-1. Deadstart Process

2

## NOTE

Modifying the deadstart decks (CMRDECK, EQPDECK, APRDECKs, and IPRDECK) does not apply to a level 3 recovery deadstart. Modifications made during the last level 0, 1, or 2 deadstart are recovered during a level 3 recovery deadstart.

# **MODIFYING THE CMRDECK**

If bit 6 of word 13 (word 12 for warmstart on a CYBER 70 or 6000 Computer System with an active PP) is set (ppp=001), or if you select the D=Y option on the \*P\* display, an instruction display entitled CMRINST appears on the console screen(s) after the CTI displays on a level 0, 1, or 2 deadstart. All valid CMRDECK entries are defined in this display. Several of the entries listed are assigned system default values. These values are assumed if the entries do not appear in the CMRDECK being used. To view the contents of the CMRDECK being used, toggle from the CMRINST display to the CMRDECK display. If either the CMRDECK or CMRINST overflows two screens, the display can be paged.

Modify the CMRDECK by entering the appropriate changes or additions from the console keyboard. These entries can be made while either CMRDECK or CMRINST is being displayed. Generally, each console entry supersedes the value currently specified in the CMRDECK (or default value in CMRINST).

Refer to section 3, Deadstart Decks, for complete information on all CMRDECK entries.

## NOTE

The modified CMRDECK remains in effect only until the next level 0 deadstart is performed. Changes to the CMRDECK are not recovered for the next deadstart unless a new deadstart file is created. If you want these changes to take place on the next level 0 deadstart, make the appropriate changes to the CMRDECK after NOS is up and running and use LIBEDIT to replace the record on the deadstart file.

After all CMRDECK modifications have been made and you want to modify an EQPDECK, APRDECK, or IPRDECK, enter:

NEXT.

Refer to Modifying the EQPDECK, Modifying the APRDECKs, or Modifying the IPRDECK in this section. Otherwise, to indicate that all modifications to the CMRDECK are complete and you want to begin loading the system, enter:

GO.

# **MODIFYING THE EQPDECK**

After completing all CMRDECK modifications, you can also modify the default EQPDECK, an APRDECK, or the IPRDECK being used. If no changes need to be made to any EQPDECK, but you do need to modify an APRDECK or the IPRDECK, refer to Modifying the APRDECKs or Modifying the IPRDECK later in this section.

To modify an EQPDECK, enter

NEXT.

while the CMRDECK or CMRINST is being displayed.

When processing the EQPDECK, four displays are available, which you can toggle through in a circular manner. You can make changes when the EQPDECK, EQPINST, or any one of the following four displays is being displayed at the console screen.

| Display               | Description                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------|
| Equipment Status      | Describes the hardware configurations (refer to figure $2-2$ ).                             |
| Mass Storage Status   | Describes how the system allocates files on a mass storage<br>device (refer to figure 2-3). |
| Mass Storage          | Describes initialization status of the devices (refer to figure                             |
| Initialization Status | 2-4).                                                                                       |
| Controlware Status    | Describes the status of the controlware loaded (refer to figure 2-5).                       |

Table 2-1 describes the entries that can be made only at the console keyboard at deadstart time and cannot be stored in the EQPDECK on the deadstart file. Refer to section 3, Deadstart Decks, for complete information concerning all EQPDECK entries.

After making the changes to EQPDECK you can toggle through the equipment display, mass storage display, mass storage initialization display, and controlware display to ensure all the changes are made.

### NOTE

The modified EQPDECK remains in effect only until the next level 0 deadstart is performed. Changes to the EQPDECK are not recovered for the next deadstart unless a new deadstart file is created. If you want these changes to take place on the next level 0 deadstart, make the appropriate changes to the EQPDECK after NOS is up and running and use LIBEDIT to replace the record on the deadstart file. After all EQPDECK modifications have been made and you want to modify an APRDECK or IPRDECK, enter:

NEXT.

Refer to Modifying the APRDECKs or Modifying the IPRDECK later in this section. Otherwise, to indicate that all modifications to the EQPDECK are complete and you want to begin loading the system, enter:

GO.

### EQUIPMENT STATUS DISPLAY

The equipment status display lists the status of all the devices.

Figure 2-2 illustrates the equipment status display.

|              |     | EQU  | IPMENT | STATU | IS  |       |     |   |
|--------------|-----|------|--------|-------|-----|-------|-----|---|
| (            | EST | TYPE | ST     | EQ    | UN  | CHANN | ELS |   |
|              | 0.  | RD   | ON     | 0.    | 00. | 00.   | •   |   |

TT Internal stimulation device.

### Description

The system creates the following device types at deadstart for internal use. Except for the display console, DS, physical hardware does not exist for these device types. The device types appear in the second column of the equipment status display along with the real device types.

- DS Display console (EST ordinal 18).
- NE Null equipment (EST ordinal 28).
- RD Used for online reconfiguration of mass storage (EST ordinal 0).
- TE Tape equipment (EST ordinal 38).
- TT Used for assignment of terminal files (EST ordinal 48).
- st Equipment status (ON, OFF, or DWN<sup>†</sup>).
- eq Equipment number that corresponds to switch settings on the controller that connects the equipment to the channel(s). The site engineer is responsible for setting these switches. Ask your customer engineer for the correct switch settings if you are unsure.
- un Unit number (serves as ID code for unit record devices). The identifier code (un parameter) provides a method of grouping peripheral devices when a site has several units. Output from a job read in through a card reader with identifier un can only be directed to a device with the same identifier. Changing the identifier code via the ROUTE command can direct program output to a special printer.

Most equipment has the unit number labeled on the equipment. Some equipment has the unit number as part of a switch or button. Ask your customer engineer for the correct unit numbers if you are unsure.

channels Channel(s) on which equipment is available. An asterisk (\*) instead of a
 period (.) following the channel number entry indicates that the channel is
 down.

# Header

<sup>†</sup> DWN is DOWN status. An equipment cannot be logically turned ON when in DWN status.

### MASS STORAGE STATUS DISPLAY

The mass storage status display provides detailed information about all mass storage devices. Figure 2-3 illustrates the mass storage status display.

| MASS | STORA GE | STATUS |        |  |
|------|----------|--------|--------|--|
| EST  | T YPE    | STATUS | FILES  |  |
| 5.   | DE       | A I    | S      |  |

Figure 2-3. Mass Storage Status Display

Each entry in the display appears in this format: files est type status Description Header EST ordinal. est Device type: type 885-42 Disk Storage Subsystem (1  $\leq$  i  $\leq$  3; full track). DB-i 834 Disk Storage Subsystem (1  $\leq$  i  $\leq$  8; full track). DD-i DE Extended memory. 844-21 Disk Storage Subsystem (1  $\leq$  i  $\leq$  8; half track). DI-i 844-41/44 Disk Storage Subsystem (1  $\leq$  i  $\leq$  8; half track). DJ-i 844-21 Disk Storage Subsystem (1  $\leq$  i  $\leq$  8; full track). DK-i DL-i 844-41/44 Disk Storage Subsystem (1  $\leq$  i  $\leq$  8; full track).

### Description

- DM-i 885-11/12 Disk Storage Subsystem ( $1 \le i \le 3$ ; half track).
- DP Distributive data path to extended memory.
- DQ-i 885-11/12 Disk Storage Subsystem ( $1 \le i \le 3$ ; full track).
- DV 819 Disk Subsystem (single density).
- DW 819 Disk Subsystem (double density).

status Status conditions. Any combination of conditions can exist. The following codes are listed in the order in which they appear on the display.

- S A copy of the system resides on this device.
- M Device is shared by more than one mainframe. †
- R Device is removable.
- N Independent shared device.
- A Alternate system device.
- I Initialization requested or format is pending.
- P Preset of the device requested.
- D System dayfile on this device.
- C Account dayfile on this device.
- E Error log on this device.
- B Binary maintenance log on this device.
- F System default family on this device.
- G Checkpoint device. A copy of the checkpoint file resides on this device.

Header

<sup>†</sup> If a device is shared by two or more mainframes (status M), the mainframe identification is shown on the screen as the mainframe accesses the shared device.

### Description

- Types of files that are allowed on this device. Any combination of types files can exist. The following codes are listed in the order in which they appear on the display. Refer to the MSAL EQPDECK entry in section 3, Deadstart Decks. S Secondary rollout. LGO. B L Local. Ρ Primary. D Job dayfile. Rollout. R 0 Output.
  - I Input.
  - T Temporary.

### MASS STORAGE INITIALIZATION STATUS DISPLAY

The mass storage initialization status display shows the initialization status of mass storage devices on the system.

Figure 2-4 illustrates the mass storage initialization status display.

| MASS | STORAGE | INITIALIZATION | STATUS |      |      |         |     |      |

Figure 2-5. Controlware Status Display

Each line in the display appears in this format:

 channel
 controlware

 Header
 Description

 channel
 Channel on which equipment is available.

 controlware
 Name of the controlware loaded. Refer to the LBC EQPDECK entry in section 3, Deadstart Decks, for a list of controlware types.

# Table 2-1. EQPDECK Entries (Sheet 1 of 3)

| Entry                                                                 | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTOLOAD.                                                             | Toggles the selection of buffer controller autoload-<br>ing for all 7054/7154/7152/7155/7255 control module<br>controllers. This entry is valid only when entered<br>from the console keyboard. That is, the AUTOLOAD<br>entry cannot be included as part of the EQPDECK on<br>the deadstart file. This entry, which affects all<br>7054/7154/7152/7155/7255 control module controllers<br>defined on the mainframe being deadstarted, is not<br>necessary for normal system operation but is<br>provided as an aid to hardware checkout.                                                                                                                                                                                                                      |
| GRENADE .                                                             | Toggles the selection of the grenade function. This<br>entry is valid only when entered from the console<br>keyboard. That is, the GRENADE entry cannot be<br>included as part of the EQPDECK on the deadstart<br>file. The grenade function is issued to all<br>7054/7154/7152/7155/7255 control module controllers,<br>once the controlware is loaded. This function<br>causes unit reservations to be cleared on all 834<br>and 844 units physically connected to each<br>controller. This entry is normally used when a unit<br>reservation from a downed mainframe exists on a<br>device. Use this entry with caution since it can<br>interrupt the operation of another machine that<br>could be accessing affected units through another<br>controller. |
| INITIALIZE,op,est <sub>1</sub> ,est <sub>2</sub> ,,est <sub>n</sub> . | Creates new labels for the specified mass storage<br>devices during a level 0 deadstart. This entry is<br>valid only when entered from the console keyboard.<br>That is, the INITIALIZE entry cannot be included as<br>part of the EQPDECK on the deadstart file. Before<br>any mass storage device defined in the EQPDECK (by an<br>EQ entry) can be used, it must have a label that can<br>be recognized by the system. Existing labels are<br>normally recovered automatically during all levels of<br>system deadstart. However, if the existing label is<br>destroyed (for example, during maintenance operations<br>on the device) or if a new mass storage device is<br>added to the system, you enter the INITIALIZE command<br>to create a new label. |
|                                                                       | op Level of initialization:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | est <sub>1</sub> The 1- to 3-digit number specified in<br>the EQ entry for the device (for<br>example, EQ005). This is also the<br>EST ordinal for the device. Any number<br>of devices can be initialized with the<br>same level of initialization, provided<br>the command is no more than 72<br>characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| · · · | Depending upon the levels of initialization<br>selected, all or part of the previously existing<br>information on the device is lost when the new label<br>is created. Total initialization of 844 format pack<br>(AL or FP options) destroys all information on a<br>device. The other options selectively purge<br>information. A separate INITIALIZE entry is<br>required for each option selected. Selecting FP<br>results in an automatic system selection of AL. The<br>system deletes all existing files, including a<br>system deadstart file, from a device initialized<br>with the AL option. CTI, MSL, and HIVS information<br>is not deleted when a device is initialized with the<br>AL option. You cannot initialize the device from<br>which you are deadstarting. You should initialize a<br>device if you just loaded CTI, HIVS, or MSL on it.                                                                                                                                                                                            |
|       | No options (except AL and FP) are processed until<br>deadstart is completed. At that time, the K display<br>is requested and you must enter the family name (FM)<br>and device number (DN) of the device to be<br>initialized. This is a final check to ensure that<br>the correct device is being initialized; the<br>selected options are then processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|       | If permanent files are to reside on the device being<br>initialized, the EQPDECK should contain a PF entry<br>for that device. The PF entry corresponds to the<br>EST ordinal specified in the EQ entry and indicates<br>that permanent files can reside on the device. If<br>the EQPDECK displayed contains a PF entry for the<br>device being initialized, a new PF entry is not<br>required unless the existing entry is to be altered,<br>or the associated EQ entry is altered. Redefining<br>the existing EQ entry clears all associated<br>attributes. In addition, if PF entries do not exist<br>in the EQPDECK, initializing the device causes a<br>default family name and device number to be<br>assigned. Thus, it is necessary to reestablish the<br>PF entry via the console keyboard if the device is<br>to remain a permanent file device. For this reason,<br>it is recommended that the PF entry for all mass<br>storage devices used for permanent files reside in<br>the EQPDECK. Although this is recommended, it is<br>not required. |

## Table 2-1. EQPDECK Entries (Sheet 3 of 3)

| Entry                                                          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                | If the EQ entry in the EQPDECK displayed indicates<br>that the status of a particular mass storage device<br>is off when the INITIALIZE entry is made, initialize<br>status is maintained and occurs automatically when<br>the DSD command ON is entered for that device during<br>normal system operation.                                                                                                                                                                                         |
|                                                                | Note that initialization of mass storage devices can<br>also be accomplished during normal system operation<br>via the DSD command INITIALIZE.                                                                                                                                                                                                                                                                                                                                                      |
| PRESET,n.                                                      | Initializes tables (MST, TRT, MRT, and DAT) on the<br>link device that are required for the management of<br>shared multimainframe mass storage devices. The<br>entry is valid only for level 0 deadstarts by the<br>first mainframe in the multimainframe complex to<br>deadstart. This entry is valid only when entered<br>from the console keyboard. That is, the PRESET<br>entry cannot be included as part of the EQPDECK on<br>the deadstart file.                                            |
|                                                                | n Number of shared devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                                                | If you do not specify n, the link device is preset,<br>and the amount of table space reserved for the<br>shared devices is determined by the number of shared<br>device entries in the EQPDECK.                                                                                                                                                                                                                                                                                                     |
| PRESET=est <sub>1</sub> ,est <sub>2</sub> ,,est <sub>n</sub> . | Presets independent shared devices in a<br>multimainframe complex. It is valid only on a<br>level 0 deadstart by the first mainframe in the<br>multimainframe complex. This entry is valid only<br>when entered from the console keyboard. That is,<br>the PRESET entry cannot be included as part of the<br>EQPDECK on the deadstart file.                                                                                                                                                         |
|                                                                | est <sub>i</sub> EST ordinal of independent shared device                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| RESET=estl,est2,,est <sub>n</sub> .                            | Rescinds all device-related attributes except those<br>specified on the EQ entry. It restores the values<br>specified with the last encountered EQest entry. If<br>the DOWN command was specified, EQest <sub>n</sub> will be up,<br>but off. Ranges of ordinals are not allowed; each<br>ordinal must be entered individually. This entry is<br>valid only when entered from the console keyboard.<br>That is, the RESET entry cannot be included as part<br>of the EQPDECK on the deadstart file. |

. . .

# **MODIFYING THE APRDECKs**

After completing all EQPDECK modifications, you can also modify the default APRDECK, the APRDECK for a specific equipment, or the IPRDECK being used. You can modify an APRDECK only when you are initializing the corresponding equipment. If no changes need to be made to any APRDECK, but you do need to modify the IPRDECK, refer to Modifying the IPRDECK later in this section.

The APRDECK contains entries identifying areas of mass storage that are not usable (flaws). The APRDECK used can vary from equipment to equipment. One of the parameters specified when an equipment is defined in the EQPDECK is the APRDECK number that applies to that equipment. The default (APRD00) is selected if this parameter is not specified.

To modify an APRDECK, enter

NEXT.

while the EQPDECK or EQPINST is being displayed. The APRINST display describes the valid entries. You can toggle between the APRDECK and APRINST. Enter the changes or additions to the APRDECK from the console keyboard (refer to section 3, Deadstart Decks, for a description of the entries).

If there are no changes to the APRDECK displayed, enter

NEXT.

to go to the next APRDECK. Repeat this process until the appropriate APRDECK is displayed or until you have changed all APRDECKs needing changes.

After all APRDECK modifications are complete, you can skip to the IPRDECK by entering:

IPR.

Refer to Modifying the IPRDECK, next, for more information. Otherwise, to indicate that all modifications to the APRDECKs are complete and you want to begin loading the system, enter:

GO.

## **MODIFYING THE IPRDECK**

The IPRDECK contains installation parameters that describe the mode of system operation. IPRDECK modification is seldom required during deadstart since nearly all IPRDECK commands are also valid DSD commands that make the same changes during normal system operation. Generally, installation parameters changed during normal operations (with DSD commands or by modifying the IPRDECK) are retained only across a level 3 recovery deadstart.

After entering

IPR.

when all the CMRDECK, EQPDECK, or APRDECK modifications are complete or after repeatedly entering

NEXT.

to step through all the APRDECKs, the instruction display entitled IPRINST appears on the console screen(s). This display defines all valid IPRDECK entries. Most of these entries are also valid DSD commands.

To view the contents of the IPRDECK being used, toggle from the IPRINST display to the IPRDECK display. If either the IPRDECK or IPRINST overflows two screens, you can page the display.

Enter the appropriate changes or additions from the console keyboard. These entries can be made while either IPRINST or IPRDECK is being displayed. A console entry supersedes the value currently specified in the IPRDECK.

## NOTE

The modified IPRDECK remains in effect only until the next level 0, 1, or 2 deadstart is performed. Changes to the IPRDECK are retained if a level 3 recovery deadstart is performed. If you want these changes to take place on the next level 0 deadstart, make the appropriate changes to the IPRDECK after NOS is up and running and use LIBEDIT to replace the record on the deadstart file.

For complete information concerning IPRDECK entries, refer to section 3, Deadstart Decks, and to section 5, DSD Commands.

To indicate that changes to the CMRDECK, EQPDECK, APRDECK, and/or IPRDECK are completed and you want to begin loading the system, enter:

GO.

# LOADING THE SYSTEM

If you are performing a level 0 or level 2 deadstart, the system library is automatically loaded from the deadstart file to each mass storage device specified in the EQPDECK as a system device. If no system device is specified, the system is loaded on the first nonremovable mass storage device in the equipment status table.

Mass storage labels are validated for all levels of deadstart. This ensures that the configuration matches the one specified in the EQPDECK. Normally, the device label validation display appears for only a few seconds. However, this display remains longer (from 30 to 120 seconds) if 834 disk units must first be automatically spun up in order to validate their labels.

If you specify a level 1 or level 3 recovery deadstart, the system library is not reloaded. In this case, the deadstart file is rewound and is not accessed again until another deadstart operation is performed. The system library is recovered from checkpoint information on mass storage. Central memory tables such as the system file name table (FNT), executing job table (EJT), queued file table (QFT), equipment status table (EST), and track reservation table (TRT) are either recovered from checkpoint information for level 1 or from central memory (and the link device, extended memory, if in multimainframe mode) for level 3.

If a deadstart error occurs, a message appears on the right console screen and, depending upon the nature of the error, deadstart processing may halt. Refer to Error Processing later in this section for complete information and corrective action. If the system is being loaded (level 0 or 2 only), the name of each system library program is also displayed on the right console screen as it is being loaded. This allows you to monitor deadstart progress.

The left console screen may display the message ENTER DATE YY/MM/DD. You can enter the date while the system is being loaded.

#### ENTERING THE DATE AND TIME

Each time a system deadstart function is performed, it is necessary to enter the current date and time. The system uses the date and time (updated every second) for dayfile messages and for permanent file catalogs and directories for files being accessed. This includes the creation, last modification, and last access date and time for each permanent file in the system. It is important to enter the correct date and time in order to accurately maintain these system records. If you are performing a level 3 recovery deadstart, it is possible to recover the date and time from the previous system deadstart. However, this is not recommended since the new date and time recorded for system records would no longer be accurate.

When the system loading (or recovery) phase of deadstart is about to begin, the system checks for the presence of a wall clock chip. If the clock is present, the date and time are automatically read from it. If the clock is not present, the following message appears on the left console screen requesting entry of the current date.

ENTER DATE YY/MM/DD.

Enter the current date, followed by CR, in this format:

yy/mm/dd.

- yy Year; 00 through 99.
- mm Month; 01 through 12.
- dd Day; 01 through nn (nn is the number of days in the month).

For deadstart levels 0, 1, and 2, pressing CR without first entering the date causes the system to assume the date that the deadstart file was created. For a level 3 recovery deadstart, pressing CR alone recovers both the previous date and time (time entered during the last deadstart plus time accumulated until this deadstart).

When the system accepts the date entry, it displays the following request for entry of the current time.

ENTER TIME HH.MM.SS.

Enter the current time in this format:

hh.mm.ss.

hh Hour; 00 through 23.

- mm Minute; 00 through 59.
- ss Second; 00 through 59.

For deadstart levels 0, 1, and 2, pressing CR without first entering the time causes the system to set the time to 00.00.00. If you enter CR alone following the date prompt on a level 3 recovery, this prompt to enter time does not appear (the previous time is assumed).

# **INITIATING JOB PROCESSING**

DSD commands specified in the IPRDECK automatically initiate normal job processing except on a level 3 recovery where you must enter AUTO. If a level 1 or level 3 recovery deadstart is being performed, the system recovers all jobs and active files and resumes normal operation immediately. However, if an initial deadstart (level 0) or level 2 recovery deadstart is being performed, job processing may not be initiated immediately. The time of initiation depends upon the time it takes to load the system from the deadstart file (you can monitor progress on the right console screen). If file loading is not completed when the time entry is made, the DSD commands specified in the IPRDECK are displayed on the left screen. Until file loading completes, you can clear one or more of the DSD commands.

Clearing a command prevents it from being executed when file loading completes. In this case, you must manually enter the commands necessary to initiate job processing from the console keyboard.

To initiate job processing, enter either:

AUTO.

or

MAINTENANCE.

Following entry of the AUTO or MAINTENANCE command during an initial (level 0) deadstart, the deadstart sequencing process begins. Deadstart sequencing causes job processing to be suspended until all system files in the default family are initiated. To initiate a family other than the default, enter the command:

X.ISF(FM=family)

Parameter

#### Description

family Alternate family of devices.

For additional information concerning the ISF command and deadstart sequencing, refer to section 20, System File Initialization.

Normal job processing begins after the deadstart sequencing job completes. If the AUTO command is entered, the subsystems enabled in the IPRDECK are automatically assigned to specified control points. Assuming that all standard subsystems are set to be enabled, the system calls them to specific control points as shown in the following example.

| Control Point Number | Job Sequence Name | Activity                                   |
|----------------------|-------------------|--------------------------------------------|
| 1                    | IAF               | Interactive Facility.                      |
| 2                    | NAM               | Network Access Method.                     |
| 3                    | RHF               | Remote Host Facility.                      |
| 4                    | SMF               | Screen Management Facility.                |
| 5                    | NEXT              | Available for automatic system assignment. |
|                      |                   |                                            |
| •                    | •                 |                                            |
| n-3                  | NEXT              |                                            |
| n-2                  | MAG               | Magnetic tape subsystem executive routine. |
| n-1                  | BIO               | Central site batch input/output.           |
| n                    | RBF               | Remote Batch Facility.                     |
| n+1                  | SYS               | System.                                    |

The MAINTENANCE command performs the same function as the AUTO command. Additionally, it assigns several maintenance routines, according to mainframe type, to available control points and runs them as normal jobs with minimum queue and CPU priorities. These are CPU or central memory test routines designed to detect hardware errors. The routines display error messages either at the control point on the B,O display or in the system error log. To display the error log, enter:

#### A,ERROR LOG.

You should monitor these routines from time to time. If a maintenance routine displays an error message indicating a hardware malfunction occurred, call a customer engineer. It is recommended that these programs be run at all times. The maintenance programs use little memory, are run at minimum CPU and queue priority, and are automatically rolled out if necessary; thus, system performance is not severely affected. Descriptions of the maintenance routines are in the NOS Online Maintenance Software Reference Manual.

in is the number of control points defined in the CMRDECK.

# PREPARING FOR RECOVERY DEADSTART

Sometimes during system operation an uncorrectable error occurs that prevents further system activity. Often the situation can be corrected by deadstarting the system and recovering prior activity. The success of such a recovery depends upon the severity of the problem and the extent to which system information is destroyed. There are three levels of recovery deadstart available (levels 1, 2, and 3). Table 2-2 lists each deadstart level, including level 0 (initial deadstart), and describes the extent of recovery possible.

If the MS VALIDATION installation option is enabled during a level 1 or 2 recovery, or if both the MS VALIDATION and PF VALIDATION options are enabled during a level 3 recovery, the system:

- Verifies selected mass storage files.
- Checks files identified in the queued file table (QFT) to ensure that all tracks in the chain are reserved and that no circular linkage exists.
- Depending on file type, checks the track reservation table (TRT) to ensure that the file is preserved.
- Checks all preserved files for proper length.

If the system encounters a verification failure, it clears the queued file table entry but does not release disk space assigned to the file. If a length error is detected, the system sets error idle status and terminates recovery operations on the device. To recover from an error idle condition, refer to Error Idle Recovery under Error Processing later in this section.

During level 0 deadstart, the system verifies the length of preserved files regardless of the setting of the MS VALIDATION option. If a length error is detected, the system reads the disk chain to determine the correct length of the file, issues a message to the B,O display, and stops recovery of the device. To alter the EOI for the file and proceed with recovery, enter:

GO,SYS.

To terminate recovery of the device, enter:

PAUSE, SYS.

## Table 2-2. Levels of System Deadstart

| Deadstart<br>Level | Jobs                                         | Queued Files                       | Permanent<br>Files | System                             | System<br>Dayfiles |  |
|--------------------|----------------------------------------------|------------------------------------|--------------------|------------------------------------|--------------------|--|
| 0                  | Input and output<br>queues recovered.†       | No •                               | Yes.               | No.                                | Yes.tt             |  |
| 1                  | Recovered from<br>last checkpoint.           | Recovered from<br>last checkpoint. | Yes.               | Recovered from<br>last checkpoint. | Yes.               |  |
| 2                  | Recovered from<br>last checkpoint.           | Recovered from<br>last checkpoint. | Yes.               | No .                               | Yes.               |  |
| 3                  | Recovered from<br>CM copy of EJT. <b>†††</b> | Recovered from<br>CM copy of QFT.  | Yes.               | Yes.                               | Yes.               |  |

files. Input files associated with jobs currently executing are returned to the input queues, unless the device they reside on is initialized. Permanent files are recovered unless the device is initialized.

The following topics provide general information concerning each level of system deadstart and recommended steps of preparation.

## CAUTION

Before attempting any level of recovery deadstart (including level 0), examine the current status codes listed for each mass storage device in the disk status display (E,M). Delay deadstart if status code C (checkpoint requested) appears for any device. When the system has processed the request, status code C is cleared (within 30 seconds). Refer to the NOS 2 Operations Handbook for complete information concerning the disk status display (E,M). Failure to observe this caution may result in the loss of permanent file information.

#### LEVEL 3 RECOVERY DEADSTART

Usually you perform a level 3 recovery deadstart following an equipment or system malfunction (for example, channel or PP hung), providing the system remains intact. Basically, the system FNT, QFT, EJT, TRT, EST, and control-point areas of central memory must be intact in order to successfully perform a level 3 recovery deadstart. However, unless you can determine that central memory is no longer intact, attempt a level 3 recovery deadstart before a level 0 deadstart. This is recommended because system activity, as it existed at the time of the malfunction, can best be recovered by performing a level 3 recovery deadstart. Only PP memory confidence testing occurs during a level 3 recovery deadstart; central memory is not affected.

Requests for device checkpoint are retained over a level 3 recovery. Therefore, if a system malfunction prevents a device checkpoint from being done, the checkpoint is processed after level 3 recovery is successfully completed. If a level 3 recovery fails, always do another level 3 recovery with the ABORT option selected before doing a level 0 deadstart. This ensures that all checkpoint processing is done correctly.

On a level 3 deadstart the CMRDECK, the EQPDECK, the APRDECKs, and the IPRDECK cannot be viewed or changed. The CMRDECK, the EQPDECK, the APRDECKs, and the IPRDECK specified during the last level 0 deadstart remain in effect. If you set the CMRDECK switch (bit 6 in word 13 of the deadstart panel) or select the D=Y option on the CTI \*P\* display; the system halts and displays level 3 deadstart options. The options and their default values are displayed on the left screen (figure 2-6) and instructions on the right screen (figure 2-7).

| LEVEL 3 OPTIONS |     |
|-----------------|-----|
| ABORT.          | NO  |
| ABORT, B.       | NO  |
| AUTOLOAD.       | YES |
| GRENADE.        | NO  |
| AUTO.           | YES |

Figure 2-6. Level 3 Deadstart Left Screen Display

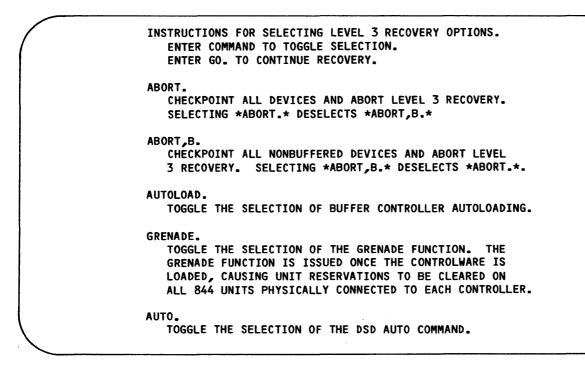

Figure 2-7. Level 3 Deadstart Right Screen Display

Entering a command will toggle the level 3 deadstart selections. The ABORT command checkpoints all the devices and aborts level 3 recovery. Selecting the ABORT command automatically deselects the ABORT,B command. The ABORT,B command checkpoints all the nonbuffered devices and aborts level 3 recovery. Selecting the ABORT,B command automatically deselects the ABORT command. The AUTOLOAD command toggles the selection of buffer controller autoloading. The GRENADE command toggles the selection of the grenade function. The AUTO command toggles the selection of the DSD AUTO command. Refer to table 2-1 for more information about the AUTOLOAD and GRENADE commands. When you are done making changes, enter

GO.

to continue the deadstart recovery. If you choose not to display the level 3 options, the default values are used.

A level 3 recovery deadstart is impossible after:

- An attempted checkpoint recovery (level 1).
- An aborted level 0 (initial) deadstart.
- The MREC utility (refer section 8, K-Display Utilities) has been run for the machine to be deadstarted while in multimainframe mode.

It is recommended that you stop system activity prior to beginning the system deadstart procedure. To accomplish this, enter the following DSD commands.

| Command             | Description                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E,M.                | Displays the disk status display (E,M).                                                                                                                                                                                                                                                                          |
| CHECK POINT SYSTEM. | Provides for termination of job processing and for writing the<br>contents of central memory tables to mass storage. For a<br>complete description of this process, refer to the CHECK POINT<br>SYSTEM command in section 5, DSD Commands.                                                                       |
| STEP.               | Prevents the system from processing PP requests. This stops<br>all central memory input/output (I/O) operations. You should<br>enter the STEP command after all device checkpoints are<br>completed. Determine checkpoint status from the disk status<br>display (E,M) (refer to the NOS 2 Operations Handbook). |

## NOTE

To recover interactive users after a level 3 recovery, sense switch 1 must be set in the IAF procedure. Sense switch 1 is set by default in the released IAF procedure.

#### LEVEL 1 RECOVERY DEADSTART

Usually you perform a level 1 recovery deadstart to resume normal processing following maintenance procedures. The system, all jobs, and all active files are recovered from checkpoint information on mass storage.

NOTE

A level 1 recovery deadstart is not intended to be a recovery process after a system/ equipment malfunction. You should never attempt it after a level 3 recovery deadstart fails.

Level 1 recovery is also useful in system test situations. If two systems are being alternated, separate mass storage devices and tapes<sup>†</sup> must be available for both systems. Tapes are not repositioned after a level 1 deadstart. Thus, if a job was previously assigned to the tape unit that has been used for deadstarting, the job cannot be recovered. The tape unit should be left unloaded after recovery until it is no longer assigned to the job (job aborted).

The following rules apply when performing a level 1 recovery deadstart.

- The DSD command CHECK POINT SYSTEM must have been successfully completed immediately before the end of the last NOS operating period.
- The contents of the extended memory must not be destroyed from the time of the CHECK POINT SYSTEM command.
- Memory dumps must be completed before level 1 recovery deadstart begins since memory confidence testing destroys the contents of both central memory (except on CYBER 180-class machines) and PPs.
- The mass storage equipment configuration must be the same as specified during the most recent level 0 deadstart; that is, the same EQPDECK must be used.
- The system devices (mass storage devices on which the system library resides) must be the same as or fewer than those specified during the most recent level 0 deadstart.

<sup>&</sup>lt;sup>†</sup>Separate tapes are necessary only if tape jobs are being checkpointed.

It is recommended that you stop system activity before beginning the system deadstart procedure. To accomplish this, enter the following DSD commands.

| Command             | Description                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| CHECK POINT SYSTEM. | Provides for termination of job processing and for writing the contents of central memory tables to mass storage. |
| UNLOCK.             | Necessary only if console is currently locked.                                                                    |
| STEP.               | Prevents the system from processing PP requests. This stops all central memory I/O operations.                    |

#### LEVEL 2 RECOVERY DEADSTART

Usually you perform level 2 recovery deadstart in system test situations; it is not recommended for the normal production environment. If you select level 2 recovery, all jobs and active files are recovered from checkpoint information on mass storage as in level 1 recovery. However, no attempt is made to recover the system. Instead, the system is loaded from the deadstart file as in level 0 deadstart. In all other respects, level 2 recovery is identical to that described for level 1, and all level 1 rules apply.

## LEVEL O INITIAL DEADSTART

Use level 0 or initial deadstart in cases where a recovery deadstart is not possible. This is a complete or initial load from the deadstart file. Only preserved files, which include permanent files, queued files, and system dayfiles, are recovered (preserved files are recovered on all levels of system deadstart). Because memory confidence testing destroys the contents of central memory (except on CYBER 180-class machines) and PPs, all memory dumps must be completed before deadstart begins.

NOTE

If the machine is the first machine being deadstarted in a shared device multimainframe environment, you must enter a PRESET command (refer to section 13, Multimainframe Operations).

# **ERROR PROCESSING**

If no CTI display appears when you initiate a deadstart, perform the following steps as needed. After each step, reinitiate the deadstart to see if the problem has been eliminated.

Deadstart from tapet:

- 1. If the unit select switch on the deadstart tape unit is not on (tape does not move), check the channel, controller, and unit selections on the deadstart panel or display to ensure they are set correctly.
- 2. If the unit select switch is on, the correct unit was selected; however, check word ll of the deadstart panel or display to ensure it is set correctly.
- 3. Ensure that a 7-track tape is not mounted on a 9-track drive or vice versa. Also, ensure that a deadstart tape is not mounted on a tape unit that does not support the density of the deadstart tape.
- 4. Ensure that the deadstart tape is an I-format unlabeled tape.
- 5. Ensure that the card reader and tape unit (667 or 669 only) are not on the same channel and that the card reader is not on a channel with a PP. Also, ensure that two or more units do not have the same physical unit number.
- 6. If still no display appears after initiating the deadstart, there might be a parity error on one of the first records of the deadstart tape or the magnetic tape controller might have detected a channel parity error on a CYBER 170 Computer System.

<sup>&</sup>lt;sup>†</sup>When deadstarting a CYBER 180-class machine, the disk containing the CIP module must be used.

Deadstart from disk:

- la. For an 844 or 885 disk, ensure that the disk is spinning, the READY light is on, and the SELECT light is on.
- lb. For an 834 disk, ensure that the start button is pushed in and the power switch is on.
- 2. Ensure that the disk has the CIP module loaded.
- 3. Ensure that the deadstart panel or display is set correctly.
- 4. Select an alternate channel.
- 5. If still no display appears after initiating the deadstart, there might be a parity error on one of the first records of the deadstart file or the disk controller might have detected a channel parity error on a CYBER 170 Computer System.

For a proper understanding of the problems that can occur during deadstart, you should be familiar with several basic concepts. For example, because most errors that occur involve mass storage devices, you should be familiar with their use in the system. Each mass storage device has a label that contains descriptive information about its contents. For certain levels of recovery deadstart, this information must be consistent with corresponding information either contained in central memory or provided through deadstart procedures. Conflicts can result in the system issuing deadstart error messages. An attempt is made to recover all mass storage devices defined in the EST during all levels of system deadstart.

The specific recovery function performed depends upon the level of deadstart selected. Table 2-3 describes the recovery function performed for each deadstart level and the types of errors you can encounter. The system response to errors and the recommended action are also listed.

Refer to the NOS 2 Operations Handbook for information concerning all deadstart messages.

|                                                                                 |                       |                                                                                                                                  |                                                           |                                                                                                                                                                                                                                                               | ····                                                                                                                                                                                                                     |

.

Table 2-3. Mass Storage Device Recovery (Sheet 5 of 5)

## **ERROR IDLE RECOVERY**

Setting the device error idle status helps to prevent error propagation by inhibiting new file assignment on the device and by inhibiting any new PFM, PFLOAD, or QLOAD activity from occurring on the device. The error idle status is indicated by the EI error code on the E,M display. Error idle status is set when:

- Mass storage read or write errors occur in the catalog or permit chains.
- There is an incorrect user index in the permit sector.
- Direct or indirect access files are too long or too short.

Correcting the error idle condition requires total initialization of the affected device. This can be accomplished online for a removable device, but must be performed during a level O deadstart for a nonremovable device. Suggested recovery procedures follow.

#### **Removable Device**

- 1. Dump inactive queued files, if present on the device (QDUMP).
- 2. Dump permanent files (PFDUMP).
- 3. Perform a total initialization of the device (INITIALIZE,AL,est.). If the error idle status was caused by a mass storage error, the appropriate track should be flawed.
- 4. Reload inactive queued files, if applicable (QLOAD).
- 5. Reload permanent files (PFLOAD).

## Nonremovable Device

- 1. Dump queued files (QDUMP).
- 2. Terminate any dayfiles that must be saved (DFTERM).
- 3. Dump permanent files (PFDUMP).
- 4. Idle the system and perform a level 0 deadstart.
- 5. Perform a total initialization of the device affected by the error idle condition (INITIALIZE,AL,est.). If the error idle status was caused by a mass storage error, the appropriate track should be flawed.
- 6. Reload queued files (QLOAD).
- 7. Reload permanent files (PFLOAD).

# **DEADSTART DECKS**

Deadstart decks are text records that reside on the deadstart file. This section describes the following deadstart decks.

| Deck    | Description                            |
|---------|----------------------------------------|
| CMRDECK | Central memory resident deck.          |
| EQPDECK | Equipment deck.                        |
| APRDECK | Auxiliary mass storage parameter deck. |
| IPRDECK | System installation parameter deck.    |
| LIBDECK | System library deck.                   |

This section contains detailed information about how you can modify the released versions of the deadstart decks.

# CMRDECK

The central memory resident deck (CMRDECK) resides on the deadstart file as a text record that is processed during system initialization. It contains entries defining the following types of information.

- Central memory.
- Table sizes.
- Configuration information not oriented to equipment.

The deadstart file can contain up to  $100_8$  CMRDECKs. Having several CMRDECKs on the same deadstart file is advantageous because one file can deadstart several configurations. You can obtain a listing of all CMRDECKs by accessing the system file SYSTEM with an ASSIGN or COMMON command, then using the T parameter on the CATALOG command (refer to the NOS 2 Reference Set, Volume 3 for more information concerning these commands). CMRDECKs are named CMRDnn, where nn is from 00 to  $77_8$ .

You can modify the released settings of the CMRDECK in two ways: type a new entry when the CMRDECK is displayed during deadstart, or create a new deadstart file. The usual method of modifying a CMRDECK follows.

1. Deadstart, using the released deadstart file, and select the CMRINST and the CMRDECK to be displayed (refer to section 2, Deadstart).

CMRINST lists all valid CMRDECK entries. Default values, described in this section, are assumed if the entries do not appear in the CMRDECK being used. If either CMRDECK or CMRINST overflows two screens, you can page the display.

2. Modify the released version of CMRDECK by entering the changes or additions from the system console while either the CMRDECK or CMRINST is displayed. Each console entry supersedes the value currently specified in the CMRDECK (or the default value).

## NOTE

The modified CMRDECK remains in effect only until the next deadstart is performed, except for a level 3 deadstart. That is, changes to the CMRDECK are not recovered across level 0, 1, and 2 deadstarts unless a new deadstart file is created to reflect them.

3. To expedite subsequent deadstarts, modify the CMRDECK on the deadstart file using SYSGEN (refer to the NOS 2 Installation Handbook).

When constructing or modifying a CMRDECK, separate parameters with commas and terminate each entry with a period. When an error exists in an entry in a CMRDECK on the deadstart file, the CMRDECK is displayed and the error is indicated. This occurs even if you do not select the display CMRDECK option.

## **CENTRAL MEMORY DESCRIPTIONS**

The general function of central memory description entries is to assign the amount of central memory to be used for central memory resident (CMR) and the amount to be used for job processing. The simplified relationship is: the more central memory that is assigned to tables in CMR, the less is available for job field lengths.

If you will run only a few batch jobs, fewer control points may be required. Thus, you could decrease the control point area in CMR, which requires 200g words per control point.

The following entries are specified in the SET program with the released default values listed.

| Entry Format | Released<br>Default Value | Significance                                                                                                                                                                                         |
|--------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLT=number.  | 0                         | Specifies the octal number of common library table (CLT) entries allowed. The number can range from 0 to $100_8$ .                                                                                   |
|              |                           | If the table exists, the first entry is reserved for<br>the system, so you should equate CLT with the number<br>of entries you want, plus l. For example, if you<br>want three entries, enter CLT=4. |
|              |                           | Common library table entries are described in the IPRDECK entry COMLIB.                                                                                                                              |

| Entry Format | Released<br>Default Value |                                                                                                                                                          | Significance                                                                                                                                  |
|--------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| EJT=number.  | 620 <sub>8</sub>          | Specifies an octal number of entries for the executing job table (EJT). The system uses the EJT entries to keep track of executing jobs.                 |                                                                                                                                               |
|              |                           | The maximum val<br>value is 3.                                                                                                                           | we for number is $7777_8$ ; the minimum                                                                                                       |

| FOT=number.  | 10 <sub>8</sub>                       | Sets the number of entries in the family ordinal<br>table (FOT). Each family is allowed one entry in the<br>table. The first entry in the FOT is reserved for<br>system use. The system uses family name and user<br>index for job ownership and file routing. The family<br>ordinal is a 6-bit number that corresponds to a<br>particular family name. The FOT maintains the family<br>name to family ordinal relationship. If a family is<br>unloaded and later reloaded, it continues to use the<br>same family ordinal. |
|              |                                       | The maximum value for number is 1008; the minimum value is 3. The size of the FOT need not be the same for each mainframe in a multimainframe environment.                                                                                                                                                                                                                                                                                                                                                                  |
| IPD=number.  | First IPRDECK<br>on deadstart<br>file | Specifies the number of the IPRDECK to use at<br>deadstart. The IPRDECK contains installation<br>parameters. Up to 1008 IPRDECKs can exist on a<br>deadstart file; the number can range from 00 to 778.                                                                                                                                                                                                                                                                                                                     |
|              |                                       | If an IPD entry is not included in the CMRDECK, the first IPRDECK on the deadstart tape is processed and is not displayed.                                                                                                                                                                                                                                                                                                                                                                                                  |
| LDT=number.  | 0                                     | Specifies the number of central memory words allocated to the LID table. The minimum value is $0$ ; the maximum value is $1100_8$ . The value to be specified can be determined by using this formula:                                                                                                                                                                                                                                                                                                                      |
|              |                                       | (3+1id)*pid                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|              |                                       | lid is the maximum number of LIDs allowed per PID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|              |                                       | pid is the total number of PIDs in all networks defined on this mainframe.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|              |                                       | One central memory word is always allocated for the LID table header.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|              |                                       | As an example, assume lid=5 and pid=6. By using the formula, you come up with (3+5)*6=48. Adding one word for the LID table header makes 49, or 618, central memory words that should be allocated to the LID table.                                                                                                                                                                                                                                                                                                        |
| LIB=number.  | 0                                     | Specifies the number of the LIBDECK to use at<br>deadstart; the number can range from 00 to 77 <sub>8</sub> .<br>LIBDECK is a directive record used by SYSEDIT.                                                                                                                                                                                                                                                                                                                                                             |
| MID=id.      | AA                                    | Specifies the 2-character machine identification (id)<br>that is associated with the mainframe. The id<br>characters must be alphanumeric.                                                                                                                                                                                                                                                                                                                                                                                  |

|              |                           | number                                                                                                                                                                                                                        | The number of blocks (each block has a length of $102_8$ words) reserved for PP I/0. It must be sufficient to handle the demand for PP access to the buffered device I/0 handler. Ideally, there should be one block for each pool PP. More blocks mean better performance. The maximum value for the number parameter is $17_8$ . |

If name is not<br>terminated with a period, one will be                                                 |

appended. If name is 18 characters, the

last character must be a period.

<sup>†</sup> A PP that has been turned off by CTI is physically unavailable and cannot be turned on by the PPU entry.

## EQPDECK

The equipment deck (EQPDECK) resides on the deadstart file as a text record that is processed during system initialization. It contains entries defining the following types of information.

- Dayfile buffer size.
- Hardware configuration.
- File residence on mass storage devices.
- Permanent file family residence.
- Multimainframe configurations.
- Software attributes associated with hardware (such as forms code).

An EQPDECK entry is described under the type of information it defines.

The deadstart file can contain up to  $100_8$  EQPDECKs. Having several EQPDECKs on the same deadstart file is advantageous because one file can deadstart several configuraions. You can obtain a listing of all EQPDECKs by accessing the system file SYSTEM with a COMMON command, then using the T parameter on the CATALOG command (refer to the NOS 2 Reference Set, Volume 3 for more information concerning these commands). EQPDECKs are named EQPDnn, where nn is from 00 to  $77_8$ .

You can modify the released settings of the EQPDECK in two ways: type a new entry when the EQPDECK is displayed during deadstart, or create a new deadstart file. The usual method of modifying an EQPDECK follows.

1. Deadstart, using the released deadstart file, and select the EQPINST and the EQPDECK to be displayed (refer to section 2, Deadstart).

EQPINST lists all valid EQPDECK entries. Default values, described in this section, are assumed if the entries do not appear in the EQPDECK being used. If either EQPDECK or EQPINST overflows two screens, you can page the display.

2. Modify the released version of EQPDECK by entering the changes or additions from the system console while either the EQPDECK or EQPINST is displayed. Each console entry supersedes the value currently specified in the EQPDECK (or the default value).

# NOTE

The modified EQPDECK remains in effect only until the next deadstart is performed, except for a level 3 deadstart. That is, changes to the EQPDECK are not recovered across level 0, 1, and 2 deadstarts unless a new deadstart file is created to reflect them.

3. To expedite subsequent deadstarts, modify the EQPDECK on the deadstart file using SYSGEN (refer to the NOS 2 Installation Handbook).

Several equipment status displays are available during deadstart (refer to section 2, Deadstart).

When constructing or modifying an EQPDECK, the following restrictions apply.

• The equipment assignment entry (EQ) must precede any other assignments for a device (such as assigning it for permanent file, system, or temporary file use). If you redefine the EQ entry (by clearing the entry and retyping a new entry or by changing the device type in the entry), reenter all other assignments for that equipment. If you need to modify an EQ entry, you need only enter the changes rather than reentering the entire entry. You do not need to reenter other assignments for that equipment. This is especially useful for changing channels or units and for reconfiguring around hardware malfunctions.

Example:

The following mass storage assignments are in the EQPDECK.

EQ7=DI,ST=ON,UN=60,CH=1.

PF=7,F,125,125,SYSTEM,3,200.

If you want to specify unit 70 rather than 60, you need only enter:

EQ7=DI,UN=70.

You do not need to modify the PF entry.

- EST ordinals range from 1 to 7778. This range depends on the value of ESMX (refer to PPCOM parameters in the NOS 2 Installation Handbook). Ordinals 1 through 4 are reserved for psuedoequipment EST entries that are automatically defined by the system and cannot be changed. Ordinal 5 is reserved for extended memory equipment (refer to EQ - Extended Memory EST Entry later in this section). This entry need not be defined, but cannot be used for any other device type.
- The device from which you are deadstarting must be defined.
- Commas must separate parameters.
- A period must terminate each entry.
- Except where explicitly specified that controllers and/or equipment can be shared between mainframes, assume they cannot be shared. For example, NOS does not support sharing a two-channel tape controller between mainframes; nor does it support sharing mass storage controllers, except as specified in section 13, Multimainframe Operations.

When an error exists in an entry in an EQPDECK on the deadstart file, the EQPDECK is displayed and the error is indicated. This occurs even if you do not select the display EQPDECK option or if you enter GO after displaying the EQPDECK.

# **DAYFILE DESCRIPTIONS**

One of the functions of dayfile description entries is to assign the amount of central memory to be used for buffers. The more central memory assigned to dayfile buffers in CMR, the less central memory available for job field lengths.

If, for example, you need a large portion of central memory to run a job, it might be advisable to decrease the size of the dayfile buffers area in CMR to accommodate that job. However, when dayfile buffers are smaller, the information stored in them is written to mass storage more often, which requires more system overhead.

The following entries are specified in the SET program with the released default values listed.

| Entry Format        | Released<br>Default Value |                                                                                                                                                                                                                                                                                                                                                                                                               | Significance                                                                                                                                                                                                                                                                                                                                                     |  |  |  |

If 0 (zero) is<br>specified, messages issued to the                                                                                                                                                          |  |  |  |

account dayfile are discarded.

Released Default Value

DAYFILE=est,length.

,400<sub>8</sub>

# Significance

Sets the residence of the system dayfile and the length of the system dayfile buffer.

The dayfile buffer contains the dayfile information, which is maintained in the same way as the account dayfile buffer. It resides in CMR in the dayfile buffer area.

#### Parameter

est The 1- to 3-digit octal EST ordinal of equipment on which the dayfile is to reside. A null value means the system uses the first system device it can find. The residence of this dayfile is normally determined by the recovery of the existing dayfile. Use this parameter if no system dayfiles are recovered.

Description

length The 3- or 4-digit octal length of the system dayfile buffer in CMR; must be a multiple of 100g and less than or equal to 1000g. If 0 is specified, messages issued to the system dayfile are discarded.

ERRLOG=est,length.

,100<sub>8</sub>

Sets the residence of the error log and the length of the error log buffer.

The error log is a record of hardware error and status messages. This information is maintained in the same way as the account dayfile buffer.

## Parameter Description

est The 1- to 3-digit octal EST ordinal of equipment on which the error log is to reside. A null value means the system uses the first system device it can find. If the existing error log is recovered, the error log buffer resides on that equipment and the est parameter is ignored.

length The 3- or 4-digit octal length of the error log buffer in CMR; must be a multiple of 100g and less than or equal to 1000g. If 0 is specified, messages issued to the error log are discarded.

| Entry Format        | Released<br>Default Value | Significance                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                             |  |  |
|---------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| MAINLOG=est,length. | ,100 <sub>8</sub>         | Sets the residence of the binary maintenance<br>log and the length of the binary maintenance<br>log buffer. The binary maintenance log is a<br>record of hardware diagnostic information. |                                                                                                                                                                                                                                                                                                                                                             |  |  |

discarded.

### **GENERAL DESCRIPTION OF EQUIPMENT ASSIGNMENT ENTRIES**

The general format of the EQ entry is:

 $EQest=type, keyword_1 = value_1, \dots, keyword_n = value_n$ .

Keyword=value entries are order independent.

Depending on the type of equipment being defined, certain keywords are required, while others are optional, as shown in table 3-1.

You can redefine an EST entry by entering an EQ entry for the EST ordinal with a different equipment type. This action clears the original entry before creating the new entry. You can also modify an EST entry by entering an EQ entry with the same equipment type and only the keyword(s) you want changed.

| Equipment<br>Type | Required<br>Keywords     | Optional<br>Keywords | Equipment<br>Type | Required<br>Keywords | Optional<br>Keywords |
|-------------------|--------------------------|----------------------|-------------------|----------------------|----------------------|
| сс                | EQ,CH                    | ST                   | DV                | UN,CH,HT             | ST,AP                |

Table 3-1. Required And Optional Keywords

# **Clear EST Assignment Entry**

Use the following entry to clear an assignment that currently exists for an EST ordinal. Clearing the assignment does not clear flaw entries for that equipment. The EQ=0 entry is not required when you are assigning the EST entry to a different type of equipment.

EQest=0.

or

EQest=.

### Parameter

## Description

est

EST ordinal of the equipment; est can be from 5 to 7778.

60459300 D

### EQUIPMENT ASSIGNMENTS: NONMASS STORAGE

The following EST entries are described in this subsection.

- Nonstandard equipment
- Pseudoequipment
- Unit record equipment
- Magnetic tape equipment
- Mass Storage Facility equipment
- Mass Storage Archival Subsystem equipment
- Stimulator equipment
- Network processing unit
- Network access device
- Two-port multiplexer
- MAP III or IV equipment
- 6683 Satellite Coupler
- CYBERPLUS ring port equipment

### Nonstandard Equipment EST Entry

The nonstandard equipment EST entry allows you to define nonstandard equipment or to add site debugging modifications.

Use the following format to enter the actual octal value that is to reside at that EST ordinal.

EQest=\*\*,W0=value0,W1=value1

| Parameter          | Description                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| est                | EST ordinal of the equipment; est can be from 6 to 777 <sub>8</sub> .                                                                                                                          |
| value <sub>i</sub> | The 1- to 20-digit octal value; this value is entered in the EST word i for the specified ordinal. The word is right-justified and zero-filled if value <sub>i</sub> has fewer than 20 digits. |

### Pseudoequipment

The system automatically defines EST ordinals 0 through 4 as psuedoequipment EST entries; they cannot be used for other equipment definitions. You cannot declare, change, or remove psuedoequipments.

Ordinal O (RD)

This ordinal reserves an EST entry and MST entry to be used for device reconfiguration.

#### Ordinal 1 (DS)

This ordinal reserves an entry for the system display console.

### Ordinal 2 (NE)

The system uses 2 internally to signify that a file is assigned, but that no space exists on the device. If a read is tried, end-of-information (EOI) status occurs. If a write is attempted, the data is discarded.

For example, you can use ordinal 2 with the permanent file utility (PFDUMP) to validate the integrity of a permanent file device, without taking the time to actually create a dump file on tape. In this case, enter:

X.DIS. ASSIGN,NE,TAPE. PFDUMP.

This causes all dump data to be discarded, even though the permanent file device is read and informative messages about the permanent file device are issued to the system console. These messages are described in the NOS 2 Operations Handbook.

#### Ordinal 3 (TE)

If an association is established between file name and volume serial number with an ASSIGN, LABEL, REQUEST, or VSN command, the system automatically enters EQ3 in the file's FNT/FST entry. When a tape having the desired volume serial number is assigned to the file, the system replaces EQ3 in the file's FNT/FST entry with the EST ordinal of the tape unit on which the tape is mounted. If a file that has had the file name and volume serial number association established by a VSN command is returned prior to attempting to assign the tape equipment to the file, the FNT/FST entry is canceled.

# Ordinal 4 (TT)

The system assigns to this equipment a file used for either input form or output to an interactive terminal. This allows the system to determine whether a file requires the special handling needed to accomplish terminal input/output. Byte 4, set by the NAMIAF IPRDECK entry, stores the number of network terminals.

### Unit Record Equipment EST Entry

A unit record equipment EST entry defines card readers, card punches, and line printers.

EQest=type,ST=status,TN=tn,EQ=eq,CH=ch,ID=id,FC=fc,PS=ps.

or

EQest=type-P,ST=status,TN=tn,EQ=eq,CH=ch,ID=id,FC=fc,PS=ps.

Parameter

EST ordinal of the unit record equipment; from 6 to  $777_8$ .

type

est

Unit record equipment type; NOS supports the following unit record equipments.

-

| type | Equipment                    |  |  |  |  |
|------|------------------------------|--|--|--|--|
| CR   | Card reader<br>405-3447/3649 |  |  |  |  |
|      | Card punch                   |  |  |  |  |
| CP   | 415-3446/3644                |  |  |  |  |
| CP   | 415-30                       |  |  |  |  |
|      | Line printer                 |  |  |  |  |
| LP   | Any line printer             |  |  |  |  |
| LR   | 580-12                       |  |  |  |  |
| LS   | 580-16                       |  |  |  |  |
| LT   | 580-20                       |  |  |  |  |

P

TN=tn

Specifies that a 580 printer is equipped with a programmable format controller.

Print train for local batch line printer; from 1 to 7. NOS supports the following print trains.

| <u>tn</u> | Print Train | Description                                                                                |
|-----------|-------------|--------------------------------------------------------------------------------------------|
| 1         | 595-1/596-1 | CDC graphic 63/64-character set.                                                           |
| 5         | 595-5/596-5 | ASCII graphic 63/64-character set.                                                         |
| 6         | 595-6/596-6 | ASCII graphic 95-character set.                                                            |
| 7         | 595-6/596-6 | ASCII graphic 95-character set used as an ASCII 63/64-character set (as on a 595-5/596-5). |

If you set a nonsupported print train value, tn defaults to a supported value. If you omit tn or specify 2 or 3, the actual value of tn is 1. If you specify 4, the actual value is 5.

ST=status

EQ=eq

Specifies whether unit record equipment is available for system use; enter one of these values:

| status | Description                                                                             |
|--------|-----------------------------------------------------------------------------------------|
| ON     | Unit record equipment is available.                                                     |
| OFF    | Unit record equipment is ignored during system operation.                               |
|        | nber for equipment; from 0 to 7. To determine the at the dial switch on the controller. |

### Parameter

# Description

CH=ch

Number of channel to which unit record equipment is connected; from 0 to 138 and from 208 to 338.

### NOTES

When performing a coldstart, a card reader must be available on channel 12g or 13g.

To ensure that all printers are restored to their original states (such as 8 lines per inch and auto page eject) after a master clear has been issued, all unit record equipment should be available on dedicated channels. If it is not, printers revert to 6 lines per inch, and no auto page eject status after a master clear is issued.

ID=id The 1- or 2-digit octal numeric identifier assigned to the device; from 0 to 678. This id is assigned to any output created by a job. For card readers, all jobs loaded from this card reader are assigned the identifier id.

FC=fc The 2-character optional forms code assigned to a line printer or card punch. If the forms code is not present, the forms code field is cleared. The forms code must either be null (not specified) or in the range from AA to 99.

### NOTE

The forms code cannot be assigned to a card reader.

PS=ps Paper size, L or S, for local batch line printer. Default is L. L Long (11 inch) paper will be mounted.

S Short (8 1/2 inch) paper will be mounted.

Examples:

EQ11=CR,ST=ON,EQ=4,CH=12. EQ11=CP,EQ=5,CH=12,ST=ON. EQ20=LR,ST=ON,CH=12,EQ=6,ID=15,FC=AA. EQ21=CR,ID=15,ST=ON,EQ=7,CH=12. EQ22=LT-P,TN=6,ST=ON,EQ=2,CH=12.

# Magnetic Tape Equipment EST Entry

The released tape subsystem supports a maximum of 16 magnetic tape units. The minimum number of magnetic tape units that NOS requires is two 667s, 669s, 677s, or 679s. The format of the entry is:

EQest=MT-n,ST=status,EQ=eq,UN=un,CH=ch1/ch2/.../chn,TF=tf.

EQest=NT-n,ST=status,EQ=eq,UN=un,CH=ch1/ch2/.../chn,TF=tf.

| Parameter | Description                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of the tape unit; from 6 to 7778. Refer to the MT-n or NT-n parameter.                                                                                                                                                                              |
| MT-n      | Equipment type; MT specifies 7-track tape units, and NT specifies<br>9-track tape units. n is the total number of magnetic tape units                                                                                                                           |
| or        | connected to the controller, from 1 to $20_8$ for $677$ and $679$ units with a $7021-31/32$ controller and from 1 to $10_8$ for $667$ and $669$                                                                                                                 |
| NT-n      | units with a 7021-21/22 controller. The system automatically<br>generates n EST entries with consecutive EST ordinals beginning with<br>the ordinal specified in the est parameter. The n units begin with<br>the unit number specified in the UN=un parameter. |
|           | For 639 units, n should not be specified; if it is specified, it should be given a value of 0 (zero).                                                                                                                                                           |
|           | NOTE                                                                                                                                                                                                                                                            |

To clear an MT-n or NT-n assignment, enter an EQest=0 entry for all n units. For example, to clear EQ50=MT-4,ST=ON,..., enter:

EQ50=0. EQ51=0. EQ52=0. EQ53=0.

| ST=status | Indicates whether of these values: | the | tape | unit   | is   | available | for | access; | enter | one |
|-----------|------------------------------------|-----|------|--------|------|-----------|-----|---------|-------|-----|
|           | status                             |     | ]    | Descri | lpti | Lon       |     |         |       |     |

# Description

- ON Magnetic tape unit is available for access.
- OFF Magnetic tape unit is ignored during system operation.

#### Parameter

#### Description

# NOTE

If a magnetic tape unit is accessible from more than one mainframe, concurrent use must be disabled by one of these methods:

- Set access switches on the tape controller so that only one mainframe can access the unit at any time.
- Make sure that the EST entry for each shared unit is defined as ON in only one of the mainframes.

EQ=eq Controller number for the tape unit; from 0 to 7. This number is usually 0 unless the controller is switched to a different number. Ask your customer engineer for the correct number if you are unsure.

UN=un Number of the lowest numbered magnetic tape unit to be processed; units must have consecutive physical unit numbers; from 0 to 7 for 667 and 669 units or from 0 to 178 for 677 and 679 units. The unit number is on the front of the tape unit, either as a switch or a label.

CH=ch<sub>i</sub> Number of the channel to which the tape unit is connected; from 0 to 13g and from 20g to 33g.

A controller can be connected to from one to four channels, depending on the controller model. However, a maximum of four channels can be handled regardless of the number of controllers.

TF=tf Hardware features available. This parameter specifies the following hardware characteristics of the tape unit(s) being defined; select one option.

677/679 units:

# <u>tf</u> <u>Description</u>

ATS The unit(s) being defined cannot process 6250-cpi group-encoded (GE) tapes. If the system detects a unit with this capability, it automatically changes this value to ATSGE, indicating the availability of the GE feature.

ATSGE The unit(s) being defined can process 6250-cpi GE tapes. Specify this value only if a unit being defined has the capability of processing GE tapes but is down. In such a case, the system would not be able to connect to the unit to determine the availability of the GE feature.

| 667/669 units: |                                                                                                                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tf             | Description                                                                                                                                                                                                                                                                    |
| MTS            | The FCOs needed to implement the block<br>identification feature have been installed in the<br>7021 controller for the unit(s) being defined. If<br>the controller is a two-channel model, the block<br>identification feature must have been implemented on<br>both channels. |
| 639 units:     |                                                                                                                                                                                                                                                                                |
| tf             | Description                                                                                                                                                                                                                                                                    |
| 639            | For 639 units, specify TF=639.                                                                                                                                                                                                                                                 |

Description

# Mass Storage Facility Equipment EST Entry

The Mass Storage Facility (MSF) hardware consists of a cartridge storage unit (CSU) and from one to four mass storage transports. The CSU and each transport is represented by a unique EST entry. The EST entries for the transports on a CSU must immediately follow the EST entry for that CSU. There must be no other EST entry between the entry describing a CSU and those describing its transports.

A mainframe that runs MSSEXEC in slave mode must have a CSU equipment type entry, even though no MSF hardware is actually configured for this mainframe.

### CSU Entry

Parameter

The CSU entry format is:

EQest=CS,ST=status,EQ=eq,UN=un,PT=pt,CH=ch,CI=ci,MI=mi,UI=ui.

| Parameter | Description                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of CSU; from 6 to $777_8$ . Although the software allows an ordinal of $777_8$ , the ordinal must be lower than that value because the entries for transports must follow the CS entry. |
| CS        | Indicates a CSU.                                                                                                                                                                                    |
| ST=status | Specifies whether the CSU is available for use; enter one of these values:                                                                                                                          |
|           | status Description                                                                                                                                                                                  |
|           | ON CSU is available.                                                                                                                                                                                |
|           | OFF CSU is ignored during system operation.                                                                                                                                                         |
| EQ=eq     | Number of the mass storage coupler (MSC); from 0 to 7.                                                                                                                                              |

| Parameter | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| UN=un     | Mass storage adapter (MSA) unit number; from 0 to 3.                                              |
| PT=pt     | Number of the MSA port to which the CSU is connected; from 0 to 7.                                |
| CH=ch     | Number of the channel to which the CSU is connected; from 0 to $13_8$ and from $20_8$ to $33_8$ . |

CI=ci Identifier of the CSU; one of the letters A through M.

# NOTE

The following two parameters are the MSA and CSU identifiers that are hardwired into the MSA and CSU equipment.

MI=mi

Number from 0 to  $17_8$ . Obtain this number from the customer engineer. Use 0 if the FCO that supports this parameter is not installed.

UI=ui Number from 0 to 3778. Obtain this number from the customer engineer. Use 0 if the FCO that supports this parameter is not installed.

### Mass Storage Transport Entry

The format of the mass transport entry is:

EQest=CT,ST=status,EQ=eq,UN=un,PT=pt,CH=ch,CP=cp,MI=mi,UI=ui.

| Parameter | Description                                                                      |
|-----------|----------------------------------------------------------------------------------|
| est       | EST ordinal of the transport; from 6 to 7778.                                    |
| CT        | Indicates the mass storage transport.                                            |
| ST=status | Specifies whether the transport is available for use; enter one of these values: |
|           | status Description                                                               |
|           | ON Transport is available.                                                       |

OFF Transport is ignored during system operation.

ParameterDescriptionEQ=eqNumber of MSC; from 0 to 7.UN=unMSA unit number; from 0 to 3.PT=ptNumber of the MSA port to which the transport is connected; from 0 to 7.CH=chNumber of the channel to which the transport is connected; from 0 to 13g and from 20g to 33g.CP=cpPhysical position of the transport in the CSU; from 0 to 3. Obtain this number from the customer engineer.

# NOTE

The following two parameters are the MSA and transport identifiers that are hardwired into the MSA and transport equipment.

- MI=mi Number from 0 to 17g. Obtain this number from the customer engineer. Use 0 if the FCO that supports this parameter is not installed.
- UI=ui Number from 0 to 3778. Obtain this number from the customer engineer. Use 0 if the FCO that supports this parameter is not installed.

### Mass Storage Archival Subsystem EST Entry

The Mass Storage Archival Subsystem (MSAS) hardware consists of a 7991 storage module and a 7990 controller.

A mainframe that runs SSEXEC in slave mode must have an MSAS EST entry, even though no MSAS hardware is actually configured for this mainframe.

The MSAS EST entry format is:

EQest=SS,ST=status,EQ=eq,UN=un,CH=ch.

| Parameter | Description                                            |
|-----------|--------------------------------------------------------|
| est       | EST ordinal of the 7990 controller; from 6 to $77_8$ . |
| SS        | Indicates a 7990 controller.                           |

| Parameter | Description                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------|
| ST=status | Specifies whether the 7990 controller is available for use; enter one of these values:                                                    |
|           | status Description                                                                                                                        |
|           | ON 7990 controller is available.                                                                                                          |
|           | OFF 7990 is ignored during system operation.                                                                                              |
| EQ=eq     | Logical controller number.                                                                                                                |
|           | This number sets the controller location in the unit device table within SSEXEC's memory. Enter one of these values:                      |
|           | eq Description                                                                                                                            |
|           | 0 First 7990 controller.                                                                                                                  |
|           | 2 Second 7990 controller.                                                                                                                 |
|           | 4 Third 7990 controller.                                                                                                                  |
|           | 6 Fourth 7990 controller.                                                                                                                 |
| UN=un     | 7991 storage module unit number; must be $0$ (zero).                                                                                      |
| CH=ch     | Number of the channel to which the $7990$ controller is connected; from 0 to 13g and from 20g to 33g. You can specify up to two channels. |

# Stimulator Equipment EST Entry

NOS supports a stimulator called STIMULA. However, there are other stimulators such as PACER that can use this EST entry. (PACER is a product that can be ordered from the Special Products Library.)

The format of the EST entry used by the interactive subsystem during stimulation is:

EQest=TT,ST=status,EQ=eq,CH=ch,PT=lines.

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| est       | EST ordinal of the interactive stimulator; from 6 to $777_8$ .                                |
| TT        | Indicates an interactive stimulator.                                                          |
| ST=status | Specifies whether the interactive stimulator is available for use; enter one of these values: |
|           | status Description                                                                            |
|           | ON Stimulator is available.                                                                   |

OFF Stimulator is ignored during system operation.

| Parameter | Description                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| EQ=eq     | Number of the controller; from $0$ to $7$ . Refer to the description of the channel parameter.                                                     |
| CH=ch     | Number of the channel; from 0 to $13_8$ and from $20_8$ to $33_8$ . The channel/controller combination must not have any equipment attached to it. |
| PT=lines  | Number of lines to stimulate; from 1 to $1000_8$ . If this parameter is omitted, $100_8$ is used.                                                  |

# Network Processing Unit EST Entry

The format of the EST entry is:

EQest=NP,ST=status,EQ=eq,PI=pip,CH=ch,ND=node,SA=sa.

| Parameter | Description                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of the NPU; from 6 to 7778.                                                                                                                                                                                                                                                                 |
| NP        | Indicates a 255X NPU.                                                                                                                                                                                                                                                                                   |
| ST=status | Specifies whether the NPU is available for use; enter one of these values:                                                                                                                                                                                                                              |
|           | status Description                                                                                                                                                                                                                                                                                      |
|           | ON NPU is available.                                                                                                                                                                                                                                                                                    |
|           | OFF NPU is ignored during system operation.                                                                                                                                                                                                                                                             |
| EQ=eq     | Number of the controller for the NPU; from 0 to 7.                                                                                                                                                                                                                                                      |
| PI=pip    | Peripheral interface program index, which determines which copy of<br>the PP driver drives this NPU; from 1 to 4. Up to four EST entries<br>can have the same PIP index (that is, one PP can drive four NPUs).                                                                                          |
| CH=ch     | Number of the channel to which the NPU is connected; from 0 to $13_8$ and from $20_8$ to $33_8$ .                                                                                                                                                                                                       |
| ND=node   | Node number of coupler associated with the NPU being defined; from 1 to $77_8$ . This value is the same as the NODE parameter on the COUPLER statement in the network configuration file definition. For the procedure to assign this value, refer to the Network Definition Language Reference Manual. |

-

#### Parameter

### Description

SA=sa

System autostart module (SAM) flag. This parameter is required.

| sa  | Description     |
|-----|-----------------|
| ON  | SAM is present. |
| OFF | SAM is absent.  |

If an NPU is channel-connected to a single host in a single-host network, the NPU does not need a SAM. However, if an NPU is channel-connected or remotely connected to more than one host, the NPU should have a SAM. The NPU EST entries for channel-connected hosts should specify SA=ON.

# NOTE

The node parameter is specified as an octal value on the NPU entry. The NODE parameter is specified on NDL statements as a decimal value.

Example:

Assume that three NPUs exist on channels 4, 5, and 6, all with controller 7. The NPUs are connected to coupler nodes 2, 8, and 11, respectively. The NPU on channel 5 has a system autostart module; the others do not. The first two NPUs are to be driven by the same PP. The EST entries for these NPUs follow.

EQ70=NP, ST=ON, CH=4, EQ=7, PI=1, ND=2, SA=OFF.

EQ71=NP, ST=ON, CH=5, EQ=7, PI=1, ND=10, SA=ON.

EQ72=NP, ST=ON, CH=6, EQ=7, PI=2, ND=13, SA=OFF.

The NDLP input for the network configuration would include the following statements (refer to the Network Definition Language Reference Manual for a complete description of these statements).

- CPL1: COUPLER NODE=2, HNAME=HOST1.
- CPL2: COUPLER NODE=8,HNAME=HOST1.
- CPL3: COUPLER NODE=11, HNAME=HOST1.

The node parameter of the EST entry and NODE on the COUPLER statement have the same numeric values, in this case 2, 8 ( $10_8$ ), and 11 ( $13_8$ ).

# Network Access Device EST Entry

The format for the network access device (NAD) EST entry is:

EQest=NC,ST=status,CH=ch.

| Parameter | Description                                                                                    |
|-----------|------------------------------------------------------------------------------------------------|
| est       | EST ordinal of the NAD; from 6 to 7778.                                                        |
| NC        | Indicates a NAD.                                                                               |
| ST=status | Specifies whether the NAD is available for use; enter one of these values:                     |
|           | status Description                                                                             |
|           | ON NAD is available.                                                                           |
|           | OFF NAD is ignored during system operation.                                                    |
| CH=ch     | Number of the channel to which the NAD is connected; from 0 to $13_8$ and from 20g to $33_8$ . |

# Two-Port Multiplexer EST Entry

The two-port multiplexer (TPM) must be described in the EST to allow use of the Remote Diagnostic Facility (RDF) on models 865 and 875 and CYBER 180-class machines.

The format of the TPM EST entry is:

EQest=RM,ST=status,PT=pt,CH=ch.

| Parameter | Description                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------|
| est       | The 1- to 3-digit octal EST ordinal of the TPM; 6 to $777_8$ .                                                                  |
| RM        | TPM equipment type.                                                                                                             |
| ST=status | Specifies whether the TPM is available for use; enter one of these values:                                                      |
|           | status Description                                                                                                              |
|           | ON TPM is available.                                                                                                            |
|           | OFF TPM is ignored during system operation.                                                                                     |
| PT=pt     | Port number to be used by RDF; 0 or 1. RDF normally uses port 1.<br>RDF and the system console cannot use the same port number. |
| CH=ch     | Channel number on models 865 and 875 and CYBER 180-class machines; channel 15 is required.                                      |

# MAP III or MAP IV Equipment EST Entry

The MAP III or IV equipment EST entry allows use of the matrix algorithm processor (MAP). The format of the MAP III or IV EST entry is:

EQest=MP,ST=status,CH=ch.

| Parameter | Description                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of MAP; from 6 to 778.                                                                                  |
| мр        | Indicates MAP equipment.                                                                                            |
| ST=status | Specifies whether the MAP is available for use; enter one of these values:                                          |
|           | status Description                                                                                                  |
|           | ON MAP is available.                                                                                                |
|           | OFF MAP is ignored during system operation.                                                                         |
| CH=ch     | Number of the channel to which the MAP is connected; from 0 to $13_8$ and from 20 <sub>8</sub> to 33 <sub>8</sub> . |

# 6683 Satellite Coupler EST Entry

The 6683 satellite coupler EST entry allows use of the NOS-SCOPE 2 Station Facility. The format for the entry is:

EQest=CC,ST=status,EQ=eq,CH=ch.

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| est       | EST ordinal of 6683 coupler; from 6 to 7778.                                                  |
| сс        | Indicates 6683 coupler.                                                                       |
| ST=status | Specifies whether the 6683 coupler is available for use; enter one of these values:           |
|           | status Description                                                                            |
|           | ON 6683 coupler is available.                                                                 |
|           | OFF 6683 coupler is ignored during system operation.                                          |
| EQ=eq     | Controller number for equipment; from 0 to 7.                                                 |
| CH=ch     | Number of channel to which coupler is connected; from 0 to $13_8$ and from $20_8$ to $33_8$ . |

# CYBERPLUS Ring Port EST Entry

The CYBERPLUS ring port equipment EST entry allows use of the CYBERPLUS Subsystem. The format of the entry is:

EQest=RP,ST=status,CH=ch.

| Parameter | Description                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of the ring port; from 6 to 7778.                                                                            |
| RP        | Indicates ring port.                                                                                                     |
| ST=status | Specifies whether the ring port is available for use; enter one of these values:                                         |
|           | status Description                                                                                                       |
|           | ON Ring port is available.                                                                                               |
|           | OFF Ring port is ignored during system operation.                                                                        |
| CH=ch     | Number of the channel to which ring port is connected; from 0 to $13_8$ and from 208 to 338. This parameter is required. |

## EQUIPMENT ASSIGNMENTS: MASS STORAGE

This subsection describes the following EST entries and mass storage equipment assignments.

| Equipment                       | Entry  |
|---------------------------------|--------|
| Disk units                      | EQ     |
| Control module                  | EQ     |
| Extended memory                 | EQ     |
| Equipment Assignment            | Entry  |
| Mass storage allocation control | MSAL   |
| Permanent files device          | PF     |
| System library device           | SYSTEM |
| Alternate system library device | ASR    |
| System checkpoint file device   | SCKP   |
| Logical device removal          | DOWN   |
| Default family name             | FAMILY |
| Removable device                | REMOVE |
| Shared device                   | SHARE  |

| Equipment Assignment       | Entry  |
|----------------------------|--------|
| Independent shared device  | ISHARE |
| Load buffer controllers    | LBC    |
| Extended memory allocation | XM     |

#### NOS Mass Storage Concepts

Following are descriptions that define the NOS mass storage terminology and summarize the kinds of mass storage equipment assignments that can be specified in the EQPDECK. Table 3-2 summarizes the various functions that a particular mass storage device can serve. For example, if a device is an alternate system device (listed under the Alternate System column in table 3-2), then it cannot be a system device; it can contain temporary files, direct access files, and indirect access files; it can be a master device or a nonmaster device; it cannot be removable; it can be either an auxiliary device or a family device; and it can be a shared device or a link device.

### Alternate System Device

Whereas a system device contains all the routines in the system library, an alternate system device contains copies of selected system library routines. The ASR entry in the EQPDECK (refer to ASR - Alternate System Library Device Assignment Entry later in this section) specifies which mass storage devices are to be alternate system devices; the \*AD LIBDECK entry on the deadstart file specifies which system library routines are to reside on these alternate system devices. During system processing, the routines on the alternate system device are used instead of the ones on the system device.

This feature allows each routine in the system library to reside on the mass storage device that is most appropriate to the routine's use. For example, instead of using an 844 system device, a routine that is frequently used could use extended memory, which has a faster transfer rate, as an alternate system device.

### NOTE

Use care when specifying alternate system devices. A mistake could result in no alternate system device defined. For example, suppose you specify the following in your EQPDECK:

ASR=7. ASR=11.

and you specify the following in the corresponding LIBDECK:

\*AD,5,ABS/COMPASS \*AD,11,PP/1SJ

Since the system could not match equipment numbers between the EQPDECK and the corresponding LIBDECK, the system library routine COMPASS will not be on equipment 7 or 5. However, 1SJ will be on equipment 11 as specified.

# Table 3-2. Mass Storage Device Functions

| Removable device                 | No     | No                  | No                               | Yes                                     | Yes                                       | Yes       | No                | Yes           | No   |
| Nonremovable<br>device           | Yes    | Yes                 | Yes                              | Yes                                     | Yes                                       | Yes       | Yes               | Yes           | Yes  |
| Auxiliary device                 | Yes    | Yes                 | Yes                              | Yes                                     | Yes                                       | -         | No                | Yes           | Yes  |
| Family device                    | Yes    | Yes                 | Yes                              | Yes                                     | Yes                                       | No        | -                 | Yes           | Yes  |
| Shared device                    | Yes    | Yes                 | Yes                              | Yes                                     | Yes                                       | Yes       | Yes               | -             | -    |
| Link device                      | Yes    | Yes                 | Yes                              | Yes                                     | Yes                                       | Yes       | Yes               | -             | -    |
|                                  |        |                     |                                  |                                         |                                           |           |                   |               |      |
|                                  |        |                     |                                  |                                         |                                           |           |                   |               |      |

1

### Alternate Permanent File Family

More than one permanent file family can exist in a system: one default permanent file family and one or more alternate permanent file familes. One permanent file family is defined as the default family by the EQPDECK FAMILY entry (refer to FAMILY - Default Family Name Assignment Entry later in this section). If another system's permanent file family is introduced, it is an alternate permanent file family; it can be added without interrupting the default permanent file family's operation.

This is a useful feature if a site has more than one system or has groups of installations. If one system fails, its permanent files can be accessed from another system.

As an example, a site with two systems might run with the mass storage configuration shown in table 3-3.

| System | Ordinal | Device | Spindles | Access<br>Used | Contents            |
|--------|---------|--------|----------|----------------|---------------------|
| X      | 7       | 844    | 2        | A              | Direct access files |
| Y      | 7       | 844    | 2        | В              | Direct access files |

Table 8-3. Mass Storage Configuration for Two Systems at One Site

If system Y became inoperative, the B access could be connected to system X. This could be done without interrupting operations of system X.

The EQPDECK entries in system X would be:

| Entries                       | Comments                                                        |
|-------------------------------|-----------------------------------------------------------------|
| EQ7=DI,ST=ON,UN=0/1,CH=0/3.   | Defines access A.                                               |
| EQ10=DI,ST=OFF,UN=0/1,CH=1/4. | Defines access B.                                               |
| REMOVE=10.                    | Allows introduction of access B into system X during operation. |

The EQPDECK entries in system Y would be:

|     | Entries                      | Comments                                                        |
|-----|------------------------------|-----------------------------------------------------------------|
| E   | Q7=DI,ST=ON,UN=0/1,CH=1/4.   | Defines access B.                                               |
| . E | Q10=D1,ST=OFF,UN=0/1,CH=0/3. | Defines access A.                                               |
| R   | EMOVE=10.                    | Allows introduction of access A into system Y during operation. |

To allow for introduction of an alternate permanent file family:

- 1. Define the equipment to be introduced or removed in the EQPDECKs for both systems (refer to the previous example).
- 2. Specify all of the equipment that may be introduced or removed during system processing as removable.
- 3. When you want to introduce the equipment into a system, use the ON operator command to indicate that the equipment that was set to the OFF position in the system in operation is now available. This introduces the alternate permanent file family.
- 4. Enable the validation files for the family by entering X.ISF(FM=familyname). Refer to section 20, System File Initialization.

#### Auxiliary Device

An auxiliary device is a mass storage device that is not part of a family. It is a supplementary permanent file storage device, which may be privately owned (PRIVATE) or may be shared by many users (PUBLIC). An auxiliary device resides on either a removable or nonremovable device. On the permanent file entry (PF) for an auxiliary device (for both a removable device and a fixed device without packs), a pack name is specified instead of a family name.

Refer to the NOS 2 Reference Set, Volume 3, for additional information about private and public auxiliary devices.

As an example, four 844 spindles to be used as a public auxiliary device could be defined as follows:

EQ6=DI,ST=ON,UN=1-4,CH=2. PF=6,X,name.

Private auxiliary devices can be created only after the system is up and running. An operator can make a public device a private device by entering the INITIALIZE command with the UN and TY=X parameters (refer to section 8, K-Display Utilities).

### Family Device

A family device is a mass storage device that is part of a family. It can be either a removable device or a nonremovable device. The only difference between the two is that a nonremovable device containing permanent files can also contain a copy of the system library and/or temporary files. Refer to Alternate Permanent File Family earlier in this section.

On the PF entry, the family name is important if two systems' permanent files are to run on the same system. A user can only use one family of permanent files at one time; if the user does not specify one, the default FAMILY entry is used.

A family device can contain direct and indirect access files. These files are defined in the NOS 2 Reference Set, Volume 3. The files that are allowed are set by the device mask and secondary mask on the PF entry.

### Link Device

Either extended core storage or extended semiconductor memory is the medium through which several computer systems are linked to form a multimainframe operating environment (shared MMF). The link device contains the information necessary for the orderly management of the mass storage that can be shared by more than one mainframe. For a description of shared mass storage, refer to SHARE - Shared Device Entry and ISHARE - Independent Shared Device Entry later in this section.

#### Master Device

The master device contains all of the permanent file catalog entries and indirect access files for a specific user. If permanent file access is required, the user's master device must be available on the system, unless all access is to be to an auxiliary device. The user index and family name uniquely describe a user's master device.

Each master device is organized into five logical sections.

1. Allocation information.

A master device, like all mass storage devices, maintains device labels and track reservation tables (TRTs).

The device label contains information describing the device, such as family name and user mask, as well as locations of permit and catalog information and indirect access files. Refer to the INITIALIZE - Initialization Entry later in this section.

The TRT is the key to allocating information on the master device and to describing the physical layout of data on the device. Refer to APRDECK later in this section.

2. Catalog information.

Catalog entries are used to determine the locations and attributes of permanent files. The catalogs for a master device are allocated to contain catalog entries for a specific group of user indexes. A particular catalog track may contain entries for many users, the number depending upon the number of catalog tracks defined for the device. The user index provides the mechanism for differentiating between user's files on a particular catalog track.

3. Permit information.

Users can explicitly or implicitly allow other users to access their permanent files. Refer to the PERMIT command in the NOS 2 Reference Set, Volume 3. Information describing the permission for all permanent files is in the permit file. Catalog entries contain a relative sector address within this permit file for permissions that have been granted for the file.

4. Indirect access files.

The master device contains all of the user's indirect access files. These files can be accessed by commands that generate working copies for manipulation by the user.

5. Direct access files.

Direct access files can reside either on the master device or on another device in the family, depending on the device masks specified on the PF entries. Direct access files are files that can be accessed at their location on mass storage. A working copy is not generated, so any updates or alterations made to the files are permanent.

### Multispindle Device

To accommodate files that are larger than one device, you can specify multispindle device assignments. Up to eight spindles of 844 disk drives or up to three spindles of 885 disk drives can be included in the equipment definition of one logical device, when the device is first defined. All spindles must be available for access whenever the device is accessed.

Multispindle devices are treated as one logical device, having a track size equal to n times the single-spindle track size (n is the number of spindles in the device). The tracks of an n-spindle device are broken down into n equally-sized segments, each having a length equal to the single-spindle track size. Each segment is contained on a different physical unit.

### 844 Expander

A nonexpanded controller can have up to eight disk drives connected to it. Each of the connection paths is called a port and is identified by a port number ranging from 0 to 7. An expander (10304 extender) is a hardware device that can be connected between controllers and 844 disk drives to increase the number of disk drives that each controller can access.

The expander can be used only with 844-21 drives, although all equipment definitions and equipment driving software support the 64-drive addressing scheme for both 844-21 (DI/DK) and 844-41 (DJ/DL) type equipment.

Each expander consists of either two or four expansion elements. An expansion element connects to a single controller port and forms a connection path from that port to from one through eight disk drives. The connection paths between an expansion element and the eight possible disk drives are called ranks and are identified by a rank number ranging from 0 to 7. Two expanders with four expansion elements each can be connected to a single controller to allow that controller to access a maximum of 64 disk drives. Each expansion element, however, is logically independent and, as such, could be connected to any port of any controller.

|               |   |    |    | Cont | roller | Port    |    |    |                          |
|---------------|---|----|----|------|--------|---------|----|----|--------------------------|
|               |   | 0  | 1  | 2    | 3      | 4       | 5  | 6  | 7                        |
|               | 0 | 00 | 01 | 02   | 03     | 04      | 05 | 06 | 07                       |
|               | 1 | 10 | 11 | 12   | 13     | 14      | 15 | 16 | 17                       |
| Expander Rank | 2 | 20 | 21 | 22   | 23     | 24      | 25 | 26 | 27                       |
|               | 3 | 30 | 31 | 32   | 33     | 34      | 35 | 36 | 37                       |
|               | 4 | 40 | 41 | 42   | 43     | 44      | 45 | 46 | 47                       |
|               | 5 | 50 | 51 | 52   | 53     | 54      | 55 | 56 | 57                       |
|               | 6 | 60 | 61 | 62   | 63     | 64      | 65 | 66 | 67                       |
|               | 7 | 70 | 71 | 72   | 73     | 74      | 75 | 76 | Unit Numbers<br>(octal)  |
|               | İ | L  |    | I    | 1      | <u></u> |    | L  | Port Digit<br>Rank Digit |

A single controller maximum configuration can be visualized as an 8- by 8-square checkerboard with each square representing one of 64 disk drives (figure 3-1).

Figure 3-1. Expander Addressing Map

A column of squares in figure 3-1 represents all the drives that are accessed through a single controller port. A row of squares represents all the drives that have the same expander rank. Each disk drive that can be accessed by the controller is addressed by a 6-bit unit number. The rightmost 3 bits of this unit number select to which of the eight controller ports the drive is connected. The leftmost 3 bits of the unit number select to which of the eight ranks on an expansion element the drive is connected. This unit number is specified as a 2-digit octal number in the mass storage equipment EST entry (refer to EQ - Disk Equipment EST Entry later in this section). The right digit (port digit) of the unit number is the port number and the left digit (rank digit) is the rank of the unit in the particular expansion element.

If two disk drives are vertically adjacent on the expander addressing map (figure 3-1), their unit numbers are considered to be vertically ordered; that is, both drives are connected to the same expansion element, both have the same port number, and their rank numbers differ by one (refer to example 1).

If two disk drives are horizontally adjacent on the expander addressing map (figure 3-1), their unit numbers are considered to be horizontally ordered; that is, both drives have the same rank number, and their port numbers differ by one (refer to example 2). The special case of rank numbers of 0 for two horizontally adjacent drives is equivalent to the definition of consecutive unit numbers for other equipment.

All drives connected to a controller, either directly or through an expansion element, are supported as single-unit or multiunit logical devices. Unit numbers can range from 0 to 778, rather than from 0 to 7, as for other equipment. Thus, a maximum of sixty-four 844 disk drives connected to a single controller can be addressed. However, a maximum of eight units can be specified per multiunit device. In addition, all units of a multiunit device must be connected to the same channel and, therefore, to the same controller.

Figure 3-2 illustrates a configuration in which two expansion elements and 20 disk drives are connected through one controller. An expansion element with eight drives is connected to port 0, an expansion element with six drives is connected to port 1, and six drives are connected to six ports (ports 2 through 7). Each disk drive is shown as a square with its appropriate unit number inside. This configuration is used in the following three examples to illustrate multiunit device assignments. The controller is assumed to be connected to channel 1. Refer to EQ - Disk Equipment EST Entry later in this section for specific information on assigning these devices.

|               |   |    |    | Con | troller | Port |    |    |    |
|---------------|---|----|----|-----|---------|------|----|----|----|
|               |   | 0  | 1  | 2   | 3       | 4    | 5  | 6  | 7  |
|               | 0 | 00 | 01 | 02  | 03      | 04   | 05 | 06 | 07 |
|               | 1 | 10 | 11 |     |         |      |    |    |    |
| Expander Rank | 2 | 20 | 21 |     |         |      |    |    |    |
|               | 3 | 30 | 31 |     |         |      |    |    |    |
|               | 4 | 40 | 41 |     |         |      |    |    |    |

Figure 3-2. 844 Expander Configuration With 20 Drives

|--|

The following examples illustrate multiunit device assignment of devices. For a description of the mass storage EST entry in the EQPDECK, refer to EQ - Disk Equipment EST Entry later in this section. Example 1:

Figure 3-3 illustrates a possible configuration for a three-unit vertically adjacent multiunit device. This device could be assigned in the EQPDECK, specifying EST ordinal 6, as:

|               |   |    |          | Conti | roller | Port     |         |        |        |          |    |
|---------------|---|----|----------|-------|--------|----------|---------|--------|--------|----------|----|
|               |   | 0  | 1        | 2     | 3      | 4        | 5       | 6      | 7      |          |    |
|               | 0 | 00 | 01       | 02    | 03     | 04       | 05      | 06     | 07     |          |    |
|               | 1 | 10 | 11       |       |        |          |         |        |        |          |    |
| Expander Rank | 2 | 20 | 21       |       |        |          |         |        |        |          |    |
|               | 3 | 30 | 31       | 1     |        |          |         |        |        |          |    |
|               | 4 | 40 | 41       |       |        |          |         |        |        |          |    |
|               | 5 | 50 | 51       |       |        |          |         |        |        |          |    |
|               | 6 | 60 |          | -     |        |          |         |        |        |          |    |
|               | 7 | 70 | <b>~</b> |       | — v    | ertical  | ly Adja | cent T | hree-T | Jnit Dev | ic |
|               | • |    |          |       | v      | erticali | гу Адја | cent 1 | uree-l |          | L  |

EQ6=D1,ST=ON,UN=50/60/70,CH=1.

Figure 3-3. Vertically Adjacent Three-Unit Device

Example 2:

Figure 3-4 illustrates a possible configuration for a two-unit horizontally adjacent multiunit device. This device could be assigned in the EQPDECK, specifying EST ordinal 7, as:

EQ7=D1,ST=ON,CH=1,UN=40-41.

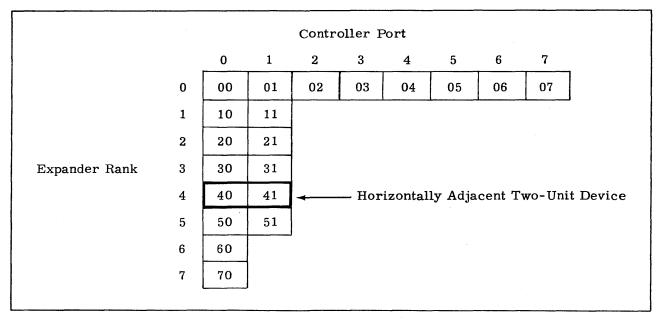

Figure 3-4. Horizontally Adjacent Two-Unit Device

Example 3:

Figure 3-5 illustrates a possible configuration of 20 disk drives into seven devices. These devices could be assigned in the EQPDECK as follows:

EQ6=DI, ST=ON, UN=60, CH=1. EQ7=DI, ST=ON, UN=70, CH=1. EQ10=DI, ST=ON, UN=50-51, CH=1. EQ11=DI, ST=ON, UN=10/20/30/40, CH=1. EQ12=DI, ST=ON, UN, 11/21/31/41, CH=1. EQ13=DI, ST=ON, UN=0-3, CH=1. EQ14=DI, ST=ON, UN=4-7, CH=1.

Devices on ordinals 6 and 7 are defined as single units. These units may be initialized online into a two-unit device if they are also defined as removable.

|               |   |      | Cont | roller | Port | -    |    |    |    |    |  |
|---------------|---|------|------|--------|------|------|----|----|----|----|--|
|               |   |      | 0    | 1      | 2    | 3    | 4  | 5  | 6  | 7  |  |
|               |   |      | EQ13 |        |      | EQ14 |    |    |    |    |  |
|               | 0 |      | 00   | 01     | 02   | 03   | 04 | 05 | 06 | 07 |  |
|               | 1 | (    | 10   | 11     |      |      |    |    |    |    |  |
| Expander Rank | 2 | EQ11 | 20   | 21     |      | 10   |    |    |    |    |  |
|               | 3 |      | 30   | 31     | } EQ | 12   |    |    |    |    |  |
|               | 4 | l    | 40   | 41     |      |      |    |    |    |    |  |
|               | 5 | EQ10 | 50   | 51     | ,    |      |    |    |    |    |  |
|               | 6 | EQ6  | 60   |        | -    |      |    |    |    |    |  |
|               | 7 | EQ7  | 70   |        |      |      |    |    |    |    |  |
| L             |   |      |      |        |      |      |    |    |    |    |  |

Figure 3-5. Hardware Configured into Seven Devices

### Nonremovable Device

A nonremovable device cannot be physically removed during system operation. It can contain a copy of the system library, which means it is a system device; it can also be available for temporary files. It may or may not contain permanent files.

### Removable Device

A removable device can be logically or physically added or removed during system operation without causing system malfunction.

A device is specified as removable with the REMOVE entry in the EQPDECK. During deadstart, a removable device is recovered just as is any other mass storage device, if the status is on. If the device is not available, then the status is displayed for the operator (E,M display).

Removable devices can contain permanent files but cannot contain the system library or temporary files, because a device containing active files (such as temporary or library files) cannot be removed from the system. It can be either an auxiliary device or an alternate permanent file family device.

### Shared Device

A shared device contains permanent files that can be accessed by more than one mainframe. To have these permanent files accessible to the mainframe, the device must be defined as shared in the mainframe. Refer to SHARE - Shared Device Entry and ISHARE - Independent Shared Device Entry later in this section.

A shared device can be removable. However, when unloading a shared device, it must be in global unload status before you remove it. Refer to the DSD commands UNLOAD and MOUNT in section 5 for more information concerning removable shared devices.

#### System Device

The system device is a nonremovable device on which the system library resides. It can also contain permanent and temporary files.

### Temporary File Device

The temporary file device is a nonremovable device on which the following temporary system files reside:

- Library files
- Local files
- Queued files
- Rollout files
- System files
- Timed/event rollout files

### Buffered Mass Storage Devices

Buffered mass storage devices are those devices for which the system provides an extended memory data buffer. For the model 176 only, an 819 mass storage device with the buffer in LCME is a buffered device. For all models except models 176 and CYBER 180-class machines, the buffered device is an 885-42 Mass Storage Subsystem with the buffer in ESM. Using extended memory as a data buffer provides the following capabilities.

- The system treats the buffer as a disk cache so that multiple requests for a particular disk data block can potentially be satisfied by doing only one disk read.
- The system buffers data to maintain maximum transfer rates regardless of the user's buffer size.

To maintain maximum transfer rates, a CPU program that resides in CPUMTR controls the buffered device I/O request processing. The system maintains the standard disk I/O interface to the user's programs.

The buffered device error reporting process logs read/write errors in the binary maintenance log but not in the system error log or dayfile. When an unrecovered read/write error occurs, the error message appears at the system control point. The binary maintenance log must be processed by the Hardware Performance Analyzer (HPA) to get detailed information concerning buffered device errors.

The following considerations are important to system performance.

- The amount of I/O buffer space in extended memory. Refer to XM Declare Extended Memory Space for Buffers or User Access later in this section.
- The size of the hash buffer parameter. Refer to EQ Mass Storage Equipment EST Entry later in this section.
- The amount of space reserved in central memory for providing PP access to buffered devices. Refer to the PPB=number entry under Central Memory Descriptions earlier in this section.

There may be situations when a particular user job runs slower with buffered devices. This happens if the job issues CIO reads when a buffer is full or issues CIO writes when a buffer is empty. (Both cases indicate inefficient programming techniques.) You can speed up the job by entering the DSD command ENABLE,LOGGING. The system will perform faster I/O and issue warning messages to the job dayfile.

### **Specifying Ranges of EST Ordinals**

Several EQPDECK entries allow you to specify multiple EST ordinals in the same entry. For example, instead of entering

REMOVE=6,7,10,11,12.

you can enter:

REMOVE=6-12.

Ranges of ordinals can be mixed with individual ordinals, such as:

REMOVE=6,10-16,23.

Empty ordinals within a range are ignored. For example, specifying a range of 6 through 12 will ignore an unassigned ordinal 7. However, inappropriate devices within a range or specified individually (such as specifying a printer as a removable device) are diagnosed as errors.

### EQ — Disk Equipment EST Entry

The purpose of the mass storage equipment (EQ) entries is to describe all mass storage peripheral equipment. This includes disk equipment and extended memory equipment. NOS requires that at least 6 million words of mass storage be available.

There can be up to 200 logical mass storage devices, and therefore, up to 200 mass storage EST entries (this number does not include ordinals 0 through 4, which are reserved for specific uses). An entry, however, can refer to more than one physical unit. For example, two 844 spindles can be defined as either two logical devices with two EQ entries or as one logical device with one EQ entry.

A unit is a dual-access unit if it is accessed by one mainframe through two different controller-channel access routes. To define a unit as a dual-access unit with its EQ entry, specify two channel parameters. The channels should be from two controllers. Only one channel of a dual-channel access controller is recommended for use on a single mainframe, since using both channels of the controller results in a performance degradation rather than an improvement. Therefore, if both channel accesses of a controller are physically connected to the same mainframe, you should define only one of them on an EQ entry.

# NOTE

A device's EQ entry must precede any of the following entries for that device: ASR, MSAL, REMOVE, PF, SYSTEM, FAMILY, INITIALIZE, SHARE, ISHARE, DOWN, and XM. If you redefine a device's EQ entry, then you must also redefine those entries. The format of the EQ entry for disk units is:

EQest=type,ST=status,UN=units, CH=ch<sub>1</sub>/ch<sub>2</sub>,AP=ap,HT=ht.

# Parameter

# Description

EST ordinal of the disk units; from 6 to 7778.

type

est

Equipment type. The following disk units are supported by NOS.

| type   | Equipment                                 | Number<br>of Units |
|--------|-------------------------------------------|--------------------|
| db‡    | 885-42, 7155-401 (full track)             | l through 3        |
| dd††   | 834, 7255-1 (full track)                  | l through 8        |
| DI     | 844-21, 7054/7154 (half track)            | l through 8        |
| DJ     | 844-41/44, 7054/7154 (half track), 7155-1 | 1 through 8        |
| DK     | 844-21, 7154 (full track)                 | l through 8        |
| DL     | 844-41/44, 7154 (full track), 7155-1      | l through 8        |
| DM     | 885-11/12, 7155-1 (half track)            | l through 3        |
| DQ     | 885-11/12, 7155-1 (full track)            | 1 through 3        |
| dvttt  | Single-density 819                        | 1                  |
| DW TTT | Double-density 819                        | 1                  |

Not applicable for CYBER 180-class machines.

<sup>##</sup>Applicable for models 810, 815, 825, and 830 only. You must also specify the control
module EQ entry.

tftApplicable to model 176 only.

#### Parameter

### Description

ST=status

Specifies whether or not the equipment is available for access; enter one of these values:

status

#### Description

ON Equipment is available.

OFF Equipment is not accessed during system operation. Specify OFF if the equipment is malfunctioning and access is not desirable.

If the equipment is removable and is not available at deadstart, the system determines that it is unavailable, even if its EQ status entry specifies ON. If INITIALIZE is entered, the equipment is not initialized until it is set to ON status. During system operation, the operator can initiate access to this device by entering the ON command.

If the equipment can be used with either one of two different systems (removable devices, not dual access), define the status of the EQ entry as ON in the system to which it is currently available for access; define the status of the EQ entry as OFF in the system to which it is not currently available for access.

UN=units

Defines unit number(s).

For 834 units, unit numbers are generated as follows:

unit number = (control module equipment number)\*10<sub>8</sub>+ (834 disk equipment number)

For 819 units, unit numbers are either from 0 to 3, if on FLPP channels 2 and 3, or from 4 to 7, if on FLPP channels 6 and 7.

For 844 and 885 units, unit numbers are from 0 to  $77_8$ .

You can define the 834, 844, and 885 physical units with a separate EQ entry for each unit, or, if more continuous storage is needed than is possible with one unit, you can define more than one physical unit as one logical device with one EQ entry. If the EQ entry is defining more than one unit of a multispindle device, unit numbers can be specified as  $UN=un_1-un_n$ , if units are contiguous, or as  $UN=un_1/un_2/.../un_n$ , if units are noncontiguous. For 834 units, contiguous means that the units are all on the same control module.

For example, three 844 units (0, 1, and 2) to be accessed as three units are defined as follows:

EQest=DI,ST=status,UN=0,CH=ch,AP=ap.

EQest=DI,ST=status,UN=1,CH=ch,AP=ap.

EQest=DI,CH=ch,UN=2,AP=ap,ST=status.

Parameter

#### Description

Three 844 units (0, 1, and 2) to be accessed as one logical unit are defined as follows:

EQest=DI,ST=status,UN=0-2,CH=ch,AP=ap.

or

EQest=DI,ST=status,UN=0/1/2,CH=ch,AP=ap.

An advantage to accessing the three units as one logical unit is that less space is used in CMR ( $662_8$  words for the 844-21). A disadvantage is that if any of the units malfunctions or is destroyed, all units are affected.

CH=ch1

For all devices except 819s and 834s, number of the channel or channels to which the controller is connected; from 0 to  $13_8$  and from 208 to 338. For 819s, the channel pair for input/output (I/O) multiplexer (primary access); enter one of these values:

| <sup>ch</sup> 1 | Description       |  |  |  |
|-----------------|-------------------|--|--|--|
| 2               | Channels 2 and 3. |  |  |  |
| 4               | Channels 4 and 5. |  |  |  |
| 6               | Channels 6 and 7. |  |  |  |

For 834s, the channel number is specified on the control module EQ entry.

/ch<sub>2</sub>

For all devices except 819s and 834s, indicates dual-access unit; cannot be 0;  $ch_1$  and  $ch_2$  should be connected to different controllers. Ch<sub>2</sub> is assigned first if it is free.

For 819s, the secondary access channel pair; one of the values described for  $ch_1$ .

For 834s, dual access is indicated on the control module EQ entry.

The 1- or 2-digit octal number that indicates which APRDECK to use. If AP=ap is omitted, the first APRDECK, APRDOO, is assumed.

HT=ht

AP=ap

Length of hash table segment for this unit; must be a power of 2 and from 10g to 400g. The hash table is maintained in extended memory. The hash table keeps track of the extended memory copies of disk segments for DV, DW, and DB disk units. The ht parameter should be as large as possible for maximum efficiency. If the hash buffer is too small, the system's ability to recognize disk data already in buffers is diminished, thus causing unnecessary disk reads.

## EQ — Control Module EST Entry

The 834 Disk Storage Subsystem consists of from one to eight 834 disk units and from one to eight control modules. To be operational, both the disk units and the control modules must be defined in the EQPDECK. The EQ entry for the 834 disk unit is described under EQ - Disk Equipment EST Entry earlier in this section. The description of the EQ entry for the control module follows.

A control module for the 834 Disk Storage Subsystem is a controller that drives up to four 834 disks and that interfaces with the operating system using one or two 7255-1 adapters (one per channel). The control module EQ entry is used to:

- Specify the channels to be used to access the 834 drives defined on the control module. Channel entries are not allowed on the 834 disk unit EQ entries.
- Specify what level of controlware is to be loaded into the control module during deadstart or when you use a LOADBC command.
- Allow maintenance access to a control module without affecting other control modules on the same channel(s).

The format of the control module entry is:

EQest=CM,EQ=eq,CH=ch<sub>1</sub>/ch<sub>2</sub>,CW=cw.

| Parameter | Description                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| est       | EST ordinal of the control module; from 6 to 7778.                                                                                                                                                                                                          |
| EQ=eq     | Physical equipment number of the control module; from 0 to 7.                                                                                                                                                                                               |
| CH=ch1    | Number of the channel to which the control module is connected; from 0 to $13_8$ and from 208 to $33_8$ .                                                                                                                                                   |
| / ch2     | Indicates a dual-access control module; from 1 to 13g and from $20_8$ to 33g.                                                                                                                                                                               |
| C₩=cw     | Indicates if controlware is to be installed in the control module.<br>The control module load sequence takes at least 15 seconds for each<br>control module. It is advised that you load controlware only when<br>necessary. cw can be one of these values: |
|           | <u>cw</u> <u>Description</u>                                                                                                                                                                                                                                |
|           | CM Install controlware (default).                                                                                                                                                                                                                           |
|           | NCM Do not install controlware.                                                                                                                                                                                                                             |

#### EQ — Extended Memory EST Entry

Three possible extended memory configurations exist. The first configuration is for ECS, LCME, and ESM. It allows a CPU (or two, if dual CPUs are available) to communicate with extended memory. The second configuration is the same as the first except additionally it uses the distributive data path (DDP) or low-speed port (LSP). This configuration allows PPs in the system, as well as the CPU, to communicate directly with ECS or ESM. It does not apply to LCME. NOS supports up to two DDPs or LSPs per mainframe. (Refer to both User Extended Memory and XM - Declare Extended Memory Space for Buffers or User Access later in this section for information regarding user-access extended memory.) For the third configuration, part of central memory is used as unified extended memory (UEM) on models 865 and 875 and CYBER 180-class machines.

You can use extended memory as an alternate system residency for often accessed system routines. The faster access may result in a performance improvement. However, you should use caution when placing system routines in UEM to avoid possible performance degradation instead of an improvement. This can happen because a portion of central memory is reserved for UEM and therefore that portion is unavailable to users. Also, accessing the system routines that reside in UEM may require additional CPU overhead. Use the TRACER utility to determine the impact on system resources when using UEM.

# NOTE

If extended memory is not included in the hardware configuration, do not make an extended memory EST entry. EST ordinal 5 cannot be used to define any other equipment.

The format of the entry is:

EQ5=type,ST=status,MA=mode,ET=xmem/ddp,SZ=size,CH=ch1/ch2,AP=ap,MC=mc.

Parameter

Description

| type      | Extended memo                  | ry equipment type; enter one of these values:               |
|-----------|--------------------------------|-------------------------------------------------------------|
|           | type                           | Description                                                 |
|           | DE                             | DDP or LSP is not available.                                |
|           | DP                             | DDP or LSP is available (not applicable for UEM).           |
| ST=status | Specifies whe<br>of these valu | ther extended memory is available for access; enter one es: |
|           | status                         | Description                                                 |
|           | ON                             | Extended memory is available.                               |
|           | OFF                            | Extended memory is ignored during system operation.         |

| Parameter   |                                              | Description                                                                                                                                                                                                                                                                                          |

## Description

Size of extended memory; one of the values in the following table for ECS I. For ECS II, ESM, and LCME, size ranges from a minimum value of 10g, which specifies 4K (K represents 1024 words) through a maximum value of 100008, which specifies 2048K. For UEM, size ranges from a minimum value of 108, which assigns 4K for UEM, through a maximum value of 100008-MINCM, which assigns 2000K-MINCM (convert MINCM to decimal) for UEM. Size can be specified in increments of 1, if necessary (for example, 108, 118, 128, 4018, or 20038).

| Size (Octal) | ECS I Available | Number of Banks |
|--------------|-----------------|-----------------|
| 400          | 125K            | 1               |
| 1000         | 250K            | 2               |
| 2000         | 500K            | 4               |
| 4000         | 1000K           | 8               |
| 10000        | 2000K           | 16              |

CH=ch1,/ch2

Numbers of the channels to which the DDP is connected; from 0 to 13g and from 20g to 33g.

If the equipment type is DE, do not specify a channel parameter. If a channel parameter is specified, the system recognizes the DE entry as a DP entry.

If the equipment type is DP, specify either one or two channels. The second channel cannot be 0 (zero). If a DDP is present, the loading of CPU programs residing in ECS or ESM still occurs via the CPU. A DDP must be connected to a channel by itself.

AP=ap The 1- or 2-digit octal number that indicates which APRDECK to use. If you omit AP=ap, the first APRDECK, APRDOO, is assumed.

MC=mc Number of the channel to which the maintenance port is connected; from 0 to 13 and from 20g to 33g. This channel is for ESM only. If MC=mc is specified, you must also specify MA=ON.

#### Examples:

EQ5=DE, ST=OFF, SZ=1000, AP=21. EQ5=DP,ST=ON,SZ=2000,CH=2/3,AP=10. EQ5=DE, ST=ON, MA=ON, ET=E2, SZ=1000. EQ5=DP,ST=OFF,ET=E1/D2,SZ=2000,CH=2,AP=6. EQ5=DP,ST=ON,ET=ES/D2,SZ=10000,CH=5/6,MC=7.

Parameter

SZ=size

## MSAL — Mass Storage Allocation Control Entry

The MSAL entry assigns job files of the specified type to the mass storage devices defined by the specified EST ordinal.

The format of the MSAL entry is:

 $MSAL, t=est_1, est_2, \dots, est_n$ .

Parameter

#### Description

t

File type; one of these values:

- <u>t</u> <u>Description</u> B LGO files. D Job dayfiles.
  - I Input files.†
  - L Local files.
  - 0 Output files.†
  - P Primary files.
  - R Rollout files.
  - S Secondary rollout files.
  - T Temporary files.

esti

EST ordinal of a nonremovable mass storage device, from 5 to 578. Ranges of ordinals can be specified.

# NOTE

In most cases, using ESM as a secondary rollout device improves system performance. UEM, on the other hand, may not improve system performance since it takes more CPU overhead. Use the TRACER utility to determine the best use of system resources.

<sup>&</sup>lt;sup>†</sup> Routing a file to queues changes a file's type, not its residency. Thus specifying an MSAL,I=est or MSAL,O=est entry does not necessarily force all input or output queue files to the specified devices.

Secondary rollout files are rollout files whose size in sectors is smaller than a threshold specified by the IPRDECK or DSD entry SRST. These files are rolled out to devices specified by the MSAL,S= entry. All files selected for rollout that are equal to or greater in size than the threshold are rolled out to devices specified by the MSAL,R= entry. The default value of SRST is 0 (zero); thus, no secondary rollout files exist unless this value is changed. A possible use of this feature is:

```
Entries <u>Comments</u>
EQPDECK
EQ5=DP,ST=ON,SZ=1000,CH=27. Specify equipment 5 as extended memory with a DDP.
MSAL,S=5. Direct secondary rollout files to extended memory.
IPRDECK
SRST=20. Set threshold count so that no large rollout files are rolled out to extended memory.
```

## **PF** — Permanent Files Device Assignment Entry

Before initializing a mass storage device (with the INITIALIZE entry in the EQPDECK), add a PF entry for that device to the EQPDECK anywhere after the device's EQ entry. The PF entry information becomes part of the device's label when it is initialized; this label is recovered during subsequent deadstarts. For subsequent deadstarts, it is not necessary that the PF entry be part of the EQPDECK on the deadstart file; if it is, it is ignored.

If the unit is a family device, the format is:

PF=est,type,dm,sm,name,device,nc.

If the unit is an auxiliary device, the format is:

PF=est,type,name,nc.

#### Parameter

#### Description

est

type

Type of device; one of these values:

EST ordinal of the device; from 5 to  $777_8$ .

## type

#### Description

- F Family device. It can contain indirect access files if the dm parameter is from 1 to 3778. It can contain direct access files if the sm parameter is from 1 to 3778. It is a master device if the dm parameter is specified.
- X Auxiliary device, which can contain both direct and indirect access files. X must be specified on a unit's PF entry if any of the auxiliary device commands are to be used for the device.

Refer to table 3-4 for dependencies.

Table 3-4. PF Entry

|                      |                                           |      | PF Ent             | ry Parameter | Settings |        |
|----------------------|-------------------------------------------|------|--------------------|--------------|----------|--------|
| Type of<br>PF Device | Files Permitted<br>on Device              | type | dm                 | name         | device   | SM     |
| Auxiliary †          | Indirect and/or<br>direct                 | X    | Omit               | pack         | Omit     | Omit   |
| Family               | Direct only                               | F    | 0                  | family       | 1-778    | 1-3778 |
|                      | Indirect only<br>(master device)          | F    | 1-377 <sub>8</sub> | family       | 1-778    | 0      |
|                      | Indirect and<br>direct (master<br>device) | F    | 1-377 <sub>8</sub> | family       | 1-778    | 1-3778 |

<sup>†</sup> If the device is to be a private auxiliary device, enter the INITIALIZE command after deadstart and specify the user name. Refer to section 8, K-Display Utilities, for the procedure.

## Parameter

# Description

| dm   | Specifies the unit's device mask; from 0 to $377_8$ . Set according to information in section 17, PF Utilities. Omit this parameter if the device is an auxiliary device.                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | The device mask for a permanent file device defines the groups of users whose catalogs reside on the device for a particular family.                                                                                                                                        |
| sm   | Specifies the unit's secondary mask; from 0 to 3778. Set<br>according to information in section 17, PF Utilities. Omit this<br>parameter if the device is an auxiliary device.                                                                                              |
|      | This parameter controls the residence of direct access files in the same way that dm controls the residence of indirect access files.                                                                                                                                       |
| name | Designates either the name of the family to which the unit belongs<br>or its pack name if it is an auxiliary device; from 1 to 7<br>alphanumeric characters. Do not use the family name 0: it is<br>reserved.                                                               |
|      | The family name describes the permanent file devices available to a user.† A family may consist of from 1 to 63 logical devices; however, the master devices within the family must have device masks totaling $377_8$ if all possible user indexes are to be accommodated. |

<sup>&</sup>lt;sup>†</sup> If not otherwise specified, the default family name becomes part of the tape label information. It is checked and verified if the user specifies the FA=A parameter on a command. Refer to the NOS 2 Reference Set, Volume 3 for a discussion of FA=A.

#### Parameter

device

nc

## Description

Usually a system runs with one family of permanent file devices available. But you can activate additional families on a system, in order to allow the users of these families to access their permanent files through an alternate system. This might be helpful if one system supplies backup service to another system. When more than one family is active on a system, users with matching user indexes access the same permanent files on a public auxiliary device. You can avoid this situation by predetermining a range of user indexes for each family running on a system. When a new family is introduced into a system, its user indexes should be checked against those of the family or families currently running and any matching indexes should be changed. Refer to the IPRDECK entry COMLIB later in this section.

The pack name is the unique 7-character name associated with an auxiliary device. An auxiliary device is a self-contained permanent file device: all permanent files (whether direct or indirect access) represented by the catalogs on the device reside on that device. To access a file on an auxiliary device, users must specify the pack name as part of the permanent file request. The pack name is used instead of the usual algorithm for determining catalog location (user masks and family name). An auxiliary device can be private or public. Any user who knows the pack name and has the appropriate permissions and validations can access files on an auxiliary device. Only the owner user name can create files on a private auxiliary device (perform DEFINE, SAVE, or REPLACE requests).

Number of the device in the family; from 1 to  $77_8$ . Omit this parameter if the device is an auxiliary device.

A permanent file that does not reside on the master device has a device number in the catalog entry or on the master device. The device number specifies on which alternate device within the family the file resides.

Number of catalog tracks (optional) used only for master devices; from 1 to  $200_8$ . This value must be a power of 2. If you do not specify nc, one of the following default values (based on the equipment type) is supplied.

| Default |           |       | Default |                        |       |
|---------|-----------|-------|---------|------------------------|-------|
| nc      | Equipment | Туре  | nc      | Equipment              | Туре  |
| 40      | 834       | DD    | 10      | 819                    | DV/DW |
| 40      | 844-21    | DI/DK | 4       | Extended<br>memory     | DE    |
| 40      | 844-41/44 | DJ/DL |         | •                      |       |
| 10      | 885-11/12 | DM/DQ | 4       | ECS or ESM<br>with DDP | DP    |
| 10      | 885-42    | DB    | 1       | Private<br>device      |       |

Examples:

PF=6,F,125,125,SYSTEM,3,200. PF=17,X,PACK.

### SYSTEM — System Library Device Assignment Entry

The SYSTEM entry specifies which mass storage devices are to contain copies of the NOS system library from the deadstart file. A system device can be any mass storage device as well as extended memory.

Throughput can be greatly improved by specifying more than one system device. For example, if two system devices are specified and they are on different channels, the time required to access system programs can be reduced. When the channel for one system device is busy, the other is accessed. Also, if hardware problems occur on one system device, the other system device can still be accessed.

The following restrictions apply.

- The EQ entry for a system device cannot have the status set to OFF.
- A REMOVE entry cannot exist in the EQPDECK for a device being specified as a system device.
- If more than one device is specified as a system device, all devices specified must be of the same type. For example, if there are two system devices and the equipment EST ordinal for one of them specifies DI, the equipment EST ordinal for the other one must also specify DI.
- If no devices are specified as system devices, the system library resides on the first nonremovable mass storage device.
- An ASR entry cannot exist in the EQPDECK for a device being specified as a system device.

The SYSTEM entry format is:

 $SYSTEM=est_1, est_2, \dots, est_n$ .

#### Parameter

#### Description

est<sub>i</sub>

EST ordinal of the device to contain a copy of the system library on the deadstart file; from 5 to 7778. The EQ entry must be set to ON status. One or more ordinals can be specified with one SYSTEM entry. Ranges of ordinals can be specified. The maximum number of system devices allowed depends upon the value of MXSY (refer to COMSMSC Parameters in the NOS 2 Installation Handbook).

## ASR — Alternate System Library Device Assignment Entry

This entry specifies which mass storage devices are to be alternate system devices. An alternate system device is a mass storage device on which duplicate copies of system routines can be placed by the system, either for faster access than is possible from a system device or because they are frequently used programs. The following restrictions apply.

- The device must be a mass storage device, including extended memory.
- The device cannot be a removable device.
- The device cannot be a system device.

When loading a system routine, the system will access the routine from the alternate system device if practical. However, if the alternate system device is down or its access is more congested than the system device, the system will access the routine from the system device.

The procedure for selecting the records to be placed on the alternate device is in LIBDECK.

The ASR entry format is:

 $ASR=est_1, est_2, \dots, est_n$ .

#### Parameter

## Description

est<sub>i</sub>

EST ordinal of mass storage device to be used as an alternative system device; from 5 to  $777_8$ . Ranges of ordinals can be specified.

## SCKP — System Checkpoint File Device Assignment Entry

The SCKP entry specifies on which mass storage devices the checkpoint file is to reside. This entry is processed during a level 0, 1, or 2 deadstart. If no checkpoint devices are defined, the checkpoint file will reside on the first default mass storage device.

A level 0 deadstart clears the checkpoint status on all mass storage devices. To clear the checkpoint status for a specific mass storage device, use the RESET entry.

The SCKP entry format is:

 $SCKP=est_1, est_2, \dots, est_n$ .

#### Parameter

#### Description

esti

EST ordinal of the mass storage device to be defined as a system checkpoint file device; from 5 to  $777_8$ . Ranges of ordinals can be specified.

#### DOWN --- Logical Device Removal Entry

The DOWN entry specifies which EST ordinals will be logically removed (or down) at deadstart time. You can use this entry for all types of equipment that are defined as nonshared and removable. It is particularly useful either in allowing online diagnostics of nonshared extended memory or in removing mass storage devices that cannot be removed online (perhaps due to hardware malfunctioning).

The DOWN entry format is:

DOWN=est1,est2,...,estn.

Parameter

## Description

est<sub>i</sub>

EST ordinal of the device to be logically removed; from 5 to 7778. Ranges of ordinals can be specified.

The DOWN entry has the following characteristics.

- It can be entered anywhere after the EQ entries for nonmass storage devices.
- For removable, nonshared mass storage devices, it can be entered anywhere after the EQ and REMOVE entries.
- Shared devices (including the link device) cannot be defined as DOWN in an MMF environment.
- It forces down and off status for the EST ordinal, regardless of what was specified in the EQ entry.
- The deadstart device cannot be defined as DOWN at deadstart time.
- If extended memory is not shared, it can be specified as DOWN at deadstart time, and it will remain DOWN until another level 0 deadstart is performed. Extended memory cannot be brought up online.
- DOWN cannot be specified for a device that has initialization requested.

If a control module is to be downed, all of the above characteristics must be true for each 834 disk unit defined on that control module.

DOWN entry examples follow.

EQ6=DI, ST=ON, UN=3, CH=32/26. REMOVE=6. DOWN=6. EQ25=CR, ST=OFF, EQ=4, CH=12. EQ26=LP, ST=ON, EQ=6, CH=12. DOWN=25, 26. EQ5=DE, ST=OFF, SZ=400. DOWN=5.

#### FAMILY — Default Family Name Assignment Entry

The FAMILY entry defines the default family. The family that is to be defined as the default family may reside on more than one device. The EST ordinal of any device within the family can be specified on the FAMILY entry, except in the following situation. If the member of the family whose device mask will have bit  $2^7$  (2008 in mask) set is being initialized, the FAMILY entry must specify the ordinal of this device. In all cases, the FAMILY entry must follow the EQ entry for the device specified.

The following restrictions apply.

- The status parameter for a family device's EQ entry cannot be set to OFF.
- A REMOVE entry cannot exist in the EQPDECK for a device being specified as a family device.

The FAMILY entry format is:

FAMILY=est.

Parameter

#### est

EST ordinal number of the mass storage device that the system automatically uses to determine your family when the you do not specify a family name at login or job initiation; from 5 to 7778.

Description

#### **REMOVE** — Removable Device Assignment Entry

If a mass storage device is to be considered removable, you must specify it as such at deadstart with the REMOVE entry. This allows it to be introduced or removed during system operation. A device specified as removable cannot also have associated with it an ASR, SYSTEM, MSAL,T=, FAMILY, DAYFILE, ACCOUNT, ERRLOG, or MAINLOG entry (refer to Dayfile Descriptions earlier in this section for the last four entries).

The format is:

REMOVE=est<sub>1</sub>,est<sub>2</sub>,...,est<sub>n</sub>.

Parameter

#### Description

est<sub>i</sub>

EST ordinal of mass storage device that is to be removable; from 6 to 7778. One or more ordinals may be specified with one REMOVE entry. Ranges of ordinals can be specified.

## SHARE — Shared Device Entry

This entry identifies the rotating mass storage devices to be shared through a link device (ECS or ESM) by from two to four mainframes in a multimainframe complex. The tables necessary for the management of these devices (MST, TRT, MRT, and DAT) are maintained on the link device. The presence of the SHARE entry implies a multimainframe complex; shared status will be set for the link device. If the link device is the only device to be shared, it must be specified in the SHARE entry. If the SHARE entry is specified, the ISHARE entry must be omitted. Refer to PRESET - Present the Link Device Entry later in this section.

Following is a list of the equipment types that can be shared.

| Equipment           | Туре  |
|---------------------|-------|
| Extended memory     | DE    |
| ECS or ESM with DDP | DP    |
| 844-21              | DI/DK |
| 844-41/44           | DJ/DL |
| 885-11/12           | DM/DQ |

The format of SHARE is:

-- ·

SHARE=est,,est,,...,est,.

Parameter

Description

est<sub>i</sub> EST ordinal of the mass storage device being shared; from 5 to  $777_8$ . Ranges of ordinals can be specified.

Refer to section 13, Multimainframe Operations, for suggestions on shared device configurations.

### **ISHARE** — Independent Shared Device Entry

This entry identifies the rotating mass storage devices that are to be independently shared by from 2 to 16 mainframes in a multimainframe complex. The tables necessary for the management of these devices (MST, TRT, MRT, and DIT) are maintained on the shared device. You cannot designate ECS or ESM in an ISHARE entry. When the ISHARE entry is specified, the SHARE entry must be omitted. Refer to PRESET - Preset the Independent Shared Device Entry later in this section.

Listed are the equipment types that can be independent shared devices.

| Equipment | Туре  |
|-----------|-------|
| 834       | DD    |
| 844-21    | DI/DK |
| 844-41/44 | DJ/DL |
| 885-11/12 | DM/DQ |

The ISHARE entry format is:

ISHARE=est<sub>1</sub>,est<sub>2</sub>,...,est<sub>n</sub>

### Parameter

### Description

esti

EST ordinal of the mass storage device shared; from 6 to 7778. Ranges of ordinals can be specified, as described under Specifying Ranges of EST Ordinals earlier in this section.

Refer to section 13, Multimainframe Operations, for suggestions on shared device configurations.

#### LBC — Load Buffer Controllers Entry

This entry identifies the type of controlware to be installed on the specified disk channels. Depending on the specified parameters, this entry can identify the channels as having half-track or full-track controlware but not install the controlware.

Unless you specify the LBC entry, the system examines the mnemonics of the device in the EQPDECK entry and causes the default version of controlware to be installed as follows:

| Device Type | Controlware<br>Version Number |
|-------------|-------------------------------|
| db †        | MA722                         |
| dd ‡‡       | MA462                         |
| DI          | MA710                         |
| DJ          | MA710                         |
| DK          | MA401                         |
| DL          | MA401                         |
| DM          | MA721                         |
| DQ          | MA721                         |
|             |                               |

<sup>&</sup>lt;sup>†</sup> Not applicable for CYBER 180-class machines.

*<sup>†</sup>*<sup>†</sup>Applicable for models 810, 815, 825, and 830 only.

Use the LBC entry to override these defaults. The LBC entry format is:

LBC, type,  $c_1, c_2, \ldots, c_n$ .

Parameter

# Description

type

| Controlware to | be installed; one of these values.                                                             |
|----------------|------------------------------------------------------------------------------------------------|
| type           | Description                                                                                    |
| FM             | Install controller with full-track (MA721) controlware.                                        |
| FT             | Install controller with full-track (MA401) controlware.                                        |
| НТ             | Install controller with half-track (MA710) controlware.                                        |
| ID             | Install 7255-1 adapter with full-track (MA462) controlware.                                    |
| M8             | Install 7990 controller with MB466 controlware.                                                |
| NF             | Identify channel(s) as having full-track controller,<br>but do not install the controlware.    |
| NH             | Identify channel(s) as having half-track controller,<br>but do not install the controlware.    |
| NI             | Identify channel(s) as having full-track 7255-1<br>adapter, but do not install controlware.    |
| NM             | Identify channel(s) as having full-track 7155-1 controller but do not install the controlware. |
| NN             | Identify channel(s) as having NADs, but do not install the controlware.                        |
| NP             | Identify channel as having 7155-401 controller, but do not install the controlware.            |
| N8             | Identify channel(s) as having 7990 controller, but do not install the controlware.             |
| рн             | Install 7155-401 controller with MA722 controlware.                                            |
|                |                                                                                                |

ci

Disk channels; type determines if controlware is installed on these channels.

The controlware version number that can be loaded into the adapter or controller types is:

| Adapter<br>Controller | Controlware<br>Version Number |
|-----------------------|-------------------------------|
| 7054                  | MA710                         |
| 7152                  | MA710, MA401                  |
| 7154                  | MA710, MA401                  |
| 7155-1                | MA721                         |
| 7155-401              | MA722                         |
| 7255 <del>-</del> 1   | MA462                         |
| 380-170               | MG101                         |
| <b>799</b> 0          | MB466                         |

## XM — Declare Extended Memory Space for Buffers or User Access

The XM entry reserves space for I/O buffers and causes initialization of tables for user access to extended memory.

# NOTE

Except on models 865 and 875, the assignment of user access to extended memory forces jobs using user access to use CPU 0. This prevents CPUMTR from being locked out during large block transfers to or from extended memory on dual-CPU mainframes.

The XM entry is required if the system contains UEM or buffered devices. If UEM is the only use for extended memory, you do not need to specify EST ordinal 5 in the EQPDECK.

## The XM entry format is:

XM=id,iob,uec,EM.

| Parameter | Description                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id        | Identifier of the mainframe that will access the reserved extended memory space; id is required.                                                                                                                                                                                                                          |
| ·         | In a multimainframe complex, you must specify XM entries for each<br>mainframe in the complex in all EQPDECKs, enabling the first<br>mainframe to reserve ECS or ESM space for all mainframes in the<br>complex.                                                                                                          |
| iob       | Number of words/ $1000_8$ reserved for buffers for DB, DW, or DV devices; from $40_8$ to 77778. The optimum number of words to reserve is the amount left after the alternate system library and user ECS are taken into account. If no buffered devices are defined, enter 0.                                            |
| uec       | Number of words/1000g of extended memory to reserve for user access; maximum value is $7774_8$ .                                                                                                                                                                                                                          |
| EM        | For models 865 and 875 and CYBER 180-class machines, user access<br>extended memory can be allocated in UEM without allocating UEM as an<br>equipment. If you want only user-access extended memory in UEM,<br>clear or do not specify EST ordinal 5 in the EQPDECK and enter XM<br>with the uec size and the EM keyword. |
|           | For models 865 and 875, if you specify EM, user access extended<br>memory is allocated in UEM regardless of the presence of ECS or ESM;<br>if you omit EM, user access extended memory is allocated in the<br>device defined in the extended memory EST entry.                                                            |

## ACCESS

The ACCESS entry allows you to specify equipment access level limits for mass storage, magnetic tape, two-port multiplexer, stimulator multiplexer, and unit record type equipment. This entry is invalid for other types of equipment. This entry determines the upper and lower limits for the range of access levels of the data allowed to be read from or written to the equipment. The default equipment access level limits are zero; no secure data can be read from or written on the equipment. Values for this entry should be supplied by a site security administrator.

If you want the equipment access level limits specified by this entry to become the device access level limits for mass storage equipment, that equipment must be initialized. Refer to the NOS 2 Security Administrator's Handbook for more information about equipment access and device access level limits.

This entry is ignored if the system is running in unsecured mode.

The format of the ACCESS entry is:

ACCESS, lower, upper, list.

#### Parameter

Description

- lower Access level name specified in deck COMSMLS (refer to the NOS 2 Installation Handbook) corresponding to the desired lower limit.
- upper Access level name specified in deck COMSMLS corresponding to the desired upper limit.
- list One or more EST ordinals, separated by commas, or a range of ordinals as described in Specifying Ranges of EST Ordinals earlier in this section.

#### EQPDECK ENTRIES MADE ONLY DURING DEADSTART

The following entries are valid only from the system console at deadstart time. They cannot be included as part of the EQPDECK on the deadstart file.

## AUTOLOAD

The AUTOLOAD entry toggles the selection of buffer controller autoloading for all 7054/7152/7155 controllers and the 7255 adapter. The AUTOLOAD format is:

AUTOLOAD.

## GRENADE

The GRENADE entry causes unit reservations to be cleared on all 844 units physically connected to each 7054/7154/7152/7155 controller and any 834 units connected to a 7255 adapter. The GRENADE format is:

GRENADE .

## **INITIALIZE** — Initialization Entry

To use a mass storage device that is defined with an EQ entry, it must have a label. A label is written on a device when you initialize it by using either the INITIALIZE command, during system operation, or the INITIALIZE entry in the EQPDECK, when it is displayed at the system console at deadstart time.

A mass storage device's label is contained on a logical track (usually track 0). It contains information about the allocation and characteristics of a device (and its units, if there is more than one unit on a device). This information is in the form of a label sector for the first unit, a TRT for the device, and a label sector for each unit.

Initialization does not automatically occur at each deadstart because mass storage device labels are recovered during all deadstarts. Therefore, initialize a device only in the following situations.

- To add a new mass storage device (no label exists on the device) use the INITIALIZE entry.
- If parts of the label on a permanent file device have been destroyed by maintenance operations (permanent files having been dumped to another device before diagnostics were run), use the INITIALIZE entry during deadstart to write a new label. Then reload the permanent files.
- If a device (usually a private auxiliary, public auxiliary, or alternate permanent file family device) is added to a system during operation, use the DSD INITIALIZE command to initialize it if it does not have a valid label on it when it is added to the system.
- When an extended memory device is initially placed in maintenance mode, all mainframes using extended memory must initialize it (the maintenance mode parameter is described under EQ - Extended Memory EST Entry earlier in this section). You must also enter the PRESET entry for multimainframe operation.

During a deadstart, the INITIALIZE entry has the following characteristics.

• During a level 0 deadstart, it can be entered at the system console only when the EQPDECK is displayed. It can be entered anywhere after the EQ entry for the device.

If it is placed in the deadstart file EQPDECK, the system issues the error message INCORRECT ENTRY when the EQPDECK is read from the tape.

- A total initialization (op=AL) assumes that no valuable information exists on the device and creates a new label. When the new label is created, all previously existing information on the device, except CTI, CDA, HIVS, and MSL, is lost.
- If the EQ status for the device is OFF when INITIALIZE is entered, initialization of the device occurs whenever the device is set to ON status by the operator with the DSD ON command during normal system operation.
- If the device is not a master device, INITIALIZE (op=AL) only writes a label; if it is a master device, then it also initializes the catalog track and writes EOIs at the beginning of the permit track, the indirect access track (data chain), and each catalog track.
- During a deadstart initialization (op=AL), all flaw reservations specified for a device are lost and must be reentered, except for 844 type devices with factory-formatted disk packs.

The format of INITIALIZE is:

# INITIALIZE, op, est, est, ..., est,

Parameter

op

#### Description

Level of initialization; one of these values:

- op Description
- AF Initialize account dayfile.
- AL Total initialization.
- DF Initialize system dayfile.
- EF Initialize error log.
- MF Initialize binary maintenance log.
- PF Initialize permanent files.
- QF Initialize queued files.

est<sub>i</sub> EST ordinal of mass storage device to be initialized; from 5 to  $777_{8}$ .

If the ordinal refers to a family permanent file device, then family name, device number, and mask (if it is a master device) are specified on the PF entry.

If it is an auxiliary device, the pack name is specified on the PF entry.

Total initialization (op=AL or FP) is the only initialization that is independent of the content of the pack, if the initialization occurs during deadstart. If the initialization is done while the system is running, it is applied to the device after the check mass storage (CMS) routine has recovered it. If CMS cannot recover the device, the initialization is similar to a deadstart initialization (that is, all information on the device is lost).

The device number, family name, and device masks can only be changed during a total initialization. Since all devices may contain permanent files, you should include a PF entry for a device when performing a total initialization. If you do not, the device is assigned a default family name, device number, and device masks. It is possible that these parameters may conflict with other devices in the system. If a conflict occurs, resolve it by using PF entries. If you do not specify a PF entry when initializing a device, the default family name is SYSTid (where id is the machine identifier), and the default device numbers begin at 1 and increase by 1 for each device that you initialize without a PF entry. If you initialize equipment 5 without a PF entry, the device mask and secondary mask are set to 3778. For all other equipment, the default masks are set to 0 (zero).

The INITIALIZE entry operates in conjunction with the dayfile entries DAYFILE, ACCOUNT, ERRLOG, and MAINLOG (refer to Dayfile Descriptions earlier in this section) to determine where the dayfiles actually reside. The following examples illustrate the various cases. Assume that the system has three mass storage devices (EST ordinals 6, 7, and 10). Example 1:

For this example, no dayfile entries are made and no previous dayfiles exist.

The following EQPDECK entry is made.

INITIALIZE, AL, 6, 7, 10.

All dayfiles reside on ordinal 6.

Example 2:

In this example dayfile entries are made, but no previous dayfiles exist.

The following EQPDECK entries are made.

DAYFILE=6,200. ACCOUNT=7,200. ERRLOG=10. MAINLOG=10,200. INITIALIZE,AL,6,7,10.

In this case, the dayfiles reside on the indicated devices (system dayfile on ordinal 6, account dayfile on ordinal 7, error log and binary maintenance log on ordinal 10). The default buffer length is used for the error log buffer.

Example 3:

In this example, dayfile entries are made and previous dayfiles do exist.

Assume that the EQPDECK entries in example 2 are used.

Since a total initialization has been done on each device, no dayfiles are recovered. They reside on the indicated devices.

Example 4:

In this example, dayfile entries are made, previous dayfiles exist, but no dayfile initialization entries are made.

The following EQPDECK entries are made.

```
DAYFILE=6.
ACCOUNT=7.
ERRLOG=10.
INITIALIZE,PF,6.
```

The dayfiles may already reside on the specified devices, or they may reside on some combination of the possible devices. In either case, since no dayfile initialization entries are made, the old dayfiles are recovered. The residence of these dayfiles is governed by the residence of the old dayfiles. The PF initialization entry returns all permanent file space and relabels the device based on the recovered device parameters. The dayfiles and queued files on this device are not affected by this entry.

#### Example 5:

In this example, dayfile entries are made, previous dayfiles exist, no dayfile initialization entries are made, and duplicate dayfiles are in existence.

Assume that the EQPDECK entries in example 4 are used.

For the dayfiles that do not have duplicates, the residence is defined by the current residence of the files, not the EQPDECK entries. But assume that an error log is recovered from ordinals 6 and 10. In this case, the most recent file becomes the active error log. Its previous residence overrides the EQPDECK entry. The other file becomes an inactive error log (an entry exists in the mass storage table of the device pointing to the inactive file, but the file is not in use by the system).

To produce an inactive error log, the site must run in the following manner.

- 1. Assume an 844 disk subsystem with two or more spindles is being used. Run with unit 1 equated to EQ6 and unit 0 unused.
- 2. Redeadstart, equate unit 0 to EQ6, and do not use unit 1.
- 3. Redeadstart, equate unit 0 to EQ6, and unit 1 to EQ7.

Since unit 0 has the most recent copy of the error log, this copy would become an active error log and the copy on unit 1 would become an inactive error log.

Example 6:

In this example, dayfile entries are made, the previous dayfiles from example 2 exist, and initialization entries are made.

The following EQPDECK entries are made.

DAYFILE=7. ACCOUNT=7. ERRLOG=10,300. MAINLOG=10. INITIALIZE,DF,6. INITIALIZE,QF,6.

In this case, the account dayfile is recovered and continued on ordinal 7. The binary maintenance log is recovered and continued on ordinal 10 with a CM buffer length of 100. The error log is recovered and continued on ordinal 10 with a CM buffer of 300g words. The system dayfile space on ordinal 6 (from example 2) is released and the new system dayfile starts on ordinal 7. The QF initialization entry releases all space reserved by queued files on ordinal 6.

The CM buffer length is not affected by dayfile recovery. It is always specified by the values defined in the EQPDECK entries. If no buffer length entries exist, the system default values are used.

### **PRESET** — Preset the Link Device Entry

This entry defines allocation space and initializes the tables (MST, TRT, MRT, and DAT) on the link device that are required for management of shared multimainframe mass storage devices. The entry is valid only for level 0 deadstarts by the first mainframe in the multimainframe complex to deadstart.

Once PRESET is issued, the SHARE entry is disabled. Therefore, all SHARE entries must precede the PRESET entry. The PRESET entry has two formats:

PRESET.

or

PRESET, n.

Parameter

Description

n

Number of shared devices; from 1 to 778.

If you specify n, space is allocated for the specified number of shared devices. Use this entry when the total number of shared devices is greater than the number of shared devices defined in the EQPDECK of the first mainframe in the multimainframe complex to do a level 0 deadstart.

If you do not specify n, the link device is preset, and the amount of table space reserved for the shared devices is determined by the number of shared entries in the EQPDECK.

## **PRESET** — Preset the Independent Shared Device Entry

This entry presets the independent shared devices in a multimainframe complex. The MST, TRT, MRT, and DIT are maintained on the mass storage device itself and are not affected by the PRESET entry. This entry is used in conjunction with the ISHARE entry. It is valid only on a level 0 deadstart by the first mainframe in the multimainframe complex to deadstart. All ISHARE entries must precede the PRESET entry.

The format is:

PRESET=est<sub>1</sub>, est<sub>2</sub>, ..., est<sub>n</sub>.

Parameter

### Description

esti

EST ordinal of the ISHARE device; from 6 to 7778.

Refer to section 13, Multimainframe Operations, for suggestions on shared device configurations.

## RESET

The RESET entry rescinds all device-related attributes resulting from entries such as REMOVE, SYSTEM, MSAL, and so on. It restores the values specified with the last EQest entry encountered. If the DOWN entry was specified, EQest will be OFF, regardless of what was specified on the ST= parameter on the EQ entry. The format is:

RESET=est<sub>1</sub>,est<sub>2</sub>,...,est<sub>n</sub>.

Ranges of ordinals are not allowed; each ordinal must be entered individually.

# APRDECK

The auxiliary mass storage parameter deck (APRDECK) is a text record on the deadstart file that is processed during system initialization. APRDECK entries identify areas of mass storage that are unusable (flawed areas) and prevent the system from accessing them. The system uses the information in the APRDECK entries to build the TRT for each device that resides in CMR and also in the mass storage device label.

You can place up to 1008 APRDECKs on the deadstart file. Placing several APRDECKs on the same deadstart file allows you to use the same file to deadstart several configurations.

## APRDECK FORMAT

The first line in an APRDECK is the deck name. The format of the APRDECK name is:

APRDnn

nn is the number identifying the APRDECK; from 00 to 778.

An APRDECK must have a name and may have flaw entries. The first APRDECK must contain the deck name APRD00 and nothing else. Subsequent APRDECKs must be numbered consecutively and can contain flaw entries.

The released version of the APRDECK contains no entries. You can enter flaws at three different times:

- During deadstart, after entering all EQPDECK modifications.
- During system operation, using the FLAW entry (refer to section 8, K-Display Utilities).
- During the configuration of a deadstart file.

If during deadstart you initialize a device and then enter NEXT, the system displays both the parameters on the device's EST entry and the APRDECK referenced by the EST entry. You can then change the flaws for the device. If the first APRDECK is referenced by the EST entry, the system displays the parameters on the device's EST entry and the APRDECK name, APRD00. You can then enter flaws for the device. These changes to the APRDECKs remain in effect until the next deadstart.

For example, in a EQPDECK, the EST entry for an 844-21 disk is:

EQ07=D1,ST=ON,EQ=0,CH=31/33,AP=5,UN=2.

After you initialize equipment 07 and enter NEXT, the following display appears.

| EQ TYPE ST EQ UNITS CHANNELS<br>07 DI-1 ON 0 02 31 33<br>APRD05<br>STK=4173.<br>STK=7062. |       |      |    |    |       |          |  |
|-------------------------------------------------------------------------------------------|-------|------|----|----|-------|----------|--|
| APRD05<br>STK=4173.                                                                       | EQ    | TYPE | ST | EQ | UNITS | CHANNELS |  |
| STK=4173.                                                                                 | 07    | DI-1 | ON | 0  | 02    | 31 33    |  |
|                                                                                           | STK=4 | 173. |    |    |       |          |  |

The APRDECK entries described in this section are those to be used for entering flaws during deadstart or during the configuration of the deadstart file. Use the entries as follows.

- Use the CAF entry to clear all flaw reservations on a device.
- Use the SPF entry to specify the physical address of a flaw in extended memory. (If a reservation for that physical address already exists, it remains in effect.)
- Use the SPF entry to specify the cylinder, track, and sector of a flaw in a disk. (If a reservation for that physical area already exists, it remains in effect.)
- Use the CPF entry to cancel a particular SPF entry.
- Use the SLF entry to specify the logical address of a flaw. (If a reservation for that logical address already exists, it remains in effect.)
- Use the CLF entry to cancel an SLF entry.

Either obtain flaw addresses from a customer engineer, or run the MST (mass storage test) on the device to determine the bad areas. MST specifies the physical address of flaws.

The system reads the flaw information recorded on the utility flaw map of an 881/883/885 disk pack during the initialization of 844/885 equipment and reserves the appropriate areas. For multiunit devices, the flaw reservation is the union of all utility flaw maps. This automatic flawing process occurs in addition to any APRDECK entries. However, you cannot clear areas recorded as flawed on the utility flaw map of an 881/883/885 disk pack with the CAF entry. Refer to appendix F for information on clearing these flaws.

You can list all APRDECKs on the deadstart file by accessing the system file SYSTEM with an ASSIGN or COMMON command, then using the T parameter on the CATALOG command. Refer to the NOS 2 Reference Set, Volume 3 for more information.

# CAF — Clear All Flaw Reservations

The CAF entry clears all flaw reservations previously made with SLF or SPF entries. The format is:

CAF.

## SLF — Set Logical Flaws on Any Mass Storage Device

Use this entry to specify the logical address of a flaw. If the track was previously reserved, that reservation remains in effect. The format is:

SLF=track.

Parameter

Description

track

Logical track number. Refer to table 3-5 for valid ranges of track numbers.

### CLF — Clear Logical Flaws on Any Mass Storage Device

To cancel a reservation made with an SLF entry, enter the identical track number using the CLF entry. The format is:

CLF=track.

Parameter

track

Logical track number. Refer to table 3-5 for valid ranges of track numbers.

Description

# SPF — Set Physical Extended Memory Track or Disk Area Flaws

Two formats exist for the SPF entry. One format prevents the system from using blocks (tracks) of extended memory. The other format prevents the system from using sectors on disks.

Use the following SPF format to prevent the system from using blocks (tracks) of extended memory.

SPF=Aaddress.

or

SPF=Aaddress1-Aaddress2.

### Parameter

## Description

Aaddress

The 1- to 7-digit octal logical address in a track of extended memory; track containing the absolute address is reserved. The letter A must precede the address.

Aaddress1-Lowest (Aaddress1) and highest (Aaddress2) addresses in a range Aaddress<sub>2</sub> of logical addresses in one or more tracks of extended memory. All tracks in the range are reserved. The letter A must precede the addresses; the hyphen is required.

Use the following SPF format to prevent the system from using sectors on disks.

SPF=Ccylinder,Ttrack,Ssector.

Refer to table 3-5 for the number of cylinders, tracks, and sectors for each device.

| Parameter | Description                                            |
|-----------|--------------------------------------------------------|
| Ccylinder | Cylinder number; the letter C must precede the number. |
| Ttrack    | Track number; the letter T must precede the number.    |
| Ssector   | Sector number; the letter S must precede the number.   |

## CPF — Clear Physical Extended Memory Track or Disk Area Flaws

To cancel a reservation made with an SPF entry, enter the identical information with a CPF entry. The format is the same as for the SPF entries.

Table 3-5. Information for Setting or Clearing Flaw Areas

| Device                  | Device<br>Type | Logical<br>Track Range† | Cylinders/<br>Device † | Tracks/<br>Cylinder† | Sectors/<br>Track † |
|-------------------------|----------------|-------------------------|------------------------|----------------------|---------------------|
| 844-21, half track      | DI             | 4000-7137               | 630                    | 22                   | 30                  |
| 844-41/44, half track   | DJ             | 4000-7147               | 1464                   | 23                   | 30                  |
| 844-21, full track      | DK             | 4000-7137               | 630                    | 23                   | 30                  |
| 844-41/44, full track   | DL             | 4000-7147               | 1464                   | 23                   | 30                  |
| 885-11/12, half track   | DM             | 4000-7221               | 1511                   | 50                   | 40                  |
| 885-11/12, full track   | DQ             | 4000-7221               | 1511                   | 50                   | 40                  |
| 834                     | DD             | 4000-7133               | 1456                   | 12                   | 40                  |
| 819, single density     | DV             | 4000-5465               | 633                    | 12                   | 21                  |
| 819, double density     | DW             | 4000-7153               | 1466                   | 12                   | 24                  |
| 885-42, full track      | DB             | 4000-7221               | 1511                   | 12                   | 40                  |

# **IPRDECK**

The IPRDECK contains the system installation parameters that determine the system's operation mode. From 1 to 100g IPRDECKs can exist on a deadstart file. The IPD entry in the CMRDECK specifies which IPRDECK to use. If you omit the IPD entry, the system uses the first IPRDECK on the deadstart file. IPRDECKs are named IPRDnn, where nn is from 00 to  $77_8$ .

There are two IPRDECK console displays. The initial display, IPRINST, is an instruction display. It gives a brief description of all valid IPRDECK entries. The second display is the current IPRDECK. If either display overflows two screens, you can page the display.

You can modify the IPRDECK by entering the appropriate changes or additions from the console keyboard. Make these entries while either the IPRINST or IPRDECK is displayed. Each console entry supersedes the value currently specified in the IPRDECK.

# NOTE

The modified IPRDECK remains in effect only until the next deadstart is performed; that is, changes to the IPRDECK are not recovered across deadstart unless you create a new deadstart file to reflect those changes.

You can list all IPRDECKs on your system by accessing the system file SYSTEM with a COMMON command, then using the T parameter on the CATALOG command. Refer to the NOS 2 Reference Set, Volume 3 for more information concerning these commands.

Most of the IPRDECK entries are also valid DSD commands that can be used to make changes during system operation. Changes to the IPRDECK using DSD commands are not retained after any level of recovery deadstart.

### JOB CONTROL INFORMATION

The QUEUE, SERVICE, and DELAY entries in the IPRDECK relate to job control. General information concerning job control follows.

## Job Scheduling

Job scheduling is the control of jobs in the input (IN), executing (EX), and output (OT) queues for each service class. Scheduling in the input and output queues is based on the priority of a queue entry relative to all queue entries in the system. The priority of a queue entry depends both upon how long the entry has been waiting in the queue and upon the parameters specified on the QUEUE entry in the IPRDECK. The following formula shows how the system computes the priority; all values are octal.

$$p = \frac{(ct-et)}{WF} + LP$$

Variable

#### Description

- p Priority; LP  $\leq p \leq$  UP. UP (a parameter on the QUEUE entry) is the highest priority.
- WF Weighting factor; a parameter on the QUEUE entry.
- ct Current time in seconds.
- et Time in seconds at which the job entered the queue.
- LP Lowest priority; a parameter on the QUEUE entry.

When an input or output queue entry is created, its priority is the lowest priority (LP) for its service class. The queue priority of the queue entry increases as time passes. The rate at which the priority increases depends upon the weighting factor (WF). The larger the weighting factor, the slower the priority increases. (The queue priority of an entry with a WF of 10g increases eight times slower than an entry with a WF of 1.) The queue priority increases either until the queue entry is selected for processing or until the queue priority reaches the highest priority (UP). If the queue priority of an entry reaches UP, it remains at UP until the entry is selected for processing. If the queue priority is zero, the job or file is never selected by the job scheduler and stays in the queue until the operator either enters a DROP command or resets the priority to a nonzero number.

Queue control for job execution determines how much continuous execution time a job gets. The amount of execution time depends both on the parameters specified on the QUEUE and SERVICE entries in the IPRDECK and whether other jobs are waiting for execution.

When a job in the input queue is selected for execution, it gets an initial priority (IP; a parameter on the QUEUE entry) for the execution queue. Scheduling priority increases for a job in the execution queue in the same way as in the input and output queues. When the job is selected for execution, it executes either until completion or until it is preempted by a higher priority job. When the job is preempted by a higher priority job, it goes to the rollout queue with the queue priority increases like any other job in the rollout queue. When a job exceeds its first time slice, its priority becomes the initial slice priority (IL; a parameter on the QUEUE entry). On expiration of subsequent time slices the job reenters the execution queue with the lowest priority (LP; a parameter on the QUEUE entry). The IL and LP parameters provide two opportunities for you to change the job's scheduling priority.

For the interactive service class, there is an additional execution queue priority, TP (a parameter on the QUEUE entry). It is assigned to the execution queue entry of a job restarting after terminal I/O. The value of TP aids response time to program prompts. Also, for the interactive service class, the initial priority (IP) has an added significance. In addition to being the priority at which jobs are scheduled from the input queue to the execution queue, IP is the priority assigned to each newly initiated interactive job step. Using separate TP and IP parameters allows the system to give faster responses to users interacting with a job. To achieve this, a value for the TP parameter slightly greater than the value for the IP parameter is recommended (refer to table 3-6 and figure 3-6).

The relative values of the QUEUE and SERVICE parameters, both among service classes and within a service class, affect system performance. For an example of ranges of service class priorities, refer to figure 3-6. For an example set of specific entries for the QUEUE and SERVICE parameters, refer to table 3-6.

## **Job Control**

The parameters on the SERVICE entry in the IPRDECK direct control of the jobs. The parameters set the following conditions:

- Initial CPU priority at job initiation.
- CPU time slice in milliseconds divided by 64.
- Central memory time slice in seconds.
- Number of jobs per service class.
- Time-out delay for interactive and detached jobs.

A job leaves a central memory control point when the following conditions are present:

- A job completes, aborts, or is suspended.
- A system request causes a job to be rolled out.

A system request includes a job request for a tape or disk pack, a ROLLOUT command from the generator, and execution of the ROLLOUT macro. Whenever a job rolls out, it is assigned whatever priority it has at that point. The priority increases as time passes, giving that job a better chance to be selected for execution again. When the job is selected and rolled in, its priority becomes the value of the UP parameter on the QUEUE entry, and the job scheduling priority cycle begins again. This description on job rollout applies to batch, remote batch, and interactive jobs that are not doing interactive I/O. For interactive jobs that do terminal I/O within a time slice, scheduling priority is slightly different. When I/O is complete and input, for example, is available, the system assigns the rolled-out job the terminal I/O scheduling priority (TP parameter on the SERVICE entry). The TP parameter gives the job a priority equal to the priority of jobs still within their initial time slice, an advantage over jobs in a second time slice, and a larger advantage over jobs in a third or higher time slice. Terminal input/output is required.

A job leaves central memory when the following conditions occur:

- The system requests terminal input.
- You request terminal output and the recall parameter is specified on the request.
- You issue a RECALL macro after a request for terminal output that omitted the recall parameter.
- The control point is made available for a higher priority job.

This ensures reasonable service to all users in the system. The operating system controls the amount of central processor or central memory time each type of job can use when it is at a control point. This ensures that one job does not monopolize system resources.

If a job exceeds either the central processor or central memory time slice, and it is not a subsystem, the scheduling priority is set to the lower bound priority (the IL parameter on the QUEUE entry) for its service class. Thus, any job in the queue with a higher priority forces the executing job with the lower priority to be rolled out. The rolled-out job ages normally until its priority is higher than the priorities of either the jobs in the input queue or a job that is executing; then it is again scheduled to a control point.

Once a job is scheduled, it is desirable to use the resources allocated before another job forces it out. If a job maintained its scheduling priority when it was assigned to a control point, another job could age past that job and force it to be rolled out before it had an opportunity to use its time slice. For this reason, when a job is assigned to a control point and its priority is within the queue aging range, it is given a priority equal to the highest priority (the UP parameter in the QUEUE entry) for its service class.

Selecting the number of control points available on the system depends on the amount of memory space available, the job mix, and the mode in which the system is being run. Each control point needs 200g words of CMR space. For example, if an installation is running only TAF, then four or five control points may suffice. On the other hand, if the system is running a large number of interactive terminals with heavy permanent file activity, then 20 or more control points may be needed. You may need to study memory and control point use in order to correctly determine the setting of this option. If memory use is high and control point use is low, select fewer control points. If control point use is high and memory use is low, select more control points.

## **Memory Control**

You can control the maximum memory allowed for job types and for service classes with the parameters you specify on the SERVICE entry in the IPRDECK.

These parameters specify these lengths:

- Maximum field length divided by 100g for a job in a service class.
- Maximum field length divided by 100g for all jobs of the specified service class.
- Maximum extended memory length in words divided by 1000g for a job in a service class.
- Maximum extended memory length in words divided by 1000g for all jobs of the specified service class.

Initially, the scheduler attempts to find the highest priority job that meets the memory constraints. However, if the scheduler is unable to schedule a job and has explicitly rejected one or more jobs because of these memory constraints, it attempts to schedule a job a second time. During this second attempt, any job that requires other jobs to be rolled out is not scheduled; otherwise, the constraints are ignored, and the job is scheduled at the lower bound priority, IL (a parameter on the QUEUE entry). This means that the constraints are applied as long as there are enough jobs of each service class. However, if central memory is unused because batch jobs are at a maximum and no other jobs are available, the scheduler attempts to schedule the batch jobs.

All of these parameters can be changed by using the SERVICE, QUEUE, and DELAY entries.

## **Example of Job Control Parameters**

An example set of entries for the job control parameters is shown in table 3-6. These entries fall within the example of ranges of service class priorities shown in figure 3-6. Neither the specific entries nor the ranges are recommended; they are strictly examples to aid you in selecting QUEUE and SERVICE entry parameters.

The following discussion indicates the significance of the values chosen and how they relate to each other.

The entry (lowest) priority (LP parameter in the QUEUE entry) of the system service class input queue is higher than all entry priorities, except the network supervision and subsystem entry priorities, because it is assumed that an operator-initiated job should receive prompt attention. A system job rolls out any batch job. Most system jobs and all subsystems are coded to adjust their priorities correctly, once execution begins. The entry priority (LP) of the network supervision service class input queue is set high to ensure adequate response time from network programs and facilities such as CS, NS, and NVF.

The queue priorities for batch, remote batch, and detached jobs are similar. The time slice for detached jobs is shorter than for the batch and remote batch jobs. The assumption is that detached jobs need less CPU time than either batch or remote batch jobs.

The queue priorities are explained under Job Scheduling earlier in this section.

The time slices for the various service classes reflect the following objectives.

- To keep system jobs with their high entry priority from monopolizing system resources.
- To keep at a minimum rollout activity caused by diagnostics running as maintenance service class jobs.
- To allow most interactive jobs to compile, load, and begin execution in one time slice.
- To give batch jobs a large time slice, because little is gained from rolling out batch jobs. There is no problem with the time slices for batch jobs compared to interactive jobs, because, with the priorities shown, an interactive job generally causes a batch job to roll out.
- To ensure prompt service to all interactive users, without employing an excessive number of rollouts, by setting the time slices for interactive jobs low. The time slice parameters are critical to good interactive performance. In some cases, depending on the system load, job size, and so forth, it may be desirable to change these parameters during operation.

Interactive performance is sensitive to the relative values of the QUEUE and SERVICE scheduling parameters, both within a service class and among service classes. Table 3-6 shows almost no overlaps of values except that batch, remote batch, and detached jobs could age slightly past interactive jobs if they remained rolled out for a very long time (about 26 minutes). For the interactive service class, the range between entry (lowest) priorities and the highest priority is wide, so that few jobs are at the highest priority simultaneously. If many jobs reach the highest priority, their priorities are the same, and the order in which the jobs entered the queue is lost. The job scheduler selects jobs with equal queue priority in a random manner. The terminal I/O priority (TP) is set slightly higher than the initial priority (IP) to reduce response time for the user interacting with a job as compared to the user initiating a new job step. This parameter setting improves the perceived responsiveness of the system for the interactive users.

|                                                                                                                                                                                                                                                                                                                                                                                                                                            |      | ut Queue<br>Paramet  |    |                 | Execut<br>QUEUE   |    |   |                |                                 |  | Interactive<br>Job Initial<br>Scheduling<br>TP QUEUE<br>Parameter |

# Table 3-6. Example Set of Job Control Parameters†

\_

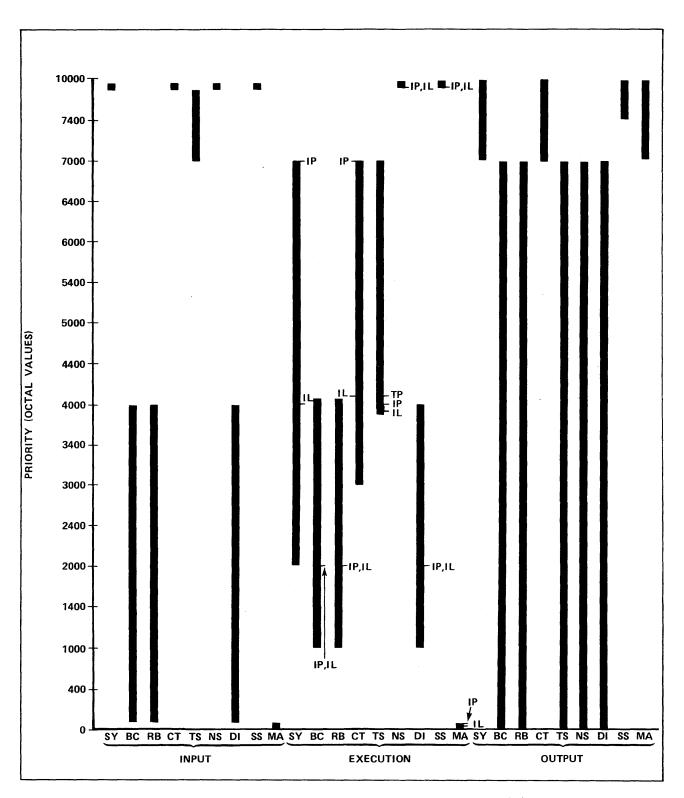

Figure 3-6. Example of Ranges of Service Class Priorities

The CPU priorities reflect the following objectives.

- The maintenance service class jobs are run at the lowest priority. This handles the background CPU and memory diagnostics.
- All other jobs, except network supervision service class jobs, run at the same priority. It is generally not desirable to run one class of jobs at a higher priority than another because the system would roll in jobs that occupy memory without executing, until they exceed the central memory time slice.
- The network supervision service class is set high to ensure adequate performance from network programs and facilities such as CS, NS, and NVF.

### **IPRDECK ENTRIES MADE ONLY DURING DEADSTART**

You can enter the following IPRDECK entries on the IPRDECK only during deadstart. They cannot be entered as DSD commands. Changes to the IPRDECK are not retained across deadstart unless a new deadstart file is created to reflect those changes. The entries are described in alphabetical order.

#### COMLIB

Format:

COMLIB, username, family, D.

#### Default:

None.

Significance:

This entry specifies a user name and family for a library of permanent files that can be accessed by users on all other families. This feature eliminates the need to maintain duplicate copies of the files on the families that require access to the files. This entry can also be used to reduce validation file accesses for user names such as LIBRARY in a single family environment. The number of COMLIB entries that can be specified is controlled by the CMRDECK entry CLT.

| Parameter | Description                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| username  | The l- to 7-character user name to be associated with the files to be accessed. This parameter should be unique to all families in the system. It cannot be associated with more than one family. |
| family    | Family name to be associated with username.                                                                                                                                                       |
| D         | If D is specified, the associated username and family are deleted from the common library table.                                                                                                  |

# CPM

### Format:

 $CPM, s_1=n_1, s_2=n_2.$ 

### Default:

System selection.

### Significance:

This entry alters the central processor multiplier of type  $s_i$ , which is used in SRU calculations. The  $s_i$  parameters are either 0 or 1 to indicate the multipliers S0 or S1, respectively. Entering 0=n obtains a multiplier to be used for S0 and entering l=n obtains a multiplier to be used for S1. (Refer to the NOS 2 Administration Handbook for a discussion of multiplier use.) The values of  $n_i$  range from 1 to 45<sub>8</sub> and are used as indexes to values defined in COMSSRU in order to determine the multiplier value. The default values are listed in table 3-7.

| n <sub>i</sub> (Octal) | COMSSRU Name | Mainframe Model | COMSSRU Default<br>Multiplier Value |
|------------------------|--------------|-----------------|-------------------------------------|
| 1                      | CP 62        | 6200            | 1.0                                 |
| 2                      | CP64         | 6400            | 1.0                                 |
| 3                      | CP 65        | 6500            | 1.0                                 |
| 4                      | CP66         | 6600            | 1.0                                 |
| 5                      | СР67         | 6700            | 1.0                                 |
| 6                      | CP71         | 71              | 1.0                                 |

| 20                     | C720         | 720                                | 1.0                                 |
| 21                     | C7 30        | 730                                | 1.0                                 |
| 22                     | C740         | 740                                | 1.0                                 |
| 23                     | C7 50        | 750                                | 1.0                                 |
| 24                     | C760         | 760                                | 1.0                                 |
| 25                     | C810         | 810                                | 1.0                                 |
| 26                     | C815         | 815                                | 1.0                                 |
| 27                     | C825         | 825                                | 1.0                                 |
| 30                     | C830         | 830                                | 1.0                                 |
| 31                     | C835         | 835                                | 1.0                                 |
| 32                     | C845         | 845                                | 1.0                                 |
| 33                     | C855         | 855                                | 1.0                                 |
| 34                     | C865         | 865                                | 1.0                                 |
| 35                     | C875         | 875                                | 1.0                                 |
| 36 through 40          | Reserved for | Control Data                       |                                     |
| 41                     | ICM1         | Model on which you are installing. | 1.0                                 |
| 42                     | ICM2         | Model on which you are installing. | 2.0                                 |
| 43                     | ICM3         | Model on which you are installing. | 3.0                                 |
| 44                     | ICM4         | Model on which you are installing. | 4.0                                 |
| 45                     | ICM5         | Model on which you are installing. | 5.0                                 |

Table 3-7. CPM Default Values for  $n_i$  (Sheet 2 of 2)

.

# CSM

#### Format:

CSM=csm.

Default:

64

Significance:

This entry sets the operating system character set mode. To change the character set mode for the products, a change must be made in IPARAMS, and the products must be reassembled.

### csm Description

- 63 63-character set.
- 64 64-character set.

The system assumes a 64-character set if there is no CSM entry in the current IPRDECK.

# NOTE

Unpredictable and possibly serious problems occur if the operating system is operating in one character set and the products are operating in another. Therefore, ensure that all installed products and the operating system are in the same mode.

# DSD

# Format:

DSD, level, command1 #command2#...#commandn

### Default:

None.

### Significance:

This entry specifies the initial command(s) to be executed by the DSD program when the deadstart is complete. The commands can be the minimum number of characters recognizable by DSD. Only the last DSD entry on the IPRDECK for a given deadstart level is processed; other DSD entries for the same level are ignored. The DSD entry cannot exceed one line.

| Parameter | Description                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| level     | Level of deadstart (0, 1, or 2).                                                                                                                                                                                                                                |
| commandi  | DSD command to be executed for the level of deadstart specified.                                                                                                                                                                                                |
|           | Several commands can be specified by separating them with the $\#$ (6-bit display code 60) or $\%$ (6-bit display code 63) character.<br>These characters may misposition parts of the console display of IPRDECK if they appear as the upper 6 bits in a byte. |
| •         |                                                                                                                                                                                                                                                                 |

#### Example:

DSD,0,MAI%X.QREC(PO=N)

# EI

Format:

EI=nn1, nn2, ..., nn<sub>x</sub>.

### Default:

None.

#### Significance:

The EI entry should be used to ensure loading of the correct environment interface for the operating system. This entry specifies up to six 2-character environment interface names, one of which must be loaded while deadstarting a CYBER 180-class machine. The deadstart will not be allowed to continue if the environment interface loaded by CTI is not one of those specified by the EI entry. You will have to load the correct environment interface or modify the EI entry in the IPRDECK. If an EI entry is not present, you will not be warned at deadstart.

# EXTENDED STACK PURGING

### Formats:

ENABLE, EXTENDED STACK PURGING.

DISABLE, EXTENDED STACK PURGING.

Default:

Disabled.

Significance:

These entries specify the default action for instruction-stack purging for nonsystemorigin jobs on CYBER 180-class machines. Refer to the MODE macro in the NOS 2 Reference Set, Volume 4 for a description of instruction-stack purging.

#### **KEYPM**

Format:

KEYPM=cc.

### Default:

26

# Significance:

This entry specifies the keypunch mode to be assumed during system operation.

cc Description

26 026 keypunch mode.

29 029 keypunch mode.

This entry is used for all batch jobs submitted if the keypunch mode is not specified on the job command. This does not apply to RBF.

# **MEMORY CLEARING**

# Formats:

ENABLE, MEMORY CLEARING.

DISABLE, MEMORY CLEARING.

Default:

Disabled.

#### Significance:

When memory clearing is enabled, central and extended memory are cleared when released from a job (that is, when a job is rolled out, terminates, or reduces its field length). When memory clearing is disabled, memory is cleared only when a job requests additional memory.

### MICRO

Format:

MICRO=name1, name2, ..., name7.

Default:

None.

Significance:

The MICRO entry should be used to ensure loading of the correct microcode for the operating system. This entry specifies up to seven 7-character microcode names, one of which must be loaded while deadstarting a CYBER 180-class machine. The deadstart will not be allowed to continue if the microcode loaded by CTI is not one of those specified by the MICRO entry. You will have to load the correct microcode or modify the MICRO entry in the IPRDECK. If a MICRO entry is not present, you will not be warned at deadstart.

### NAMIAF

### Format:

NAMIAF=maxt.

#### Default:

2008

# Significance:

This entry specifies the number of network terminals that can be connected to IAF at one time.

Parameter Description

maxt Total number of network terminals; maxt can range from 1 to 14408.

### PROBE

```
Formats:
```

ENABLE, PROBE.

DISABLE, PROBE.

#### Default:

Disabled.

Significance:

These entries enable and disable the data gathering facility of CPUMTR.

# SCP

Formats:

ENABLE, SCP.

DISABLE, SCP.

### Default:

Disabled.

# Significance:

These entries specify whether to use the system control point facility. You must enable SCP if CDCS, IAF, MAP, MAS, MCS, MSS, NAM, RBF, RHF, SSF, or TAF will be used. If none of these will be used, leave SCP disabled so that more CMR space is available.

### SCRSIM

## Formats:

ENABLE, SCRSIM.

DISABLE, SCRSIM.

#### Default:

Disabled.

#### Significance:

These entries enable or disable the simulation of the status/control register using the interlock register on CYBER 70 Computer Systems (refer to appendix D for information on the SCRSIM simulator).

### SECCATS

Format:

SECCATS=cat<sub>1</sub>, cat<sub>2</sub>,..., cat<sub>n</sub>.

#### Default:

All categories are enabled.

#### Significance:

This entry specifies the security access categories that will be allowed in the system for processing when the system is in a secured mode. The values should be supplied by a site security administrator. Refer to the NOS 2 Security Administrator's Handbook.

#### Parameter

#### Description

cati

Category names specified in deck COMSMLS corresponding to the desired access categories. Initially, all categories are enabled. The first SECCATS entry clears all categories, then sets the specified categories. Subsequent SECCATS entries set additional categories:

> SECCATS=ALL. Enables all 32 categories. SECCATS=NUL. Disables all 32 categories.

# SPC

# Format:

SPC,d=lines.

# Defaults:

64 lines at 6 lines per inch.

85 lines at 8 lines per inch.

## Significance:

This entry specifies the charge in number of lines for a page of printed output at the specified print density on non-PFC printers.

Description

### Parameter

| d     | Density in lines per inch; d can be 6 or 8 lines per inch. |
|-------|------------------------------------------------------------|
| lines | Lines per page; lines can range from 16 to 255.            |

# SPD

# Format:

SPD=d.

# Default:

# 6

# Significance:

This entry specifies the assumed density for printed output.

- d Description
- 6 6 lines per inch.
- 8 8 lines per inch.

# SPL

### Format:

SPL=length.

### Default:

60

#### Significance:

This entry specifies the assumed page length in number of lines for printed output; length can range from 16 to 255.

# SPW

#### Format:

SPW=width.

Default:

136

#### Significance:

This entry specifies the assumed page width in number of characters for printed output; width can range from 40 to 136.

# SUBCP

Formats:

ENABLE, SUBCP.

DISABLE, SUBCP.

### Default:

Disabled.

#### Significance:

These entries specify whether CPUMTR is to be initialized to handle subcontrol point (TAF) processing.

If SUBCP is disabled, CPUMTR is not initialized to handle subcontrol point processing. If you are not running TAF and if no user applications use subcontrol point processing, disable SUBCP so that CPUMTR uses less central memory.

# TCVM

# Format:

TCVM=mode.

Default:

AS

Significance:

This entry sets the tape conversion mode to be assumed during system operation.

,

| mode | Description                                                       |
|------|-------------------------------------------------------------------|
| AS   | ASCII 9-track conversion.                                         |
| US   | ANSI (previously known as USASI) 9-track conversion (same as AS). |
| ЕВ   | EBCDIC 9-track conversion.                                        |

# TDEN

Format:

TDEN=density.

# Default:

HY for 7-track tapes.

PE for 9-track tapes.

# Significance:

This entry sets the system tape density. When the density is set, any tape unit accessed is automatically set to this density unless specified otherwise by a magnetic tape request. Two TDEN entries may be present, one for 7 track and one for 9 track.

| density | Description         |
|---------|---------------------|
| LO      | 200 cpi (7 track).  |
| HI      | 556 cpi (7 track).  |
| НҮ      | 800 cpi (7 track).  |
| HD      | 800 cpi (9 track).  |
| PE      | 1600 cpi (9 track). |
| GE      | 6250 cpi (9 track). |

# TDTR

### Format:

TDTR=tracktype.

### Default:

NT

# Significance:

This entry sets the default track type.

| tracktype | Description |
|-----------|-------------|
| MT        | 7 track.    |
| NT        | 9 track.    |

# DEADSTART ENTRIES AND DSD COMMANDS

You can enter the following IPRDECK entries on the IPRDECK during deadstart and online during system operation using the L display or DSD commands. The reason for entering them online is to change the system's operation between deadstarts. Entries made during system operation are not retained across deadstarts. Entries made during deadstart are not retained across deadstarts unless a new deadstart file is created to reflect the changes.

A description of the enabling and disabling of subsystems follows. The remaining IPRDECK entries are described in alphabetical order.

#### **Subsystems**

Before you can enable or disable a subsystem that uses a system control point, you must enable the system control point facility with the ENABLE, SCP IPRDECK entry. Refer to SCP earlier in this section.

All subsystems, except BIO and MAG, are disabled by default. You must enable a subsystem before you can initiate it. You can enable or disable a subsystem by using IPRDECK entries or by using the SUBSYST L-display utility. (For information about the SUBSYST L display, refer to the NOS 2 Operations Handbook.)

The IPRDECK entries that enable and disable subsystems also assign a default control point for a subsystem. Thus, even if you do not want to enable a subsystem, you may want to explicitly disable a subsystem with an IPRDECK entry to assign a default control point for the subsystem.

Once you have enabled a subsystem, you can initiate the subsystem using either of the following methods.

- Call the subsystem procedure file by entering the name of the procedure file. ٠
- Name the subsystem procedure file the same name as the subsystem and store the file . as an indirect access permanent file under the system user name (SYSTEMX) with user index 3777778. Then, the subsystem will be automatically initiated when you enter the AUTO or MAINTENANCE commands.

Use these IPRDECK entries to enable or disable a subsystem:

ENABLE, subsystem, cp.

DISABLE, subsystem, cp.

Parameter

subsystem

Description

Three characters that select the desired subsystem; one of these values:

| subsystem | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| BIO       | Central site batch I/O for line printers, card readers, and card punches.             |
| CDC       | CYBER Database Control System.                                                        |
| IAF       | Interactive Facility. Do not specify the cp<br>parameter on the ENABLE entry for IAF. |

# TDTR

### Format:

TDTR=tracktype.

### Default:

NT

### Significance:

This entry sets the default track type.

| tracktype | Description |
|-----------|-------------|
| MT        | 7 track.    |
| NT        | 9 track.    |

### DEADSTART ENTRIES AND DSD COMMANDS

You can enter the following IPRDECK entries on the IPRDECK during deadstart and online during system operation using the L display or DSD commands. The reason for entering them online is to change the system's operation between deadstarts. Entries made during system operation are not retained across deadstarts. Entries made during deadstart are not retained across deadstarts unless a new deadstart file is created to reflect the changes.

A description of the enabling and disabling of subsystems follows. The remaining IPRDECK entries are described in alphabetical order.

#### **Subsystems**

Before you can enable or disable a subsystem that uses a system control point, you must enable the system control point facility with the ENABLE, SCP IPRDECK entry. Refer to SCP earlier in this section.

All subsystems, except BIO and MAG, are disabled by default. You must enable a subsystem before you can initiate it. You can enable or disable a subsystem by using IPRDECK entries or by using the SUBSYST L-display utility. (For information about the SUBSYST L display, refer to the NOS 2 Operations Handbook.)

The IPRDECK entries that enable and disable subsystems also assign a default control point for a subsystem. Thus, even if you do not want to enable a subsystem, you may want to explicitly disable a subsystem with an IPRDECK entry to assign a default control point for the subsystem.

Once you have enabled a subsystem, you can initiate the subsystem using either of the following methods.

- Call the subsystem procedure file by entering the name of the procedure file. .

Use these IPRDECK entries to enable or disable a subsystem:

ENABLE, subsystem, cp.

DISABLE, subsystem, cp.

Parameter

subsystem

Description

Three characters that select the desired subsystem; one of these values:

| subsystem | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| BIO       | Central site batch I/O for line printers, card readers, and card punches.             |
| CDC       | CYBER Database Control System.                                                        |
| IAF       | Interactive Facility. Do not specify the cp<br>parameter on the ENABLE entry for IAF. |

### Parameter

### Description

| subsystem | Description                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------|
| MAG       | Magnetic Tape Subsystem. Enable MAG if removable<br>auxiliary packs are used. Disabling MAG frees a<br>control point for other use. |
| MAP       | MAP III or MAP IV.                                                                                                                  |
| MAS       | Mass Stoage Archival Subsystem.                                                                                                     |
| MCS       | Message Control System.                                                                                                             |
| MSS       | Mass Storage Subsystem.                                                                                                             |
| NAM       | Network Access Method.                                                                                                              |
| RBF       | Remote Batch Facility.                                                                                                              |
| RDF       | Remote Diagnostic Facility. Do not specify the CP parameter on the ENABLE entry for RDF.                                            |
| RHF       | Remote Host Facility.                                                                                                               |
| SMF       | Screen Management Facility.                                                                                                         |
| SSF       | NOS-SCOPE 2 Station Facility.                                                                                                       |
| STM       | STIMULA. Do not specify the cp parameter on the ENABLE entry for STM.                                                               |

TAF Transaction Facility.

# NOTES

When MCS and RBF are started by the NAMI startup master file, the ENABLE and DISABLE commands are ignored.

ср

Control point where the subsystem will reside. If you omit cp, the current control point is used. If you enter 0 (zero) as the control point, the subsystem may reside at any control point.

Omit cp for IAF, RDF, and STM.

# CLASS

#### Format:

 $CLASS, ot, sc_1, sc_2, \dots, sc_n$ .

#### Default:

| Origin Type  | Service Class |
|--------------|---------------|
| Batch        | BC            |
| Remote Batch | RB            |
| Interactive  | TS            |

#### Significance:

Specifies the valid service classes for each origin type. The system stores this information in the service class table (refer to the NOS 2 Systems Programmer's Instant).

### Parameter Description Origin type; must be BC (batch), RB (remote batch), or IA ot (interactive). This parameter is required. sci Service classes. Each class selected causes validation for that service class for the origin type specified by ot. Entering a service class that already has validation clears validation for that service class. You can select from 1 to 36 service classes for each origin type. This command does not accept class SS (subsystem). Service class is one of these values: Description sc BC Batch. СТ Communication task. DI Detached interactive. TO Installation class 0. H Installation class 1. Installation class 2. 12 Installation class 3. 13 MA Maintenance. NS Network supervisor.

- RB Remote batch.
- SS Subsystem.

### Parameter

# Description

Description

| SC |  |  |
|----|--|--|
|    |  |  |
|    |  |  |
|    |  |  |
|    |  |  |

- SY System.
- TS Interactive.
- ALL Causes validation of all service classes except subsystem.
- NUL Clears validation for all service classes.

### DEBUG

Format:

DEBUG.

### Default:

Disabled.

Significance:

This entry selects or clears debug mode, depending upon the current status.

If enabled, debug mode is selected. The message DEBUG appears in the header of the left screen display. Debug mode provides system origin privileges to validated users and allows modifications to be made to the running system.

If disabled, debug mode is cleared. It is recommended that debug mode not be allowed in a normal production environment.

On a secured system, this entry is ignored. While the console is in security unlock status, debug mode can be set using DSD command DEBUG.

#### DELAY

### Format:

DELAY, CRcr, ARar, MXmx, MNmn, JQjq, JSjs.

### Default:

None.

#### Significance:

This entry specifies the system delay parameters. Refer to table 3-6 for an example set of parameter entries. Refer to figure 3-6 for an example of ranges of service class priorities.

| Parameter | Description                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CRcr      | CPU recall delay in milliseconds; cr is from 1 to 77778.                                                                                                                                 |
| ARar      | PP/auto recall delay in milliseconds; ar is from 1 to $7777_8$ .                                                                                                                         |
| MXmx      | Maximum job switch delay in milliseconds; mx is from 1 to $7777_8$ .                                                                                                                     |
| MNmn      | Minimum job switch delay in milliseconds; mn is from 1 to $7777_8$ .                                                                                                                     |
| JQjq      | Exponent used to determine the input job (QFT to EJT) scheduling delay; jq is from 0 to 148 seconds. The delay in seconds between the scheduling of input jobs is calculated as follows: |
|           | delay=2jq                                                                                                                                                                                |
| JSjs      | Job scheduler delay in seconds; js is from 1 to 77778.                                                                                                                                   |

# **DDP ROLLOUT PATH**

#### Formats:

ENABLE, DPP ROLLOUT PATH

DISABLE, DDP ROLLOUT PATH

#### Default:

Disabled.

#### Significance

These entries determine which path a rollout to extended memory will take (CPU or PP). The required supporting hardware (EM or DDP) must be present.

# ENGR

Formats:

ENABLE, ENGR.

DISABLE, ENGR.

#### Default:

Disabled.

#### Significance:

These entries enable or disable engineering mode. If enabled, the ENGR message appears in the header of the left screen display. Engineering mode allows the peripheral processing unit (PPU)/hardware diagnostics and the 881/883 pack reformatting utility FORMAT to run while the system is in operation.

On a secured system, these entries are ignored. When the console is in security unlock status, engineering mode can be enabled using the DSD command ENABLE,ENGR.

# **FILE STAGING**

### Formats:

ENABLE, FILE STAGING.

DISABLE, FILE STAGING.

Default:

Disabled.

#### Significance:

These entries specify whether permanent files that reside on the alternate storage facility (MSS or MSAS) are staged to disk. If disabled, jobs attempting to access MSS/MSAS resident files are aborted.

### LOCK

Format:

LOCK.

#### Default:

Unlocked.

#### Significance:

This entry specifies the system is locked. This software function prevents entry of restricted commands; all other DSD commands can be entered. The console is normally locked when the system is being used in a production environment.

### LOGGING

#### Formats:

ENABLE, LOGGING.

DISABLE, LOGGING.

#### Default:

Disabled.

#### Significance:

These entries specify whether dayfile messages intended for system analysis are logged in the dayfile. Typical messages deal with informing the user that the program is making inefficient CIO calls, such as reading to a full buffer or writing from an empty buffer. The dayfile messages are documented in an appendix of the NOS 2 Operations Handbook.

# MASTER MAS

## Formats:

ENABLE, MASTER MAS

DISABLE, MASTER MAS

#### Default:

Disabled.

### Significance:

These entries specify whether the MSAS executive program (SSEXEC), when initialized, is to run in master (enabled) or slave (disabled) mode.

.

# **MASTER MSS**

#### Formats:

ENABLE, MASTER MSS.

DISABLE, MASTER MSS.

### Default:

Disabled.

### Significance:

These entries specify whether the MSS executive program (MSSEXEC), when initialized, is to run in master (enabled) or slave (disabled) mode.

### **FILE STAGING**

#### Formats:

ENABLE, FILE STAGING.

DISABLE, FILE STAGING.

Default:

Disabled.

### Significance:

These entries specify whether permanent files that reside on the alternate storage facility (MSS or MSAS) are staged to disk. If disabled, jobs attempting to access MSS/MSAS resident files are aborted.

# LOCK

Format:

LOCK.

### Default:

Unlocked.

### Significance:

This entry specifies the system is locked. This software function prevents entry of restricted commands; all other DSD commands can be entered. The console is normally locked when the system is being used in a production environment.

### LOGGING

Formats:

ENABLE, LOGGING.

DISABLE, LOGGING.

#### Default:

Disabled.

#### Significance:

These entries specify whether dayfile messages intended for system analysis are logged in the dayfile. Typical messages deal with informing the user that the program is making inefficient CIO calls, such as reading to a full buffer or writing from an empty buffer. The dayfile messages are documented in an appendix of the NOS 2 Operations Handbook.

# MASTER MAS

Formats:

ENABLE, MASTER MAS

DISABLE, MASTER MAS

### Default:

Disabled.

### Significance:

These entries specify whether the MSAS executive program (SSEXEC), when initialized, is to run in master (enabled) or slave (disabled) mode.

.

# **MASTER MSS**

# Formats:

ENABLE, MASTER MSS.

DISABLE, MASTER MSS.

# Default:

Disabled.

### Significance:

These entries specify whether the MSS executive program (MSSEXEC), when initialized, is to run in master (enabled) or slave (disabled) mode.

# **MS VALIDATION**

## Formats:

ENABLE, MS VALIDATION.

DISABLE, MS VALIDATION.

#### Default:

Disabled.

Significance:

This entry enables or disables mass storage validation. If enabled, CMR is increased by  $60_8$  words, and the system verifies that, for each mass storage device, the sum of the counts of unreserved tracks and preserved files equals values specified in the device's mass storage table.

If the device is a master device (contains user catalogs), the system also verifies these conditions:

- The device's track reservation table (TRT) specifies that the first tracks of the indirect access file chain and the permit area are reserved and preserved.
- The label track is linked to the first catalog track.
- The number of catalog tracks is a power of 2.
- The catalog chain is reserved, of correct length, and contiguous if flagged as such in the device's MST.

To enable/disable mass storage validation with a DSD command entry, enable the validation in the IPRDECK during a level 0, 1, or 2 deadstart.

### OQSH

Format:

OQSH=level.

Default:

None.

Significance:

This entry specifies the value of the output queue special handling (OQSH) level. Output files with an access level equal to or greater than the output queue special handling level will remain in the queue until released by the DSD command RELEASE. When no OQSH level or access level name LVLO is selected, all files will be processed. The value for this entry is supplied by the site security administrator.

#### Parameter

#### Description

level

Access level name specified in deck COMSMLS (refer to the NOS 2 Installation Handbook) that corresponds to the desired output queue special handling level.

# PCLASS

#### Format:

PCLASS, sc0, sc1, ..., sc7.

### Default:

None.

#### Significance:

Specifies the service class associated with each priority level (PO through P7) for selection on the Job command (refer to the NOS 2 Reference Set, Volume 3).

#### Parameter

sci

Description

The 2-character service class symbol. Because parameters are positional, a comma must appear for any null parameter. The default for a null parameter is that no service class will be associated with the priority level represented by the null parameter's position in the string. This command does not accept the SS (subsystem) service class. Refer to the SERVICE IPRDECK entry later in this section for a list of service classes.

# **PF VALIDATION**

Formats:

ENABLE, PF VALIDATION.

DISABLE, PF VALIDATION.

#### Default:

Disabled.

#### Significance:

These entries enable or disable preserved file (PF) validation. If enabled, the system aborts an attach of a direct access permanent file if its end-of-information (EOI) was altered during recovery of the file. If NA (no abort) is specified on the attach request, the system attaches the file.

If mass storage validation is also enabled, TRT verification of preserved files takes place during a level 3 deadstart as follows:

- For all files, the system ensures that all tracks are reserved and that no circular linkage exists.
- For all queued, permanent direct-access, and fast-attach files, the system also ensures that the first track is preserved.

If mass storage validation is enabled on a level 1 or 2 deadstart, TRT verification takes place automatically, regardless of the status of PF VALIDATION.

#### **PRIVILEGED RDF**

# Formats:

ENABLE, PRIVILEGED RDF.

DISABLE, PRIVILEGED RDF.

#### Default:

Disabled

#### Significance:

These entries enable or disable privileged mode of RDF. If enabled, a user's commands are checked to ensure that a maintenance function is being performed.

### QUEUE

### Format:

QUEUE,sc,qt,LP1p,UPup,IPip,WFwf,ILi1,TPtp.

#### Default:

None.

#### Significance:

This entry specifies the queue priorities associated with the input, executing, and output queues for each job service class. Refer to table 3-6 for an example set of parameter entries and to figure 3-6 for an example of ranges of service class priorities.

# Parameter

#### Description

sc

#### Service class.

- sc Description
- BC Batch.
- CT Communication task.
- DI Detached interactive.
- 10 Installation class 0.
- Il Installation class 1.
- I2 Installation class 2.
- I3 Installation class 3.
- MA Maintenance.

| Parameter | Description                                                                                                                                                                                 |  |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|           | sc Description                                                                                                                                                                              |  |
|           | NS Network supervisor.                                                                                                                                                                      |  |
|           | RB Remote batch.                                                                                                                                                                            |  |
|           | SS Subsystem.                                                                                                                                                                               |  |
|           | SY System.                                                                                                                                                                                  |  |
|           | TS Interactive.                                                                                                                                                                             |  |
| qt        | Job queue type.                                                                                                                                                                             |  |
|           | <u>qt</u> <u>Description</u>                                                                                                                                                                |  |
|           | EX Executing jobs.                                                                                                                                                                          |  |
|           | IN Input queued files.                                                                                                                                                                      |  |
|           | OT Output queued files.                                                                                                                                                                     |  |
| LPlp      | Lowest priority at which a file or job can enter the specified queue; 1p ranges from 0 to 7777 <sub>8</sub> .                                                                               |  |
| UPup      | Highest priority a job or queued file can reach in the specified queue; up ranges from 0 to 77778.                                                                                          |  |
| IPip      | Initial priority only for executing jobs (EX). ip ranges from 0 to $7777_8$ .                                                                                                               |  |
| WFwf      | Weighting factor for queue priority calculation; wf must be a power<br>of 2, from 0 to 40008. The smaller the weighting factor, the<br>faster the queue entry reaches its highest priority. |  |
| ILil      | Lower bound priority for the initial time slice; il ranges from 0 to $7777_8$ . This parameter is valid only for executing jobs (EX).                                                       |  |
| TPtp      | Initial scheduling priority for online interactive jobs; tp ranges from 0 to 77778.                                                                                                         |  |

# **REMOVABLE PACKS**

### Formats:

ENABLE, REMOVABLE PACKS.

DISABLE, REMOVABLE PACKS.

### Default:

Enabled.

### Significance:

These entries enable or disable automatic label checking for mass storage devices that are defined as removable.

If enabled, automatic label checking occurs. This status must be available to perform label verification before removable devices can be accessed.

If disabled, any removable devices introduced into the system will not be recognized.

#### **RESIDENT RDF**

#### Formats:

ENABLE, RESIDENT RDF.

DISABLE, RESIDENT RDF.

#### Default:

Disabled.

# Significance:

These entries enable or disable resident mode of RDF. While in resident mode, RDF remains active, regardless of terminal inactivity, until RDF is disabled. When resident mode is disabled, RDF becomes inactive if no one is logged on at the remote diagnostic terminal for 15 minutes.

#### SECONDARY USER COMMANDS

#### Formats:

ENABLE, SECONDARY USER COMMANDS.

DISABLE, SECONDARY USER COMMANDS.

Default:

Disabled.

Significance:

The enable option allows jobs to issue more than one USER command. These entries are ignored on a secured system since secondary USER commands are not allowed on a secured system.

# SECURES

### Format:

SECURES, ot, LA=1a, UA=ua.

Default:

The security access limits of the system origin type (SY) are set to access level name LVLO. All security access limits for other origin types are set to system limits.

Significance:

This entry specifies system limits for the system origin type (ot equals SY) or limits for other origin types (ot equals BC, IA, or RB). System limits define the highest and lowest levels allowed in the system. No job may execute and no file may be accessed or created at a level outside this range.

Limits for origin types other than SY must be within the system limits. If origin type SY is specified, limits for all origin types are set to the selected values.

Both la and ua must be entered; they can be set to the same value, restricting system access or a particular origin type access to a single level. These values are supplied by a site security administrator.

This entry is not meaningful in an unsecured system.

Origin type.

### Parameter

Description

ot

- ot Description
- SY System.
- BC Batch.
- IA Interactive.
- RB Remote Batch.
- la Access level name specified in deck COMSMLS (refer to the NOS 2 Installation Handbook) corresponding to the desired lower access level limit.
- ua Access level name specified in deck COMSMLS corresponding to the desired upper access level limit.

### SERVICE

# Format:

SERVICE, sc, PRpr, CPcp, CMcm, NJnj, FLf1, AMam, ECec, EMem, FCfc, CScs, FSfs, DSds, TDtd, DTsc.

### Default:

None.

#### Significance:

This entry specifies the service limits associated with each service class. Refer to table 3-6 for an example set of parameter entries and to figure 3-6 for an example of ranges of service class priorities.

#### Parameter

# Description

sc

| Service class; one of these values:                                                                                                                                                                                                                                                                                                             |                       |  |

| CMcm      | Central memory time slice in seconds; cm ranges from 0 to 77778.<br>This parameter specifies the maximum amount of time a job of the<br>specified service class can remain at a control point before it<br>becomes eligible to be rolled out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NJnj      | Maximum number of jobs; nj ranges from 0 to $7777_8$ . This parameter specifies the number of jobs that can be active at one time in the specified service class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FLf1      | Maximum field length/100g for any job of the specified service<br>class; fl ranges from 0 to 7777g. Jobs with field length<br>requirements that exceed this value are not considered for<br>scheduling, unless no other jobs are to be run and sufficient unused<br>memory is available to run the job without rolling out a running<br>job. However, an interactive service class job that exceeds its<br>maximum field length aborts. You typically use this parameter to<br>limit the memory requirement for jobs of a specific service class<br>during certain hours of the day. For example, you may use the FL<br>parameter to specify a maximum field length for all batch service<br>class jobs between the hours of 2 p.m. and 4 p.m.                                                                     |
| AMam      | Maximum field length/100g for all jobs of the specified service<br>class; am ranges from 0 to 7777g. This parameter partitions<br>central memory by limiting the field length available to each<br>service class. For example, if a job whose field length exceeds<br>that specified for its service class is scheduled to a control<br>point, it may not be scheduled until the required field length is<br>available. This means that a lower priority job from a different<br>service class may be scheduled first. However, a job that would<br>normally exceed the field length for its service class can be<br>scheduled to a control point if not enough jobs exist to fill the<br>field length specified for another service class. The system<br>attempts to use central memory to its greatest capacity. |
| ECec      | Maximum extended memory length in words divided by $1000_8$ for any job of the specified service class; ec ranges from 0 to $7777_8$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| EMem      | Maximum extended memory length in words divided by $1000_8$ for all jobs of the specified service class; em ranges from 0 to $7777_8$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FCfc      | Number of permanent files allowed. fc indicates a limit value that is the maximum number of permanent files allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|           | fc Limit Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|           | 4                                                                                                                           | 100008                                                                                                                                  |  |
|           | 5                                                                                                                           | 50000 <sub>8</sub>                                                                                                                      |  |
|           | 6                                                                                                                           | 1000008                                                                                                                                 |  |
|           | 7                                                                                                                           | Unlimited                                                                                                                               |  |
| TDtd      | job will a                                                                                                                  | on time-out delay; td ranges from 0 to 77778. A suspended<br>not be timed out for td*108 seconds. The maximum delay<br>imately 9 hours. |  |

DTsc Service class to which a job of the service class specified by sc will be assigned if the job is detached. The default is detached interactive (DI).

# **SPINDOWN**

Formats:

ENABLE, SPINDOWN.

DISABLE, SPINDOWN.

Default:

Enabled.

Significance:

These entries enable or disable the spindown of 834 disk units. When spindown is enabled, entering a CHECK POINT SYSTEM command will cause all 834 disk units that are on and not globally unloaded to automatically spin down. When spindown is disabled, entering a CHECK POINT SYSTEM command will not spin down the 834 disk units.

### SRST

Format:

SRST=n.

Default:

0

Significance:

This entry specifies the secondary rollout sector threshold. Any rollout file smaller than n sectors ( $0 \le n \le 7777_8$ ) is considered a secondary rollout file for the purpose of equipment selection.

# NOTE

The size of the rollout file for any job must be at least seven sectors larger than the combined size in sectors of the job's central memory and extended memory field lengths.

### UNLOCK

Format:

UNLOCK.

### Default:

Unlocked.

### Significance:

This entry specifies the system console is unlocked. All DSD commands can be entered when the console is unlocked. The console is usually locked when the system is being used in a production environment. Refer to LOCK earlier in this section.

#### USER EXTENDED MEMORY

#### Formats:

ENABLE, USER EXTENDED MEMORY.

DISABLE, USER EXTENDED MEMORY.

Default:

Disabled.

### Significance:

These entries enable or disable scheduling of jobs that access user extended memory.

# LIBDECK

LIBDECK is a SYSEDIT directive record on the deadstart file. SYSEDIT reads LIBDECK during the system load. LIBDECK specifies program residence, field length, record type, and parameter format.

Up to 100<sub>8</sub> LIBDECK records can be placed on the deadstart file. LIBDECKs are named LIBDnn, where nn is 00 to 77<sub>8</sub>. A specific record can be selected with a LIB=n entry in CMRDECK. The multiple deadstart deck capability enables the use of a single deadstart file on virtually any system configuration.

You can list all LIBDECKs on the deadstart file by accessing the system file SYSTEM with a COMMON command, then using the T parameter on the CATALOG command. Refer to the NOS 2 Reference Set, Volume 3 for more information concerning these commands.

The following list provides brief descriptions of SYSEDIT directives acceptable in LIBDECK. Complete descriptions of all SYSEDIT directives are in section 19, SYSEDIT. A list of valid record types follows the directives.

#### Directive Format

\*AD,nn,ty1/rec1,ty2/rec2,...,tyn/recn

\*CM,ty<sub>1</sub>/rec<sub>1</sub>,ty<sub>2</sub>/rec<sub>2</sub>,...,ty<sub>n</sub>/rec<sub>n</sub>

\*FL,  $ty_1/rec_1-fl_1$ ,  $ty_2/rec_2-fl_2$ , ...,  $ty_n/rec_n-fl_n$ 

Significance

Specifies the alternate device to be used in addition to the system device(s) for storing ABS, OVL, PP, and REL type records. nn is either the EST ordinal or the equipment type,  $ty_1$  is the record type, and  $rec_1$  is the record name.

Defines record rec<sub>i</sub> of type ty<sub>i</sub> as being central memory resident; valid only for record types ABS, OVL, or PP. Like any other job in NOS, SYSEDIT has a field length restriction of  $376000_8$  central memory words. You cannot use more than approximately  $326000_8$  central memory words ( $376000_8$ - $50000_8$  words for SYSEDIT's program FL) when defining records to be central memory resident.

Record rec<sub>i</sub> of type  $ty_i$  is loaded with a field length specified by  $fl_i$  (fl<sub>i</sub> is field length divided by  $100_8$ ).

Defines record  $rec_i$  of type  $ty_i$  as being mass storage resident. This is the default residence for routines with no storage area specified in LIBDECK.

Defines record  $\operatorname{rec}_1$  of type PROC as a procedure file.

Defines record rec<sub>1</sub> of type  $ty_1$  as product set format commands. The command parameters are processed in product set format (refer to the NOS 2 Reference Set, Volume 3).

Defines comment lines.

\*PROC, rec1, rec2, ..., recn

\*SC,ty1/rec1,ty2/rec2,...,tyn/recn

\*MS,ty1/rec1,ty2/rec2,...,tyn/recn

\*/ comments

The following record types may be specified in SYSEDIT directives. Some directives do not allow all types.

| Type (ty <sub>i</sub> ) | Description                               |
|-------------------------|-------------------------------------------|
| ABS                     | Multiple entry point overlay.             |
| CAP                     | Fast dynamic load capsule.                |
| OPL                     | Modify old program library deck.          |
| OPLC                    | Modify old program library common deck.   |
| OPLD                    | Modify old program library directory.     |
| OVL                     | Central processor overlay.                |
| PP                      | Peripheral processor program.             |
| PPU                     | Peripheral processor unit program.        |
| PROC                    | Procedure.                                |
| REL                     | Relocatable central processor program.    |
| TEXT                    | Unrecognizable as one of the other types. |
| ULIB                    | User library program.                     |

# **DIS OPERATIONS**

| DIS Job Dayfile Display (A)      | 4-3  |
|----------------------------------|------|
| DIS Exchange Package Display (B) | 4-4  |
| DIS Memory Displays (C, D, F, G) | 4-5  |
| DIS Job Status Display (J)       | 4–7  |
| DIS Directory Display (Z)        | 4-9  |
| Console Operation                | 4-10 |
| Display Selection Commands       | 4-12 |
| DIS Keyboard Entries             | 4-13 |
| Memory Entry Commands            | 4-16 |
| PP Call Commands                 | 4-18 |

## **DIS OPERATIONS**

DIS displays information about a single job. Under DIS, the B display shows the exchange package area for the job. Central memory addresses relative to the job's reference address are used for the data and program displays.

Initiate DIS at a control point to monitor the progress of a job by using any of the following methods.

- You can call DIS by entering X.DIS,f1 (f1=field length desired) or X.DIS (field length of 600008 assumed by default). This brings DIS to an empty control point to initiate utility programs.
- Enter a command in the form DIS (the job must be system origin or have system origin privileges).
- On a secured or unsecured system, before you can call DIS, the console must be unlocked (refer to the DSD UNLOCK command in section 5). For a secured system the console must be unlocked by the security administrator. When the system display console shows UNLOCK status or SECURITY UNLOCK status, you can call DIS by entering the command:

DIS,jsn.

jsn is the job sequence name to which you want DIS assigned.

You can toggle between DSD and DIS. DIS permanently returns control to DSD when you enter DROP.; the job is not dropped unless no commands remain.

When DIS is called to a control point, automatic command processing stops and the A and J displays for DIS appear on the left and right display screens, respectively. Keyboard entry is necessary to begin processing subsequent commands. Unless automatic command processing is reenabled, is the job is stopped after each command is processed. That is, only one command can be processed at a time. Under DIS, the J display shows only the condition of the job to which it is assigned, including upcoming commands. When the job is not using the central processor, a copy of its exchange package is displayed on the B display. Displays available under DIS are selected in the same manner as DSD displays. Refer to Console Operation later in this section for information concerning display selection commands and to DIS Keyboard Entries for information about other DIS commands.

<sup>&</sup>lt;sup>†</sup>You can initiate automatic command processing by entering either a period (.) or the RCS command (refer to Console Operation and to DIS Keyboard Entries later in this section).

### The displays available under DIS are:

| Display<br>Identifier | Description                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A                     | Job dayfile. Messages and files (local FNT entries) attached to the job.                                                                                                                      |
| В                     | Exchange package. Breakpoint address and the exchange package.                                                                                                                                |
| C,D                   | Central memory. Contents of central memory words (selectable 8-word<br>groups) in five columns of four octal digits with display code equivalents<br>(same as the DSD C and D displays).      |
| F                     | Central memory. Contents of central memory words (selectable 8-word groups) in four columns of five octal digits with display code equivalents.                                               |
| G                     | Central memory. Contents of central memory words (selectable 8-word groups) in four columns of five octal digits with COMPASS instruction equivalents.                                        |
| Н                     | File status. All files assigned to the job as well as equipment assigned to files.                                                                                                            |
| J                     | Job status. Individual job status, equipment assigned, current messages, and command buffer.                                                                                                  |
| М                     | Extended memory. Contents of 60-bit words of extended memory (selectable<br>8-word groups) in five columns of four octal digits with display code<br>equivalents (same as the DSD M display). |
| N                     | Blank screen.                                                                                                                                                                                 |
| T,U                   | Text display. Displays text from central memory in coded lines (up to 60 characters per line). The display terminates after 256 words have been displayed.                                    |
| V                     | Central memory buffer. Displays directly from central memory. The display terminates after 512 words have been displayed.                                                                     |
| Y                     | Monitor functions. Displays mnemonics and the values of all monitor functions (same as the DSD Y display).                                                                                    |
| Z                     | Directory. DIS displays available.                                                                                                                                                            |

### NOTE

Although all displays listed may appear on the left screen, only the C, D, J, and N displays may appear on the right screen. If you attempt to bring any other display to the right screen, the message INCORRECT COMMAND is issued to the job dayfile and is displayed in the message buffer of the J display.

### **DIS JOB DAYFILE DISPLAY (A)**

Figure 4-l shows the DIS job dayfile display (A). The figure shows the job dayfile messages for the control point to which DIS is currently assigned and as many files attached to that control point as will fit in the display. All files attached to the job can be observed by using the file status display (H).

DIS A. JOB DAYFILE. 09.46.34.RFL (060000) 09.46.34.DIS. 09.47.31.USER, ABC1234,. 09.47.31.ABSC, S. Dayfile 09.48.43.PACKNAM, 721C, R=DL. messages 09.49.39.NOS. 09.50.06. Figure 4-1. DIS Job Dayfile Display (A)

The level field, shown in the figure, is displayed only on a secured system.

### DIS EXCHANGE PACKAGE DISPLAY (B)

The DIS B display shows the breakpoint address (BKP=addr) if a breakpoint was set at address addr. The breakpoint address is followed by the job's exchange package.

Figure 4-2 shows the DIS exchange package display (B).

DIS B. EXCHANGE PACKAGE. BKP = 100. Ρ = 452 AO =600 B0 =0 RA = B1 = 174100 A1 = 1 1 FL = 600 A2 = 0 B2 = 777776 EM = 74070000A3 = 0 B3 = 1 RAE = 0 A4 =0 B4 = 3 FLE = 0 A5 = B5 = 2 1 MA = 600 A6 = 1 B6 = 0 EEA = 0 A7 = 375 87 = 0 XO = 7777 7777 7777 7700 0000 X1 = 0000 0000 0000 0000 0000 $X2 = 0000 \ 0000 \ 0000 \ 0000 \ 0375$ С x3 = 0000 0000 0000 0000 0000X4 = 0000 0000 0000 0000 0003 С x5 = 2331 2324 0515 0000 0001 SYSTEM A X6 = 0516 0420 0000 0000 0000ENDP X7 = 0000 0000 0000 0000 0000+ AND - WILL SET \*BKP\* TO (P) +/- 1.

Figure 4-2. DIS Exchange Package Display (B)

### DIS MEMORY DISPLAYS (C, D, F, G)

Figure 4-3 shows the DIS data storage display (F). The contents of each central memory word is displayed in columns of five octal digits along with the display code equivalent. Only the memory locations currently assigned to the job can be displayed. The message \*\*\*\*SECURED AREA\*\*\*\* is displayed for all other locations.

The DIS C and D displays have the same format as the DSD C display, except that the DIS memory displays may show a managed table bias word preceding the groups of central memory words.

| DIS F. C             | ENTRAL | MEMOR | Y.    |       | ·           |  |
|----------------------|--------|-------|-------|-------|-------------|--|

### **DIS JOB STATUS DISPLAY (J)**

The DIS J display shows the status of a specific job executing at a control point. It also shows: any equipment assigned exclusively to the job by EST ordinal, message 1 and message 2 from the control point area, and the current command buffer, allowing you to anticipate future job requirements.

Figure 4-5 shows the DIS job status display (J).

DIS J. JOB STATUS. JSN = AAACEJTO =2046 5 P = SRUA = RA = 1741 1 UI = 2755 SRUL = 777777 FL =26 Job status FM = MLSTEST CS = BATCHRAE = 160 PN = 721CCONN = 0 FLE = 0 LEVEL = LVLOCPA = 600 EST = 1 Equipment assigned MS1 = DEVICE UNAVAILABLE. Current messages MS2 =NOS, PACKV2. RETURN, NOS. REVERT, NOLIST. EXIT. REVERT, ABORT. PACKC OR PACKV2 NOT FOUND. Command buffer REVERT, NOLIST. EXIT. REVERT.CCL EXIT.CCL REVERT, ABORT.CCL

Figure 4-5. DIS Job Status Display (J)

The job status portion of the display shows three columns of information. Each item has the form item=value. The items are described next in the order that they appear on the display.

| Item  | Description                                    |
|-------|------------------------------------------------|
| JSN   | Job sequence name of the DIS job.              |
| UI    | User index.                                    |
| FM    | Current family name.                           |
| PN    | Current pack name.                             |
| EJTO  | Executing job table ordinal.                   |
| SRUA  | System resource units accumulator.             |
| SRUL  | Account block limit for system resource units. |
| CS    | Connection status (interactive jobs only).     |
| CONN  | Connection number (interactive jobs only).     |
| LEVEL | Job access level (secured systems only).       |
| Р     | P register address from exchange package.      |
| RA    | Central memory reference address.              |
| FL    | Central memory field length.                   |
| RAE   | Extended memory reference address.             |
| FLE   | Extended memory field length.                  |
| СРА   | Control point area address.                    |

# DIS DIRECTORY DISPLAY (Z)

Figure 4-6 shows the DIS directory display (Z). The Z display lists all displays available under DIS control. If the letter entered to select the left screen display is not a valid display identifier, the Z display is selected automatically.

| DIS Z. DI | RECTORY. LEFT SCREEN ONLY DISPLAY      |

|           | N BLANK SCREEN.                        |

Figure 4-6. DIS Directory Display (Z)

### **CONSOLE OPERATION**

Unlike DSD, DIS is not interpretive. You must complete every entry and signal DIS to act upon the message by pressing CR or NEXT. The following rules apply to all DIS commands.

- For input, spaces in an octal field are ignored but can be inserted for readability.
- For output, all octal fields are right-justified with leading zero fill; excess octal digits are ignored.

In addition to the command entries, the following keys have special meaning to DIS when entered as the first character. The corresponding special keys for both the 721 and CC545 console types are listed along with a description of the use of each key.

| <u>721</u> | CC545                        | Description                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F15        | *                            | If DSD has relinquished the main display console to DIS,<br>this key acts as a quick hold, and DIS drops the display<br>channel so that DSD can use it.                                                                                                                                                                                                    |
| +          | +                            | Pages the left screen forward for the A, C, D, F, G, H, M,<br>T, and U displays. Increments the breakpoint address for<br>the B display.                                                                                                                                                                                                                   |
| -          | -                            | Pages the left screen backward for the C, D, F, G, M, T, and<br>U displays. Decrements the breakpoint address for the B<br>display. Resets the A and H displays to the beginning.                                                                                                                                                                          |
| (          | (                            | Pages the right screen forward for the C and D displays.                                                                                                                                                                                                                                                                                                   |
| )          | )                            | Pages the right screen backward for the C and D displays.                                                                                                                                                                                                                                                                                                  |
| 1          | /                            | Advances the left screen memory display address by the value<br>in the lower 18 bits of the first word displayed (applicable<br>only to memory displays C, D, F, G, and M).                                                                                                                                                                                |
| •          |                              | Sets AUTO MODE (initiates automatic command processing).<br>This key performs the same function as the RCS command<br>described under DIS Keyboard Entries later in this section.                                                                                                                                                                          |
| 8          | 8                            | Advances the pointer indicating the first address of managed<br>tables for the left screen (applicable only to memory<br>displays C, D, F, and G).                                                                                                                                                                                                         |
| 9          | 9                            | Decrements the pointer indicating the first address of<br>managed tables for the left screen (applicable only to<br>memory displays C, D, F, and G).                                                                                                                                                                                                       |
| <b>→</b>   | Right blank<br>(display key) | Advances the left screen display sequence established by the<br>SET,screen. command (refer to Display Selection Commands<br>later in this section).                                                                                                                                                                                                        |
| NEXT       | CR (carriage<br>return)      | Sets the repeat entry flag; the message REPEAT ENTRY is<br>displayed on the error message line of the left screen. The<br>subsequent command entry is processed but is not erased<br>after completion. That command is processed each time this<br>key is pressed. To clear the repeat entry mode, press the<br>left blank (erase) key or the <b>Key</b> . |

The following keys are interpreted as control characters by DIS.

| <u>721</u> | <u>CC545</u>            | Description                                                                                                                        |
|------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| or ERASE   | Left blank<br>(erase)   | Clears current DIS keyboard entry and any resultant error<br>message; AUTO MODE (automatic command processing) is also<br>cleared. |
| -          | BKSP<br>(backspace)     | Deletes last character displayed and clears error message (if one exists).                                                         |
| NEXT       | CR (carriage<br>return) | Initiates processing of an entered command.                                                                                        |

The following keyboard messages may appear above your entry.

| e following keyboard mess         | ages may appear above your entry.                                                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message                           | Description                                                                                                                                                              |
| AUTO MODE.                        | The command buffer is read automatically. Automatic command processing can be selected by the RCS command or by entering a period.                                       |
| COMMAND BUFFER FULL.              | The ELS command has been entered and there is insufficient room in the command buffer to add the characters requested.                                                   |
| COMMAND TOO LONG.                 | The command you entered is too long.                                                                                                                                     |
| COMMANDS ON FILE.                 | The ELS command has been entered and commands are currently located in a file instead of in a command buffer. It is not possible to add a command to the file.           |
| DIRECT CPU INPUT.                 | The N command has been entered and all data entered from the keyboard is being passed directly to central memory.                                                        |
| DISK BUSY.                        | DIS is waiting for an overlay to be loaded from a mass storage device.                                                                                                   |
| EXTENDED MEMORY<br>NOT AVAILABLE. | You entered the ENFLE command, but user extended memory is not defined.                                                                                                  |
| INCORRECT ENTRY.                  | The command cannot be processed.                                                                                                                                         |
| INCORRECT FL<br>REQUEST.          | You entered an ENFL command to set the field length. The requested field length must be greater than $10000_8$ and less than $377700_8$ including negative field length. |
| INCORRECT PRIORITY.               | The priority you entered using the ENPR command is not correct. CPU priority must be greater than 1 and less than $71_8$ .                                               |
| INSUFFICIENT FIELD<br>LENGTH.     | Your field length is not long enough to support either extended memory or 026.                                                                                           |
| JOB ACTIVE.                       | The prievious request has not completed. The command must be reentered when the job is not active.                                                                       |
| OUT OF RANGE.                     | The memory entry address is greater than the field length.                                                                                                               |
| PP BUSY.                          | DIS is waiting for a PP to be assigned in order to process a keyboard entry.                                                                                             |

| Message                         | Description                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| REPEAT ENTRY.                   | The command in the command buffer is repeated each time you press CR or NEXT. This can be cleared by pressing the left blank or $\leftarrow$ key. |
| REQUEST EXCEEDS<br>MAXIMUM FLE. | You requested more extended memory than your system can support.                                                                                  |
| STORAGE NOT<br>AVAILABLE.       | The amount of central memory requested by the ENFL command or required by the 026 file editor is not available.                                   |
| WAITING FOR<br>EXTENDED MEMORY. | DIS is waiting for extended memory after you entered the ENFLE command.                                                                           |
| WAITING FOR<br>STORAGE.         | DIS is waiting for central memory after you entered the ENFL or 026 command.                                                                      |

## **DISPLAY SELECTION COMMANDS**

Specify the displays you want shown on the console's left and right screens by using the following commands. Follow the entry with a carriage return.

| Command | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ху.     | Brings the x and y displays to the left and right screens,<br>respectively. Note that although all DIS displays may appear on the<br>left console screen, only the C, D, J, and N displays may appear on<br>the right screen. If you attempt to bring any other display to the<br>right screen, the entry is interpreted as a command and the message<br>INCORRECT ENTRY appears. In addition, if the letter entered to<br>select the left screen display (x) is not a valid display<br>identifier, the Z display is selected automatically. |
| xz,loc. | Brings specified memory display to the left screen, if not currently selected, and provides display modifications as follows:                                                                                                                                                                                                                                                                                                                                                                                                                |
|         | x Display identifier (C, D, F, G, or M).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         | z Type of display modifications:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         | z Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|         | 0-3 Changes the specified group to display the eight words beginning at location loc.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|         | 4 Changes the entire display so that all<br>8-word groups are contiguous locations<br>beginning at location loc.                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         | 5 Advances the display by loc locations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         | 6 Decrements the display by loc locations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|         | <pre>loc Location parameter (maximum of eight digits for central<br/>memory address or seven digits for extended memory<br/>address).</pre>                                                                                                                                                                                                                                                                                                                                                                                                  |

| Command    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x,addr.    | If x specifies one of the memory displays (C, D, F, G, or M), addr<br>is the address used to obtain the bias address for the managed table<br>display. (The bias address is the lower 18 bits of the word at<br>addr.)                                                                                                                                                                                                                         |
| SET, xxxx. | Sets the left screen display sequence; xxxx consists of one to four<br>display identifiers. Pressing the right blank (display) or $\longrightarrow$ key<br>after this command is entered causes the first display to appear on<br>the left console screen. Pressing the key again selects the second<br>display. The next display in the specified sequence appears on the<br>left screen each time the key is pressed, for example, SET,ACFD. |

### **DIS KEYBOARD ENTRIES**

You can enter the following commands while in DIS.

If a job is currently active (CPU active, waiting, on recall, or PP active), many commands are not accepted and the message JOB ACTIVE is displayed.

| Command              | Description                                                                                                                                                                                                                                                                                                                                               |  |  |  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| BEGIN, pname, pfile. | Sets AUTO MODE and calls the procedure pname that is on file pfile.                                                                                                                                                                                                                                                                                       |  |  |  |
| BKP,addr.            | Breakpoint to address addr in the program. Central processor<br>execution begins at the current value of P and stops when P=addr,<br>and DIS is the only PP active at the control point.                                                                                                                                                                  |  |  |  |
| BKPA,addr.           | Breakpoint to address addr in the program with assigned PPs.<br>Central processor execution begins at the current value of P and<br>stops when P=addr. PPs attached to the control point can still be<br>active. DIS clears addr to stop the program at that point. The<br>breakpoint may be cleared by setting the breakpoint address to a new<br>value. |  |  |  |
| DCP.                 | Drops the central processor and displays the exchange package area on the B display.                                                                                                                                                                                                                                                                      |  |  |  |
| DIS.                 | Reloads the main DIS overlay.                                                                                                                                                                                                                                                                                                                             |  |  |  |
| DROP.                | Drops DIS, but normal processing of the job continues (it does not drop the job until all commands are processed).                                                                                                                                                                                                                                        |  |  |  |
| ELS.commandstring.   | Allows entry of the commandstring command after the last command in the command buffer, if there is space.                                                                                                                                                                                                                                                |  |  |  |
| ENAi,addr.           | Sets register Ai=addr in the exchange package area.                                                                                                                                                                                                                                                                                                       |  |  |  |
| ENBi,addr.           | Sets register Bi=addr in the exchange package area.                                                                                                                                                                                                                                                                                                       |  |  |  |
| ENEM,n.              | Sets CPU program exit mode to n (0 $\leq$ n $\leq$ 7).                                                                                                                                                                                                                                                                                                    |  |  |  |
| ENFL,fl.             | Sets central memory field length FL=fl in the exchange package area $(0 \le f1 \le 77777_8)$ . fl must be at least 100008 if user extended memory is assigned.                                                                                                                                                                                            |  |  |  |

| Command                       | Description                                                                                                                                                                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENFLE,fle.                    | Sets extended memory field length FLE to fle000 in the exchange package area ( $1 \le fle \le 7777_8$ ). If user extended memory is assigned (fle=0), central memory FL, set by the ENFL command, must be greater than or equal to $10000_8$ .                                                 |
| ENP,addr.                     | Sets P=addr (next instruction address).                                                                                                                                                                                                                                                        |
| ENPR, pr.                     | Sets job priority to pr (2 $\leq$ pr $\leq$ 708).                                                                                                                                                                                                                                              |
| ENS.commandstring.            | Allows entry of the commandstring command as the next unprocessed<br>command in the command buffer. The command can then be processed<br>using RNS, RSS, or DROP. Use of ENS with CCL procedure files<br>produces unexpected results. This command is valid only when AUTO<br>MODE is not set. |
| ENTER./commandl/<br>command2/ | Allows entry of the commandl and command2 commands from the keyboard and sets AUTO MODE.                                                                                                                                                                                                       |
| ENTL, tim1mt.                 | Sets the job time limit to timlmt $(77777_8$ specifies no limit).                                                                                                                                                                                                                              |
| ENXi,cont.                    | Sets register Xi=cont in the exchange package area.                                                                                                                                                                                                                                            |
| ENXi,Lcont.                   | Sets register Xi=cont, left-justified, in the exchange package area.                                                                                                                                                                                                                           |
| ENXi,Dcharacters.             | Sets register Xi to characters in display code.                                                                                                                                                                                                                                                |
| ENXi,b,value.                 | Sets byte b of register Xi to value.                                                                                                                                                                                                                                                           |
| ERR.                          | Sets forced error flag (FSE), terminates program execution, and clears AUTO MODE if set.                                                                                                                                                                                                       |
| GO.                           | Restarts a program that has paused.                                                                                                                                                                                                                                                            |
| HOLD.                         | DIS relinquishes the display console, but the job is held at the present status. The console must be reassigned to continue use of DIS.                                                                                                                                                        |
| M.characters.                 | Enters characters as a CPU program command. Data is stored at RA+CCDR.                                                                                                                                                                                                                         |
| N.characters.                 | Sets DIRECT CPU INPUT mode. Characters entered from keyboard are<br>passed one character at a time, right-justified, directly into<br>central memory at RA+CCDR. Pressing the left blank (erase) or<br>key twice clears DIRECT CPU INPUT mode.                                                 |
| OFFSWs.                       | Turns off sense switch s for the job ( $1 \leq s \leq 6$ ).                                                                                                                                                                                                                                    |
| ONSWs .                       | Sets sense switch s for the job (1 $\leq$ s $\leq$ 6).                                                                                                                                                                                                                                         |
| 026.                          | Calls the 026 file editor to a control point. You will need a CC545<br>console to use the 026 file editor. It does not work with a 721<br>console. Refer to the NOS 2 Systems Programmer's Instant for a<br>description of the editing commands.                                               |

| Command            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |  |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| RCP.               | Requests central processor. Depending on job priority, execution<br>begins at the next program address for a job suspended by a DCP<br>request.                                                                                                                                                                                                                                                                                                           |  |  |
| RCS.               | Sets AUTO MODE, which initiates automatic command processing. All<br>succeeding commands are read from the command buffer and processed<br>automatically until an SCS command, an erase function, or an error<br>is encountered. A period (.) may also be used to initiate automatic<br>command processing.                                                                                                                                               |  |  |
| RNS.               | Reads and processes the next command in the DIS command buffer.                                                                                                                                                                                                                                                                                                                                                                                           |  |  |
| ROLLOUT.           | Allows the job to roll out. This command should be issued when the message ROLLOUT REQUESTED appears (or the * or F15 key may be used).                                                                                                                                                                                                                                                                                                                   |  |  |
| ROLLOUT, spr.      | Places job in rollout status for spr job scheduler delay intervals.<br>The job is automatically rolled back in after this period of time.<br>If a number greater than 7778 is specified for spr, 7778 is used.                                                                                                                                                                                                                                            |  |  |
| RSS.               | Reads the next command from the command buffer and stops prior to CPU execution. This is used to initiate breakpointing of a program.                                                                                                                                                                                                                                                                                                                     |  |  |
| RSS,commandstring. | Reads the commandstring command and stops prior to execution. The action is similar to ENS followed by RSS except that the command buffer is not cleared.                                                                                                                                                                                                                                                                                                 |  |  |
| SCS.               | Clears AUTO MODE, which stops automatic command processing.                                                                                                                                                                                                                                                                                                                                                                                               |  |  |
| SUI,userindex      | Allows access to a user index above AUIMX (3777008). Any<br>permanent file activity that is to be done on such user indices must<br>be done through system origin jobs. This command is not accepted by<br>a secured system.                                                                                                                                                                                                                              |  |  |
| T,addr.            | Changes the T display to start at address addr.                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |
| U,addr.            | Changes the U display to start at address addr.                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |
| UCC=c              | Sets the uppercase character c. This command does not terminate with a period.                                                                                                                                                                                                                                                                                                                                                                            |  |  |
| V,addr.            | Changes the V display to start at address addr.                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |
| X.commandstring.   | Processes commandstring as the next command. Only the first 50 characters following X are used. This may be used to enter a leading slant or a command that is the same as DIS display.                                                                                                                                                                                                                                                                   |  |  |
| * commandstring.   | If an asterisk (*) followed by a blank and commandstring is<br>encountered during automatic command processing (AUTO MODE),<br>commandstring is interpreted as a direct DIS display selection<br>command. For example, * C4,100. will set the left screen display to<br>the central memory C display at address 100. Using this feature, it<br>is possible to set up procedure files that use DIS to breakpoint a<br>program to a desired stopping point. |  |  |
| commandstring.     | Processes commandstring as a command if it is not a recognizable DIS command.                                                                                                                                                                                                                                                                                                                                                                             |  |  |

### **MEMORY ENTRY COMMANDS**

The following commands are used in conjunction with the C, D, F, G, and M memory displays to change the contents of central memory and extended memory. Only locations relative to the reference address (RA) of the job to which DIS is assigned can be changed. When changing the contents of memory relative to a job, the negative field length area of the job can be accessed by specifying a negative address. For example, to change the content of RA-3, enter the address  $77775_8$ .

On a secured system no memory entry commands are allowed unless the security unlock status is set. The memory display shows the message

\*\*\*\*SECURED AREA\*\*\*\*

instead of the contents of the memory locations to prevent you from examining these locations; you may not alter the contents of these locations.

Character values or numeric data can replace the current word contents. Either one 12-bit byte, one 15-bit parcel, one 30-bit parcel, or 60 bits can be changed. A single byte can be changed by inserting the byte number after the location to be changed; bytes are numbered 0 through 4 from left to right. The address and contents are assembled right-justified with leading zero fill. Leading zeros may be omitted in the entry. Only words within the field length of the job may be changed.

Improper use of these commands may result in damage to the system or to user jobs.

Formats and descriptions of the memory entry commands follow.

| Command      | Description                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| addr,cont.   | Changes the contents of memory location addr to cont. The second form of the command performs essentially the same function but  |
| or           | leaves the address at addr+1, allowing immediate entry for the next memory location.†                                            |
| addr+cont.   |                                                                                                                                  |
| addr,b,cont. | Changes the contents of byte b at memory location addr (eight                                                                    |
| or           | digits) to cont. Each location consists of five 12-bit bytes,<br>numbered 0 through 4 from left to right. The contents are octal |
|              | characters. The second form of the command performs essentially the                                                              |
| addr+b,cont. | same function but leaves the address at addr+1, allowing immediate entry for the next memory location.†                          |

<sup>&</sup>lt;sup>†</sup>If the message REPEAT ENTRY is displayed above the entry line, the cont field is not cleared and may be entered in successive memory locations as many times as desired by pressing CR or NEXT. The repeat entry mode is enabled by pressing CR or NEXT before initial entry of the command. This is also applicable to the b and n fields of the second, fifth, and seventh commands.

| Command           | Description                                                                                                                                                                                                                                                              |  |  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| addr,Dcont.<br>or | Changes the contents of memory location addr (eight digits)<br>to display code characters cont (left-justified and zero-filled).<br>The second form of the command performs essentially the same<br>function but leaves the address at addr+1, allowing immediate entry  |  |  |
| addr+Dcont.       | for the next memory location. <sup>†</sup>                                                                                                                                                                                                                               |  |  |
| addr,Lcont.       | Changes the contents of memory location addr (eight digits) to<br>left-justified cont. The second form of the command performs                                                                                                                                           |  |  |
| or                | essentially the same function but leaves the address at addr+1, allowing immediate entry for the next memory location.                                                                                                                                                   |  |  |
| addr+Lcont.       |                                                                                                                                                                                                                                                                          |  |  |
| addr,In,cont.     | Changes the contents of instruction n (O through 3 from left to right) at memory location addr (eight digits) to cont; cont may be a                                                                                                                                     |  |  |
| or                | 15- or 30-bit instruction. However, one or more bits must be set in                                                                                                                                                                                                      |  |  |
| addr+In,cont.     | the upper 15 bits of a 30-bit instruction or the entry will be<br>treated as a 15-bit instruction. The second form of the command<br>performs essentially the same function but leaves the address at<br>addr+1, allowing immediate entry for the next memory location.† |  |  |
| Eaddr,cont.       | Changes the contents of extended memory location addr to cont. The second form of the command performs essentially the same function                                                                                                                                     |  |  |
| or                | but leaves the address at addr+1, allowing immediate entry for the                                                                                                                                                                                                       |  |  |
| Eaddr+cont.       | next extended memory location.                                                                                                                                                                                                                                           |  |  |
| Eaddr,b,cont.     | Changes the contents of byte b at extended memory location addr to cont. Each location consists of five 12-bit bytes, numbered 0                                                                                                                                         |  |  |
| or                | through 4 from left to right. The contents are four octal                                                                                                                                                                                                                |  |  |
| Eaddr+b,cont.     | characters. The second form of the command performs essentially the<br>same function but leaves the address at addr+1, allowing immediate<br>entry for the next extended memory location.                                                                                |  |  |
| Eaddr,Dcont.      | Changes the contents of extended memory location addr to display code characters cont (left-justified and zero-filled). The second                                                                                                                                       |  |  |
| or                | form of the command performs essentially the same function but<br>leaves the address at addr+1, allowing immediate entry for the next                                                                                                                                    |  |  |
| Eaddr+Dcont.      | extended memory location.                                                                                                                                                                                                                                                |  |  |

<sup>&</sup>lt;sup>†</sup>If the message REPEAT ENTRY is displayed above the entry line, the cont field is not cleared and may be entered in successive memory locations as many times as desired by pressing CR or NEXT. The repeat entry mode is enabled by pressing CR or NEXT before initial entry of the command. This is also applicable to the b and n fields of the second, fifth, and seventh commands.

### **PP CALL COMMANDS**

Any PP program having a name that begins with a letter may be initiated by DIS. However, before entering any of these commands, it is necessary to have a working knowledge of the PP program to be called. This ensures correct use of the specified program.

Improper use of these commands may result in damage to the system or to user jobs.

In table 4-1, prg denotes the name of the PP program and n is the control point number.

| Command    | Description                                                                                   | Format of PP<br>Call Initiated |
|------------|-----------------------------------------------------------------------------------------------|--------------------------------|
| prg.       | Calls PP program prg to the control point.                                                    | 18/3Lprg,6/n,36/0              |
| prg,pl.    | Calls PP program prg to the control point; pl<br>is an octal parameter required by prg.       | 18/3Lprg,6/n,18/0,18/pl        |
| prg,pl,p2. | Calls PP program prg to the control point; pl<br>and p2 are octal parameters required by prg. | 18/3Lprg,6/n,18/p1,18/p2       |
|            |                                                                                               |                                |

Table 4-1. PP Call Formats

# **DSD COMMANDS**

| Dayfile Commands                       | 5-2  |
|----------------------------------------|------|
| Queued File Utility Commands           | 5-3  |
| Job Processing Control Commands        | 5-3  |
| General Job Control Commands           | 5-4  |
| Interactive Job Control Commands       | 5-6  |
| Job Communication Commands             | 5-7  |
| Job Flow Commands                      | 5-8  |
| Peripheral Equipment Control Commands  | 5-18 |
| Subsystem Control Commands             | 5-33 |
| System Control Commands                | 5-37 |
| Secured System Control Commands        | 5-46 |
| Memory Entry Commands                  | 5-47 |
| Channel Control Commands               | 5-50 |
| Extended Memory Flag Register Commands | 5-51 |

.

## DSD COMMANDS

After the system has been deadstarted successfully, you can enter the DSD commands necessary to provide optimum performance and reliability for users. The following general categories of DSD commands are available for this purpose.

| Dayfile                       | Dumps the system, account, or error log dayfile to a specified device.                                                      |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Queued file utility           | Provides control over selected queued files.                                                                                |
| Job processing control        | Provides added control over job scheduling and processing.                                                                  |
| Peripheral equipment control  | Controls the peripheral equipment available to the system.                                                                  |
| Subsystem control             | Schedules a subsystem to a control point or terminates a current subsystem.                                                 |
| System control                | Maintains system integrity in a normal production<br>environment or debugs a system that is in an abnormal<br>state.        |
| Memory entry                  | Changes the contents of central memory and extended memory.                                                                 |
| Channel control               | Controls activity on a specified data channel in circumstances where abnormal hardware and/or system operation is detected. |
| Extended memory flag register | Clears and sets bits in the extended memory flag register.                                                                  |

Although all DSD commands are generally available, many of them are seldom used in a normal production environment. Many DSD commands are used only by the system analyst for maintenance or debugging purposes. These commands include all memory entry and channel control commands as well as several commands in the other categories listed on an unsecured system. Memory entry commands and several other commands are restricted on a secured system (refer to the UNLOCK command later in this section).

When unusual problems arise, do not attempt corrective action unless you have considerable experience relating to the current problem. Misguided attempts to correct a system problem can often destroy information required to successfully analyze the problem. To assist customer engineers in maintaining the hardware, the system enters the first characters (up to 25) of the following commands into the error log after each execution.

DOWN, param.

FORM, param.

INITIALIZE, param.

LOG, param.

OFF, eq.

ON,eq.

REDEFINE, param.

99.

Memory entry commands

Channel control commands

Any other commands that you specify at installation time

These commands are prefixed by the characters DS in the error log but otherwise appear exactly as they are entered. This feature can be enabled and disabled using the 99 command (refer to System Control Commands later in this section).

The manner in which the DSD commands are entered and the use of special keyboard characters are described in the NOS 2 Operations Handbook. Command formats are fixed field; that is, the fields in the command format must be specified as shown. Embedded blanks are allowed in octal fields. Leading spaces in command entries are not allowed.

### **DAYFILE COMMANDS**

The system saves messages in five types of dayfiles.

- Account dayfile
- Binary maintenance log
- Error log
- Job dayfile
- System dayfile

The account dayfile keeps a record of all resources charged to a job. This dayfile can be used for customer billing and other accounting purposes. The binary maintenance log records the information used in Control Data maintenance in binary format. The error log records system error messages, such as disk errors. Job dayfiles keep entries for individual jobs. The system dayfile keeps a history of all commands for all jobs processed. The following commands dump the account dayfile, system dayfile, or error log to a system-defined mass storage device. The resultant mass storage file is put in the output queue for printing. The system automatically prints the job dayfile at the end of the job's output.

| Command | Description                                                                                                                                                         |  |  |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| X.AFD.  | Requests that the account dayfile be dumped to a system-defined mass<br>storage device. The resultant mass storage file is put in the<br>output queue for printing. |  |  |
| X.DFD.  | Requests that the system dayfile be dumped to a system-defined mass<br>storage device. The resultant mass storage file is put in the<br>output queue for printing.  |  |  |
| X.ELD.  | Requests that the error log be dumped to a system-defined mass<br>storage device. The resultant mass storage file is put in the<br>output queue for printing.       |  |  |

Refer to section 18, Queue/Dayfile Utilities, for more information on dayfile dumps.

The binary maintenance log is designed to be processed through an interpreter program, and therefore is normally dumped to tape or disk.

Refer to the NOS 2 Operations Handbook for descriptions of dayfile displays.

### **QUEUED FILE UTILITY COMMANDS**

The following commands are used to control queued input and output files.

| Co | m | m | a | n | d |  |
|----|---|---|---|---|---|--|
|    |   |   |   |   |   |  |

Description

X.QREC Deactivates or activates selected queued files and purges selected inactive queued files.

X.QMOVE Moves queued files from one mass storage device to another.

Refer to section 18, Queue/Dayfile Utilities, for more information on queued file utility commands.

### JOB PROCESSING CONTROL COMMANDS

Under normal circumstances, control over job processing is performed automatically by the system. Although the following commands may not be used frequently, they provide an added measure of control over job processing.

#### **GENERAL JOB CONTROL COMMANDS**

Several of the commands described here change internal system parameters which control job scheduling and processing. Give careful consideration to their use since job flow and overall system performance can be affected. Refer to the individual command descriptions for further information.

#### Command

CKP,jsn.

# Description

Checkpoints the job with job sequence name jsn. The checkpoint information includes a copy of the job's field length, the system information used for job control, and the name and contents of all local files currently assigned to the control point. It is the responsibility of the user's job to establish a magnetic tape or mass storage permanent file to receive the checkpoint information. Otherwise, checkpoint information is automatically written to a local file named CCCCCCC and is not available if a restart becomes necessary (restart is user-controlled and is accomplished using the RESTART command). Refer to the NOS 2 Reference Set, Volume 3 for supplementary information concerning the checkpoint/restart feature available to users.

### NOTE

If the current job command has secure system memory (SSM) status set, the job cannot be checkpointed. SSM status is set for certain jobs to prevent dumping of the job's field length. Subsystems cannot be checkpointed.

DROP, jsn, qt, ujn. Drops the job with job sequence name jsn from the queue qt where it currently resides. If a jsn is not specified, a 1- to 7-character user job name ujn can be specified after the queue type.

If no jsn or ujn is specified, all jobs in the specified queue type are dropped. If the queue type is not specified, the default is the executing queue.

The DROP command cannot be used to terminate a subsystem. Also the DROP command will not terminate an interactive user's session (this can be done only with a KILL command).

The queue type is one of the following.

qt

#### Queue Type

- ALL All jobs and queued files.
- EX All jobs in the executing queue (including the rolled out jobs).
- IN All jobs in the input queue.
- PL All jobs in the plot queue.
- PR All jobs in the print queue.
- PU All jobs in the punch queue.
- WT All jobs in the wait queue.

| ENQP,jsn,pr. | Enters queue priority of pr for a queue type file with job sequence<br>name jsn. The value of pr can range from the minimum to the maximum<br>for the job's service class. If the priority is zero, the file is<br>not scheduled back to a control point automatically. The value<br>specified overrides the current queue priority for the file. The<br>current queue priority can either be increased or decreased using<br>this command. |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KILL,jsn.    | Drops the job with job sequence name jsn from the executing job                                                                                                                                                                                                                                                                                                                                                                             |

KILL,jsn. Drops the job with job sequence name jsn from the executing job table (EJT) without exit processing. If you want the job to proceed with exit processing, use the DROP command. The KILL command cannot be used to drop a subsystem.

> KILL is the only command that immediately terminates an interactive user's session. The DROP and OVERRIDE commands only terminate the current job step and do not log the user out of the system. There will be no recoverable job after you issue the KILL command.

Description

| NOTE |
|------|
|      |

Before initiating the command, ensure that the correct job sequence name has been specified.

In some cases, a KILL command will be intercepted by a job's reprieve processing. If the job does not terminate after finishing its reprieve processing, issue another KILL command to terminate the job.

OVERRIDE, jsn. Certain types of job processing are unaffected by the DROP, KILL, or STOP commands. These include operations such as setting permanent file device interlocks, interlocking files/tracks, clearing VSN entries, and waiting for certain types of tape/PP activity to end. The OVERRIDE command terminates this type of processing and drops the job with job sequence name jsn from the executing job table regardless of queue priority. The OVERRIDE command will not terminate an interactive user's session (this can be done only with a KILL command). Unlock the console (refer to the UNLOCK command later in this section) to enter this command. Use of this command is recorded in the error log.

| Ν | 0 | T | E |  |
|---|---|---|---|--|
|   |   |   |   |  |

Exercise extreme caution in using the OVERRIDE command. Undesirable situations (such as interlocks being left set, VSN entries remaining uncleared, or certain tape/PP activities left outstanding) could occur that would cause potentially damaging system activity. Never use this command during normal operations.

Command

| Command         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RERUN,jsn.      | Terminates the job with job sequence name jsn, then reruns the job<br>from the beginning. The job must be in rerun status as set by the<br>RERUN command or macro.                                                                                                                                                                                                                                                                                                                                        |
| ROLLIN,jsn,L.   | Allows the job defined by job sequence name jsn to be scheduled to<br>an available control point. L is optional; if omitted, the job can<br>be selected by the scheduler for rollout.                                                                                                                                                                                                                                                                                                                     |
| ROLLOUT,jsn,sd. | Removes the currently executing job with job sequence name jsn and<br>makes it a rolled out job. A subsystem cannot be rolled out. sd is<br>the number of scheduler intervals before the job can be scheduled<br>again. The acceptable range for sd is between 0 and 7778. If sd<br>is not present or is 0, the job is not scheduled back to a control<br>point automatically. That is, your action is required to return the<br>job to a control point. This can be done by using the ROLLIN<br>command. |
|                 | The amount of time required for one job scheduler interval is<br>initially set in the IPRDECK but may be changed by using the DELAY<br>command (JS parameter) described later in this section. Normally,<br>it is a l-second interval.                                                                                                                                                                                                                                                                    |

### INTERACTIVE JOB CONTROL COMMANDS

The following commands apply only to interactive online jobs. The interactive facility subsystem must be active at control point 1.

| Command                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DIAL,jsn,<br>messagetext. | Sends message messagetext (48 characters maximum) to the terminal<br>currently assigned to the job with job sequence name jsn. Examine<br>the T display to determine the appropriate job sequence name. The<br>message is sent to the terminal immediately except when output is<br>being sent to the terminal. In that case, the message follows the<br>output data.                                                                                                                                               |
| WARN, messagetext.        | Sends message messagetext (48 characters maximum) to all terminals<br>currently logged into IAF. The message is received at a terminal<br>upon completion of the current command or at the end of a job step.<br>Each subsequent terminal that logs into IAF also receives this<br>message. This continues until either a new message is entered or<br>the message is cleared by using the WARN command. In addition, the<br>current message also appears at the IAF Subsystem control point on<br>the B,O display. |
|                           | When sent to an interactive terminal, the message messagetext is always preceded by the statement                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                           | hh.mm.ss. WARNING                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                           | specifying the time (hours.minutes.seconds) when you entered the                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

WARN command.

Command

### Description

For example, if you enter

WARN, SYSTEM SHUTDOWN AT 1500.

the following information would be transmitted to all interactive terminals.

hh.mm.ss. WARNING

SYSTEM SHUTDOWN AT 1500.

This command is typically used to notify interactive users of an interruption in service or system shutdown.

WARN.

Clears the message entered by the WARN, messagetext command. Unless this command is entered, the existing message (if any) continues to be transmitted to each new terminal that logs into IAF.

### JOB COMMUNICATION COMMANDS

The following job communication commands are used to communicate with a job currently in the executing job table.

| Command                                                         | Description                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CFO,jsn,<br>messagetext.                                        | Sends a message messagetext (36 characters maximum) from the console<br>to the job with job sequence name jsn. Bit 14 of the job's RA must<br>be set before the CFO command is accepted. The message is placed in<br>locations RA+70 <sub>8</sub> through RA+74 <sub>8</sub> of the program's field length. |
| COMMENT,jsn,<br>messagetext                                     | Enters comment messagetext (48 characters maximum) in the dayfile for the job with job sequence name jsn.                                                                                                                                                                                                   |
| GO,jsn.                                                         | Clears the pause bit of the job with job sequence name jsn. A job<br>may set the pause bit if an error is encountered or if an operator<br>response is required. If jsn is not specified, the command applies<br>to the system control point.                                                               |
| OFFSW,jsn,s <sub>1</sub> ,<br>s <sub>2</sub> ,,s <sub>6</sub> . | Turns off one or more sense switch(es) $s_i$ ( $1 \le s_i \le 6$ ) of the job with job sequence name jsn. Refer to Subsystem Control Commands later in this section for definitions of the sense switches that can be set for the BIO, IAF, MAS, and TAF Subsystems.                                        |
| ONSW,jsn,s <sub>1</sub> ,<br>s <sub>2</sub> ,,s <sub>6</sub> .  | Turns on sense switch(es) $s_1$ ( $1 \le s_1 \le 6$ ) of the job with job sequence name jsn. Refer to Subsystem Control Commands later in this section for definitions of the sense switches that can be set for the BIO, IAF, MAS, and TAF Subsystems.                                                     |

PAUSE, jsn. Sets the pause bit of the job with job sequence name jsn. If jsn is not specified, the command applies to the system control point.

#### **JOB FLOW COMMANDS**

The following job flow commands affect scheduling and execution of jobs in the system. Improper use of these commands can drastically hamper job flow as well as system performance. In certain cases, jobs may be lost.

The priority associated with each priority parameter in the following commands is established by an entry in the IPRDECK for each service class. The value of each priority parameter for each service class is listed on the system control display(s) (refer to the NOS 2 Operations Handbook for more information on the S display).

#### Command

#### Description

CLASS, ot, sc<sub>1</sub>, sc<sub>2</sub>,..., sc<sub>n</sub>. Defines the authorized service class for each origin type. Refer to the SCTD L display in section 9, L-Display Utilities, for further information.

#### Parameter

#### Description

- ot Origin type (must be batch, remote batch, or interactive). This parameter is order dependent.
  - ot Origin Type
  - BC Batch.
  - RB Remote batch.
  - IA Interactive.
- sci Authorizes service classes for the specified origin
  type.

| sc | Service | Class |
|----|---------|-------|
|    |         |       |

- BC Local batch.
- CT Communication task.
- DI Detached interactive.
- In Installation class n  $(0 \le n \le 3)$ .
- MA Maintenance.
- NS Network supervisor.
- RB Remote batch.
- SY System.
- TS Interactive.
- ALL Sets all the service classes except subsystem (SS) and deadstart (DS).
- NUL Clears all service classes.

Command

#### Description

DELAY, p1, p2,

Alters current system delay parameters. Examine the S display to determine the current delay parameter values.

 $P_i$ 

ARint PP auto recall interval in milliseconds. This parameter specifies the time interval at which peripheral processor units (PPs) in auto recall are recalled. One PP routine is activated each time period. The acceptable range for int is from 1 to 77778.

Delay

- CRrp CPU recall period in milliseconds. This parameter specifies the amount of time a job remains in recall (X status) when an RCL request is placed in RA+1. The acceptable range for rp is from 1 to 77778.
- JQdel Exponent used to determine the input job scheduler delay in seconds. The acceptable range for del is from 0 to 148. The delay in seconds between scheduling of input jobs is calculated as follows:

delay = 2\*\*del

- JSint Job scheduler interval in seconds. This parameter specifies the interval at which the job scheduler and priority evaluation routines are called. The scheduler may also be called at other times. The acceptable range for int is from 1 to 77778.
- MNsi Minimum CPU job switch interval in milliseconds. The acceptable range for si is from 1 to 7777<sub>8</sub>.
- MXsi Maximum CPU job switch interval in milliseconds. The acceptable range for si is from 1 to 7777<sub>8</sub>.

The value for each system delay parameter may be established by using a DELAY command entry in the IPRDECK. If no DELAY entry is present, default values are provided. Figure 5-1 provides space to record the original values (specified in the S display) in the event that any are altered temporarily. For additional information concerning the DELAY command, refer to section 3, Deadstart Decks.

| DELAY | VALUES |
|-------|--------|
| AR    |        |
| CR    |        |
| JQ    |        |
| JS    |        |
| MN    |        |
| MX    |        |

Figure 5-1. Record of Original Values in S Display (Delay Values)

#### Description

PCLASS,sc0,sc1,
 ...,sc7.

Command

Selects the service class associated with each priority level ( $p_0$  through P7) on the Job command. This parameter is order dependent; a comma must appear for any parameters not specified. The default for any parameters not specified is 0 (zero). Subsystem (SS) service class is not allowed with this command. Refer to the SCTD L display in section 9, L-Display Utilities, for more information.

#### Description

sci

The 2-character service class parameter.

| sc | Service Class                               |
|----|---------------------------------------------|
| BC | Local batch.                                |
| CT | Communication task.                         |
| DI | Detached interactive.                       |
| In | Installation class n (0 $\leq$ n $\leq$ 3). |
| MA | Maintenance.                                |
| NS | Network supervisor.                         |
| RB | Remote batch.                               |
| SY | System.                                     |
| TS | Interactive.                                |

QUEUE,sc,qt,qp1, qP2,,...,qPn.

Alters the queue priorities qp<sub>1</sub> associated with the input, executing, and output queues qt for each service class sc. Examine the S display to determine the priority values currently associated with each service class. These changes are valid only until the next deadstart.

| sc | Service Class |
|----|---------------|
|    |               |

- BC Local batch.
- CT Communication task.
- DI Detached interactive.
- In Installation class n ( $0 \le n \le 3$ ).
- MA Maintenance.
- NS Network supervisor.
- RB Remote batch.
- SS Subsystem.
- SY System.
- TS Interactive.

60459300 D

Command

- qtJob Queue TypeEXExecuting.
- IN Input.
- OT Output.

# <sup>qp</sup>i

#### Queue Priority

- ILpr Lowest priority pr an executing job can have for an initial time slice. The acceptable range for pr is from 0 to  $7777_8$ .
- IPpr Initial scheduling priority pr for an executing job. The acceptable range for pr is from 0 to  $7777_8$ .
- LPpr Lowest priority pr at which a job can enter the queue. The acceptable range for pr is from 0 to  $7777_8$ .
- UPpr Highest priority pr a job can reach in the specified queue; aging stops when this priority is reached. The job is also given this priority when initially assigned to a control point. The value of pr, which can range from 0 to 7777<sub>8</sub>, is normally greater than LPpr but cannot exceed the maximum of the job's service class.
- WFnn Weighting factor nn for queue priority calculations. nn must be a power of 2, from 0 to 40008.

The priority associated with each queue is established by using QUEUE command entries in the IPRDECK for each service class. These entries normally reflect the ideal queue priorities for the job mix of the particular installation. The values specified in the IPRDECK are considered critical to optimum system performance and are not normally altered. Figure 5-2 provides space to record the original values specified in the S display. For additional information on the QUEUE command, refer to section 3, Deadstart Decks.

| JOB<br>SERVICE |             | PRIORITIES FOR EACH QUEUE TYPE |    |    |                 |    |    |    |    |              |    |    |    |
|----------------|-------------|--------------------------------|----|----|-----------------|----|----|----|----|--------------|----|----|----|
| CLASS          | INPUT QUEUE |                                |    |    | EXECUTING QUEUE |    |    |    |    | OUTPUT QUEUE |    |    |    |

|                                                                  | <sup>p</sup> i | Service Limits                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                                                  | AMfl           | Maximum field length divided by 100g for all jobs of<br>the specified service class. This parameter is used to<br>partition central memory by limiting the total field<br>length available to each service class. For example, if<br>scheduling a job to a control point exceeds the field<br>length specified for its service class, it may not be<br>scheduled until the required field length is available.<br>This means that a lower priority job from a different<br>service class may be scheduled first. However, a job<br>that would normally exceed the field length for its<br>service class can be scheduled to a control point if<br>there are not enough jobs to fill the field length<br>specified for another service class. The system always<br>attempts to use central memory to its greatest<br>capacity. The acceptable range for fl is from 0 to<br>777778. |
|                                                                  | CMts           | Central memory time slice in seconds. This parameter specifies the maximum amount of time a job of the specified service class can remain at a control point before the job becomes eligible to be rolled out. A job is not necessarily rolled out when its time slice is exceeded. The job is set to a lower priority and then may be replaced by a job of higher priority. The value of ts can range from 0 to $7777_8$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                                  | CPts           | CPU time slice (milliseconds*64). This parameter specifies the maximum amount of time a job of the specified service class can use the CPU before its queue priority is set to the lower boundary. The value of ts can range from 1 to $7777_8$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                | 7 Unlimited                                                                                                                                                         |
| DTsc           | Detached service class for interactive jobs. The default value for sc is DI (detached interactive).                                                                 |
| ECf1           | Maximum extended memory divided by 1000 <sub>8</sub> for any job<br>of the specified service class. The acceptable range<br>for fl is from 0 to 7777 <sub>8</sub> . |

EMf1 Maximum extended memory divided by 10008 for all jobs of the specified service class. The acceptable range for fl is from 0 to 77778.

## Description

<sup>p</sup>i

FCv

Number of permanent files allowed; v is used to specify the corresponding values shown next:

Service Limits

| <u>v</u> | Limit Value in Octal |
|----------|----------------------|
| 0        | Unlimited            |
| 1        | 10                   |
| 2        | 20                   |
| 3        | 30                   |
| 4        | 40                   |
| 5        | 50                   |
| 6        | 100                  |
| 7        | Unlimited            |

- FLf1 Maximum field length divided by  $100_8$  for any job of the specified service class. Jobs with field lengths that exceed this value are not considered for scheduling unless no other jobs are waiting to be scheduled and sufficient field length is available without rolling out any jobs. The acceptable range for fl is from 0 to 7777<sub>8</sub>.
- FSv
  - Size in PRUs allowed for individual indirect access permanent files; v is used to specify the corresponding values shown next:

| <u>v</u> | Limit Value in Octal |
|----------|----------------------|
| 0        | Unlimited            |
| 1        | 10                   |
| 2        | 30                   |
| 3        | 50                   |
| 4        | 100                  |
| 5        | 150                  |
| 6        | 300                  |
| 7        | Unlimited            |

NJn

Maximum number of jobs. For each service class, this parameter specifies the number of jobs that can be executing in the system. The value for n can range from 0 to  $7777_8$ .

<sup>p</sup>i

#### Description

#### Service Limits

- PRpr CPU priority  $(2 \le pr \le 77_8)$ . Jobs with the highest priority get the CPU first. All service classes except maintenance (MA) and network supervisor (NS) are normally set to the same CPU priority. MA jobs are run at the lowest CPU priority. NS jobs are run at a higher priority than any of the other job service classes to provide good response time to network users. Subsystems control their own priorities.
- TDs Suspension time-out delay. A suspended job is timed out for s times  $10_8$  seconds. s can range from 0 to 77778. The maximum time-out delay is approximately 9.1 hours.
- TPpr Initial scheduling priority. This is the priority assigned to the start of a new command or after terminal I/0 for an interactive terminal. The acceptable range for pr is from 2 to 77778.

The service limits associated with each service class are established by using SERVICE command entries in the IPRDECK. These entries normally reflect the ideal service limits for the job mix of the particular installation. The values specified in the IPRDECK are important to optimum system performance and are not normally altered. However, when changes are necessary they are usually temporary and the original values will be reset. Figure 5-3 provides space to record the original values specified in the S display. For additional information concerning the SERVICE command, refer to section 3, Deadstart Decks.

SRST,t. Changes the secondary rollout sector threshold to the value t  $(0 \le t \le 7777_8)$ . Any rollout file smaller than t sectors is considered a secondary rollout file for the purpose of equipment selection.

## NOTE

The size of the rollout file for any job must be at least seven sectors larger than the combined size in sectors of the job's central memory and extended memory field lengths.

# PERIPHERAL EQUIPMENT CONTROL COMMANDS

The commands described in this category provide control of the peripheral equipment available to the system.† You should become familiar with the following DSD displays, which are closely associated with the use of these and other commands described throughout this section.

- Equipment status display (E,A).
- Disk configuration display (E,C).
- Family status display (E,F).
- Disk status display (E,M).
- Resource requests display (E,P).
- Tape status display (E,T).
- BIO status display (I).

A complete description of each of these displays is given in the NOS 2 Operations Handbook.

| Command         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ASSIGN,jsn,est. | Assigns equipment defined by EST ordinal est (normally a tape unit) to the job with job sequence name jsn. This command is entered in response to a flashing REQUEST message. Use of this command for assignment of a tape unit should not normally be required because tape assignment is performed automatically when a volume serial number (VSN) is specified in the job request. However, if a VSN is not specified in the job request for a labeled or unlabeled tape, the REQUEST message appears at the job's control point (on the B,O display), and the ASSIGN command must be entered to assign a tape unit to the job. |
| BKSP,est,rr.    | Backspaces rr octal logical records on the print file for the BIO<br>equipment defined by EST ordinal est. When rr is not specified, the<br>default is one record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| BKSPF,est,ff.   | Backspaces ff octal files on the print file for the BIO equipment<br>defined by EST ordinal est. When ff is not specified, the default<br>is one file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| BKSPRU,est,ss.  | Backspaces ss physical record units (PRUs) on the print file for the<br>BIO equipment defined by EST ordinal est. The PRU count, ss, must<br>be specified. There is no default setting. Printing resumes at the<br>beginning of a line.                                                                                                                                                                                                                                                                                                                                                                                            |
| CONTINUE,est.   | Resumes printing on the BIO equipment defined by EST ordinal est.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

<sup>&</sup>lt;sup>†</sup>Operation of peripheral equipment is described in the NOS 2 Operations Handbook.

| Command                                   | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CP,est,id.                                | Assigns a numeric identifier id to the BIO card punch defined by EST<br>ordinal est. The value of id can range from 00 to 678. Only<br>those files in the punch queue with an identifier equal to id are<br>directed to card punch est. Refer to the descriptions of the LOAD<br>and CR commands to assign an identifier to a job or queue type file. |
| CR,est,id.                                | Assigns a numeric identifier id to the card reader defined by EST<br>ordinal est. The value of id can range from 00 to 678. All<br>subsequent jobs loaded from card reader est are assigned the<br>identifier id.                                                                                                                                     |
| DOWN,CHcc,EQest.<br>or                    | The first form of the command discontinues use of channel cc for the equipment specified by EST ordinal est. If the EQest parameter is omitted, channel cc is discontinued for all equipments in the EST.                                                                                                                                             |
| DOWN, MCHcc, EQest.<br>or<br>DOWN, EQest. | The second form of the command discontinues use of MUX channel cc<br>for the equipment specified by EST ordinal est (this form only<br>applies to model 176). If the EQest parameter is omitted, MUX<br>channel cc is discontinued for all equipments in the EST.                                                                                     |
| Bonn, Equal •                             | The third form of the command discontinues the use of equipment with EST ordinal est for all channels.                                                                                                                                                                                                                                                |
|                                           | If channel cc is the only channel available to a mass storage equipment, its use is not discontinued. If channel cc is                                                                                                                                                                                                                                |

## Description

If you attempt to DOWN an equipment

- already with a DOWN status
- assigned to a job
- not listed as removable in the EST<sup>†</sup>
- listed in the EST as removable but not globally unloaded<sup>†</sup>
- that is an independent shared device (multimainframe)<sup>†</sup>

the following message appears.

#### INCORRECT ENTRY

Correct the entry and retry the command.

### NOTE

This command should be used with caution since it directly affects the operation of system peripheral equipment.

END,est,rc.

Terminates the current operation on the BIO equipment defined by EST ordinal est. If est defines a line printer or card punch, BIO then assigns the next available file to that equipment. If est defines a card reader that is actively reading cards when END, est is entered, the job terminates at the last card read. The next card is treated as the beginning of a new job. If another card deck follows the end-of-information card (multipunch 6/7/8/9), it is processed normally.

If est defines a card reader that is stopped because of a compare error when END, est. is entered, perform the following steps:

- 1. Remove the remainder of the card deck, except the end-of-information card, from the card reader input hopper.
- 2. Ready the card reader to read the end-of-information card.

The job terminates and if another card deck follows the end-of-information card, it is processed normally.

The rc parameter cancels a portion of the repeat count specified for that equipment (refer to the REPEAT command later in this section). For example, if the current operation on equipment est had been set to be repeated five times (operation performed six times), entering a value of 4 for rc would permit the operation to be performed just two times. If the repeat count is zero, this command performs the END operation once.

<sup>†</sup>Applies only to mass storage equipment.

<sup>†</sup> Sets format pending bit in the MST for 881/883 pack reformatting. Refer to the description of the FORMAT program in appendix F. †† Device must be removable.

#### Description

This command provides the capability to initialize and flaw tracks on any mass storage device during normal system operation. Each time this command is entered it is logged in the error log.

If local unload (L) status is set for the device, the INITIALIZE command is ignored and the following message appears on the left console screen.

INCORRECT ENTRY

However, the INITIALIZE command is allowed to execute while local unload status is set if an error code (CE, IL, LE) is set.

Entry of this command does not in itself initialize the specified device. It merely sets initialize status for the device so that it may be initialized. However, if fast attach files (special system files) are active on the specified device and initialization level of AL or PF is specified, initialize status cannot be set until these files are returned. In this case, the message

FAST ATTACH FILES ON DEVICE.

appears at the system control point on the system status display (B,0). Refer to the description of this message in the NOS 2 Operations Handbook for additional information.

The procedure involved in initializing a mass storage device is described in section 8, K-Display Utilities, under the heading Initialize K Display. The following describes system activity when initialization occurs.

If the device is shared in a multimainframe environment, initialization does not proceed until all other mainframes sharing the device have processed an UNLOAD command for the device and user counts on all machines are zero. If all machines have not unloaded the device, this control point message is displayed:

EQest BUSY ON ID=id.

est is the EST ordinal. id is the machine identifier of the first machine found without unload status set.

If initialize status is set on this device for another mainframe, the INITIALIZE command is ignored and this message appears at the system control point on the system status display (B,0):

INITIALIZE PENDING ON THIS DEVICE.

| Command |
|---------|
|         |

When the AL initialization option is specified, the label on the device to be initialized is either updated or a new label is created. If the label on the device is bad or cannot be recognized, the new label is created and all current data on the device is lost. If the label is found to be good, it is updated and all permanent file information is cleared. In this case, system library or temporary files (local, rollout, and so forth) residing on the device are not disturbed. If the device being initialized is a master device, the system scans all other mass storage devices in the family that contain direct access files and releases the space for files with catalogs on this device. If the device being initialized contains direct access files, the system scans all other master devices and sets the catalog entries on those devices to indicate that the files were purged. All or part of the permanent file system can be initialized and then reloaded if necessary (refer to the description of permanent file utilities in section 17, Permanent File Utilities.

LOAD, est, id. Requests that a job be loaded from equipment defined by EST ordinal est (normally tape unit). The job is assigned a numeric identifier id ranging from 00 to 678. If id is not specified, it defaults to 00. Examine the E,A display to determine the EST ordinal of the equipment to be used.

LP,est,id. or Assigns a numeric identifier id to the line printer defined by EST ordinal est. The value of the identifier can range from 00 to 678. Only those files in the print queue with an identifier equal to id LR,est,id. or or LS,est,id. LP,est,id. Assigns a numeric identifier id to the line printer est. Refer to the descriptions of the LOAD and CR commands in this section to assign an identifier to a job or queue type file. The user usually assigns the identifier to the file.

or

LT,est,id.

MSAL=est<sub>1</sub>,est<sub>2</sub>, ...,est<sub>n</sub>.

2, Reverses current set or clear condition of temporary file status for mass storage devices defined by EST ordinals est<sub>i</sub>. When temporary file status is set, the system can use the specified device for allocation of temporary files. This command is not valid if the device specified is defined as removable. Examine the disk status display (E,M) to determine:

- The EST ordinal of the device.
- If the device is defined as removable.
- If temporary file status is currently selected (set) for the device.

|                                          | t is the size in sectors of<br>threshold; the default valu<br>smaller than the threshold | not exist until the command SRST=t (where<br>the file, from 0 to 77778) defines a<br>e of a threshold is 0. All rollout files<br>are secondary rollout files. These files<br>specified with the MSAL,S command. |
|                                          | All files greater than or e rollout file devices (MSAL,                                  | qual to the threshold are assigned to the R command).                                                                                                                                                           |
|                                          | The following example illus                                                              | trates a use for secondary rollout files.                                                                                                                                                                       |
|                                          | EQPDECK                                                                                  |                                                                                                                                                                                                                 |

EQ005=DP, ST=ON, SZ=4000, CH=30.

٠ MSAL,S=5. Assigns secondary rollout files to extended memory. • . IPRDECK • • SRST=20. Sets the threshold count so rolled out files under 20 sectors ٠ long are assigned to extended . memory.

via DDP.

Equipment 5 is extended memory

For additional information concerning the SRST command, refer to section 3, Deadstart Decks.

## Description

MOUNT, est, P. Clears the local unload (L) and global unload (N) status for a mass storage device and reactivates the device. If the device is a spun down 834 drive, it will be automatically spun up. The device is defined by EST ordinal est (examine the E,A display to determine the EST ordinal).

> When you specify P in the MOUNT command for an independent shared device in a multimainframe environment, the system presets the device with EST ordinal est. The preset (P) option can be specified only on the first mainframe to access the device.

If the device defined by EST ordinal is not a mass storage device, the MOUNT command is ignored and this message appears on the left console screen:

#### **INCORRECT EQUIPMENT.**

If the device is shared in a multimainframe environment and another mainframe has an unsatisfied initialize request pending for that device, the MOUNT command is ignored and this message appears at the system control point on the system status display (B,0):

INITIALIZE PENDING ON THIS DEVICE.

- OFF,est. Logically turns off the device defined by EST ordinal est. This command allows you to logically remove a device from the operating environment. Examine the E,A display to determine the EST ordinal and current status (ON or OFF) of the device. If est specifies a mass storage device and the system library or temporary files (local, rollout, and so forth) reside on that device, it should not be turned off. Examine the disk status display (E,M) to determine which mass storage devices have system residency or allow system allocation of temporary files. In addition, if an MSAL entry is currently specified for a mass storage device, it is cleared when that device is turned off. The MSAL designation is not reset automatically when the device is turned back on and must be reset manually (if necessary) using the DSD command MSAL.
- ON,est. Logically turns on the device defined by EST ordinal est. This command allows you to activate a device currently having OFF status in the EST. If the device is a spun down 834 drive, it will be automatically spun up. Examine the E,A display to determine the EST ordinal and current status (OFF or ON) of the device.
- PRSIZE,est,ps. Sets the paper status ps to short (S) or long (L) paper for the printer with EST ordinal est. Short paper has a form length of 8.5 inches and long paper has a form length of 11 inches.
- REPEAT,est,rc.<sup>†</sup> Repeats the current operation on the BIO equipment defined by EST ordinal est the number of times specified by rc. The maximum value that can be entered for rc is 778.

<sup>&</sup>lt;sup>†</sup>When the current BIO operation is repeated, maximum line and card limits are reinitialized prior to printing or punching of the file being processed. User control limits apply individually to each output file copy produced.

| Command |
|---------|
|---------|

- REPRINT,est,pr. Terminates the current operation on the BIO printer equipment defined by EST ordinal est and reenters the job in the print queue with a queue priority specified by prOO (service class minimum  $\leq prOO \leq$  service class maximum; refer to the S display in the NOS 2 Operations Handbook; pr value is multiplied by 1008 internally). If pr is not specified, the service class default priority is assigned.
- REPUNCH,est,pr. Terminates the current operation on the BIO card punch equipment defined by EST ordinal est and reenters the job in the punch queue with a queue priority specified by prOO (service class minimum  $\leq$  prOO  $\leq$  service class maximum; refer to the S display in the NOS 2 Operations Handbook; pr value is multiplied by 1008 internally). If pr is not specified, the service class default priority is assigned.
- SCRATCH,est. Declares the tape mounted on an unassigned magnetic tape unit, defined by EST ordinal est, to be a scratch tape. This command enables a tape to be available to satisfy scratch VSN requests and still be assigned by its original VSN. Thus, the VSN defined on the tape (in VOL1 label) is not redefined as scratch although the VSN will appear as SCRATCH on the tape status display (E,T).

Scratch status is retained for only one job assignment. This allows a tape to be used for scratch purposes on a temporary basis. For example, a job requests a tape mounted on the tape unit defined in this command by specifying the current VSN for that tape in the request. The tape is then assigned to the job as a scratch tape (the original VSN is retained and not made scratch). When that job releases the tape, SCRATCH status is cleared, and unless this command is entered again, that tape would not be assigned as a scratch tape in future requests. To determine if SCRATCH status is in effect for a tape, monitor the tape status display (E,T).

SECUREQ,est, LA=lowerlevel, UA=upperlevel. Changes the equipment access level limits for the unit record equipment with EST ordinal est. On a secured system, only files that have access levels within these limits can be printed on the specified equipment. The original limits are set during deadstart by the ACCESS command entries in the EQPDECK. The parameters LA=lowerlevel and UA=upperlevel specify the lower and upper access level limits for the equipment.

## NOTE

On a secured system this command is accepted only if a security administrator has placed the system in security unlock status.

| Command        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SKIP,est,rr.   | Skips forward rr octal logical records on the print file for the BIO equipment defined by EST ordinal est. When rr is not specified the default is one record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SKIPF,est,ff.  | Skips forward ff octal files on the print file for the BIO equipment defined by EST ordinal est. When ff is not specified the default is one file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SKIPRU,est,ss. | Skips forward ss PRUs on the print file for the BIO equipment<br>defined by EST ordinal est. All parameters must be specified; there<br>are no default settings. The PRU count, ss, is limited to 10g<br>PRUs (the current buffer size) plus the number of PRUs remaining in<br>the buffer. If the buffer was empty, ss would be limited to 20g<br>PRUs. If ss is larger than the number of PRUs remaining in the<br>buffer, the buffer is filled again and the additional PRUs are<br>skipped on the new print file. For example, if five PRUs remaining five<br>PRUs would be skipped, the buffer filled again, and five additional<br>PRUs skipped. Printing resumes at the beginning of a line. |
| SPINUP,est.    | Spins up the 834 disk storage device defined by EST ordinal est. To<br>enter this command, the console must be unlocked (refer to the<br>UNLOCK command later in this section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| SPINDOWN,est.  | Spins down the 834 disk storage device defined by EST ordinal est.<br>To enter this command, the console must unlocked (refer to the<br>UNLOCK command later in this section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

NOTE

Spinning down an 834 disk storage device that does not have global unload status (N), can cause mass storage device status errors or permanent file errors when the device is spun up.

STOP, est. Stops printing on the BIO equipment defined by EST ordinal est.

SUPPRESS,est.

Suppresses automatic printer carriage control on the BIO line printer defined by EST ordinal est. This command stops the page eject function on the line printer to provide a continuous listing for the current job.

## Description

- TRAIN,est,t. Assigns or changes print train identifier t of the line printer defined by EST ordinal est. This command can set the identification if it was not specified in the EQ entry of the EQPDECK, or change an identification previously included in the EQPDECK. An LR designation in the EQ entry indicates a 580-12 line printer, LS is a 580-16 line printer, and LT is a 580-20 line printer. LP is applicable to all line printer types. Print trains supported for the 580 printers are 596-1, 596-5, and 596-6. The t field specifies the print train.
  - t Print Train
  - 0 596-1 (CDC graphic 63/64-character set); default.
  - 1 596-1 (CDC graphic 63/64-character set).
  - 2 Reserved for future use. †
  - 3 Reserved for future use. †
  - 4 Reserved for future use. †
  - 5 596-5 (ASCII graphic 63/64-character set).
  - 6 596-6 (ASCII graphic 95-character set).
  - 7 596-6 (ASCII graphic 63/64-character set or ASCII graphic 95-character set).
- UNLOAD,est. Physically unloads a tape or logically removes a removable mass storage device from the operating system. The device to be unloaded is defined by EST ordinal est (examine the E,A display to determine the EST ordinal). Also, in a multimainframe environment, the UNLOAD command must be issued if another mainframe wants to initialize a shared mass storage device, whether the device is removable or nonremovable (refer to the INITIALIZE command earlier in this section). If a magnetic tape is specified, the tape is physically unloaded. If a removable mass storage device is specified, you can dismount the disk pack on that device.

## NOTE

If a nonremovable shared mass storage device is to be specified, the console must be unlocked (refer to the UNLOCK command later in this section).

<sup>†</sup> These values are allowed but will default to 596-1.

#### Description

<u>Magnetic tape units</u>: If a tape is currently assigned to a job, it cannot be unloaded. If you attempt to unload it, the UNLOAD command is ignored and this message appears on the left console screen:

#### UNIT NOT AVAILABLE

Examine the tape status display (E,T) before entering the UNLOAD command to determine if the tape to be unloaded is currently assigned to a job. If the tape is not currently assigned, entering this command unloads the specified tape.

<u>Mass storage devices</u>: The UNLOAD command is valid for any shared mass storage device in a multimainframe environment for the purpose of initialization. Otherwise, the command is valid only for removable devices. (Only removable devices may be physically removed by unloading.) After entering the UNLOAD command, monitor the disk status display (E,M). Execution of this command immediately causes local unload (L) status to appear in the STATUS field for that device. While L status is displayed, no new users are permitted to access files on the device. A user currently accessing files on the device is attached to the job. When the user count is zero and there are no checkpoint requests pending, one of the following two actions occurs.

• If the device is removable and the L status is set in all machines accessing the device, global unload (N) status is displayed. This indicates that the device may now be physically dismounted.

#### NOTE

If a multispindle family is mounted on a single spindle device, only the first device shows the global unload status.

• If an initialize is pending on the device and all other machines accessing the device have L status set, the initialization proceeds. However, initialization cannot take place if the device has been unloaded.

NOTE

A device should be physically dismounted only if global unload status (N) is displayed on all machines accessing the device.

If a removable pack is dismounted before the N status is displayed, the following may occur.

- Mass storage device status errors.
- Permanent file errors when the pack is remounted at some later date.
- If another pack has been mounted, accesses made by a previously attached user may destroy information on the new pack or the user may retrieve information from the new device which he is not necessarily privileged to access. Mass storage device status errors are also possible in this situation.

## NOTE

If the Mass Storage Subsystem (MSS) or Mass Storage Archival Subsystem (MSAS) is active, it must be idled before unloading a removable family pack which has MSS/MSAS files. After dismounting the family pack, MSS/MSAS can be initialized again.

- UP,CHcc,EQest. or UP,MCHcc,EQest.<sup>†</sup> Resumes normal use of channel cc or the equipment with EST ordinal est by tape units and/or mass storage devices, reversing the DOWN command. If EQest is specified, use of channel cc resumes only for the mass storage equipment with EST ordinal est. The equipment specification is valid only for mass storage equipments. If you attempt to UP a channel or equipment that
  - is already UP,
  - has a DOWN status and is assigned to a maintenance job,
  - was given a DOWN status by another mainframe that is sharing the equipment,

this error message appears:

**INCORRECT ENTRY** 

If the channel or equipment is already up, no further action is necessary. If the equipment is assigned to a maintenance job, you cannot bring up the equipment until the maintenance job releases it. If the DOWN,EQest command was entered from another mainframe in a multimainframe environment, that mainframe must enter the UP,EQest command.

or

UP,EQest.

Command

<sup>&</sup>lt;sup>†</sup>Model 176 only.

## Description

Putting an equipment in an UP status does not completely reverse the DOWN status. The equipment must also be turned on using the ON,est command.

| Ν | OT | Е |
|---|----|---|

This command should be used with caution since it directly affects the operation of system peripheral equipment.

VALIDATE,est. Causes validation of mass storage tables associated with the equipment defined by EST ordinal est. The equipment must be available mass storage and the MS VALIDATION option must have been selected in the IPRDECK at deadstart.

VSN,est,. Declares the tape mounted on an unassigned magnetic tape unit, defined by EST ordinal est, to be a scratch tape. This command is similar in function to the SCRATCH command in that it enables a tape to be available to satisfy scratch VSN requests. However, if the tape is labeled and a write function is performed, the VSN specified in the VOL1 label will be rewritten as a scratch VSN, destroying the original VSN and making the tape available for future scratch VSN requests. The VSN also appears as \*\*\*est (est is the ordinal of the est) on the tape status display (E,T). Refer to the VSN,est,vsn command, next, for a discussion of the INCORRECT ENTRY message which is also applicable to VSN,est,.

VSN,est,vsn.<sup>†</sup> Assigns VSN vsn to an unassigned magnetic tape unit defined by EST ordinal est. This command allows you to specify a 1- to 6-character VSN for a mounted, unlabeled tape so it may be assigned and referenced automatically. For example, when a job specifies a VSN in the request for an unlabeled tape, an entry for that job appears in the resource requests display (E,P). This display indicates the job sequence name of the job, the type of tape unit, 7 track (MT) or 9 track (HD, PE, or GE), on which the tape is to be mounted, the required VSN, user name of the job, and the required write ring status (IN or OUT). If the correct tape is not currently mounted, mount the tape on an available unit (ensuring that track type and write ring status are correct), ready the unit, and enter this command. The system equates the VSN you enter with that specified by the job and assigns the tape automatically upon demand.

<sup>&</sup>lt;sup>†</sup>Special characters cannot be entered using this command. If a special character is encountered in vsn, the VSN entered is truncated at the character preceding the special character.

If the tape mounted on the tape unit defined by EST ordinal est is a labeled tape, has already had a VSN assigned by console command, or has not yet been checked for a label by the magnetic tape subsystem, this command is ignored. The message

INCORRECT ENTRY

appears on the left console screen. To change a VSN previously assigned by this command, clear the first VSN by entering:

Description

VSN,est.

Parameter

est EST ordinal of the tape unit.

This command can then be entered:

VSN,est,vsn.

Parameter Description

vsn New VSN.

(The preceding message and procedure for changing a VSN are also applicable to the VSN,est,. command.)

If a job specifies a VSN in the request for a labeled tape, assignment occurs automatically, without your intervention, unless the correct tape is not mounted. In this case, an entry is formed in the resource requests display (E,P), which describes the tape to be mounted. When the tape is mounted and the tape unit made ready, assignment occurs automatically without additional intervention by you. For multireel files, automatic tape assignment occurs only if the tape units on which the tapes are mounted are similar and on the same channel(s). That is, if the first reel of the file is on a 669 tape unit on channels 13 and 33, all subsequent reels must be on a 669 unit on channels 13 and 33. When assigning tapes, models 679-2, 679-3, and 679-4 drives (800/1600 cpi) are similar. Also models 679-5, 679-6, and 679-7 drives (1600/6250 cpi) are similar.

If two or more unassigned tapes having identical VSNs are mounted on units of the same track type, the message

REQUEST, dt, vsn

appears on the B,O display. The dt field is either the device type MT or the density requirement HD, PE, or GE; vsn is the VSN required.

You must assign one of the tapes using the ASSIGN command. If the duplicate VSNs are SCRATCH, the resource executive routine assigns one automatically.

#### NOTE

It is not possible to specify a VSN of SCRATCH with this command since only six characters may be used to define a VSN. To define a scratch tape (used to satisfy scratch VSN requests), refer to the description of the SCRATCH command earlier in this section.

60459300 D

#### Command

# SUBSYSTEM CONTROL COMMANDS

The commands that follow provide control over which subsystems are to be used. When a system deadstart is performed, parameters specified in the IPRDECK determine which subsystems initially are available. Scheduling other subsystems to a control point or terminating a current subsystem depends on your action.

When a subsystem is scheduled to a specific control point, any job currently assigned to that control point is rolled out if it is not another subsystem or special system job. However, if the job cannot be rolled out, the command used to call the subsystem would not be valid. In this case, either terminate the job (if the subsystem required that control point) or specify another control point for the subsystem using the SUBSYST L-display utility (refer to section 9, L-Display Utilities, for more information).

## Command

#### Description

BTO.

Calls the Batch Input/Output (BIO) Subsystem. BIO must be active in order to use any of the local batch peripheral devices. BIO equipment activity can be monitored on the I display (refer to the NOS 2 Operations Handbook).

Response to line printer errors is controlled by setting sense switch 1 or 2 as follows:

| Lntry | ] | Eı | n | t | r | y |
|-------|---|----|---|---|---|---|
|-------|---|----|---|---|---|---|

| ONSW,BIO,1. | Lines  | causing   | print | error | messages | are | not |
|-------------|--------|-----------|-------|-------|----------|-----|-----|
|             | flagge | ed or ret | ried. |       |          |     |     |

ONSW,BIO,2. Lines causing print error messages are flagged and retried. The printer halts and is placed on hold until you correct the error and enter CONTINUE,est. The line reprints and printing continues.

Response

CDCffff.<sup>†</sup> Calls the CYBER Database Control System (CDCS). CDCffff calls a procedure file named CDCffff under the system user index to initiate the CDCS Subsystem.

IAFffff.<sup>†</sup> Calls the Interactive Facility (IAF) Subsystem to control point 1. IAFffff calls a procedure file named IAFffff under the system user index to initiate the IAF Subsystem. The IAF Subsystem must be active before jobs can be entered from an interactive terminal. Use the T display to monitor activity at the IAF Subsystem control point.

Ensure that NAM is active at a control point (refer to the B,O or B,A display before you enter the IAFffff command.

<sup>†</sup> The characters ffff are optional; if required, installation personnel must supply the necessary 1 to 4 alphanumeric characters.

Several options are available to control the operation of IAF. Select these options by setting sense switches after the subsystem is initiated. Although normal operation does not require these sense switches to be set, sense switch 5 (ONSW,IAF,5) is set by default when the IAF Subsystem is initiated. Once set, the sense switches may be turned off again by entering OFFSW,IAF,s (s is the sense switch number.)

# EntryResponseONSW,IAF,1.When the IAF Subsystem is terminated (by an<br/>IDLE,IAF command), enter users into a detached<br/>state and inhibit restarting operations.ONSW,IAF,2.The IAF Subsystem will not reload after an<br/>abort. This option releases the output file to<br/>the output queue.ONSW,IAF,3.Aborts the IAF Subsystem on all abnormal<br/>conditions. This ensures that the subsystem does<br/>not approximate of a participant.

- conditions. This ensures that the subsystem does not continue to operate if an internal malfunction occurs. This may be used with sense switch 5 to enable an analyst to determine the problem. Some conditions cause the IAF Subsystem to abort even though sense switch 3 is not set.
- ONSW,IAF,4. Enables a dump on normal termination. This option should be activated whenever a dump is desired after the IDLE,IAF command.
- ONSW,IAF,5. Dumps information to the output file after the IAF Subsystem is dropped or aborted. This option provides a listing that may assist an analyst in determining the problem that existed when the subsystem dropped or aborted. This sense switch is set by default when the IAF Subsystem is activated.
- ONSW, IAF, 6. Releases the output file containing dump information written after the IAF Subsystem is dropped or aborted (refer to the ONSW, IAF, 5 option) immediately after the dump is taken. When sense switch 6 is not set, the output file is not released until the IAF Subsystem is terminated. It is then printed with the job dayfile. This switch applies only when sense switch 5 is set.
- IDLE, sub. Sets idledown status for subsystem sub, except for NAM and RHF. NAM is idled by using the procedure shown in NAM Shutdown (refer to section 15, Network Operations). RHF is idled by using the RHF K display (refer to section 8, K-Display Utilities).

The subsystem terminates when idledown conditions are met. MAG terminates when no tapes are assigned. MSS/MSAS terminates when no requests are outstanding and no MSS/MSAS utilities are connected. BIO terminates when no active equipments remain. TAF terminates when no active transactions are outstanding. For all other subsystems, there are no idledown conditions; they terminate immediately.

#### Description

The system does not initiate new activity, such as assigning tapes and beginning print jobs, when idledown status is set. It is recommended that you use this command for terminating all subsystems.

MAGffff.<sup>†</sup> Calls the Magnetic Tape Subsystem (MAG) to the control point specified in the ENABLE command. MAG must be active in order for tape processing and resource allocation to take place and to make the resource requests available. Tape use can be monitored on the tape status (E,T) and resource rquests (E,P) displays. MAGffff executes a procedure file named MAGffff under the system user index to initiate the MAG Subsystem.

## NOTE

You must not change unit numbers or power down tape units after MAG is initialized. Also, MAG should not be stopped (via the STOP command) while tapes are assigned.

- MAPffff. † Calls the Matrix Algorithm Processor (MAP) Subsystem to the control point specified in the ENABLE command. MAPffff calls a procedure file named MAPffff under the system user index to initiate the MAP Subsystem.
- MASffff.<sup>†</sup> Calls the Mass Storage Archival Subsystem (MSAS) processing program to the control point specified in the ENABLE command. MASffff calls a procedure file named MASffff under the system user index to initiate the MSAS.

You can turn the trace mode on or off by using the following sense switch entries after the subsystem is initiated.

ONSW,MAS,1. Turn the trace mode on. The trace mode issues all MSAS messages to the job dayfile.

OFFSW,MAS,1. Turn the trace mode off. Default is trace mode off.

- MCSffff.<sup>†</sup> Calls the Message Control System (MCS) to the control point specified in the ENABLE command. MCSffff calls a procedure file named MCSffff under the system user index to initiate the MCS Subsystem. NAM must be active at a control point to use MCS.
- MSSfff.<sup>†</sup> Calls the Mass Storage Subsystem (MSS) processing program to the control point specified in the ENABLE command. MSSffff calls a procedure file named MSSffff under the system user index to initiate the MSS.

† The characters ffff are optional; if required, installation personnel must supply the necessary 1 to 4 alphanumeric characters.

| n Facility (SSF) Subsystem to the control<br>NABLE command. SSFffff calls a procedure<br>the system user index to initiate the SSF                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| the last control point. STMffff calls a ffff under the system user index to initiate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ubsystem sub. Any acceptable three-letter<br>ecified. Unlock the console to enter this<br>an cause termination errors in the subsystem                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

<sup>†</sup> The characters ffff are optional; if required, installation personnel must supply the necessary 1 to 4 alphanumeric characters.

TAFffff. †

Calls the Transaction Facility (TAF) Subsystem to the control point specified in the ENABLE command. TAF must be active for transaction processing to take place.

TAFffff calls a procedure file named TAFffff under the system user index to initiate the TAF Subsystem. NAM must be active at a control point for interactive access to TAF. Batch jobs can access TAF without NAM.

Response to an operator drop or fatal error is controlled by setting sense switches as follows:

## Response

- ONSW,TAF,3. Attempt recovery after TAF is dropped or aborted. To successfully drop the transaction subsystem once this entry has been made, the command OFFSW,TAF,3 must be entered prior to the STOP,TAF command.
- ONSW,TAF,5. Dump the entire field length and release the output file after the transaction is dropped or aborted.

ONSW, TAF, 6. Print the job dayfile upon termination.

Activity at the transaction control point can be monitored on the O displays (refer to the NOS 2 Operations Handbook).

Refer to the AUTO and MAINTENANCE commands in this section and the SUBSYST L display in the NOS 2 Operations Handbook for additional information concerning subsystem control.

Entry

# SYSTEM CONTROL COMMANDS

The following DSD commands control the operating system as well as the subsystems that run under the system. Several of these commands are typically used only for debugging purposes when the system is in an abnormal state. You may use others frequently to maintain system integrity in a normal production environment. Appropriate cautions are included with individual command descriptions in cases where you do not normally use the command or it is not recommended for use in a production environment.

#### Command

#### Description

AUTO. Calls enabled subsystems to control points, initiates automatic job processing, and spins up any 834 disk drive that is ON and not unloaded. The IPRDECK used at deadstart time determines which subsystems will be activated by default. However, any of those subsystems not currently assigned to a control point can be disabled or others enabled through use of the SUBSYST L display (refer to the NOS 2 Operations Handbook). Individual subsystems can also be called to a control point or removed independent of the AUTO command by using the Subsystem Control Commands described earlier in this section. For additional information concerning the AUTO command, refer to Initiating Job Processing in section 2, Deadstart.

<sup>&</sup>lt;sup>†</sup>The characters ffff are optional; if required, installation personnel must supply the necessary 1 to 4 alphanumeric characters.

| CHECK POINT SYSTEM. | Provides for termination of job processing and writes the contents of<br>central memory tables to mass storage. The SCKP EQPDECK entry speci-<br>fies which mass storage devices will contain a copy of the checkpoint<br>file. This command is typically entered in preparation for recovery<br>deadstart. The following sequence of operations takes place:     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | <ol> <li>Sense switch 1 is set for the IAF Subsystem, which causes all<br/>users to be placed in detached job status when an operator<br/>drop occurs. When all users are in detached job status, the<br/>IAF Subsystem is dropped and the checkpoint continues.</li> </ol>                                                                                       |
|                     | <ol> <li>All job scheduling is inhibited. (This has the same effect<br/>as if the IDLE command was entered.)</li> </ol>                                                                                                                                                                                                                                           |
|                     | <ol> <li>Jobs with a zero subsystem identifier are rolled out. All<br/>of these jobs are recovered on a level 1 or level 2 recovery<br/>deadstart.</li> </ol>                                                                                                                                                                                                     |
|                     | <ol> <li>The system moves the system dayfile buffers maintained in<br/>CMR to disk.</li> </ol>                                                                                                                                                                                                                                                                    |
|                     | <ol> <li>All subsystems except the magnetic tape executive (MAG) are<br/>aborted.</li> </ol>                                                                                                                                                                                                                                                                      |
|                     | 6. MAG is rolled out when no other jobs are active. The rolling<br>out of MAG allows recovery of all tape files associated with<br>jobs rolled out if the tapes are not repositioned prior to<br>the level 1 or level 2 recovery deadstart. Because of this,<br>if a tape unit is used for deadstart, it should be unassigned<br>prior to the checkpoint command. |
|                     | 7. The system is left in an idle state. If SPINDOWN is<br>enabled, all 834 disk drives that are ON and not unloaded<br>are spun down. Normal processing may be continued with an<br>AUTO command. If this is done, no attempt should be made to<br>later perform a level 1 or level 2 recovery deadstart unless<br>another checkpoint command is performed.       |
|                     | During the processing of the checkpoint, the message                                                                                                                                                                                                                                                                                                              |
|                     | PROCESSING SYSTEM CHECKPOINT                                                                                                                                                                                                                                                                                                                                      |
|                     | is issued at the system control point. It is also possible that                                                                                                                                                                                                                                                                                                   |

under certain circumstances the checkpoint routine will not be able to properly abort a job (such as one that has NOEXIT selected and has a nonzero subsystem identifier). If such a job continues processing after it has been aborted by the system, the operator must then abort the job for the checkpoint to continue. A more desirable approach to this situation is to ensure that jobs such as permanent file dumps are finished prior to the checkpoint. For additional information concerning the CHECK POINT SYSTEM command, refer to Preparing for Recovery Deadstart in section 2, Deadstart.

Command

### Description

DATE.yy/mm/dd.

Changes the current system date. Unlock the console before entering this command (refer to the UNLOCK command later in this section).

| Parameter | Description           |
|-----------|-----------------------|
| уу        | Year; 00 through 99.  |
| mm        | Month; 01 through 12. |
| dd        | Day; 01 through 31.   |

DEBUG.

Reverses the current status of the debug mode. When the debug mode is set, the message DEBUG appears in the header of the left screen display. The debug mode provides system origin privileges to validated users and allows modifications to be made to the running system. Unlock the console before entering this command (refer to the UNLOCK command later in this section). Use of the debug mode is not commonly allowed in a normal production environment.

## NOTE

On a secured system, the console must be in security unlock status to accept this command (refer to the UNLOCK,username,password command later in this section).

DIS,jsn.

Calls the job display package (DIS) to the job with job sequence name jsn. The A and B displays for DIS automatically appear on the left and right console screen, respectively. Refer to section 4, DIS Operations, for complete information concerning the DIS package.

## NOTE

On a secured system, the console must be in security unlock status to accept this command (refer to the UNLOCK, username, password command later in this section).

DISABLE, op. Disables or enables option op.

or

ENABLE, op.

If you enter the ENABLE command and op is currently enabled, the system ignores the command. The system also ignores the DISABLE command if you enter it and op is already disabled.

op is one of the following options.

#### op

#### Description

DDP ROLLOUT PATH Enables or disables the use of the DDP for job rollout and rollin. If DDP equipment is not present, this entry has no effect.

## Description

<u>op</u>

ENGR

#### Description

Enables or disables engineering mode. When engineering mode is set, the message ENGR appears in the header of the left screen display. Engineering mode allows PP/hardware diagnostics and FORMAT/FDP to be executed if the user has system origin privileges. Unlock the console before entering this command (refer to the UNLOCK

command later in this section).

# NOTE

On a secured system, the console must be in security unlock status to accept this command (refer to the UNLOCK,username,password command later in this section).

| FILE STAGING | Enables or disables the staging of MSF/7990-<br>resident permanent files to disk. Disabling<br>FILE STAGING causes job attempts to access<br>MSF/7990-resident files to be aborted. If<br>the MSSEXEC/SSEXEC is running, enabling FILE<br>STAGING allows MSF/7990-resident files to be<br>staged to disk when accessed. |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOGGING      | Enables or disables logging of dayfile<br>messages concerned with program efficiency.                                                                                                                                                                                                                                   |
| MASTER MAS   | Enables or disables master mainframe mode<br>for MAS processing. When MAS is brought to<br>a control point, the SSEXEC program runs if<br>master mainframe mode is enabled. The SSSLV<br>program runs if master mainframe mode is<br>disabled. This entry has no effect unless<br>MAS processing is activated.          |

MASTER MSS Enables or disables master mainframe mode for MSS processing. When MSS is brought to a control point, the MSSEXEC program runs if master mainframe mode is enabled. The MSSSLV program runs if master mainframe mode is disabled. This entry has no effect unless MSS processing is activated.

MS VALIDATION Enables or disables automatic verification of mass storage tables. This command cannot be used unless the MS VALIDATION option has been selected in the IPRDECK used at deadstart. The validation that occurs for each level of recovery deadstart is described under Preparing for Recovery Deadstart in section 2, Deadstart.

. . . . .

#### Description Description op **PF VALIDATION** Enables or disables verification of BOI/EOI on preserved files. Selection of this option causes BOI/EOI information to be verified when a direct access file is attached or purged, and when an existing local file is defined as a direct access permanent file. PRIVILEGED RDF Enables or disables privileged mode of the Remote Diagnostic Facility (RDF). When enabled, a user's commands are checked to ensure that a maintenance function is being performed. **REMOVABLE PACKS** Enables or disables automatic label checking for mass storage devices defined as removable. Examine the disk status display (E.M) (refer to the NOS 2 Operations Handbook) to determine which mass storage devices (if any) are defined as removable. If this option is disabled, all removable devices subsequently introduced into the system cannot be accessed. This option must be enabled to perform label verification before those devices can be accessed. RESIDENT RDF Enables or disables resident mode of RDF. While in resident mode, RDF remains active, regardless of terminal activity, until you disable RDF. When resident mode is disabled (the default condition), RDF becomes inactive if no one logs into the remote diagnostic terminal for 15 minutes. To allow terminal activity to resume, you must reactivate RDF with a call to RDFffff. SECONDARY USER Enables or disables the acceptance of more COMMANDS than one USER command in a job. If disabled, any USER command encountered after the first one causes the job to be aborted with no exit processing. An interactive origin type job that issues a USER command is logged off. Unlock the console (refer to the UNLOCK command later in this section) to enable or disable this option. This command is not accepted on a secured system. SPINDOWN Enables or disables the spinning down of the 834 disk storage devices during a system checkpoint. USER EXTENDED Enables or disables use of the user MEMORY accessible area of extended memory. If disabled, no job can access the user area of extended memory and, other than subsystems,

all jobs currently accessing the area are

rolled out.

| Command       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDLE.         | Prevents any new jobs from being scheduled to a control point but<br>does not terminate the jobs currently assigned. If a job is rolled<br>out while this command is in effect, it will not be scheduled back<br>to a control point until the AUTO or MAINTENANCE command is<br>entered. When the BIO Subsystem is idle, it is terminated.                                                                                                                                                                                                                                              |
| K.messagetext | Allows entry of data messagetext in the user- or system-defined CPU<br>buffer for control when the K display is active. Refer to section<br>8, K-Display Utilities, for information about the K display.                                                                                                                                                                                                                                                                                                                                                                                |
| LOCK.         | Locks the console keyboard. This command prevents entry of<br>restricted commands (refer to the UNLOCK command later in this<br>section for a list of restricted commands). All other DSD commands<br>can be entered when the console is locked. The console is normally<br>locked when the system is being used in a production environment.                                                                                                                                                                                                                                           |
| MAINTENANCE.  | This command performs the same functions as the AUTO command but<br>additionally starts several maintenance routines. Refer to<br>Initiating Job Processing in section 2, Deadstart, for complete<br>information concerning this command.                                                                                                                                                                                                                                                                                                                                               |
| STEP.         | Sets the monitor in step mode. Setting the monitor in step mode<br>stops all central memory I/O operations and prevents the system from<br>processing PP requests when the next monitor function is encountered.<br>Pressing the space bar releases the present step and stops again for<br>each subsequent monitor function. <sup>†</sup> If a DSD command is entered<br>while the system is in step mode and all PPs are assigned, it is<br>possible the request cannot be satisfied. In that case, the<br>screen(s) blinks until you correct the condition by clearing the<br>entry. |
|               | When step mode is set, the message STEP appears in the header of the<br>left screen display. Unlock the console before entering this<br>command (refer to the UNLOCK command later in this section).                                                                                                                                                                                                                                                                                                                                                                                    |
|               | This command is generally used for debugging purposes and should not<br>be used in a normal production environment. In addition, the system<br>may set step mode automatically upon detection of a main power<br>failure or abnormal environmental condition.                                                                                                                                                                                                                                                                                                                           |
|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

 $<sup>^\</sup>dagger \, \text{Monitor}$  functions are described in the NOS 2 Systems Programmer's Instant.

| Command                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STEP,jsn,ff,b,v.<br>or<br>STEP,,ff,b,v. | Sets step mode for the job with job sequence name jsn (first form of the command) or all jobs (second form of the command) at the next occurrence of monitor function ff when output register byte b has value v.                                                                                                                                                                                                                                                                                                                                                                                                               |
| 51EP,,II,D,V.                           | If jsn is specified (first form of the command), the monitor function ff, the output register byte number b, and the output register value v can be optionally specified for more precise control of when the step mode is executed. The values for b can be from 0 to 4; the values for v can be from 0 to $7777_8$ .                                                                                                                                                                                                                                                                                                          |
|                                         | If jsn is not specified (second form of the command), the monitor function ff must be specified. The output register byte number b and value v can be optionally specified for more precise control of when the step mode is executed. The values for b can be from 0 to 4; the values for v can be from 0 to $7777_8$ .                                                                                                                                                                                                                                                                                                        |
|                                         | For either form of the command, pressing the spacebar releases the<br>current step and steps the job or system at the next occurrence of<br>the monitor function ff, if specified, or the next monitor function<br>from the job if the first form is used and no monitor function is<br>specified.                                                                                                                                                                                                                                                                                                                              |
|                                         | Using the second form of the command may stop all central memory I/O operations and prevent the system from processing PP requests. If a DSD command is entered while the system is in step mode and all PPs are assigned, it is possible the request cannot be satisfied. In this case, the screens blink until you clear the entry. The message STEP followed by the monitor function number ff (if specified) appears in the header of the left screen displays while this command is in effect. The console must be unlocked before entry of this command is permitted (refer to the UNLOCK command later in this section). |
|                                         | These commands are generally used only for debugging purposes. Do<br>not enter these commands if the system has automatically set step<br>mode because of a power failure or abnormal environmental condition.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TIME.hh.mm.ss.                          | Changes the current system time. Unlock the console before entering this command (refer to the UNLOCK command later in this section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                         | Parameter Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| hh | Hour; 00 through 23.   |
|----|------------------------|
| mm | Minute; 00 through 59. |
| SS | Second; 00 through 59  |

Command UNLOCK.

Unlocks the console keyboard. When this command is active, the message UNLOCK appears in the header of the left screen display. Although all DSD commands can be entered when the console is unlocked, the following commands are restricted to entry only when the console is unlocked.

DATE.yy/mm/dd.

DEBUG.T

DIS, jsn.†

DISABLE, SECONDARY USER COMMANDS.

ENABLE, ENGR.†

ENABLE, SECONDARY USER COMMANDS.

OVERRIDE, jsn.

QDSPLAY,jsn.†

SPINDOWN,est.

SPINUP,est.

STEP.

STEP, jsn, ff, b, v.

STOP, sub.

TIME.hh.mm.ss.

UNLOAD, est. (est specifies a nonremovable shared mass storage device)

UNSTEP.

All memory entry commandst

All channel control commands

All extended memory flag register commands

Always lock the console when the system is being used in a production environment. However, you can unlock the console to enter the STEP command if a system failure requiring a recovery deadstart occurs (refer to Preparing for Recovery Deadstart in section 2, Deadstart) or to enter the UNSTEP command after a power or environmental interrupt.

<sup>&</sup>lt;sup>†</sup>Refer to Secured System Control Commands later in this section for information on unlocking the console keyboard on a secured system.

#### 60459300 D

Command

UNSTEP.

X.MDD(p,d)

### Description

Clears step mode. This command clears the effect of any format of STEP command. Unlock the console before entering this command (refer to the UNLOCK command later in this section). Depending on current syntax overlay residency, you may have to enter the 99 command before entering the UNSTEP command (refer to the 99 command description later in this section). If the system has set step mode because of a main power failure or abnormal environmental condition, do not enter this command until the conditions that caused the automatic setting have returned to normal.

Initiates the monitor display driver (MDD). MDD is a PP program and is independent of the operating system. Refer to the NOS Online Maintenance Software Reference Manual for more information.

# Parameter P

d

#### Description

- Port number parameter. If you enter 1, the first port is connected. If you enter 2, the second port is connected. If you do not specify this parameter, the second port is connected by default.
- Time-out parameter. If you enter 0 (zero), MDD waits 15 minutes for a terminal to be connected before timing out. If you enter a nonzero, MDD waits indefinitely for the terminal connection. The default is 0.

Calls a system program or utility specified by name to an available control point. If parameters are to be passed to the program, the second form of the command is used where (parameters) specifies the meters) parameters. In both the first and second form of the command, the field length specified in the library for the command is used. If no field length is specified in the library, a value of 60000<sub>8</sub> is assumed. If a field length different from the default is required, the third form of the command is used. The field length is specified by fl. Only the first 38 characters following X. are used.

Disables or enables syntax overlay processing and logging of DSD commands in the system dayfile and error log. That is, depending upon current status, syntax overlay processing and logging are reversed. When this mode is enabled, 99 appears on the left screen header.

When syntax overlay processing and logging of DSD commands is disabled, DSD does not allow you to enter any command requiring the loading of an overlay from mass storage. Disable overlay loading only when the system is in an abnormal state to prevent PPs from being requested when they cannot perform the necessary tasks (for example, when a system disk channel is hung). A 99 command that enables logging will be logged itself, but a 99 command which disables logging will not be logged.

This command is normally used only for debugging purposes. When the system is in an abnormal state, the commands that require entry of the 99 command depend on which syntax overlays for DSD are in central memory.

X\_name.

X.name(parameters) or

X.name(f1)

99.

## SECURED SYSTEM CONTROL COMMANDS

The following commands are allowed only on a secured system.

<u>Command</u> OQSH=level. Specifies the output queue special handling (OQSH) level on a secured system. The (OQSH) level is set initially during deadstart by the OQSH IPRDECK entry. The current OQSH level appears on the DSD S display. The OQSH command can be entered at any time from the system console to change the current level. Output files with an access level greater than or equal to the OQSH level specified in this command are not printed but remain in the queue until released by the operator (refer to the RELEASE command, next). If level is set to the lowest access level or no level is specified, no files are held in the queue.

RELEASE, jsn. Allows the operator to release a file from the output queue whose access level is equal to or above the OQSH level on a secured system. Output queue files and their access levels can be examined using the DSD Q display. The output file with job sequence name jsn is released from the output queue and is processed by the Batch Input/Output Subsystem. The RELEASE command can be entered at any time from the system console. Other restrictions based on device access levels and file access levels set by your site continue to apply.

SECURES,ot, LA=lowerlevel, UA=upperlevel. Sets the security access level limits for the system (ot=SY) or the security access level limits for a particular origin type (ot=IA, BC, or RB). The system limits determine the range of access levels allowed in the system; jobs may not execute at an access level outside this range, and files may not be created or accessed at an access level outside this range. Origin type limits determine the range as it applies to jobs of one particular origin type. By default, all origin type limits are the same as the system limits.

> The options available for using this command to change the system limits (that is, whether they can be raised, lowered, or both) are controlled by the OPSECM CMRDECK entry (refer to section 3, Deadstart Decks). The origin type limits for ot=IA, BC, and RB can be changed to any values within the system limits. When the system limits are changed (ot=SY), all origin type limits are reset to the new system limits.

The parameters LA and UA specify the lower and upper access level limits. Both parameters must be specified. The value corresponding to the lower access level must be less than or equal to the value corresponding to the upper access level.

## Description

UNLOCK, username, password. Unlocks the console keyboard. When this command is active, the message SECURITY UNLOCK appears in the header on the left screen display. The following commands are restricted to entry only when the console is in security unlock status.

DEBUG.

DIS,jsn.

ENABLE, ENGR.

QDSPLAY, jsn.

SECURES, ot, LA=1owerlevel, UA=upperlevel.

SECUREQ, est, LA=lowerlevel, UA=upperlevel.

All memory entry commands.

All memory display commands.

# **MEMORY ENTRY COMMANDS**

The following commands are used to change the contents of central memory and extended memory. Either absolute locations or those relative to a specific job's reference address (RA) can be changed.

CAUTION

Use these commands with extreme caution to avoid damage to the system or to user jobs.

Before entering these commands you must unlock the console keyboard (refer to the UNLOCK command earlier in this section). To change central memory, you must bring a central memory display (C, D, F, or G) to the left screen. To change extended memory, you must bring the M display to the left screen. It is this display that controls whether the memory entry commands change absolute memory locations or relative memory locations.

For example, if you enter

С,.

to bring up the C display, any memory entry commands entered make changes to absolute memory locations. If you enter

C,jsn.

where jsn is a valid job sequence name, any memory entry commands entered make changes to memory locations relative to the job's RA.

Character values or numeric data can replace the current word contents. Either one 12-bit byte or a 60-bit word can be changed. A single byte can be changed by inserting the byte number after the location; bytes are numbered 0 through 4 from left to right. The address and contents are assembled right-justified with zeros filling unused leading positions. Leading zeros may be omitted in the entry.

When you are changing the contents of memory relative to a specific job (a valid job sequence name was specified when the memory display was brought to the left screen), the negative field length area of the job can be accessed. This area is accessed by specifying a negative address in the memory entry command. For example, to change the contents of word RA-3, you enter the address 77777758.

On an unsecured system when you are changing a memory location relative to a specific job's RA, the system checks for field length violations. If you specify an address larger than your job's RA plus field length, you cannot change its contents.

On a secured system no memory entry commands are allowed unless the security unlock status is set. The memory display shows the message

#### \*\*\*\*SECURED AREA\*\*\*\*

instead of the contents of the memory locations to prevent you from examining these locations; you may not alter the contents of these locations. When you are displaying the absolute memory you can see only the system tables.

Formats and descriptions for these commands are:

| Command                | Description                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addr,cont.             | Changes the contents of central memory location addr (maximum of eight digits) to cont (maximum of 20 digits). The second form of                                        |
| or                     | the command performs essentially the same function but is used when<br>it is necessary to change successive memory locations.                                            |
| addr <u>+</u> cont.†   | it is necessary to change successive memory locations.                                                                                                                   |
|                        |                                                                                                                                                                          |
| addr,b,cont.           | Changes the contents of byte b at central memory location addr<br>(maximum of eight digits) to cont. Each location consists of five                                      |
| or                     | 12-bit bytes, numbered 0 through 4 from left to right. The contents                                                                                                      |
| addr <u>+</u> b,cont.† | are four octal characters. The second form of the command performs essentially the same function but is used when it is necessary to change successive memory locations. |

<sup>&</sup>lt;sup>†</sup>If the + sign is specified, the address is incremented by one location (addr+1) after the initial entry is processed; the - sign causes the address to be decremented by one location (addr-1). This allows immediate entry for the next (or previous) memory location. If the message REPEAT ENTRY is displayed above the entry, the cont field is not cleared and can be entered in successive memory locations as many times as desired.

| Command                 | Description                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addr,Dcont.             | Changes the contents of central memory location addr (maximum of eight digits) to display code characters cont (left-justified and                                                      |
| or                      | zero-filled). The second form of the command performs essentially                                                                                                                       |
| addr <u>+</u> Dcont.†   | the same function but is used when it is necessary to change successive memory locations.                                                                                               |
| Eaddr,cont.             | Changes the contents of extended memory location addr (maximum of seven digits) to cont (maximum of 20 digits). The second form of                                                      |
| or                      | the command performs essentially the same function but is used when                                                                                                                     |
| Eaddr <u>+</u> cont •†  | it is necessary to change successive extended memory locations.                                                                                                                         |
| Eaddr,b,cont.           | Changes the contents of byte b at extended memory location addr (maximum of seven digits) to cont. Each location consists of five                                                       |
| or                      | 12-bit bytes, numbered 0 through 4 from left to right. The contents                                                                                                                     |
| Eaddr <u>+</u> b,cont.† | are four octal characters. The second form of the command performs<br>essentially the same function but is used when it is necessary to<br>change successive extended memory locations. |
| Eaddr,Dcont.            | Changes the contents of extended memory location addr (maximum of                                                                                                                       |
| or                      | seven digits) to display code characters cont (left-justified and zero-filled). The second form of the command performs essentially                                                     |
| Eaddr+Dcont.†           | the same function but is used when it is necessary to change successive extended memory locations.                                                                                      |

<sup>&</sup>lt;sup>†</sup>If the + sign is specified, the address is incremented by one location (addr+1) after the initial entry is processed; the - sign causes the address to be decremented by one location (addr-1). This allows immediate entry for the next (or previous) memory location. If the message REPEAT ENTRY is displayed above the entry, the cont field is not cleared and can be entered in successive memory locations as many times as desired.

# CHANNEL CONTROL COMMANDS

The following commands enable control activity on a specified data channel in circumstances where abnormal hardware and/or system operation is detected. Extreme caution must be exercised if any of these commands are entered during normal system operation. In addition, the console keyboard must be unlocked before entry of any of these commands is permitted (refer to the UNLOCK command earlier in this section). DSD does not reserve the channel specified in any of the channel control commands. The channels are numbered 0 to 13g in a 10 PP system and 0 to 13g, 20g to 33g in a 20 PP system.

Extreme caution must be exercised when using the following channel control commands.

| Command      | Description                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACN,cc.      | Activates channel cc. This command alerts and prepares peripheral equipment on channel cc for the exchange of data.                                                               |
| DCH,cc.      | Drops channel cc. This is a software function to release the current reservation of channel cc.                                                                                   |
| DCN,cc.      | Deactivates channel cc. As a result, peripheral equipment on channel cc stops and any current $I/O$ operation is terminated.                                                      |
| FCN,cc,func. | Outputs a function code func to channel cc. This releases all<br>equipment selections on that channel. If func is not specified, a<br>zero function code (no activity) is output. |
| IAN,cc.      | Inputs data to the pseudo A register from channel cc.                                                                                                                             |
| LDC,nnnn.    | Loads the pseudo A register with nnnn (normally a peripheral equipment function code). The current value of nnnn is shown in the channel staus display (W,C).                     |
| MCH,cc.      | Master clears and removes all 3000 Computer Systems peripheral equipment selections on channel cc (6681 function code $1700_8$ is issued).                                        |
| OAN,cc.      | Outputs the contents of the psuedo A register to channel cc.                                                                                                                      |

# **EXTENDED MEMORY FLAG REGISTER COMMANDS**

The extended memory flag register commands are used to set or clear specific bits in the extended memory flag register. These commands are typically used when debugging a problem in a multimainframe environment. The console must be unlocked (refer to the UNLOCK command earlier in this section).

# NOTE

Extreme caution must be exercised when using these commands.

| Command | Description                                                              |  |
|---------|--------------------------------------------------------------------------|--|
| CFR,bb. | Clears the extended memory flag register bit bb (0 $\leq$ bb $\leq$ 17). |  |
| SFR,bb. | Sets the extended memory flag register bit bb (0 $\leq$ bb $\leq$ 17).   |  |

The deadstart dump interpreter (DSDI) is a utility program that converts selected portions of the binary information on an express deadstart dump (EDD) file into reports to be listed. The EDD file is generated on magnetic tape by the EDD utility, which may be run at deadstart time after a system malfunction has occurred. Refer to the CIP User's Handbook for complete information concerning the use of EDD.

Selection of data to be listed by DSDI is provided through input directives, either on an input file or on the DSDI command. Normal octal dumps of central memory, extended memory, and PP memory can be produced by these directives as well as specially formatted dumps of specific system tables and buffers.

EDD and DSDI offer these features:

- The EDD tape file contains a dump of memory, the executing exchange packages, the CYBER 170 status and control (S/C) registers, where applicable; maintenance registers for models 865 and 875 and CYBER 180-class machines, register file, exchange package, processor control store, where applicable; and all PPs except for PPO, which can be saved by either copying it to another PP or by biasing the PP switch on the deadstart panel. EDD can optionally dump all or part of extended memory and the selected buffer controllers. This permits analysis of a system malfunction to be performed entirely offline.
- Because DSDI copies the EDD file to a word-addressable random file on mass storage, dump data can be accessed in any order.
- EDD requires only a small amount of time during deadstart because the data is transferred in binary form to magnetic tape.
- The tape file created by EDD can be retained on magnetic tape or mass storage until it is no longer needed. Thus, a selective listing can be generated at any time.
- General information from the EDD file appears in the title and subtitle line of each page of listed output. The first 50 columns of each input directive are included in the title line of the output list it produces. An input directive is provided that enables insertion of comments into the subtitle line.
- Use of DSDI is possible from an interactive terminal as well as from the batch environment. The output produced by several directives is formatted for terminal output (72 columns). From a batch environment, output is formatted for a 136-column printer.

DSDI can also be used to create a message file containing the contents of the maintenance registers (input/output unit, memory, and processor) that were dumped to the EDD file for CYBER 180-class machines. This message file, which is similar in format to the binary maintenance log (BML), can then be analyzed by an interpreter progam, such as the Hardware Performance Analyzer (HPA), to produce maintenance register reports. Refer to the IOUMR, MEMMR, and PROMR DSDI input directives later in this section for additional information.

DSDI writes up to three messages to this message file: one message each for input/output unit errors, memory errors, and processor errors. If the status summary register for a particular element is zero (signifying no errors for that element), DSDI does not write the corresponding message to the message file.

# CALLING THE EXPRESS DEADSTART DUMP INTERPRETER

Processing of the EDD file is initiated with the DSDI command. The format of the command is:

DSDI, $p_1, p_2, \dots, p_n$ .

Each parameter  $\textbf{p}_{1}$  is either a keyword or a keyword equated to a value. All parameters are optional and order independent.

| <sup>p</sup> i | Description                                                                                                                                                                                                                                                                                                                                                                 |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| B=bmlfile      | The 1- to 7-character name of the message file on which the<br>maintenance register messages are to be written. This parameter is<br>valid only if maintenance registers have been dumped to the EDD file.                                                                                                                                                                  |  |
| B omitted      | No message file is to be created.                                                                                                                                                                                                                                                                                                                                           |  |
| D              | This parameter creates a random dump file with the same name as the<br>EDD file and returns the original EDD file. The created file can<br>then be used as the dump file on subsequent executions of DSDI,<br>eliminating the need to read the entire dump tape on each call.                                                                                               |  |
| D omitted      | No random dump file is to be created.                                                                                                                                                                                                                                                                                                                                       |  |
| DMB            | A binary dump file produced by the DMB or LOADBC command is to be analyzed instead of an EDD file.                                                                                                                                                                                                                                                                          |  |
| DMB omitted    | EDD file is to be analyzed.                                                                                                                                                                                                                                                                                                                                                 |  |
|                | When the DMB parameter is specified for a DMB-created dump, DSDI<br>uses directives as though the job were running at control point 1.<br>The DMB command dumps the exchange package, central memory, and<br>extended memory in binary (refer to the NOS 2 Reference Set, Volume<br>3). Use the following directives to dump selected portions of<br>memory to be analyzed. |  |
|                | Directive Description                                                                                                                                                                                                                                                                                                                                                       |  |
|                | CP,1 Dump exchange package.                                                                                                                                                                                                                                                                                                                                                 |  |

|                | RA,O/EC/C,fwa,lwa Dump extended memory in C format.                                                                                                                                                                                                                                                                                                                         |  |
|                | RA,O/EC/D,fwa,lwa Dump extended memory in D format.                                                                                                                                                                                                                                                                                                                         |  |
|                | fwa and lwa are the first and last word addresses of memory to be<br>dumped. When this parameter is specified to analyze a LOADBC<br>controlware dump, the only DSDL directive that each he wood is:                                                                                                                                                                        |  |

controlware dump, the only DSDI directive that can be used is:

BCDUMP/ops.

Refer to the BCDUMP directive described later in this section for a description of the ops parameter.

| <sup>p</sup> i | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

| F=dumpfile     | The 1- to 7-character name of the EDD file that DSDI will interpret.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |
| F omitted      | Same as F=DUMP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| I=infile       | The 1- to 7-character name of file on which input directives are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| I omitted      | Same as I=INPUT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| L=outfile      | The 1- to 7-character name of file on which list output is to be written. The user must save or print the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| L omitted      | Same as L=OUTPUT, except that the file is automatically printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| NR             | EDD file is not to be rewound.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| NR omitted     | EDD file is to be rewound before processing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |
| P              | CMR pointers from the running system are to be used. Selecting this parameter causes the CMR pointers from the running system to be used to locate tables and buffer areas on the EDD file. This parameter is typically used when it is known that the CMR pointers on the EDD file were destroyed by system malfunction (for example, a CPUMTR error exit leaves an exchange package in memory locations 0 through $20_8$ ). Directives used to dump CMR will dump the pointers contained on the EDD file, not those from the running system. This parameter should be used only when the configuration of the running system is the same as the system in use when the EDD file was created. |  |
| P omitted      | CMR pointers from EDD file are to be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
| PD=n           | Print density in number of lpi (3, 4, 6, or 8).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| PD             | Same as PD=8.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| PD omitted     | Same as the job's default print density.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
| Z              | Input directives are contained on the command after the terminator.<br>The I parameter is ignored. This eliminates the need to use a<br>separate input file for the directives when only a few directives<br>are needed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |

# Description

P<sub>i</sub> Z omitted

Input directives are not contained on the command. The system uses the I parameter.

When input directives appear on the DSDI command, the first character following the command terminator is the separator character for all directives on the command. Any display code character that is not used in any of the directives, including a space, can be used as the separator character. Each directive must be preceded by a separator and terminated by a period. The directives can extend to column 72 on the command. Continuation lines are not permitted.

For example, (slant used for separator):

DSDI,Z./SC./XP./P./D,0,20000./EC./D,0,10000.

If the directives are included in the input file, the following equivalent job would appear.

| :          |                                                     |
|------------|-----------------------------------------------------|
| DSDI.      |                                                     |
| EOR        |                                                     |
| SC.        | Dump CYBER 170 S/C register.                        |
| XP.        | Dump executing exchange packages.                   |
| Ρ.         | Dump all PPs.                                       |
| D,0,20000. | Dump the first 200008 locations of central memory.  |
| EC.        | Set memory type to extended memory.                 |
| D,0,10000. | Dump the first 100008 locations of extended memory. |
| E0I        |                                                     |

A request for the EDD tape must precede the DSDI command. Since EDD writes information on an unlabeled, 7- or 9-track tape at a density of 800 characters per inch (cpi) for 7 track and 1600 cpi for 9 track, the request should appear as follows:

LABEL, DUMP, D=density, tape, F=S, LB=KU, VSN=DUMP.

| Parameter | Description                                             |
|-----------|---------------------------------------------------------|
| density   | 800 cpi for 7-track tape.<br>1600 cpi for 9-track tape. |
| tape      | MT for 7-track tape.<br>NT for 9-track tape.            |

It is recommended that the vsn parameter be specified in the request. If this is done, the request is presented in the resource mounting preview display and the job is rolled out until the tape is mounted and assigned. Although the default express dump file name (DUMP) is used in this example, a different file name can be specified, provided the same file name is also specified on the DSDI command (F parameter).

# INPUT DIRECTIVES

DSDI input directives provide the capability to selectively dump only those portions of the EDD file that are of interest. The input directives are grouped into the following categories.

• List Control Directives

Enable you to control line printer page eject and print density, and to specify comments in subtitle line of the output listing.

• File Manipulation and Control Directives

Enable you to specify alternate files for DSDI input directives and listing output.

• Central Memory/Extended Memory Dump Directives

Provide octal dumps of specified portion of central memory or extended memory. Absolute or relative addresses can be printed (three print formats are available). Two additional dump formats are available to print 64-bit memory in hexadecimal for CYBER 180-class machines.

• PP Dump Directives

Provide octal memory dumps of all or selected PPs (two print formats are available). PP analysis data can be included in the dumps. Six additional formats are available to print 16-bit PP memory for CYBER 180-class machies.

• CMR Dump Directives

Provide specially formatted dumps of selected areas in central memory resident. These areas are specified by name rather than by address.

• Subsystem Dump/Analysis Directives

Provide specially formatted dumps of subsystem control points and associated tables and buffers.

• Hardware Register Dump Directives

Provide dumps of specified hardware registers.

Several of the DSDI input directives have interactive capabilities. The output produced by these directives is specially formatted for listing at an interactive terminal. Refer to Interactive Use of DSDI later in this section for information concerning directive entry and use of DSDI from an interactive terminal.

Refer to Printer Output Listing Examples, later in this section, for examples of listings produced by several of the DSDI input directives.

# DIRECTIVE FORMAT

A directive has the following format.

directive,p1,p2,...,pn.comments

| Field     | Description                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| directive | The directive name starts in column 1. It is terminated by a separator or terminator character.                                                                                                                                                                                         |
| Pi        | Parameter(s) for the directive. Depending on the requirements of<br>the directive, the directive may have no parameters or a number of<br>parameters.                                                                                                                                   |
| comment   | Any characters following the directive terminator are considered<br>comments and are ignored by DSDI. However, the comments are<br>included with the directive in the title line of each page of the<br>output listing (a combined total of 50 characters appear in the<br>title line). |
| separator | You can use any character, includng a space, to separate the fields<br>of a directive. The exceptions are:<br>A to Z<br>0 to 9<br>+<br>-<br>*                                                                                                                                           |

Refer to Interactive Use of DSDI later in this section for additional information concerning directive entry from an interactive terminal.

#### LIST CONTROL DIRECTIVES

The list control directives provide the capability to specify print density and page eject options, and to add comments in the subtitle line of each page listed.

# EJ — Force Page Eject

The EJ directive forces DSDI to issue a page eject function before listing the output produced by the next directive processed. The EJ directive can also force a page eject upon reaching a specified point on the page being printed. The page eject function is performed automatically unless disabled by the EJOFF directive.

Format:

EJ,nn.

Parameter

nn

Force page eject only if less than nn decimal lines remain on the current page. If nn is omitted, page eject is forced before listing the output from the next directive processed.

Description

#### EJOFF — Turn Off Auto Page Eject

The EJOFF directive disables auto page eject. Until this directive is processed, DSDI automatically issues a page eject function before listing the output produced by each new directive.

Format:

EJOFF.

### EJON — Turn On Auto Page Eject

The EJON directive enables auto page eject (default condition). DSDI automatically issues a page eject function before listing the output produced by each new directive processed. This directive has no effect unless auto page eject has been disabled by the EJOFF directive.

Format:

EJON.

#### PD — Reset Print Line Density

The PD directive resets the print line density to a value other than that specified on the DSDI command.

Format:

PD,n.

Parameter

n

New print line density in number of 1pi (3, 4, 6, or 8). If n is omitted or an incorrect value is specified, a diagnostic message is issued.

Description

#### \*. -- Comment in Subtitle Line

The \*. directive specifies a comment that appears in the subtitle line of each page listed.

Format:

\*.ccc...ccc

Parameter

Description

222...222

Comment; up to 36 characters are printed.

#### FILE MANIPULATION AND CONTROL DIRECTIVES

File manipulation and control directives provide the capability to specify alternate files for DSDI input directives and listing output.

#### **DISPOSE** — Dispose Alternate List File to Print Queue

The DISPOSE directive causes the alternate list file specified by the OUTPUT directive to be disposed to the print queue. DSDI listing output then resumes on the original output file. This directive has no effect unless output has previously been assigned to an alternate list file (refer to the OUTPUT directive, next). Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

#### Format:

| DISPOSE . | username. |
|-----------|-----------|
|-----------|-----------|

Parameter

username

User name under which the remote batch terminal to receive the listing is logged in. If username is omitted, the listing is printed at a central site line printer.

Description

# OUTPUT — Assign Output to Alternate List File

The OUTPUT directive temporarily assigns DSDI listing output to a file other than that specified on the DSDI command. When the alternate file is disposed to the print queue (refer to the DISPOSE directive, above), output resumes on the original output file. If the alternate file is not disposed, both the original and the alternate output files remain at the job control point as local files. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

OUTPUT, filename.

#### Parameter

#### Description

filename

Name of alternate list file (from 1 to 7 characters). Only one alternate output file may be active at a time; filename cannot be the same name as the normal output file. If filename is omitted, the system assumes file name ALTRNT.

# **READ** — Read Alternate Directives File

The READ directive causes DSDI to temporarily stop reading the current directives file and begin reading directives from the specified record on the named alternate file or from the current position if the record name is omitted. DSDI reads from the specified alternate directives file until an end-of-record is encountered (end-of-file or empty record if \* is specified) and then resumes with the next directive on the original input directives file.

#### Format:

| READ,filename,rec,*. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| filename             | Name of alternate directives file (local file).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |
| rec                  | Optional record name. If rec is specified, file filename is<br>searched for record rec from the current position to end-of-file or<br>an empty record. If rec is not found, DSDI issues an error<br>message. If rec is not specified, DSDI reads directives from the<br>current position to end-of-record. Records must be in text format<br>where the first word of the record is the record name, unless the<br>file is assigned to an interactive terminal; then, directives may be<br>entered directly. |  |
| *                    | Optional character specifying that DSDI is to read directives from all records until an end-of-file or an empty record is encountered.                                                                                                                                                                                                                                                                                                                                                                      |  |

#### **REWIND** — Rewind File

The REWIND directive repositions the specified file to beginning-of-information.

# Format:

REWIND, filename.

Parameter

Description

filename

Name of file to be rewound.

# **CENTRAL MEMORY/EXTENDED MEMORY DUMP DIRECTIVES**

The central memory/extended memory dump directives provide the capability to dump any portion of central memory or extended memory in instruction parcel, byte, or word format. There are 6-bit display code character equivalents included with each format. Either absolute or relative memory locations may be dumped. Refer to CMR Dump Directives later in this section for directives used to dump specific portions of NOS central memory resident (CMR).

#### **Dump Control Directives**

Dump control directives select the type of memory to be dumped (central memory or extended memory) and the addressing mode to be used (absolute or relative).

#### ALLMEM - Extend Central Memory Dumps

The ALLMEM directive enables central memory dumps to extend past the central memory boundary on machines with central memory extension.

Format:

ALLMEM.

### CM - Set Memory Type to Central Memory

The CM directive specifies that subsequent C, D, and E directives dump central memory locations. Unless the EC or UEC directive is specified, central memory locations are dumped by default.

Format:

CM.

#### EC - Set Memory Type to Extended Memory

The EC directive specifies that subsequent C, D, and E directives dump extended memory or unified extended memory (UEM) locations. Unless the EC or UEC directive is specified, central memory locations are dumped by default. The second format is for models 865 and 875 and CYBER 180-class machines.

Format:

| EC.       | Subsequent C, D, and E directives dump extended memory.                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| or        |                                                                                                                                                                                                                                                                                                                                          |
| EC,fwa.   | Subsequent C, D, and E directives dump UEM.                                                                                                                                                                                                                                                                                              |
| Parameter | Description                                                                                                                                                                                                                                                                                                                              |
| fwa       | First word address (fwa) divided by 1000g. fwa is added to the<br>fwa and last word address (lwa) parameters in subsequent C, D, and E<br>directives. If fwa is omitted, DSDI determines the beginning of<br>unified extended memory from the pointer in CMR and adds it to the<br>fwa and lwa parameters of the C, D, and E directives. |

This parameter is ignored on any machine other than models 865 and 875 and CYBER 180-class machines.

# RA - Reset Reference Address

The RA directive specifies that subsequent C, D, and E directives dump memory locations relative to a specified reference address. Unless the RA or RAC directive is entered, absolute memory locations are dumped by default.

Format:

RA,nnnnnn.

Parameter

Description

nnnnnn

Reference address; addresses specified on subsequent C, D, and E directives are relative to this address.

Clearing the reference address specified on the most recent RA or RAC directive reenables absolute addressing. This is done by entering the RA directive in this format:

RA,0.

#### RAC - Reset Reference Address to RA of Control Point

The RAC directive specifies that subsequent C, D, and E directives dump memory locations relative to the reference address of a specified control point. Unless the RA or RAC directive is entered, absolute memory locations are dumped by default.

Format:

RAC,nn.

## Parameter

#### Description

nn

Control point number; addresses specified on subsequent C, D, and E directives are relative to the reference address of this control point.

Refer to the description of the RA directive to reenable absolute addressing.

# UEC - Set Memory Type to User-Access Extended Memory

The UEC directive specifies that subsequent C, D, and E directives dump user-accessible extended memory locations. Unless the EC or UEC directive is specified, central memory locations are dumped by default.

Format:

UEC,fwa.

Parameter fwa

#### Description

First word address divided by 10008 for user-accessible extended memory. fwa is added to the fwa and lwa parameters in subsequent C, D, and E directives. If fwa is omitted, DSDI determines the beginning of user-accessible extended memory from the pointer in CMR and adds it to the fwa and lwa parameters of the C, D, and E directives.

#### **Memory Dump Directives**

Memory dump directives specify the area of memory to be dumped and determine the format of the output listing (refer to Printer Output Listing Examples later in this section for a sample output listing). The CM and EC or UEC directives determine the type of memory to be dumped (default is central memory). Absolute memory locations are dumped unless relative addressing has been enabled (refer to RA and RAC directives earlier in this section).

# C - Dump Memory in Instruction Parcel Format

The C directive causes the specified locations of central memory or extended memory to be dumped in four groups of five octal digits (three words per line) with 6-bit display code character equivalents. Repetitive data is suppressed.

Format:

C,fwa,lwa.

 Parameter
 Description

 fwa
 First word address to be dumped (mandatory).

 lwa
 Last word address, plus one location, to be dumped. If lwa is

omitted, fwa+l is assumed by default.

The output listing is read from top to bottom by column rather than across the page. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

#### D - Dump Memory in Byte Format

The D directive causes the specified locations of central memory or extended memory to be dumped in five groups of four octal digits (three words per line) with 6-bit display code character equivalents. Repetitive data is suppressed.

Format:

D,fwa,lwa.

Parameter

#### Description

fwa 1wa

Last word address, plus one location, to be dumped. If lwa is

First word address to be dumped (mandatory).

omitted, fwa+1 is assumed by default.

The output listing is read from top to bottom by column rather than across the page. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

#### E - Dump Memory in Word Format

The E directive causes the specified locations in central memory or extended memory to be dumped in word format (four words per line) with 6-bit display code character equivalents.

#### Format:

| E,fwa,lwa. |                                                                                              |           |
|------------|----------------------------------------------------------------------------------------------|-----------|
| Parameter  | Description                                                                                  |           |
| fwa        | First word address to be dumped (mandatory).                                                 |           |
| 1wa        | Last word address, plus one location, to be dumped.<br>omitted, fwa+1 is assumed by default. | If lwa is |

#### I - Dump 64-Bit Memory in Instruction Parcel Format

The I directive is valid on CYBER 180-class machines only. It prints the specified locations of central memory in four groups of four hexadecimal digits (three words per line) with 7-bit ASCII code character equivalents.

#### Format:

I,fba,lba,ei.

| Parameter | Description                                                                                                                                                   |  |  |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| fba       | First byte address (fba), hexadecimal, to be printed (mandatory).                                                                                             |  |  |
| 1ba       | Last byte address (lba), plus one location, to be printed. If lba<br>is omitted, fba+8 is assumed by default.                                                 |  |  |
| ei        | If ei is 1, fba and 1ba specify byte addresses relative to byte<br>the environment interface. If ei is omitted, fba and 1ba speci<br>absolute byte addresses. |  |  |

The output listing is read from top to bottom by column rather than across the page.

#### W - Dump 64-Bit Memory in Word Format

The W directive is valid on CYBER 180-class machines only. It prints the specified locations of 64-bit memory in hexadecimal (4 words of 16 digits per line) with 7-bit ASCII code character equivalents.

#### Format:

W,fba,lba,ei. <u>Parameter</u> <u>Description</u> fba First byte address, hexadecimal, to be printed (mandatory). lba Last byte address, plus one location, to be printed. If lba is omitted, fba+8 is assumed by default. ei If ei is 1, fba and lba specify byte addresses relative to byte 0 of the environment interface. If ei is omitted, fba and lba specify absolute byte addresses. 60459300 D

#### **PP DUMP DIRECTIVES**

PP dump directives provide the capability to obtain a memory dump of all or selected PPs. Two dump formats are available, block format and line format.

#### AP — Dump Analysis of PP and PP Memory in Octal Line Format

The AP directive causes PP memory to be dumped in line format with 6-bit display code character equivalents (same format as the Q directive). Repetitive lines are suppressed and zero bytes are represented by hyphens (----). An analysis of the PP is printed before the memory dump. Analysis data includes the associated PP communications area, resident entry point call addresses, and read-only variables in directive cells. Certain direct cell variables are verified and those in error are indicated.

#### NOTE

Correct operation of this directive requires that the PP communication area on the EDD file be intact.

#### Format:

AP,n1,n2,...,nm.

Parameter

ni

# Description

Number of PP to be dumped or a program name. If a program name is specified, all PPs executing that program are dumped. A warning message is issued if an incorrect number is specified or the program name is not found in any PP. If n<sub>i</sub> is omitted, all active PPs are dumped.

Refer to Printer Output Listing Examples for a sample of the printer output listing produced by this directive.

#### MPP — Move PP

The MPP directive causes the correct logical PP to be dumped if the logical position of PPOO has been changed prior to the full dump to tape. If the PPS-0/PPS-1 toggle switch has been toggled, the n parameter should not be specified. If PPOO has to be moved to another PP via a deadstart panel program, the n parameter should be specified.

Format:

MPP,n.

Parameter

#### Description

n

Number of PP to which PPOO was moved. n cannot equal O. If n is omitted, 10 is assumed (CYBER 170 and CYBER 70 Computer Systems with 20 PPs).

#### P — Dump PP Memory in Octal Block Format

The P directive causes PP memory to be dumped in block format, where each block represents 64 words of memory. The blocks are read by column (top to bottom), where each column contains eight 12-bit words in octal format numbered 0 through 7. There are eight columns in each block, numbered 0 through 7. Repetitive data is not suppressed and zero words are represented by hyphens (----). For models 865 and 875, bytes 77768 and 77778 contain the PP's R register.

Format:

P,n<sub>1</sub>,n<sub>2</sub>,...,n<sub>m</sub>.

Parameter

ni

Number of PP to be dumped. If omitted, all PPs are dumped.

Description

#### PF — Dump FLPP† Memory in Octal Block Format

The PF directive causes first-level peripheral processor (FLPP) memory to be dumped in block format, where each block represents 64 words of memory. The blocks are read by column (top to bottom), where each column contains eight 12-bit words in octal format numbered 0 through 7. There are eight columns in each block, numbered 0 through 7. Repetitive data is not suppressed and zero words are represented by hyphens (----).

Format:

PF,n1,n2,...,nm.

Parameter

ni

Number of FLPP to be dumped. If omitted, all FLPPs are dumped.

Description

#### PMS — Read PP Select Switches

The PMS directive causes the dump of the S/C register (maintenance register for models 865 and 875) to be read to determine the current value of the PP memory select switches and the correct logical PP to be dumped, if the logical position of PP00 has been changed prior to the full dump to tape. If the PP memory select switches have been changed, this directive should be specified with the binary value of the switches prior to the change. This directive is meaningful only on a CYBER 170 Computer System with the exception of models 815, 825, 835, 845, and 855.

Format:

PMS,n.

Parameter

Description

Previous select switch setting; 0 through 118. If n is the same value as that read from the S/C register, this directive is not meaningful.

<sup>†</sup> Hardware manuals define peripheral processors making up a peripheral processor subsystem as PPs, and the first-level peripheral processors as peripheral processing units (PPUs). In this manual, first-level peripheral processors are referred to as FLPPs. FLPPs are available only on model 176.

#### PO — Dump 16-Bit PP Memory in Octal Block Format

The PO directive is valid on CYBER 180-class machines only. It prints PP memory in block format, where each block represents 64 words of memory. DSDI represents each 16-bit word by six octal digits. Words whose upper 4 bits are zero are represented by four octal digits. Blocks are read by columns (top to bottom), where each column contains eight 16-bit words numbered 0 through 7. There are eight columns in each block, numbered 0 through 7. Repetitive data is not suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump.

Format:

| PO,n1,n2,,nm.  |                                                             |
|----------------|-------------------------------------------------------------|
| Parameter      | Description                                                 |
| n <sub>i</sub> | Number of PP to be dumped. If omitted, all PPs are printed. |

#### PX — Dump 16-Bit PP Memory in Hexadecimal Block Format

The PX directive is valid on CYBER 180-class machines only. It prints 16-bit memory in block format, where each block represents 256 words of memory. Each 16-bit word is represented by four hexadecimal digits. Blocks are read by columns (top to bottom), where each column contains sixteen 16-bit words in hexadecimal format numbered 0 through F. There are 16 columns in each block, numbered 0 through F. Repetitive data is not suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump.

Format:

PX, n1, n2, ..., nm.

Parameter

 $n_i$ 

Number of PP to be printed. If omitted, all PPs are printed.

Description

Q — Dump PP Memory in Octal Line Format

The Q directive causes PP memory to be dumped in line format with 6-bit display code character equivalents. Each line contains 16 bytes (PP words) printed in two sets of 8 bytes in octal format. Each set consists of an address, 8 bytes, and display code character equivalents. Repetitive lines are suppressed and zero bytes are represented by hyphens (----). Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

Q,n1,n2,...,nm.

Parameter

#### Description

Number of PP to be dumped. If omitted, all PPs are dumped.

ni

### QF — Dump FLPP † Memory in Octal Line Format

The QF directive causes FLPP memory to be dumped in line format with 6-bit display code character equivalents. Each line contains 16 bytes printed in two sets of 8 bytes in octal format. Each set consists of an address, 8 data bytes, and 6-bit display code character equivalents. Repetitive lines are suppressed and zero bytes are represented by hyphens (----).

Format:

QF,n1,n2,...,nm.

Parameter

ni

Description

Number of FLPP to be dumped. If omitted, all FLPPs are dumped.

#### QOA — Dump 16-Bit PP Memory in Octal/ASCII Line Format

The QOA directive is valid on CYBER 180-class machines only. It prints PP memory in line format with 7-bit ASCII code character representation. Each line contains 16 words printed in two sets of eight. Each set consists of an octal address, eight words (six digits per word if the upper 4 bits are nonzero, four digits otherwise), and 7-bit ASCII code character equivalents. Repetitive lines are suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

QOA, n1, n2, ..., nm.

Parameter

ni

Description

Number of PP to be printed. If omitted, all PPs are printed.

<sup>&</sup>lt;sup>†</sup>Hardware manuals define peripheral processors making up a peripheral processor subsystem as PPs, and the first-level peripheral processors as peripheral processing units (PPUs). In this manual, first-level peripheral processors are referred to as FLPPs. FLPPs are available only on model 176.

# QOD — Dump 16-Bit PP Memory in Octal/Display Line Format

The QOD directive is valid on CYBER 180-class machines only. It prints PP memory in line format with 6-bit display code character representation. Each line contains 16 words printed in two sets of eight. Each set consists of an octal address, eight words (six digits per word if the upper 4 bits are nonzero, four digits otherwise), and 6-bit display code character equivalents. Repetitive lines are suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

QOD, n1, n2, ..., nm.

Parameter

n;

Description

Number of PP to be printed. If omitted, all PPs are printed.

# QXA — Dump 16-Bit PP Memory in Hexadecimal/ASCII Line Format

The QXA directive is valid on CYBER 180-class machines only. It prints PP memory in line format with 7-bit ASCII code character representation. Each line contains 16 words printed in two sets of eight. Each set consists of a hexadecimal address, eight words (four hexadecimal digits per word), and 7-bit ASCII code character equivalents. Repetitive lines are suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

QXA,n1,n2,...,nm.

Parameter

ni

Number of PP to be printed. If omitted, all PPs are printed.

Description

# QXD — Dump 16-Bit PP Memory in Hexadecimal/Display Line Format

The QXD directive is valid on CYBER 180-class machines only. It prints PP memory in line format with 6-bit display code character representation. Each line contains 16 words printed in two sets of eight. Each set consists of a hexadecimal address, eight words (four hexadecimal digits per word), and 6-bit display code character equivalents. Repetitive lines are suppressed and zero words are represented by hyphens (----). The PP's R register is displayed preceding the first line of the dump. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

QXD, n1, n2,..., nm.

Parameter

Description

Number of PP to be printed. If omitted, all PPs are printed.

<sup>n</sup>i

# **CMR DUMP DIRECTIVES**

The CMR dump directives provide the capability to selectively dump specified areas of central memory resident. Refer to the NOS 2 Systems Programmer's Instant for detailed illustrations of central memory resident.

Successful use of the CMR dump directives is dependent upon the integrity of central memory resident at the time EDD was performed. Most important is the integrity of the CMR pointers on the EDD file. If these pointers are not intact, the dump produced by DSDI may prove meaningless. Thus, if it is suspected that the CMR pointers are not intact, specifying the P keyword on the DSDI command allows DSDI to use the CMR pointers from the running system. This option should be used only when the configuration of the running system is the same as the system in use at the time the EDD file was created. If the CMR pointers on the EDD file are not intact, the integrity of the other areas of central memory is also questionable. In this case, the output produced by the CMR dump directives may be unpredictable.

#### ACCOUNT — Dump Account Dayfile Buffer

The ACCOUNT directive causes the account dayfile pointers and buffer to be dumped in word format (four words per line) with 6-bit display code character equivalents. This format is the same format as that for the E memory dump directive. This directive also dumps the buffer in a line-by-line format, as on the DSD A display.

Format:

ACCOUNT .

# CBT — Dump Control Buffer Table

The CBT directive causes all control buffer table entries to be dumped unless ordinal numbers are specified, then only the specified control buffer table entries are dumped. The dump is formatted to reflect the appropriate parameter fields for each word. Control buffer table entries that are output to a printer are listed in two columns. The format is the same format as that for the MST directive. The control buffer table entries can also be output to a terminal, but only when ordinal numbers are specified. Control buffer table entries that are output to a terminal are listed in a single column format.

Format:

CBT, n1, n2, ..., nm.

Parameter

ni

Description

Ordinal number of the control buffer table entry to be dumped. If  $n_i$  is omitted, all control buffer table entries are dumped.

#### CCT — Dump Channel Control Table

The CCT directive causes all nonzero channel control table entries to be dumped unless ordinal numbers are specified, then only the specified channel control table entries are dumped. The dump is formatted to reflect the appropriate parameter fields for each word. Channel control table entries that are output to a printer are listed in two columns. The format is the same format as that for the MST directive. The channel control table entries can also be output to a terminal, but only when ordinal numbers are specified. Channel control table entries that are output to a terminal are listed in a single column format.

Format:

CCT,n1,n2,...,nm.

Parameter

n<sub>i</sub>

#### Description

Ordinal number of the channel control table entry to be dumped. If  $n_i$  is omitted, all nonzero channel control table entries are dumped.

# **CP** — Dump Active Control Point Areas

The CP directive causes all active control point areas, or a selected subset, to be dumped. List options provide the capability to dump only desired portions of the control point area and other control point related data. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

#### Format:

 $CP, n_1/ops_1, n_2/ops_2, \dots, n_m/ops_m$ .

| Parameter        | Description                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n <sub>i</sub>   | Control point number.                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                              |
| ops <sub>i</sub> | List options; a string of up to 10 characters indicating the portion<br>of the control point area, or control point related data, to be<br>dumped. If list options are specified, they apply only to the<br>control point number with which they are associated. Valid options<br>are: |                                                                                                                                                                                                                                                                                                                                                              |
|                  | opsi                                                                                                                                                                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                  |
|                  | x                                                                                                                                                                                                                                                                                      | Dumps the exchange package, parameter summary,<br>control point's entry in the executing job table,<br>and contents of the memory locations indicated by<br>the values in each exchange package register. These<br>register values are treated as relative addresses<br>within the field length; invalid addresses are<br>represented with contents of zero. |
|                  |                                                                                                                                                                                                                                                                                        | The current command and special entry point<br>parameters are not printed for the system control<br>point. Refer to Printer Output Listing Examples<br>later in this section for a sample of the printer<br>output listing produced.                                                                                                                         |
|                  | Т                                                                                                                                                                                                                                                                                      | Provides a detailed dump of the control point area<br>with a description of each parameter field and<br>NOSTEXT symbol for each word.                                                                                                                                                                                                                        |
|                  | AŤ                                                                                                                                                                                                                                                                                     | Dumps the job dayfile pointers and buffer in word<br>format with 6-bit display code character<br>equivalents. This format is the same format as the<br>E memory dump directive. This option also dumps the<br>buffer in a line-by-line format, as on the DSD A<br>display.                                                                                   |
|                  | Fţ                                                                                                                                                                                                                                                                                     | Provides a dump of the 3-word FNT entry, EST, and<br>mass storage track chain, if one exists, for all<br>files attached to the specified control point.                                                                                                                                                                                                      |
|                  | C†                                                                                                                                                                                                                                                                                     | Dumps the field length of a specified control point<br>in instruction parcel format with 6-bit display code<br>character equivalents. This format is the same<br>format as the C memory dump directive. Repetitive<br>data is suppressed.                                                                                                                    |

<sup>†</sup>This option does not dump information for the system control point.

| G                | Dumps the control point area in instruction parcel<br>format with 6-bit display code character<br>equivalents. This format is the same format as the<br>C memory dump directive.                                                                                                                      |  |
| H                | Dumps the control point area in byte format with<br>6-bit display code character equivalents. This<br>format is the same format as the D memory dump<br>directive.                                                                                                                                    |  |
| I                | Dumps the control point area in word format with<br>6-bit display code character equivalents. This<br>format is the same format as the E memory dump<br>directive.                                                                                                                                    |  |
| ለ†               | Dumps the user-accessible extended memory of a<br>specified control point in byte format with 6-bit<br>display code character equivalents. This format is<br>the same format as the D memory dump directive.                                                                                          |  |
| NŤ               | Dumps the negative field length of a specified control point. This format is the same format as the D memory dump directive.                                                                                                                                                                          |  |
| P                | Provides a dump and analysis of all active PPs associated with control point n.                                                                                                                                                                                                                       |  |
| default          | If n is specified with no corresponding list<br>options, options XTAF are selected automatically.<br>Refer to Printer Output Listing Examples later in<br>this section for a sample of the printer output<br>listing produced. The default options selected can<br>be changed with the CPO directive. |  |

All of the list options specified for a particular control point area (up to 10) are processed. For example, if the C and D options are both specified, the control point field length is dumped twice, once in instruction parcel (C) format and again in byte (D) format.

<sup>&</sup>lt;sup>†</sup>This option does not dump information for the system control point.

#### CPO — Reset Default List Options

The CPO directive selects a new string of default list options for the CP directive.

Format:

CPO,ops.

 Parameter
 Description

 ops
 New default list options for CP directive, a string of up to 10 characters. Refer to the description of the CP directive for a list of valid option characters.

#### CT — Dump Channel Tables

The CT directive causes the channel status table, EJT assignment table, and channel controlware table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

CT.

#### DAYFILE — Dump System Dayfile Buffer

The DAYFILE directive causes the system dayfile pointers and buffer to be dumped in word format (four words per line) with 6-bit display code character equivalents. This format is the same format as that for the E memory dump directive. This directive also dumps the buffer in a line-by-line format, as on the DSD A display.

Format:

DAYFILE.

#### **DB** — Dump Disk Buffers

DB,id,n1,n2,...,nm.

The DB directive causes all disk buffers, or a selected subset, to be dumped to a printer in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

| Parameter | Description                                                                                                                                                                                                        |  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| id        | Specifies the machine identifier of the mainframe from which to dump<br>the disk buffers. If id is omitted, the default machine identifier<br>is taken from CMR of the mainframe that is dumping the disk buffers. |  |
| ni        | Number assigned to a disk buffer to be dumped. If $n_1$ is omitted, all active disk buffers are dumped.                                                                                                            |  |

# DBW — Dump Buffered Device/Buffer Statistics/PP-I/O Buffer Link Tables

The DBW directive causes the list control words from the buffered device table, the buffer statistics table, and the PP-I/O buffer link table to be dumped. The dump is formatted to reflect the appropriate parameter fields for each word. Output to a printer is listed in two columns. Output to a terminal is listed in one column. The format is the same format as that for the MST directive.

Format:

DBW.

#### DDB — Dump Dayfile Dump Buffer

The DDB directive causes the dayfile dump buffer to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

DDB.

### **DP** — Dump Dayfile Buffer Pointers

The DP directive causes the dayfile buffer pointers to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

DP.

# EJT — Dump Executing Job Table

The EJT directive causes the executing job table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

EJT.

#### EPB — Dump Extended Memory/PP Buffer

The EPB directive causes the extended memory/PP buffer to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

EPB.

#### ERRLOG — Dump Error Log Buffer

The ERRLOG directive causes the error log pointers and buffer to be dumped in word format (four words per line) with 6-bit display code character equivalents. This format is the same format as that for the E memory dump directive. This directive also dumps the buffer in a line-by-line format, as on the DSD A display.

#### Format:

ERRLOG.

#### EST — Dump Equipment Status Table

The EST directive causes the equipment status table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

EST.

#### FNT — Dump System File Name/File Status Table

The FNT directive causes the system file name/file status table (FNT/FST) to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

FNT.

# FOT — Dump Family Ordinal Table

The FOT directive causes the family ordinal table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

FOT.

#### HAT — Dump Hash Table

The HAT directive causes all nonzero hash table entries to be dumped unless ordinal numbers are specified, in which case only the specified hash table entries are dumped. The dump is formatted to reflect the appropriate parameter fields for each word. Hash table entries that are output to a printer are listed in two columns. The format is the same format as that for the MST directive. The hash table entries can also be output to a terminal, but only when ordinal numbers are specified. Hash table entries that are output to a terminal are listed in a single-column format.

Format:

HAT, n1, n2, ..., nm.

Parameter

Description

ni

Ordinal number of the hash table entry to be dumped. If  $n_i$  is omitted, all nonzero hash table entries are dumped.

#### JC — Dump Job Control Area for Each Service Class

The JC directive causes the job control area for each job service class to be dumped. The dump is formatted to reflect the appropriate parameter fields and NOSTEXT symbol for each word. This directive also dumps the service class control table (SCT) in a line-by-line format.

Format:

JC.

#### LC — Dump Low Central Memory

The LC directive causes DSDI to dump the contents of low central memory (that is, central memory locations 0 through 1778). Each word is divided into the appropriate parameter fields. Each field is listed on a separate line with a description of the parameter. The absolute address and 6-bit display code character equivalents are also listed for each word.

Format:

LC.

#### LDIS — Dump L-Display Buffer

The LDIS directive causes the L-display buffer to be dumped in instruction parcel format with 6-bit display code character equivalents. This format is the same format as that for the C memory dump directive.

Format:

LDIS.

#### LIDT — Dump Logical Identifier Table

The LIDT directive causes the logical identifier table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

LIDT.

### MAINLOG — Dump Binary Maintenance Log Buffer

The MAINLOG directive dumps the binary maintenance log pointers and buffer in word format, four words per line, with 6-bit display code character equivalents.

Format:

MAINLOG.

#### MST — Dump Mass Storage/Track Reservation Tables

The MST directive causes all mass storage and track reservation tables to be dumped unless EST ordinals are specified, in which case only the specified MSTs are dumped. The dump format for the mass storage tables reflects the appropriate parameter fields and NOSTEXT symbol of each word. The portion of the dump describing the track reservation tables is presented in byte format with 6-bit display code character equivalents. The track link byte ordinal and status bits (three groups of 4 bits) are indicated for each word. Refer to Printer Output Listing Examples later in this section for a sample of the printer output listing produced by this directive.

Format:

MST,est, est, ..., est, .

Parameter

Description

est<sub>i</sub> EST ordinal of equipment whose mass storage table is to be dumped. If est<sub>i</sub> is omitted, all mass storage and track reservation tables are dumped.

#### MTR — Dump CPU Monitor

The MTR directive causes the CPU monitor to be dumped. Exchange packages are dumped in exchange package format while the program area is dumped, using relative addressing, in instruction parcel format with 6-bit display code character equivalents. This format is the same format as that for the C memory dump directive.

Format:

MTR.

# MTRQUEUE — Dump CPUMTR Request and Recall Queues

The MTRQUEUE directive causes all CPUMTR request and recall queues, or a selected subset, to be dumped.

#### Format:

MTRQUEUE, idents.

| Parameter |                                                                                                                                                                                                                                            | Description     |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| idents    | A string of up to four characters indicating the queues to be<br>dumped. The queue identifiers can be specified in any order and are<br>dumped in the order specified. Default is to dump all four queues.<br>Valid queue identifiers are: |                 |
|           | idents                                                                                                                                                                                                                                     | Queue Name      |
|           | С                                                                                                                                                                                                                                          | CPUCIO Request. |
|           | P                                                                                                                                                                                                                                          | PP Request.     |

**ODIS** — Dump Operator Display Buffer

R

W

# The ODIS directive causes the operator display buffer (used for communication between an operator and a remote diagnostic user) to be dumped in instruction parcel format with 6-bit

Recall.

CPU Request.

display code character equivalents. This format is the same format as that for the C memory dump directive.

Format:

ODIS.

# PLD — Dump Peripheral Library Directory

The PLD directive causes the PP library directory to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

PLD.

#### PP — Dump PP Communication Areas

The PP directive causes the contents of all PP communication areas to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive. The control point assignment, channel assignment, and monitor function are listed with each communication area. Refer to Printer Output Listing Examples later in this section for a sample of the printer output listing produced by this directive. Refer to Interactive Use of DSDI later in this section for additional information concerning use of this directive from an interactive terminal.

Format:

PP.

#### **PROBE** — Dump **PROBE** Data Tables

The PROBE directive causes the PROBE data tables to be dumped in byte format with 6-bit display code character equivalents.

Format:

PROBE .

## PST — Dump Program Status Table and Entry Point Directory

The PST directive causes the program status table and the entry point directory to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

PST.

#### PUT --- Dump Physical Unit Table

The PUT directive causes all nonzero physical unit table entries to be dumped unless ordinal numbers are specified, then only the specified physical unit table entries are dumped. The dump is formatted to reflect the appropriate parameter fields for each word. Physical unit table entries that are output to a printer are listed in two columns. The format is the same format as that for the MST directive. The physical unit table entries can also be output to a terminal, but only when ordinal numbers are specified. Physical unit table entries that are output to a terminal are listed in a single column format.

Format:

PUT,n1,n2,...,nm.

Parameter

#### Description

ni

Ordinal number of the physical unit table entry to be dumped. If  $n_i$  is omitted, all nonzero physical unit table entries are dumped.

### QFT — Dump Queued File Table

The QFT directive causes the queued file table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

QFT.

#### **RCL** — Dump Resident Central Library

The RCL directive causes the resident CPU library to be dumped in instruction parcel format with 6-bit display code character equivalents. This format is the same format as that for the C memory dump directive. A warning is printed if the resident central library is empty.

Format:

RCL.

#### RPL — Dump Resident Peripheral Library

The RPL directive causes the resident PP library to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive. A header line for each PP program dumped indicates the name of the program and its length in bytes. Each succeeding line contains 10 bytes (two central memory words) of the PP program. The PP address of the first byte in each line, relative to address zero of the PP, is also listed.

Format:

RPL.

### SDA — Dump Extended Statistical Data Area

The SDA directive causes the extended statistical data area to be dumped. Each word is divided into the appropriate parameter fields and is listed with a description of the parameter. The absolute address and 6-bit display code character equivalents are also listed for each word.

Format:

SDA.

## SECDED — Dump SECDED Identifier Table

The SECDED directive causes the single error correction double error detection (SECDED) identifier table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

SECDED.

#### SST — Dump Subsystem Control Point/Subsystem Assignment Tables

The SST directive causes the subsystem control point table and subsystem assignment table to be dumped in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

Format:

SST.

#### SUBSYSTEM DUMP/ANALYSIS DIRECTIVES

The subsystem dump/analysis directives provide the capability to selectively dump portions of central and/or PP memory associated with a specific subsystem (BIO, MAG, and IAF). Although many other directives already described in this section can be used to dump the same areas of memory, these directives dump those areas most frequently analyzed when subsystem-related malfunctions occur. In addition, many of the dumps are specially formatted to provide a detailed description of the area being dumped. If the specified subsystem was not active at the time the EDD file was created, an error message is issued.

## BATCHIO (BIO) — Dump Associated Memory for Analysis

The BATCHIO directive causes the areas of central and/or PP memory that are most frequently analyzed when BATCHIO malfunctions are indicated to be dumped. The areas and type of memory dumped are determined by the list options specified.

#### Formats:

BATCHIO, ops.

or

#### BIO,ops.

#### Parameter

ops

## Description

List options; a string of characters indicating the areas of memory to be dumped. If no options are specified, all three options (PBN) are selected by default and are processed in order as listed.

#### ops

#### Description

P Provides analysis and full memory dump of PPs having resident copies of ICD, IIO, QAP, QAC, or DSP. The output listing generated is the same (in format and content) as that produced by entering the AP directive in this format:

## AP,1CD,110,QAP,QAC, DSP.

Refer to the description of the AP directive earlier in this section for additional information.

- B Provides specially formatted dumps of each active BATCHIO buffer point. Included with the dump of each buffer point is the associated equipment type and FET, as well as EST and FNT/FST entries.
- N Provides a dump of the negative field length associated with the BATCHIO control point in byte format with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.

#### IAF — Dump Associated Memory for Analysis

The IAF directive causes the areas of central and/or PP memory that are most frequently analyzed when IAF malfunctions to be dumped. The areas and type of memory are determined by the list options specified. The IAF current entry word (SSPA) is always printed at the beginning of the listing, in byte format, regardless of which list options are specified.

#### Format:

IAF,ops.

Parameter

ops

#### Description

List options; a string of up to five characters indicating the areas of memory to be dumped. If no options are specified, four options (ETLP) are selected by default and processed in order as listed.

#### ops

Ρ

## C Provides analysis of the IAF command table.

E Dumps the IAF reentry table in byte format (two words per line) with 6-bit display code character equivalents. The first word in each line is preceded by its ordinal within the table.

Description

- T Provides a specially formatted dump of the IAF terminal table in which each word reflects the appropriate parameter fields. The message status table entry is included when dumping network terminal tables. In addition, each word is preceded by a description of the parameter fields and its COMSREM symbol. Terminal table entries that are empty, except for having status bit 0 in word 3 (VROT entry) set, are not printed.
- L Provides a dump of pot link table and all pots. The pot link table is dumped in byte format with pot link byte ordinals indicated for each word, but no 6-bit display code character equivalents. Repetitive pot link table entries are suppressed. The pots are dumped in word format, three lines per pot, with the first line containing only the pot number.
  - Provides analysis and full memory dump of all PPs having resident copies of TLX, ITA, ITN, and ITO. This option also provides an analysis and dump of all PPs having resident copies of 1RO and 1RI that are associated with control points of interactive origin. The output listing generated is the same (in format and content) as that produced by entering the AP directive in this format:

AP,TLX,1TA,1TN,1TO,1RO,1RI.

The exception is that the AP directive also dumps all PPs having copies of 1R0 and 1RI rather than only those associated with control points of interactive origin. Refer to the description of the AP directive, earlier in this section, for additional information.

#### MAGNET (MAG) — Dump Associated Memory for Analysis

The MAGNET directive causes the areas of central and/or PP memory that are most frequently analyzed when a malfunction within the Magnetic Tape Subsystem is indicated to be dumped. The areas and type of memory dumped are determined by the list options specified.

Format:

MAGNET, ops.

or

MAG, ops.

Parameter

ops

Description

List options; a string of characters indicating the areas of memory to be dumped. If no options are specified, all three options (UQP) are selected by default and are processed in order as listed.

## ops U

Q

Ρ

#### Description

- Provides a specially formatted dump of the Magnetic Tape Subsystem unit descriptor tables with associated FET, EST, and FNT/FST. Each word of a unit descriptor table is formatted to reflect appropriate parameter fields. In addition, each word is preceded by a description of the parameter fields and its COMSMTX symbol. If extended labels are present, they appear with the FET in the output listing. The FET also indicates the address and control point number of the user.
- Provides a dump of the Magnetic Tape Subsystem queue table in byte format (two words per line) with 6-bit display code character equivalents. The first word in each line is preceded by its ordinal within the table.
- Provides analysis and full memory dump of all PPs having resident copies of IMT. The output listing generated is the same (in format and content) as that produced by entering the AP directive in this format:

#### AP,1MT.

Refer to the description of the AP directive earlier in section for additional information.

## **RHF** — Dump Associated Memory for Analysis

The RHF directive causes the areas of central and/or PP memory that are most frequently analyzed when RHF malfunctions are indicated to be dumped. The areas and type of memory dumped are determined by the list options specified.

Format:

| RHF,ops.  |                                                                                                                                                                                                            |                                                                                                                                                                                                                                     |  |  |  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| Parameter |                                                                                                                                                                                                            | Description                                                                                                                                                                                                                         |  |  |  |
| ops       | List options; a string of characters indicating the areas of memory<br>to be dumped. If no options are specified, all three options (ACP)<br>are selected by default and are processed in order as listed. |                                                                                                                                                                                                                                     |  |  |  |
|           | ops                                                                                                                                                                                                        | Description                                                                                                                                                                                                                         |  |  |  |
|           | Α                                                                                                                                                                                                          | Provides a dump of the RHF dayfile buffer in word format<br>with 6-bit display code character equivalents. This<br>format is the same format as that for the E memory dump<br>directive. This option also dumps a standard dayfile. |  |  |  |
|           | C                                                                                                                                                                                                          | Provides a dump of the RHF field length in byte format                                                                                                                                                                              |  |  |  |

- with 6-bit display code character equivalents. This format is the same format as that for the D memory dump directive.
- P Provides analysis and full memory dump of all active PPs associated with the control point.

## HARDWARE REGISTER DUMP DIRECTIVES

The hardware register dump directives provide the capability to dump specified hardware registers.

#### FMFREG — Dump PP Registers

The FMFREG directive is valid on CYBER 180-class machines only. For each PP register (P, Q, K, A) stored while processing a fatal mainframe error, DSDI prints the PP register contents.

Format:

FMFREG.

#### IOUMR — Dump IOU Maintenance Registers

The IOUMR directive is valid on CYBER 180-class machines only. For each input/output unit (IOU) maintenance register specified, DSDI prints the hexadecimal register number, the register contents, and the register description. For registers containing error indicators, DSDI prints a description of each error.

Format:

| Parameter | Description                                                                                    |
|-----------|------------------------------------------------------------------------------------------------|
| first     | First register (hexadecimal) to be printed. If omitted, printing begins with register 00.      |
| last      | Last register +1 (hexadecimal) to be printed. If omitted, printing ends with register first+1. |

If no parameters are specified, DSDI prints all maintenance registers.

#### **MEMMR** — Dump Memory Maintenance Registers

The MEMMR directive is valid on CYBER 180-class machines only. For each memory maintenance register specified, DSDI prints the hexadecimal register number, the register contents, and the register description. For registers containing error indicators, DSDI prints a description of each error.

Format:

MEMMR, first, last.

IOUMR, first, last.

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| first     | First register (hexadecimal) to be printed. If omitted, printing begins with register 00.     |
| last      | Last register+1 (hexadecimal) to be printed. If omitted, printing ends with register first+1. |

If no parameters are specified, DSDI prints all maintenance registers.

#### PROCW — Dump Processor Controlware Part Number and Revision Level

The PROCW directive is valid on CYBER 180-class machines only. It prints the processor controlware part number and the revision level.

Format:

PROCW.

#### **PROMR** — Dump Processor Maintenance Registers

The PROMR directive is valid on CYBER 180-class machines only. For each processor maintenance register specified, DSDI prints the hexadecimal register number, the register contents, and the register description. For registers containing error indicators, descriptions of each error are printed.

#### Format:

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| first     | First register (hexadecimal) to be printed. If omitted, printing begins with register 00.     |
| last      | Last register+1 (hexadecimal) to be printed. If omitted, printing ends with register first+1. |

If no parameters are specified, all maintenance registers for both processors are printed. If first and last are specified, then the specified registers are dumped for all processors.

#### **PRORF** — Dump Processor Register File

The PRORF directive is valid on CYBER 180-class machines only. It prints the maintenance channel interface port number followed by the hexadecimal register number and contents of each processor register specified.

#### Format:

PRORF, first, last.

PROMR, first, last.

| Parameter | Description                                                                     |  |  |  |  |  |  |
|-----------|---------------------------------------------------------------------------------|--|--|--|--|--|--|
| first     | First register to be printed. If omitted, printing begins with register 00.     |  |  |  |  |  |  |
| last      | Last register+1 to be printed. If omitted, printing ends with register first+1. |  |  |  |  |  |  |

If no parameters are specified, the entire register file for both processors is printed. If first and last are specified, then the specified registers are dumped for all processors.

## PROXP — Dump Processor Exchange Package

The PROXP directive is valid on CYBER 180-class machines only. It prints the maintenance channel interface port number followed by the hexadecimal register number, the contents of each processor register, and (for most registers) a description of the register's contents. The exchange packages for all processors are printed.

Format:

PROXP.

## SC — Dump S/C Register

The SC directive is valid only on CYBER 170 Computer Systems with the exception of models 815, 825, 835, 845, and 855; it causes the S/C registers (maintenance registers for models 865 and 875) to be dumped.

Format:

SC.

#### XP — Dump Deadstart Exchange Package

The XP directive causes the CPU exchange package executing at the time of deadstart to be dumped. If there are two CPUs in the system, both exchange packages in execution at the time of deadstart are dumped.

Format:

XP.

#### **BUFFER CONTROLLER DIRECTIVE**

The buffer controller directive provides the capability to dump specified buffer controllers and list verification information for controlware dump files produced by the LOADBC utility. The BCDUMP directive causes the selected buffer controllers to be dumped.

Format:

BCDUMP/ops.

or

BCDUMP,  $cc_1, cc_2, \dots, cc_n$ .

or

BCDUMP,  $cc_1/ops_1, cc_2/ops_2, \dots, cc_n/ops_n$ .

### Parameter

## Description

 $cc_i$ 

Channel number of buffer controller to be dumped. If no channels are specified, all buffer controllers are dumped.

opsi

List options; a character string indicating the line format, interpretation, and verification of the selected buffer controllers to be dumped. If no options are specified, options H and D are selected by default.

| opsi  | Line Format                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------|
| Н     | Hexadecimal line format (default).                                                                  |
| 0     | Octal line format.                                                                                  |
| ops i | Interpretation                                                                                      |
| A     | 7-bit ASCII code interpretation.                                                                    |
| D     | 6-bit display code interpretation (default).                                                        |
| ops i | Verification                                                                                        |
| V     | List verification information (used with the controlware dump file produced by the LOADBC utility). |

V omitted Do not list verification information.

## INTERACTIVE USE OF DSDI

,

Incorporated within DSDI is an interactive facility that allows several of the directives already described in this section to be entered interactively from a terminal. This interactive facility is designed to provide the following additional capabilities.

- Allows preliminary examination of the EDD file to determine which areas should be listed in detail at a line printer.
- Allows examination of certain areas of the EDD file not listed during normal operational procedures following a system malfunction. Typically, predefined portions of the EDD file are listed following a system malfunction.
- Allows online examination of the EDD file from a remote location.

Refer to Example of DSDI Terminal Use later in this section for an example showing interactive use of DSDI.

When the DSDI command is entered from an interactive terminal, there will be a 10- to 60-second delay before input directives can be entered. During this delay, DSDI is copying the EDD file to a random-access mass storage file. The length of the delay depends on device speed and current system activity. When DSDI is able to accept input directives, it will issue the following prompt to the terminal.

ENTER DIRECTIVES- - ?

Directives are entered following the question mark prompt. Only one directive can be entered at a time, and each directive is restricted to one line. The format is the same as described for batch input (refer to Directive Format earlier in this section).

Generally, any of the DSDI input directives can be entered at an interactive terminal. However, the output produced by many of the directives is formatted for listing only at a line printer (136 columns) and cannot be listed at the terminal (72 columns). The L parameter on the DSDI command initially determines the disposition of the list output. If a file name is not specified, list output is assigned to file OUTPUT by default (that is, the terminal). In this case, entry of directives that produce output that cannot be listed at the terminal results in the message:

DIRECTIVE RESTRICTED TO PRINTER OUTPUT.

If a list output file name is specified on the DSDI command, all input directives can be entered at the terminal. All list output (including error messages) is written to the specified file. These two input directives are provided to further control the disposition of list output:

#### Directive

#### Description

- OUTPUT, filename. Assigns output to alternate file filename (file name OUTPUT is not allowed; that is, alternate list output cannot be assigned to the terminal). If filename is omitted, the system assumes file name ALTRNT. While this directive is active, all input directives can be entered at the terminal. All list output (except error messages) is written to file filename and is formatted for transmission to a line printer. Error messages are written directly to the terminal.
- DISPOSE. Disposes the alternate list file (specified in the OUTPUT directive) to the print queue. Output will be printed at the central site line printer. All subsequent list output resumes on the original output file specified on the DSDI command.

Refer to File Manipulation and Control Directives earlier in this section for additional information concerning use of these directives.

#### **TERMINAL OUTPUT DIRECTIVES**

The following directives produce output formatted for listing at an interactive terminal.

#### C — Dump Memory in Instruction Parcel Format

The C directive causes the specified locations of central memory or extended memory to be dumped in four groups of five octal digits (one word per line) with 6-bit display code character equivalents. No pagination is processed for terminal output. The CM, EC, and UEC directives (refer to Central Memory/Extended Memory Dump Directives earlier in this section) determine the type of memory to be dumped; default is central memory. The RA or RAC directive (refer to Central Memory/Extended Memory Dump Directives earlier in this section) must be entered to dump relative addresses; default is absolute addressing.

Format:

C,fwa,lwa.

#### Parameter

#### Description

fwa

First word address to be dumped (mandatory).

lwa

Last word address, plus one location, to be dumped. If omitted, fwa+l is assumed by default.

Example of terminal output:

? C,6230,6240. 0006230 34240 10100 00012 50036 1TAA. AU 3 0006231 00764 70000 00000 10113 \* AAK 0006232 04154 70000 00000 10113 DM\* AAK 0006233 00004 67446 74000 10005 - - A E 0006234 05153 05700 00000 00000 EMX. 0006235 00000 00000 00000 00000 0006236 00000 00000 00000 00000 0006237 00000 00005 05111 14422 EEII9R

#### **CP** — Dump Active Control Point Areas

The CP directive causes the job sequence name and control point area address for each control point to be dumped.

Format:

CP.

Example of terminal output:

| CP 01<br>IAF<br>0200  | CP 02<br>AALT<br>0400 | CP 03<br>NAM<br>0600  | CP 04<br>1000         | CP 05<br>AAKW<br>1200            | CP 06<br>AAAG<br>1400 | CP 07<br>AAAF<br>1600 | CP 10<br>AAAE<br>2000 |
|-----------------------|-----------------------|-----------------------|-----------------------|----------------------------------|-----------------------|-----------------------|-----------------------|
| CP 11<br>AAAD<br>2200 | CP 12<br>AAAC<br>2400 | CP 13<br>AAAB<br>2600 | CP 14<br>AALN<br>3000 | CP 15<br>3200                    | CP 16<br>AALU<br>3400 | CP 17<br>3600         | CP 20<br>4000         |
| CP 21<br>4200         | CP 22<br>4400         | CP 23<br>4600         | CP 24                 | CP 25<br>5200                    | CP 26<br>5400         | CP 27<br>5600         | CP 30<br>RBF<br>6000  |

#### D — Dump Memory in Byte Format

The D directive causes specified locations of central memory or extended memory to be dumped in five groups of four octal digits (one word per line) with 6-bit display code character equivalents. No pagination is processed for terminal output. The CM, EC, and UEC directives (refer to Central Memory/Extended Memory Dump Directives earlier in this section) determine the type of memory to be dumped; default is central memory. The RA or RAC directive (refer to Central Memory/Extended Memory Dump Directives earlier in this section) must be entered to dump relative addresses; default is absolute addressing.

Format:

D,fwa,1wa.

| -   |    |     |   |
|-----|----|-----|---|
| Par | ລຫ | ete | r |

## Description

fwa

First word address to be dumped (mandatory).

lwa Last word address, plus one location, to be dumped. If omitted, fwa+l is assumed by default.

Example of terminal output:

? D,6230,6240. 0006230 3424 0101 0000 0125 0036 1TAA AU 3 0006231 0076 4700 0000 0001 0113 \* AAK 0006232 0415 4700 0000 0001 0113 DM\* AAK 0006233 0000 4674 4674 0001 0005 \_ \_ ΑE 0006234 0515 3057 0000 0000 0000 EMX. 0006235 0000 0000 0000 0000 0000 0006236 0000 0000 0000 0000 0000 0006237 0000 0000 0505 1111 4422 EEII9R

## PP — Dump PP Communication Areas

The PP directive causes the PP number, executing program name, control point assignment, and input register address for each PP communication area to be dumped.

Format:

PP.

Example of terminal output:

**PP** Number Program in Execution Control Point Assignment PP 04 PP06 PP00 PP 01 PP02 PP03 PP'05 🖌 PP07 PP10 PP11 MTR-34 DSD-34 QAC-16 1R0-05 1SJ-34 1MT-31 QAC-14 7310 7200 7210 7220 7230 7240 7250 7260 7270 7300 PP20 PP 21 PP22 **PP23 PP24** PP 25 **PP26 PP27** PP 30 PP 31 PIP-03 CPD-34 QAC-02 -----110-32 1MA-01 ----7340 7350 7400 7410 7430 7320 7330 7360 7370 7420 PP00 Input Register Address 7440

## Q — Dump PP Memory in Line Format

The Q directive causes the specified locations of PP memory to be dumped in line format. Each line contains 8 bytes (PP words) with 6-bit display code character equivalents. Repetitive lines are suppressed and zero bytes are represented by hyphens (----).

Format:

Q,n,fwa,lwa.

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| n         | Number of PP to be dumped.                          |
| fwa       | First word address to be dumped.                    |
| lwa       | Last word address, plus one location, to be dumped. |

## NOTE

fwa and lwa are automatically adjusted so that the dump limits fall within a multiple of 10g words.

This format is valid only for terminal output. If attempted from a job of batch origin or while an alternate list file is active, the fwa and lwa parameters will be interpreted as PP numbers.

Example of terminal output:

| ? Q, | 5,0,100 | •    |      |      |      |      |      |      |                |

#### QOA, QOD, QXA, QXD — Dump 16-Bit PP Memory in Line Format

These four directives are valid on CYBER 180-class machines only. Each directive prints specified locations of 16-bit PP memory in line format. Each line contains eight PP words in octal or hexadecimal with 6-bit display code or 7-bit ASCII code character representations. Repetitive lines are suppressed and zero bytes appear as hyphens (----).

----

| Directive Format | Numeric<br>Representation | Character<br>Representation |  |  |
|------------------|---------------------------|-----------------------------|--|--|
| QOA,n,fwa,1wa,R. | Octa1                     | 7-bit ASCII code            |  |  |
| QOD,n,fwa,lwa,R. | Octal                     | 6-bit display code          |  |  |
| QXA,n,fwa,1wa,R. | Hexadecimal               | 7-bit ASCII code            |  |  |
| QXD,n,fwa,1wa,R. | Hexadecimal               | 6-bit display code          |  |  |
| Parameter        | Description               |                             |  |  |

| n   | Number of PP to be printed.                          |
|-----|------------------------------------------------------|
| fwa | First word address to be printed.                    |
| lwa | Last word address, plus one location, to be printed. |
| R   | If specified, the R register is printed.             |

This directive format is valid only for terminal output. If it is used in a job of batch origin or while an alternate list file is active, DSDI interprets the fwa and lwa parameters as PP numbers.

#### PP — Dump PP Communication Areas

The PP directive causes the PP number, executing program name, control point assignment, and input register address for each PP communication area to be dumped.

Format:

PP.

Example of terminal output:

**PP** Number Program in Execution Control Point Assignment PP00 PP01 PP02 PP03 PP04 PP'05 PP06 PP07 PP10 PP11 MTR-34 DSD-34 QAC-16 1R0-05 1SJ-34 1MT-31 QAC-14 \_\_\_\_ 7200 7210 7220 7230 7240 7250 7260 7270 7300 7310 PP 20 **PP21** PP22 **PP23 PP24** PP 25 PP26 **PP27** PP30 PP31 PIP-03 CPD-34 QAC-02 -110-32 1MA-01 \_\_\_\_ 7400 7410 7430 7320 7330 7340 7350 7360 7370 7420 PP00 Input Register Address 7440

## **Q** — Dump PP Memory in Line Format

The Q directive causes the specified locations of PP memory to be dumped in line format. Each line contains 8 bytes (PP words) with 6-bit display code character equivalents. Repetitive lines are suppressed and zero bytes are represented by hyphens (----).

Format:

Q,n,fwa,lwa.

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| n         | Number of PP to be dumped.                          |
| fwa       | First word address to be dumped.                    |
| lwa       | Last word address, plus one location, to be dumped. |

## NOTE

fwa and lwa are automatically adjusted so that the dump limits fall within a multiple of  $10_8$  words.

This format is valid only for terminal output. If attempted from a job of batch origin or while an alternate list file is active, the fwa and lwa parameters will be interpreted as PP numbers.

Example of terminal output:

Parameter

| ? Q,5 | 5,0,100 | •    |      |      |      |      |      |      |        |           |

#### QOA, QOD, QXA, QXD — Dump 16-Bit PP Memory in Line Format

These four directives are valid on CYBER 180-class machines only. Each directive prints specified locations of 16-bit PP memory in line format. Each line contains eight PP words in octal or hexadecimal with 6-bit display code or 7-bit ASCII code character representations. Repetitive lines are suppressed and zero bytes appear as hyphens (----).

|                  | Numeric        | Character          |
|------------------|----------------|--------------------|
| Directive Format | Representation | Representation     |
| QOA,n,fwa,1wa,R. | 0cta1          | 7-bit ASCII code   |
| QOD,n,fwa,lwa,R. | Octal          | 6-bit display code |
| QXA,n,fwa,lwa,R. | Hexadecimal    | 7-bit ASCII code   |
| QXD,n,fwa,lwa,R. | Hexadecimal    | 6-bit display code |
|                  |                |                    |

Description

| n   | Number of PP to be printed.                          |
|-----|------------------------------------------------------|
| fwa | First word address to be printed.                    |
| lwa | Last word address, plus one location, to be printed. |
| R   | If specified, the R register is printed.             |

This directive format is valid only for terminal output. If it is used in a job of batch origin or while an alternate list file is active, DSDI interprets the fwa and lwa parameters as PP numbers.

## **EXAMPLE OF DSDI TERMINAL USE**

This example illustrates how DSDI might be used following a system malfunction to analyze portions of the EDD file from an interactive terminal. It is assumed that an EDD file was created during normal system recovery procedures. Vertical spacing has been expanded to permit commentary. The example begins after the login sequence has been completed.

| batch<br>RFL,0.                          | Enter Batch Subsystem.                                                                                                                                                                                                                    |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /label,dump,vsn=dump,lb=ku,f=s,mt,d=800  | The LABEL command is entered to<br>assign the EDD dump tape to this job.<br>Use of the vsn parameter allows the job<br>to be rolled out while the tape is mounted<br>and assigned.                                                        |
| /get,altdir                              | Retrieve alternate directives file<br>ALTDIR (refer to the example in figure 6-1).                                                                                                                                                        |
| /dsdi.                                   | Calls DSDI, which copies EDD tape to a random mass storage file.                                                                                                                                                                          |
| ENTER DIRECTIVES                         | Enter terminal output directives (refer<br>to Terminal Output Directives earlier in<br>this section) to list any portion of the EDD<br>file at the terminal. DSDI issues the<br>prompt (?) when it is ready to accept a new<br>directive. |
| ? output,altout.                         | List output produced by subsequent direc-<br>tives is written to local file ALTOUT. This<br>allows entry of directives that produce line<br>printer formatted output.                                                                     |
| ? read,altdir.<br>•<br>•<br>•            | All input directives in alternate direc-<br>tives file ALTDIR are read and processed.<br>List output is written to local file<br>ALTOUT. DSDI does not request terminal<br>input until the last directive on ALTDIR is<br>processed.      |
| ? dispose.                               | Dispose local file ALTOUT to the print<br>queue for listing at the central site line<br>printer. Output produced by subsequent<br>directives is listed at the terminal.                                                                   |
| EXPRESS DUMP COMPLETE (FL USED xxxxxB) / | DSDI is terminated by entering a carriage return in response to the ? prompt.                                                                                                                                                             |

In summary, the following operations were performed by DSDI. First, small areas of the dump file were listed at the terminal for preliminary examination. This was done both to analyze the cause and effect of the system failure, as well as determine the extent of line printer listings required. An appropriate comment may be placed in the list file subtitle at this time via the \*.ccc...ccc directive.

Next, directives were entered to generate the necessary line printer listings. These listings are generally extensive, or contain specially formatted output that cannot be listed at the terminal. Thus, output was written to an alternate list file named ALTOUT.

After all necessary directives had been entered from the terminal, an alternate directives file (ALTDIR) was read. ALTDIR is a permanent file containing input directives necessary to obtain a printer listing of specific areas in the dump file that are frequently examined following a system failure (for example, CMR tables and buffers, PP memory, and so forth). Figure 6-1 illustrates a typical alternate directives file. Comments describing areas of the dump file to be listed appear, along with the directive, in the title line of the output listing.

When DSDI finished processing the last directive in file ALTDIR, it again issued the ? prompt to the terminal requesting further directive input from the keyboard. At this time, the DISPOSE directive was entered causing file ALTOUT to be printed at the central site line printer. Refer to Printer Output Listing Examples later in this section for examples of printer output listings.

| DUMPT     |                                                          |

## PRINTER OUTPUT LISTING EXAMPLES

The listings illustrated in this section are samples of the line printer output listings produced by several of the input directives described under Input Directives earlier in this section.

Each page of output listings begins with two header lines: a title line and a subtitle line. The header lines are formatted as follows.

RA = current input directive DUMP nn DSDI yy/mm/dd.hh.mm.ss. PAGE n 0000000 dump type hh.mm.ss. yy/mm/dd.CDC NETWORK OPERATING SYSTEM. NOS 2 comments

| Header                     | Description                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RA=000000                  | Indicates absolute addressing is in effect. If relative<br>addresses were being dumped (RA or RAC directive entered), a<br>nonzero reference address would appear in this field.                                           |
| current input directive    | Input directive currently being processed, including comments (50-character field).                                                                                                                                        |
| DUMP nn                    | Reflects the EDD tape number currently being used (nn is a 2-digit dump identifier assigned during EDD).                                                                                                                   |
| yy/mm/dd. hh.mm.ss.        | This field reflects the date and time when DSDI was executed.                                                                                                                                                              |
| dump type                  | Indicates type of memory currently being dumped (central<br>memory, extended memory, or a PP number). If the AP<br>directive is processed, the PP number is followed by the<br>name of the program currently being dumped. |
| hh.mm.ss. yy/mm/dd. CDC NE | WORK OPERATING SYSTEM. NOS 2                                                                                                                                                                                               |
|                            | Time of day, date, system title line, and system version name taken from CMR.                                                                                                                                              |
| comments                   | Up to 36 characters of comments specified on a *.cccccc                                                                                                                                                                    |

input directive.

## Example 1:

The following sample illustrates the printer output listing produced by the PP directive (dump PP communication areas).

| RA = PP.<br>0000000 CM   | 16.52.11. 82/01/06. ## Example 3:

The following sample illustrates the printer output listing produced by the CP directive (dump active control points). The default list options (XTAF) are used to dump the control point. This example consists of six pages. Also, notice that the columns cross page boundaries; that is, the left column is read continuously, from the top of the second page to the middle of the fourth page. The sequence then continues at the top of the right column on the second page.

#### Example 4:

The following sample illustrates the printer output listing produced by the MST directive (dump mass storage/track reservation table). The MST is listed in two columns. The left column is read from top to bottom, perhaps across page boundaries, and continues at the top of the right column. The track reservation table is listed in single column following the MST.

## Example 5:

The following sample illustrates the printer output listing produced by the C, D, and E memory dump directives (instruction parcel, byte, and word format, respectively). The same portions of central memory are dumped in each format. Auto page eject has been disabled using the EJOFF directive to allow listing the output from all three memory dump directives on one page.

## **INSTALL COMMAND**

NOS allows multiple copies of the running system to reside on several disk devices of the same type. The system deadstart file (SDF) is defined to be a copy of the deadstart tape that resides on a deadstart disk. When you deadstart the system from this disk, the SDF is read to generate copies of the running system.

The INSTALL command installs a copy of the running system or a deadstart file you specify to a deadstart disk. The disk selected must be on, available, a single-unit device such as an 844 or 885-11/12,† and must have the Common Test and Initialization (CTI) software. (For more information about CTI, refer to the CIP User's Handbook.) If the deadstart disk is a shared device in a multimainframe evnvironment, a full INITIALIZE must have been previously done. The calling job must be of system origin or you must be validated for system origin privileges and the system must be in debug mode. In addition, in a secured system, INSTALL is allowed only from jobs with security administrator privileges.

The format of the command is:

INSTALL, filename, EQest.

Parameter

#### Description

filename Disk file (assigned to the job) to be installed as an SDF. Default is SYSTEM, which must be assigned to the job. SDF is a reserved file name and cannot be specified for filename.

If the deadstart file to be installed is on tape, it must first be copied to disk before INSTALL can be used.

est

EST ordinal of the deadstart disk on which file filename is to be installed.

7

<sup>†</sup>SDF cannot be installed to an 819 or 885-42 device.

# **K-DISPLAY UTILITIES**

This section documents the K displays listed next, along with the utilities used to present them. Other K-display utilities described elswhere in this manual include the permanent file utilities, queue file utilities, and the status/control register simulator.

| K Display                                 | Description                                      |
|-------------------------------------------|--------------------------------------------------|
| CYBERLOG                                  | Gathers information on the system's performance. |
| Flaw                                      | Disk flaw mapping.                               |
| Initialize                                | Disk initialization.                             |
| Machine Recovery (MREC)                   | Multimainframe device recovery.                  |
| Mass Storage Archival<br>Subsystem (MSAS) | K display of the MSAS.                           |
| Mass Storage Subsystem (MSS)              | K display of the MSS.                            |
| Network Access Method (NAM)               | Operator interface to NAM.                       |
| Queue File Transfer Facility (QTF)        | K display of the QTF application.                |
| Redefine                                  | Online reconfiguration display.                  |
| Remote Batch Facility (RBF)               | K display of the RBF Subsystem.                  |
| Remote Host Facility (RHF)                | K display of the RHF Subsystem.                  |
| SCOPE 2 Station Facility (SSF)            | K display of the SSF Subsystem.                  |
| Transaction Facility (TAF)                | K display of the TAF Subsystem.                  |

By using the K display, a job can place information on the console screen and receive information from the keyboard. The information is passed to the job by DSD. Normally, these displays are used for utility programs.

The job first issues a request message on the B,0 display, asking you to bring up the K display.

When this happens, enter:

K,jsn.

jsn Job sequence name of the requesting job.

Once the display is assigned to a job, you can enter data by typing K. followed by data. The data is transferred to a specified area of the job's field length when you terminate the entry. If more than 50 characters are entered as data, the message

LINE TOO LONG.

appears on the screen. DSD does not accept the entry until the data string is shortened.

60459300 D

8

K displays are job oriented. The job sequence name associated with each K display appears at the top of the screen next to the display designator and name.

All parameter entries must be prefixed by K period (K.). However, after pressing CR or NEXT for the first parameter entry, everything but the K. is erased. This allows another parameter to be entered without entering K. first. All examples in this section show K. although you may not have to enter it. If you have to enter a DSD command during parameter entry, backspace to erase the K., enter the command, and then continue parameter entry by entering K. and the parameter.

# CYBERLOG K DISPLAY

The CYBERLOG utility gathers information on system performance. CYBERLOG gathers the information from operator responses after deadstart is complete. The information gathered contains the number and type of service interruptions, the elapsed and lost time from the interruption, and the level of severity or impact of each interruption.

Initiate CYBERLOG by entering:

X.CYBRLOG.

When CYBERLOG appears at a control point, a request message on the B,O display asks you to assign the K display to the CYBERLOG job. Enter:

K,jsn.

jsn Job sequence name of CYBRLOG.

# **RESPONDING TO CYBERLOG DISPLAYS**

The CYBERLOG displays request data about the event that causes the system to be down or degraded. Your selection of the event type, scheduled or unscheduled, determines the path through the displays. The data requested for the two event types are:

| Event Type  | Data Requested |
|-------------|----------------|
| Scheduled   | Reason         |
|             | Elapsed time   |
|             |                |
| Unscheduled | Reason         |
|             | Component      |
|             | Elapsed time   |
|             | Lost time      |
|             | Impact         |
|             |                |

### **EVENT TYPE**

The initial display (figure 8-1) requests the type of event being recorded. Enter 0 for a scheduled event and 1 for an unscheduled event.

|         | CYBERLOG                      |  |
|---------|-------------------------------|--|
| ENTER T | HE CODE FOR THE TYPE OF EVENT |  |
| CODE    | DESCRIPTION                   |  |
| 0<br>1  | SCHEDULED<br>UNSCHEDULED      |  |

Figure 8-1. CYBERLOG Display for Type of Event

In the resulting reason display, the item you select appears on the line labeled EVENT TYPE, and the next list of options appears on the bottom.

### REASON

After you identify the type of event that occurred, a display appears that asks you to identify the reason for the event. The specific display depends on the type of event (figure 8-2 or 8-3).

For a scheduled event, enter the code that corresponds to the reason. On the resulting elapsed-time request display, the item you select appears on the line labeled REASON.

For an unscheduled event, select the most likely reason. In the resulting display, the item you select appears on the line labeled REASON. Selecting 0, 1, 2, or 3 leads to a display that requests the component causing the failure. Selecting 4 (UNKNOWN) causes a branch to the elapsed time request display.

## NOTE

Exact information is required. If you do not know the reason for the event, enter the code for unknown.

Figure 8-3. CYBERLOG Reason for Unscheduled Event Display

## COMPONENT

After you enter the reason for an unscheduled event, a display appears that asks you to identify the component that caused the event. The specific display that appears depends on the reason you've entered (figure 8-4, 8-5, 8-6, or 8-7). Enter the code of the component that caused the failure. The component you select appears on the line labeled COMPONENT on the resulting elapsed-time request display.

# NOTE

Exact information is required. If you do not know the component causing the failure, enter the code for UNKNOWN.

Figure 8-7. CYBERLOG Component Request Display (Reason COMMUNICATIONS)

#### **ELAPSED TIME**

After you either enter the reason for a scheduled event or enter the component causing the failure for an unscheduled event, a display appears that asks you to record the amount of time that has elapsed since the event occurred (figure 8-8).

Enter the elapsed time in hours and minutes in the format shown. The range of values for hours is from 0 to 99 and the range of values for minutes is from 00 to 59. A leading zero is not required for hours, but is required for minutes. A period is required to delimit the hours from the minutes. The time you enter appears on the line labeled ELAPSED TIME in the resulting display.

| CYBERLOG                                                                     |  |

Figure 8-8. CYBERLOG Elapsed-Time Request Display

## LOST TIME

After you enter the elapsed time for an unscheduled event, a display appears that asks you to enter the length of time during which the system or part of the system was down or degraded (figure 8-9). For scheduled events the field is set to 00.00.

Enter the lost time in hours and minutes in the format shown. The same restrictions in format apply as in the elapsed-time entry.

Figure 8-9. CYBERLOG Lost-Time Request Display

# IMPACT

After you enter the lost time for an unscheduled event, a display appears that asks you to identify the impact of the event (figure 8-10). Enter the code for degraded if the system resources were reduced; enter the code for down if the system resources were unavailable. The item you select appears on the line labeled IMPACT on the resulting edit display.

Figure 8-10. CYBERLOG Request for Impact Display

### EDIT

After you make all the entries, you have an opportunity to change any of your responses (figure 8-11). By entering the number that now precedes each line with an entry, that line is blanked; subsequent lines that depend on the blanked line are removed from the display. Those choices are then presented again.

To add a comment to an entry, enter:

CYB, comment.

The maximum length of the comment (excluding CYB, and the period) is 35 characters. The system inserts the word COMMENT on the display before the comment (figure 8-11).

After completing edit entries, enter NEXT or END to transfer the data to the error log. If you enter NEXT, the CYBERLOG program transfers the data to the error log and restarts from the beginning to allow a different event to be recorded. If you enter END, the CYBERLOG program terminates after the message is written to the error log.

**CYBERLOG** EVENT TYPE: UNSCHEDULED 0 1 **REASON:** HARDWARE DISK SUBSYSTEM 2 COMPONENT: 3 ELAPSED TIME: 03.15 LOST TIME: 03.15 4 5 IMPACT: DEGRADED COMMENT CYB, THIS IS A SAMPLE COMMENT LINE. TO CHANGE ANY LINE, ENTER THE LINE NUMBER TO WRITE CURRENT MESSAGE AND REPEAT FOR NEW MESSAGE, ENTER "NEXT" TO EXIT, ENTER END TO WRITE A COMMENT, ENTER \*CYB,\* FOLLOWED BY NO MORE THAN 35 CHARACTERS, TERMINATED BY A PERIOD.

# FLAW K DISPLAY

The FLAW utility reserves (flaws) tracks on any mass storage device during normal system operation. Each entry identifies an area of mass storage that is unusable (flawed area) and prevents the system from accessing it. Since 881 and 883 disk packs normally contain flaw information in the utility sector, the FLAW utility should be used on an 881 or 883 only to specify additional areas not currently in the utility sector. Obtain flaw addresses from the customer engineer.

```
Flawing tracks on mass storage devices is accomplished using the FLAW K displays (figures 8-12 and 8-13).
```

| K. FLAW. AAAM                                                                      |  |
|------------------------------------------------------------------------------------|--|

Figure 8-12. FLAW K Display (Left Screen)

K. FLAW. AAAM MASS STORAGE DEVICE FLAWING SLF, CLF, SPF AND CPF ENTRIES SLF = NNNN SET LOGICAL TRACK FLAW. CLF = NNNNCLEAR LOGICAL TRACK FLAW. SPF = XXSET PHYSICAL TRACK FLAW. CPF = XXCLEAR PHYSICAL TRACK FLAW. WHERE NNNN = VALID LOGICAL TRACK NUMBER. XX = COOO,TOO,SOO (CYLINDER,TRACK,SECTOR.) = A0000000 (ADDR/10B, FOR DE/DP ONLY.) NUMERIC VALUES ARE CONSIDERED OCTAL UNLESS THE DIGITS 8 OR 9 APPEAR IN THE NUMBER, OR A \*D\* IS APPENDED TO THE NUMBER. SEE LEFT SCREEN FOR CURRENT ENTRIES, UP TO 14 ENTRIES ALLOWED

Figure 8-13. FLAW K Display (Right Screen)

All console entry is performed under DSD control. The sequence is:

1. Call the FLAW utility by entering:

X.FLAW.

2. Bring the K display to the left console screen by entering:

K,jsn.

jsn Job sequence name of the job requesting the K display (the message REQUEST\*K\*DISPLAY appears on the B,O display).

- 3. You can bring the flawing instructions up on the right screen by entering KK.
- 4. Specify the mass storage device on which tracks are to be flawed. Enter:

K.EQ=est.

est EST ordinal of the mass storage device.

5. Enter flaws. A maximum of 14 flaw entries is allowed for each call to the FLAW utility. In addition, there are four types of flaw entries that may be specified. The general format for the K display entry is:

K.xtk=ta.

- xtk Specifies one of the following types of flaw entries.
  - Description Entry SPF Sets the track reservation table (TRT) entry for the specified physical block (track) address(es) in extended memory or disk to indicate that the block is unavailable for use. CPF Clears that TRT flaw entry for the specified physical block address(es) in extended memory or disk to indicate that the block is available for use. SLF Sets the TRT flaw entry for the specified logical track to indicate that the track is unavailable for use. Clears the TRT flaw entry for the specified logical CLF track to indicate that the track is available for use.
- ta Specifies the track address to be reserved. ta can be one of the following.
  - taDescriptiontrkLogical track address for a disk or extended<br/>memory. (Use with SLF and CLF.) The variable trk<br/>can be any octal number in the specified range for<br/>the particular type of disk drive or extended<br/>memory. Refer to table 8-1.AaddrPhysical block (track) address for extended memory.
    - (Use with SPF or CPF.) addr is the extended memory address divided by 108. Refer to table 8-1.
  - Aaddr-Range of physical block addresses for extendedAaddrmemory. (Use with SPF or CPF.) Refer to table 8-1.
  - Ccyl,Physical track address for the disk. (Use with SPFTtrk,or CPF.) The variables cyl, trk, and sec can be anySsecoctal number in the specified range for the<br/>particular type of disk drive. Refer to table 8-1.
- 6. Initiate flawing of the specified device by entering:

K.GO.

The FLAW utility provides two messages in the system dayfile that indicate the results of the flawing operation. The first message is:

nn TRACKS FLAWED.

nn Octal number of tracks that were successfully flawed.

The second message appears only if some of the flaws specified were not processed. This occurs when the track specified for flawing is already reserved by the system (but not as a flawed track). In this case, the following message also appears in the system dayfile.

nn FLAWS NOT PROCESSED, list.

nn Octal number of flaws not processed.

list List of the logical tracks that were not flawed.

The entries described here are similar to those entered in the APRDECK (refer to section 3, Deadstart Decks) for flawing a device at deadstart time. However, the flaw entries specified using the FLAW utility or DSD command INITIALIZE are not recovered if the device is initialized at deadstart time. Only the flaw entries specified in the APRDECK will be recovered. If a device is initialized during normal system operation (INITIALIZE command), all flaws specified in the devices TRT, including those entered using the FLAW utility or INITIALIZE command, will be recovered providing the device has a good label at the time of initialization. If the label is bad, or cannot be recognized, all current flaws are cleared. The left console screen (figure 8-14) shows all flaw entries made through the FLAW utility and INITIALIZE command. It lists the flaw entry and its logical track equivalent. If the same logical track is referenced by more than one flaw entry, an asterisk appears to the right of those entries, so that you are aware that only the last entry takes effect.

| CURRENT SLF,                            | CLF, SPF, AND CPF ENTRIES                          |  |

Table 8-1. Flawing Information for Disks and Extended Memory

# **INITIALIZE K DISPLAY**

The INITIALIZE command can be used to reconfigure certain removable devices (844-21 and 844-41/44) to suit your needs. For example, if you currently have two single-unit 844 packs (DK-ls), both packs can be initialized and linked together to form a multispindle device (DK-2). However, this can be done only if the devices to be linked meet the following requirements.

- Same device type.
- Same channels.
- Same share status (shared or nonshared).
- Removable.
- Not currently in use.

The INITIALIZE command must be entered to set the initialize status for each device to be chained. Current multispindle devices can also be initialized providing all packs that form the device are mounted in a logical order as determined by the unit numbers list on the E,C display. It is only necessary to enter the INITIALIZE command for the first unit of a current multispindle device. The format of the INITIALIZE command is described in section 5, DSD Commands.

## NOTE

Examine the FAMC and DAFC fields in the family status display (E,F) before entering the INITIALIZE command. The user count for the device must be zero before this command is valid. The following steps describe the procedures to initialize and (if necessary) flaw tracks on a mass storage device.

1. Enter the INITIALIZE command for the device(s) to be initialized. Examine the B,O display for the following message.

REQUEST\*K\*DISPLAY.

Note the job sequence name of the job displaying the message is CMS.

2. Activate the K display for that job by entering:

K,CMS.

The INITIALIZE K display (figure 8-15) appears on the left console screen. All parameters required to initialize and (if necessary) flaw the specified device are entered through the K display.

| K. INITIALIZ         | E. CMS                                                                  |  |
|----------------------|-------------------------------------------------------------------------|--|
| MASS STORAGE         | DEVICE INITIALIZATION                                                   |  |

|------------|--------|----------------|---------|--------|------|------|---|

| <b>D</b> ption | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EQ             | EST ordinal of the device to be initialized. For multispindle devices, this ordinal must be the first of the consecutive units in the multispindle chain.                                                                                                                                                                                                                                                                                                                                                                               |
| FM             | The 1- to 7-character family name. Specifies the permanent file family in which<br>the initialized device is to be included. All devices must have a family name or<br>pack name. The name 0 (single character zero) is reserved and cannot be used.<br>This option cannot be used to change the family name of the link device in a<br>multimainframe environment. If you specify TY=X, this option specifies a 1- to<br>7-character packname to be associated with an auxiliary device. To clear an<br>existing entry, enter FM=NULL. |
| DN             | The 2-digit (octal) logical device number (from 1 to 778) that uniquely identifies the device in its permanent file family. This option cannot be entered if you specify TY=X.                                                                                                                                                                                                                                                                                                                                                          |
| UN             | The 1- to 7-character user name. This option is specified only when initializing<br>an auxiliary device (TY=X). If specified, the device is considered to be a<br>private auxiliary device. Only the user name specified will be allowed to create<br>files on the device (use SAVE, REPLACE, or DEFINE commands). To clear an<br>existing entry, enter UN=NULL.                                                                                                                                                                        |
| TY=F           | Initialized device may contain direct and indirect access permanent files.<br>However, if you specify DM=0, only direct access files can reside on the device.<br>If you specify SM=0 and DM=0, the device can contain only special system<br>permanent files. Indirect access files can reside only on a master device (that<br>is, DM≠0).                                                                                                                                                                                             |
| ТҮ=Х           | Initialized device is an auxiliary device. This is a mass storage device that is<br>not part of a permanent file family. An auxiliary device is a supplementary<br>permanent file storage device that may be privately owned (UN option specified)<br>or can be shared by many users (UN not specified). Auxiliary devices can contain<br>direct or indirect access permanent files.                                                                                                                                                    |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Table 8-2. | Device Initialization | Options (Sheet | : 2 of 2)† |
|------------|-----------------------|----------------|------------|

| Option | Description                                                                                                                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LA     | Lower limit for the access level of the device. This establishes the lowest<br>access level of files that can be stored on the device (must not be less than the<br>lower limit for the access level of the device as given in its EST entry).                           |
| UA     | Upper limit for the access level of the device. This establishes the highest<br>access level of files that can be stored on the device (must not be greater than<br>the upper limit for the access level of the device as given in its EST entry).                       |
| DM     | The 3-digit (octal) device mask (from 0 to 3778). This option is required<br>whenever a permanent file master device is being initialized. It defines which<br>users will have this device as their master device. This option cannot be<br>entered if you specify TY=X. |
| SM     | The 3-digit (octal) secondary device mask (from 0 to 377 <sub>8</sub> ) used to control the residence of direct access files. This option cannot be entered if you specify TY=X.                                                                                         |
| NC     | Octal number of catalog tracks (from 0 to 200 <sub>8</sub> ; must be a power of 2). This<br>option is used only if the number of catalog tracks specified as the system<br>default for the device type is not satisfactory.                                              |
| NP     | Number of physical units to be included in a multispindle device. The default<br>value is l. Each unit to be included in the multispindle chain must be defined<br>as removable in the current disk status display (E,M).                                                |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |
|        |                                                                                                                                                                                                                                                                          |

#### Table 8-3. Track Flawing Options †

| Option †† | Description                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPF       | Sets the track reservation table (TRT) entry for the specified physical block (track) address(es) in extended memory or disk to indicate that the block is unavailable for use.                                   |
| CPF       | Clears the TRT flaw entry for the specified physical address(es) in extended memory or disk to indicate that the block is available for use.                                                                      |
| SLF       | Sets the TRT flaw entry for the specified logical track to indicate that the track is unavailable for use.                                                                                                        |
| CLF       | Clears the TRT flaw entry for the specified logical track to indicate that the track is available for use.                                                                                                        |
| informa   | of 881 and 883 disk packs is automatic; only flaws additional to the current flaw<br>tion in the utility sector should be entered.<br>o the APRDECK description in section 3, Deadstart Decks, for entry formats. |

3. Enter the INITIALIZE command for each additional device to be initialized. This can also be done before activating the K display. In either case, only the first device specified will be listed (by EST ordinal) in the K display. Thus, to update the K display to show additional devices, enter the following command.

K.RERUN.

If more than one device is listed, they are initialized one at a time as they appear in the list from left to right. Multispindle devices (more than one EST ordinal) are considered one device.

4. The system has already checked the label on each mass storage device. If the label was found to be good, it is necessary to enter device initialization options (requested in messages that appear in the K display) to identify the device. This is to ensure that the device selected is indeed the correct device to be initialized. The messages appear automatically and are displayed until the correct options are entered. If an incorrect option is entered, it is ignored. Refer to table 8-2 for a description of each option.

Examine the family status display (E,F) to determine the current option values.

The following messages may be displayed and the appropriate response should be entered. If none of these messages appears, the device label was not recognized or was found to be bad. In this event, proceed to step 5.

#### Message

#### Description

ENTER OLD DEVICE NUMBER

This message appears if the device to be initialized is a permanent file family device. Enter the following response.

K.DN=devicenumber.

#### Message

### Description

ENTER OLD FAMILY NAME This message appears only if more than one family of permanent file devices is currently active in the system. Enter the following response.

K.FM=familyname.

This message appears only if the device to be initialized is an auxiliary device. Enter the following response.

K.PN=packname.

ENTER OLD USER NAME

ENTER OLD PACK NAME

This message appears only if the auxiliary device to be initialized is a private auxiliary device (associated with a specific user name). Enter the following response.

K.UN=username.

The user name is written to the account dayfile when the device is mounted.

If you discover that the wrong device was specified in the INITIALIZE command, you can clear the initialize status for that device by entering:

K.CLEAR.

The device to be processed by the clear entry must be a valid device. That is, the device cannot have a device number that conflicts with another device in its family name or a pack name that duplicates one already in the system. Its mask bits must meet standard requirements. The leftmost device in the list of devices to be initialized is cleared. One of the preceding messages will then be displayed for the next device to be initialized (if any) providing the label on that device is good.

5. When the following message appears on the K display, enter the parameters that specify the new characteristics to be associated with the device when it is initialized (refer to tables 8-2 and 8-3).

ENTER PARAMETERS

The new parameters can be entered as a string or one at a time. For example:

K.option<sub>1</sub>=value<sub>1</sub>,...,option<sub>n</sub>=value<sub>n</sub>.

or

K.option1=value1.

K.option2=value2.

K.option<sub>n</sub>=value<sub>n</sub>.

If flaw entries are to be specified (refer to table 8-3), they must be entered singly, as shown in the last example. If the label on the device being initialized was good, all current flaws on that device are normally recovered. However, if the label was not recognized or was bad, the flaw entries cannot be recovered and must be entered (if necessary) using this mechanism. A maximum of 14 flaw entries are permitted. In addition to the SLF, CLF, SPF, and CPF entries, the flaw information recorded in the utility sector on an 881, 883, or 885 disk pack is read during initialization of 844 equipment, and the appropriate areas are reserved by the system automatically.

If the NP option is specified (NP > 1), the device is to be initialized as a multispindle device. In this case, the number of packs specified by NP indicates the number of spindles to be linked. This is the next n number of devices waiting to be initialized. Each device must be defined as removable and mounted on consecutive physical unit numbers. To determine if a device is defined as removable, examine the disk status display (E,M). If the units are configured correctly, the label on each unit is checked. If any label is not recognized or is bad, that unit is free for initialization and chaining. However, if the label is good, the message

ENTER IDENTITY OF EQest

appears in the K display (est is the EST ordinal of the device). Enter one of the following responses.

K.DN=devicenumber.

K.FM=familyname,DN=devicenumber.

K.PN=packname.

K.PN=packname,UN=username.

This is a precautionary measure to ensure that the devices specified are the correct devices to be chained.

6. After all the necessary parameters have been entered for a specific device, enter the following command to proceed with the initialization.

K.GO.

If more devices are waiting to be initialized, repeat steps 4 through 6 of this procedure for each device.

# MACHINE RECOVERY (MREC) UTILITY K DISPLAY

When a machine that has been in a multimainframe configuration has a malfunction that requires a level 0 deadstart, before you can begin the deadstart, the machine recovery utility program (MREC) must be run on every machine that shares devices with the machine that is not working properly. MREC releases local mass storage space on the shared devices and clears interlocks set before the malfunction occurred.

For example, assume that machines A and B share disk unit 12 and machines B and C share disk unit 13 as shown in figure 8-16.

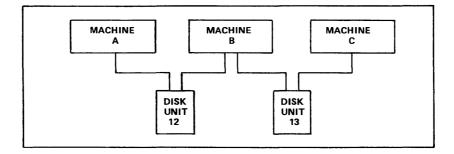

Figure 8-16. Machine Configurations

If machine A must be deadstarted using a level 0 deadstart, MREC must be run on machine B to recover disk unit 12. Machine C need not be involved since it is not aware of the existence of disk unit 12. However, if machine B must be deadstarted using a level 0 deadstart, MREC must be run on machine A to recover disk unit 12 and on machine C to recover disk unit 13.

## NOTE

Once MREC has been run for an inoperative machine, any level of deadstart on the machine other than 0 is not possible.

# **MREC PROCEDURES**

The MREC utility can be used through keyboard entry to a K display or by direct keyboard entry under DSD or DIS control without using the K display.

### USING MREC WITH THE K DISPLAY

The following procedure describes K-display usage for MREC operations.

1. Call the MREC utility by entering this DSD command:

X.MREC.

2. Examine the DSD system status display (B,0). When MREC is scheduled to a control point, it is indicated on the B,0 display. The message

**REQUEST \*K\* DISPLAY** 

appears in the message field for that control point.

<sup>&</sup>lt;sup>†</sup>Under DIS control, the command MREC calls the MREC utility.

3. Activate the K display for that control point by entering:

K,jsn.

jsn MREC job sequence name.

The K display for MREC (figure 8-17) appears on the left console screen.

|    |       |        | **   | * MACHINE | RECOVER | RY UTILIT | Y ***        |  |

| EQ | = ALL |        |      |           |         | EQ(S) TO  | RECOVER      |  |

Figure 8-17. MREC K Display (Left Screen)

The MREC left screen K display lists all of the devices that are shared by the machine on which MREC is being run. The machine identifier (MID) of this machine is also given. Information describing the shared devices is given in the following format.

eq type un dn fm/pn mid(s)

Header

Description

eq EST ordinal of the shared device.

type Device type.

un Unit number of the device.

- dn Device number.
- fm/pn Family name/pack name.
- mid(s) Machine identifiers of other machines that are currently accessing the device. If there is an \* by the machine identifier, the machine is determined to be down.
- 4. The MREC right screen K display contains the parameters and commands that may be selected. Refer to table 8-4 (MREC parameters) and table 8-5 (MREC commands) for more information. To activate the MREC right screen K display (figure 8-18), enter:

KK.

5. Enter the MREC parameters in the following format.

K.param<sub>1</sub>=value<sub>1</sub>,param<sub>2</sub>=value<sub>2</sub>,...,
param<sub>n</sub>=value<sub>n</sub>.

The parameters entered (and error messages, if any) are displayed on the lower portion of the MREC left screen K display.

6. If you want to reset the parameters to their default values or refresh the device descriptions on the MREC left screen K display, enter:

K.RERUN.

The parameters can then be reentered.

7. Enter the desired parameters and initiate MREC processing by entering:

K.GO.

When processing is complete, the message

PROCESSING COMPLETE

appears at the bottom of the left screen.

 After all MREC operations are complete, end the MREC utility by entering: K.STOP.

| ( | *** MACHINE RECOVERY UTILITY ***                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

THESE<br/>PARAMETERS ARE ONLY VALID FOR THE CURRENT RESERVED<br/>844 UNIT AND MUST BE REENTERED UPON REOCCURENCE OF<br/>ANOTHER RESERVE SITUATION.</li> </ul> |
|   | DESCRIPTION OF K DISPLAY COMMANDS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|   | GO - INITIATE PROCESSING OF DEVICES SPECIFIED.<br>RERUN - REINITIALIZE K DISPLAY AND RERUN PROGRAM.<br>STOP - TERMINATE PROGRAM.<br>+ - PAGE RIGHT DISPLAY IF .GT. 24D SHARED DEVICES.                                                                                                                                                                                                                                                                                                                                                                                                         |

Figure 8-18. MREC K Display (Right Screen)

## USING MREC WITHOUT THE K DISPLAY

You can also call the MREC utility and specify the appropriate parameters without using the K display. You can do this by making a single keyboard entry (under DSD or DIS control) in the following format.

X.MREC(param1=value1, param2=value2,..., paramn=valuen)

param<sub>i</sub>=value<sub>i</sub> Parameters described in table 8-4.

The ID=id parameter must be entered.

When the MREC command is entered with parameters, the K display is not activated and processing occurs automatically. If an error occurs using this procedure, the message

REQUEST \*K\* DISPLAY

appears on the DSD B,O display. Activate the K display and continue as described under Using MREC With the K Display earlier in this section.

Table 8-4. MREC Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID=id     | The 1- or 2-character machine identifier of the inoperative machine that is to be processed. This parameter must be entered before processing can take place.                                                                                                                                                             |
| EQ=est    | EST ordinals of the devices to be processed. Only devices shared between<br>the machine that is down and the machine on which MREC is running are<br>processed. The form of the entry is:                                                                                                                                 |
|           | EQ=est <sub>l</sub> ,est <sub>2</sub> ,,est <sub>n</sub> .                                                                                                                                                                                                                                                                |
|           | If you omit this parameter, EQ=ALL is assumed. In this case, all devices shared between this machine and the inoperative machine are processed.                                                                                                                                                                           |
| OP=x      | You can enter this parameter only when using the K display (that is, it<br>cannot be used if the MREC utility is called by a command) and then, use it<br>only if a unit or controller cannot be accessed by MREC due to physical<br>hardware reservations. Its use is invalid if a unit reservation is not in<br>effect. |
|           | x Description                                                                                                                                                                                                                                                                                                             |
|           | R Directs the MREC utility to release all unit reservations (using the GRENADE function; refer to section 2, Deadstart) for 834, 844-41/44, or 885-11/12 equipment.                                                                                                                                                       |
|           | I Directs the MREC utility to ignore certain functions on the<br>equipment for which the reservation message was issued.<br>Functions that do not require the unit to be accessed are still<br>performed.                                                                                                                 |

| Command | Description                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GO .    | Directs the MREC utility to proceed with processing the entered parameters.                                                                                              |
| RERUN.  | Reinitializes the device descriptions and parameters on the K display and reruns the MREC utility.                                                                       |
| STOP.   | Terminates the MREC utility and ends the K-display interaction.                                                                                                          |
| +       | Toggles the right screen K display between the K-display instructions and<br>the second page of device descriptions if there is more than one page of<br>shared devices. |
|         |                                                                                                                                                                          |

# **MREC UNIT AND CONTROLLER RESERVATIONS**

When attempting to access a device, MREC may find the controller access or unit reserved by another machine. When this occurs, the following message appears on the left screen K display.

EQest, CHcc, CONTROLLER RESERVED.

or

EQest, UNuu, UNIT RESERVED.

est EST ordinal of the device.

cc Channel number.

uu Physical unit number (from 0 to  $77_8$ ).

Assuming the inoperative machine is the machine holding the reservation, you can clear the reservation or direct MREC to clear it by using the following procedures.

To clear a controller reservation, activate the deadstart switch on the machine that is down.

To clear a unit reservation, perform one of the following procedures.

- On a device that is connected to a 7155 controller, activate the deadstart switch on the machine that is down.
- On a device that is not connected to a 7155 controller, toggle the OFF LINE/ON LINE switch on the back of the drive to OFF LINE and then back to ON LINE.
- If none of the preceding procedures can be performed, select the OP=R parameter to clear an 834, 844, or 885 device reservation.

NOTE

Do not select the OP=R parameter unless the other reservation clearing procedures cannot be performed. It is recommended that all machines in a multimainframe environment be put in IDLE status or put in STEP mode when you select the OP=R parameter.

Once the correct action has been taken, enter

K.GO.

to continue processing. If the reservation is still not cleared, the appropriate reserved message reappears on the left screen K display. Repeat one of the reservation clearing procedures described above or enter:

K.OP=I.

This directs the MREC utility to ignore certain functions on the device. Processing may then continue.

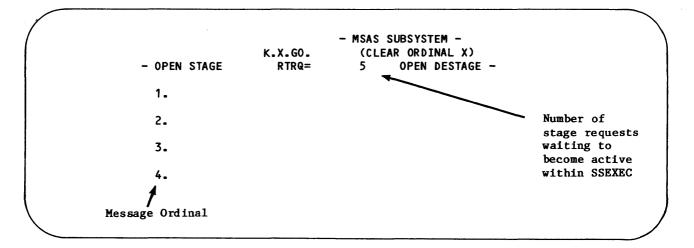

If a device or controller in an independent shared device multimainframe environment is reserved by a down machine, the previously mentioned messages appear on the system status display (B,0) instead of on the K display. Use the procedures already described to clear the reservation.

# MASS STORAGE ARCHIVAL SUBSYSTEM (MSAS) K DISPLAY

MSAS uses the K display to present messages that require your action. You can use the MSAS K display to reply to these messages and to open and close staging/destaging operations.

When MSAS enters messages into the K display, a request for the K display appears on the B,0 display. Enter K,MAS to activate the display for MSAS. After you have responded to all K-display messages, the request for the K display terminates.

The MSAS K display provides space for four messages with up to three lines per message. Figure 8-19 shows a sample MSAS K display.

### Figure 8-19. MSAS K Display

Valid MSAS commands are:

Command

#### Description

K.m.GO.Enters a GO response to the message at message ordinal m.K.STAGE.Toggles staging operations between open and close. Staging is<br/>normally open (permitted).

K.DESTAGE. Toggles destaging operations between open and close. Destaging is normally open (permitted).

MSAS clears a message when an acceptable action is taken. Usually this action is entering a GO response to the message at message ordinal m. However, for actions such as emptying the exit tray on a storage module, the message is cleared when the hardware status indicates the action has occurred and you enter the GO response. Refer to appendix B of the NOS 2 Operations Handbook for the appropriate action for each message.

# MASS STORAGE SUBSYSTEM (MSS) K DISPLAY

MSS uses the K display to present messages that require your action. You can use the MSS K display to reply to these messages and to control the rate that files are staged/destaged between the MSF hardware and a disk.

When MSS enters messages into the K display, a request for the K display appears on the B,O display. Enter K,MSS to activate the K display for MSS. After you have responded to all K-display messages, the request for the K display terminates.

The MSS K display provides space for four messages with up to three lines per message. If you enter an incorrect command, the incorrect command appears under a line containing \*\*\* REJECT \*\*\*. Figure 8-20 shows a sample MSS K display.

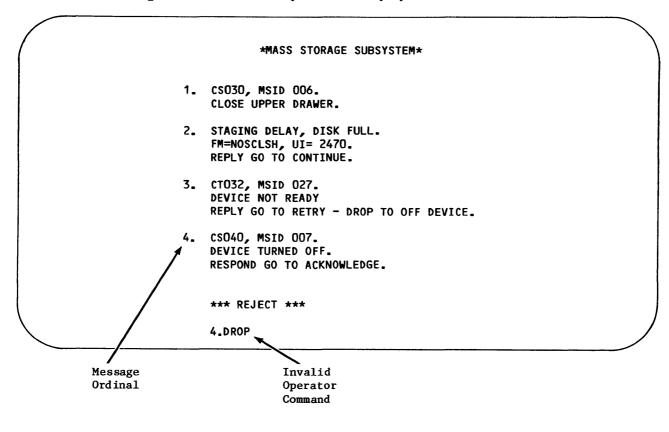

Figure 8-20. MSS K Display

Valid MSS commands are:

| Command    | Description                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.FILES,x. | Controls the rate that files are staged/destaged by changing the number, x, of concurrent files to be staged/destaged between the MSF and a disk. Increasing or decreasing the number of concurrent files by one results in a corresponding increase or decrease in field length of approximately 65008 central memory words. The number x must be a single digit. |
| K.m.GO.    | Enters a GO response to the message at message ordinal m.                                                                                                                                                                                                                                                                                                          |
| K.m.DROP.  | Enters a DROP response to the message at message ordinal m.                                                                                                                                                                                                                                                                                                        |
| K.         | Clears the previously entered incorrect command and the *** REJECT ***                                                                                                                                                                                                                                                                                             |

MSS clears a message when an acceptable action is taken. Usually this action is entering the K.m.GO or K.m.DROP command. However, for actions such as closing or emptying the input or output drawers on a cartridge storage unit, the message is cleared automatically when the hardware status indicates the action has occurred.

If you enter an invalid command, the \*\*\* REJECT \*\*\* line and the command are both displayed. Valid commands are those described previously. However, the K.m.GO and K.m.DROP commands are invalid if there is no message displayed at message ordinal m or if the GO or DROP response is not appropriate. Clear the \*\*\* REJECT \*\*\* line by entering a valid command. Refer to appendix B of the NOS 2 Operations Handbook for the appropriate action for each message.

# NETWORK ACCESS METHOD (NAM) K DISPLAY

line.

The NAM K display provides a common, centralized interface by which network applications (CS, NS, NVF) can communicate with the host operator (HOP).

Figure 8-21 shows the format of the NAM K display. Table 8-6 explains the fields that appear on the NAM K display.

|                                |               | data area                          |                |  |

#### Table 8-6. NAM K-Display Fields

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data area        | The portion of the screen that receives the output or diagnostic<br>message as a result of a command that you entered. This portion<br>of the NAM K display is operated as a scrollable paged device.<br>Each line of data enters the display at the bottom of the data<br>area and forces the previous lines to shift up by one line. The<br>previous top line is lost. However, whenever you turn the<br>page-wait status on and more than a screen full of information<br>is written to the data area, the prompt MORE DATA is displayed<br>on the bottom line of the data area. The display remains fixed<br>until you enter the + character to display the next page of<br>information (refer to Display Control Characters later in this<br>sction). |
| message          | The system prompt READY indicates that you can make additional<br>keyboard entries. The system prompt MORE DATA indicates that<br>you can enter + to see more data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| app1app5         | The alert line is a list of applications requesting your attention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| hop message line | This field contains a message received from another host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| appname          | The name of the application (CS, NS, NAM, or NVF) with which you are currently interacting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| operator entry   | This field contains up to 40 characters of the last command that you entered. Commands of more than 40 characters are truncated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| repeat message   | Whenever a command cannot be accepted because the system was not<br>done processing a previous command, you get the system prompt<br>REPEAT in this field. Repeat the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

NAM supports both the right and left screen K displays. The right K display provides help information.

The NAM K display is available at all times during NAM execution, the message REQUEST K DISPLAY appears on the B,O display when the K display is not assigned to NAM and some application has requested operator intervention. You must assign the K display to NAM to interact with NAM or an application.

You assign the K display to NAM by entering:

K,NAM.

Figure 8-22 shows the NAM K display as it appears when you initially assign it.

READY.. ALERTS NAM

Figure 8-22. NAM K Display

The NAM K display has two operating modes: NAM mode and application mode. Initially, the display is in NAM mode. The appearance of NAM indicates that you are interacting directly with NAM.

### **DISPLAY CONTROL CHARACTERS**

You can use the following four characters to control the NAM K display. They are valid in both NAM mode and application mode. Each of the following characters must be entered in the first character position after K.

#### Character

#### Description

- \* When in application mode, the \* character causes the display to revert to NAM mode. The last command is aborted and any information generated by the application, after the asterisk is entered, is discarded by NAM. The page-wait status is automatically turned on. The \* character is ignored if the display is already in NAM mode.
- / When in application mode, the / character aborts the last command without altering the assignment of the NAM K display. The / character always results in a READY.. prompt.

When in NAM mode, the / character is ignored.

- + When in application mode, the + character turns the page-wait status on, if the current page-wait status is off. If the current page-wait status is on, then the command K.+ displays the next available page of information. The page-wait status is always on in NAM mode. The page-wait status is initialized to off each time you enter application mode. Therefore, whenever you select an application, the page-wait status automatically changes from on to off and you can set it as desired.
- The character turns off the page-wait status. The character is ignored if entered in application mode while the page-wait status is off.

Any attempt to turn the page-wait status off while in NAM mode is ignored without sending any diagnostic message.

### NAM K-DISPLAY OPERATION

Initially, the display is in NAM mode. The application mode is invoked by a NAM mode command that indicates the application with which you wish to interact. The application mode is indicated by the appearance of the name of that application in the appname portion of the response line (refer to figure 8-21). In application mode, all entries except the asterisk are passed by NAM to a previously designated application. An asterisk character returns the display to NAM mode.

Entering any command (processed either by NAM or by an application) immediately causes the command to appear in the operator entry field. When processing of the command completes, the prompt READY.. appears in the bottom line of the data area. If you key something in, other than one of the display control characters \*, /, +, or - before the prompt READY.. appears, the character is displayed in your entry field but the command is not acted upon and the message REPEAT.. appears to the right of your entry.

Table 8-7 describes the commands for assigning the K display to one of the applications CS, NS, or NVF, and other frequently used commands. If appname or the remote host number are invalid or the application is not currently active, you will receive a diagnostic message. These commands are available in NAM mode only.

| Command      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.AP=appname | Assigns the NAM K display to the specified application. The<br>application name appears in the appname portion of the response line<br>(refer to figure 8-21). appname is one of the supervisory programs<br>CS, NS, or NVF. The command satisfies any alert request posted by<br>the application. When you type the application name, that<br>application name is removed from the alert line, the page-wait<br>status is turned off, and the last page of the application's recent<br>history buffer appears in the data area of the display (refer to<br>Recent History Command in section 15, Network Operations. |
| К.АР         | Assigns the NAM K display to the application whose name appears in<br>the leftmost position of the alert line. The page-wait status is<br>turned off and the last page of the application's recent history<br>buffer appears in the data area of the display.                                                                                                                                                                                                                                                                                                                                                         |
| K.HELP       | Displays information about the NAM mode commands on the right K display.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| K.IG=appname | Causes NAM to ignore all alert requests from the specified<br>application. If the application had an alert request pending, its<br>name is removed from the alert list. NAM informs the application<br>that its alert request was acknowledged and ignored. The rest of<br>the display remains unaltered. This command is cancelled<br>automatically when you enter the AP=appname command. The assignment<br>of the NAM K display is not altered by the IG=appname command.                                                                                                                                          |

Table 8-7. NAM Mode Commands (Sheet 1 of 2)

# Table 8-7. NAM Mode Commands (Sheet 2 of 2)

| Command              | Description                                                                                                                                                                                                                                                                                                                               |  |  |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| K.IG                 | Causes NAM to ignore all alert requests from the application who<br>name appears in the leftmost position of the alert line. NAM<br>informs the application that its alert request was acknowledged<br>ignored. The rest of the display remains unaltered. This comma<br>is cancelled automatically when you enter the AP=appname command |  |  |
| K.END                | Clears the NAM K display. It causes the data area of the displa<br>go blank but leaves the alert line and response line unaltered.<br>END command is used to stop the generation of the status display<br>(figure 8-23). Otherwise, if the K display is dropped, NAM<br>automatically ends after 60 to 90 seconds.                        |  |  |
| K.SEND, rrr, string. | Causes NAM to send the message text if a logical link exists bet<br>the specified remote host and this host. Use the NAM ST command<br>determine which hosts are connected.                                                                                                                                                               |  |  |
|                      | Parameter Description                                                                                                                                                                                                                                                                                                                     |  |  |
|                      | rrr Host node number of the remote host (from 1 to 2                                                                                                                                                                                                                                                                                      |  |  |
|                      | string Message text of no more than 40 characters.                                                                                                                                                                                                                                                                                        |  |  |
|                      | The message                                                                                                                                                                                                                                                                                                                               |  |  |

|                      | sss Host node number of the sending host (from 1 to 2                                                                                                                                                                                                                                                                                     |  |  |
|                      | string Message text of no more than 40 characters.                                                                                                                                                                                                                                                                                        |  |  |
| K.ST                 | Causes the NAM status display to appear on the K-display screen.                                                                                                                                                                                                                                                                          |  |  |
|                      |                                                                                                                                                                                                                                                                                                                                           |  |  |

### NAM MODE MAINTENANCE COMMANDS

While in NAM mode, the HOP can enter the following network maintenance commands. The commands are sent to NAM or to applications to determine the status of the network and aid in the debugging of network problems. The HOP may select NAM or a single supervisory application or NAM and all applications using the following commands.

| Command | Description                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------------------|
| DB      | Activates the online debugging code.                                                                                             |
| DE      | Deactivates the online debugging code.                                                                                           |
| DU      | Causes NAM to dump its field length and/or request an application to dump its field length.                                      |
| FL      | Changes NAM's maximum field length.                                                                                              |
| LB      | Begins the logging of network traffic in the debug log file.                                                                     |
| LE      | Ends the logging of network traffic in the debug log file.                                                                       |
| LR      | Releases the debug log file.                                                                                                     |
| RS      | Dumps the statistics data to a permanent file, resets the statistics counters to $0$ (zero), and continues gathering statistics. |
| ST      | Causes the NAM status display to appear on the K-display screen (refer<br>to figure 8-23).                                       |

### **DB Command**

The debug begin (DB) command causes NAM to turn on its online debugging code and/or request an application to turn on its online debugging code.

The command format is:

DB=mode.

| DL | -mode. |                                                                                                                                                                                |
|----|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ē  | ode    | Description                                                                                                                                                                    |
| AI | L      | NAM turns on its online debugging code and requests all applications to turn on their online debugging code.                                                                   |
| aŗ | opname | NAM requests the specified application to turn on its online debugging code. The specified application must be accessing the network or you will receive a diagnostic message. |
| NA | м      | NAM turns on its online debugging code.                                                                                                                                        |

### **DE Command**

The debug end (DE) command causes NAM to turn off its online debugging code and/or request an application to turn off its online debugging code.

The command format is:

DE=mode.

| mode    | Description                                                                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL     | NAM turns off its online debugging code and requests all applications to turn off their online debugging code.                                                                  |
| appname | NAM requests the specified application to turn off its online debugging code. The specified application must be accessing the network or you will receive a diagnostic message. |
| NAM     | NAM turns off its online debugging code.                                                                                                                                        |

# **DU Command**

The dump (DU) command causes NAM to dump its field length and/or request an application to dump its field length.

The command format is:

DU=mode.

mode

Description

- ALL NAM dumps its field length and requests all applications to dump their field length.
- appname NAM requests the specified application to dump its field length. The specified application must be accessing the network or you will receive a diagnostic message.

NAM NAM dumps its field length.

### FL Command

The field length (FL) command changes NAM's maximum field length to the specified value. If the field length specified is less than NAM's current maximum field length or NAM's running field length plus 10008, you will receive a diagnostic message.

If NAM reaches its maximum field length, use the FL command to increase NAM's maximum field length. If the K display is in application mode when NAM reaches its maximum field length, NAM automatically switches the K display to the NAM mode.

Until you enter the FL command, all other NAM commands are rejected and NAM stops servicing the network. Frequent need for this command indicates that the initial field length for NAM is inadequate and should be increased by changing the MAXNIP build parameter described in the NOS 2 Installation Handbook.

The command format is:

FL=f1.

#### Parameter

### Description

f1

Specified maximum field length in octal.

### **LB Command**

The log begin (LB) command causes NAM to begin logging network traffic in its debug log file and/or request an application to begin logging network traffic in its debug log file (refer to the NAM/CCP Host Application Programming Reference Manual for information on creating the application's log file).

The command format is:

LB=mode.

| mode    | Description                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL     | NAM begins logging network traffic in its debug log file 'and requests all applications to begin logging network traffic in their debug log files.                                                             |
| appname | NAM requests the specified application to begin logging network traffic in<br>its debug log file. The specified application must be accessing the network<br>or you will receive a diagnostic message.         |
| NAM     | NAM begins logging network traffic in its debug log file. NAM must be<br>installed with the network trace option or this command is ignored. Refer<br>to the NOS 2 Installation Handbook for more information. |

To release the debug log file, enter the log release (LR) command.

#### LE Command

The log end (LE) command causes NAM to end logging network traffic in its debug log file and/or request an application to end logging network traffic in its debug log file.

The command format is:

LE=mode.

modeDescriptionALLNAM ends logging network traffic in its debug log file and requests all<br/>applications to end logging network traffic in their debug log files.appnameNAM requests the specified application to end logging network traffic in its<br/>debug log file. The specified application must be accessing the network or<br/>you will receive a diagnostic message.NAMNAM ends logging network traffic in its debug log file.

To release the debug log file, enter the log release (LR) command.

#### LR Command

The log release (LR) command causes NAM to release its debug log file (if one exists) and/or request an application to release its debug log file. When the local debug log file is released, its contents are copied to a permanent file. Logging continues on a new local debug log file.

The command format is:

LR=mode.

modeDescriptionALLNAM releases its debug log file and/or requests all applications to release<br/>their debug log files.appnameNAM requests the specified application to release its log debug file. The<br/>specified application must be accessing the network or you will receive a<br/>diagnostic message.

NAM NAM releases its debug log file.

## **RS Command**

The reset statistics (RS) command causes NAM to dump its statistics to a permanent file and restart gathering statistics and/or request an application to dump its statistics to a permanent file and restart gathering statistics (refer to the NAM/CCP reference manuals for descriptions of the network statistics). You can use this command to help anaylze NAM and/or application performance.

The command format is:

| RS=mode. |
|----------|
|----------|

| mode    | Description                                                                                                                                                                                                                                                                                         |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL     | NAM dumps its statistics to a permanent file, resets the statistics counters<br>to 0 (zero), and continues gathering statistics and/or requests all<br>applications to dump their statistics to permanent files, reset their<br>statistics counters to 0 (zero), and continue gathering statistics. |
| appname | NAM requests the specified application to dump its statistics to a permanent<br>file, reset its statistics counters to 0 (zero), and continue gathering<br>statistics. The specified application must be accessing the network or you<br>will receive a diagnostic message.                         |
| NAM     | NAM dumps its statistics to a permanent file, resets the statistics counters to $0$ (zero), and continues gathering statistics.                                                                                                                                                                     |

## ST Command

The status (ST) command causes the NAM status display (figure 8-23) to appear on the K-display screen.

The command format is:

ST.

The NAM status display provides status information regarding all applications, couplers, and logical links currently active in the host. This display is refreshed periodically to display the current conditions of the applications and logical links.

The first line of the NAM status display contains the network invocation number (NIN), host regulation level (REG LVL), the number of applications accessing the network, and the maximum field length of NAM.

|          | = 014 |      | LVL = |     |     | OF APPL |      |      | _ = 100 |          |

| PTF, PTFS         | Permament File Transfer Facility (PTF) and Permanent File Transfer<br>Facility Sevicer (PTFS). PTF and PTFS provide access to remote<br>permanent files. A local user activates PTF with the MFLINK command<br>(refer to the NOS 2 Reference Set, Volume 3). When a remote user enters<br>the MFLINK command, NAM activates a PTFS application on the local host |

QTF, QTFS Queue File Transfer Facility (QTF) and Queue File Transfer Facility Servicer (QTFS). QTF and QTFS transfer input and output files to a remote system. When NAM is initiated, the system automatically activates QTF. When a remote host QTF application has a file to transfer, NAM initiates QTFS on the local host to service the remote request.

to service the remote request.

The

app

jsn

After initiation, QTF periodically rolls in to check for files to transfer. You can change the time interval between periodic executions of QTF. For information on changing this time interval, refer to the NOS 2 Installation Handbook.

The NAM status display shows the coupler status entries in the following format.

| est     | hn                             | nsm   | nhm                                                                  | nlm                                                                                             | ivtstat                                                                               | prust                                                                                               | npurej                                                                                                                                                                                                                                                    |

# QUEUE FILE TRANSFER FACILITY (QTF) K DISPLAY

The following procedure describes K-display usage for QTF operations under DSD control. QTF is used by both the RHF and NAM Subsystems.

1. When RHF or NAM is initiated, QTF is reinitiated automatically. If QTF is no longer running and must be restarted, either bring up the RHF application table display (described later in this section) and enter

ENABLE, ord.

ord QTF ordinal in the application table display.

or use the NAMI utility (described in section 16, Network Utilities).

2. Examine the DSD system status display (B,0). When QTF is scheduled to a control point, it is indicated on the B,0 display. The message

REQUEST \*K\* DISPLAY

appears on the B,O display.

3. Activate the K display for that control point by entering:

K,jsn

jsn QTF job sequence name.

The QTF K display (figure 8-24) appears on the left screen.

| * QUEUE FILE  | TRANSFER F  | ACILITY * |    | . \ |
|---------------|-------------|-----------|----|-----|
| NUMBER OF FIL | ES TRANSFEI | RRED XXXX |    |     |
| ACTIVE TRANSF | ERS         |           |    |     |
| FILE NAME     | LID         | PID       | DC |     |
| ABCD          | LD9         | M90       | LP |     |
| ABCG          | LD1         | M90       | IN |     |
| ACCC          | LD1         | M90       | PU |     |
| ADBA          | LD9         | M90       | SB |     |

Figure 8-24. QTF K Display

Each entry in the QTF K display has the following form.

| filename | lid pid dc           |
|----------|----------------------|
| Header   | Description          |
| filename | Name of the file.    |
| lid      | Logical identifier.  |
| pid      | Physical identifier. |
| dc       | Disposition code.    |

PIDs must be defined in the LID configuration file. Also LIDs should be defined in the LID configuration file, but can be added or deleted using the LIDOU utility (refer to section 9, L-Display Utilities).

## **REDEFINE K DISPLAY**

Use the REDEFINE utility to reconfigure 844 and 885-11/12<sup>†</sup> disk drives online and thereby logically eliminate a unit that is malfunctioning without performing a level 0 initial deadstart. A single unit or multiunit device <sup>††</sup> that fails can be replaced with an unused unit. Unused units must be available or made available across channels or on the same channel as the failing unit by physically moving the disk pack from the failing unit to the replacement unit. Table 8-8 gives the equipment requirements for reconfiguration.

<sup>†</sup>When reconfiguring an 885-11/12 disk drive, a customer engineer must be present.

the reconfiguring a multiunit device, all units of the device must be on the same controller(s).

| Operation<br>To Be<br>Performed | Current Equipment                                                        | Replacemen        | t Equipment                       | Special Considerations                                                                                                                                                                                                                                                                                             |
|---------------------------------|--------------------------------------------------------------------------|-------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Replace a<br>Unit               | No                                                                       | Not<br>necessary  | Yes, if<br>in EST                 | The system does not perform<br>perform label verification<br>on packs that are unloaded<br>before the failing unit is<br>replaced. If the unloaded<br>pack is not moved from the<br>failing unit or the wrong<br>pack is moved, the system<br>issues an error message<br>when the replacement unit<br>is accessed. |
| Recable a<br>Unit               | No                                                                       | NA                | No                                | None.                                                                                                                                                                                                                                                                                                              |

## Table 8-8. Equipment Requirements for Reconfiguration

## NOTE

There are special cases when you cannot perform an online reconfiguration. In these cases, you must perform a level 0 deadstart and define the failing device to another drive. The special cases are:

- Reconfiguring an 885-11/12 disk drive that is the only system device defined.
- Reconfiguring an 844 or 885-11/12 disk drive that is the only temporary device defined.
- Reconfiguring a device designated as an independent shared device.
- The reconfiguration sequence follows:
  - 1. Request the reconfiguration of the disk device defined by EST ordinal est by entering:

REDEFINE, est.

The message REQUEST \*K\* DISPLAY appears at the appropriate control point on the system status display (B,O). You can reenter the REDEFINE command as many times as there are devices to be reconfigured. Multispindle devices that include two or more units are considered to be one device.

If an INITIALIZE command is being processed, the REDEFINE entry is not processed until the initialization is complete.

2. Bring the REDEFINE K display (see figure 8-25) to the left console screen by entering:

K,jsn.

jsn Job sequence name of the job requesting the K display.

As shown in figure 8-25, the current EST description of the device being reconfigured appears under the heading CURRENT EQUIPMENT CONFIGURATION. The EST description of the device as changes are made appears under the heading REQUESTED EQUIPMENT CONFIGURATION. Any devices listed under IDLED EQUIPMENTS are devices that have been previously selected by your REDEFINE command but have yet to be processed in the reconfiguration run.

The K display may not list all relevant devices. If more than one device is listed, they are processed one at a time as they appear in the list with one exception: all shared devices are processed prior to nonshared devices.

You are guided through the reconfiguration process in two ways. First, by the list of commands and parameters shown on the K display, and second, by the system responses and error messages.

\*\*\*\* MASS STORAGE FAILURE RECOVERY \*\*\*\* K DISPLAY COMMANDS CLEAR CLEARS IDLE AND SUSPEND ON CURRENT EQUIPMENT. CLEAR ALL DEVICE IDLES, AND END \*CONFIG\*. INITIATES PROCESSING OF ENTERED CONFIGURATION. END GO RERUN **RESTARTS \*CONFIG\* UTILITY PROCESSING.** RESETS CURRENT EQUIPMENT TO DEFAULT PARAMETERS. RESET SUSPEND SUSPEND ALL SYSTEM OPERATION ON CURRENT EQUIPMENT. PARAMETER DEFINITIONS C1 AND OPTIONALLY C2 ARE NEW CHANNELS FOR ACCESS. CH=C1,C2 EQ=EEE SET EST ORDINAL EEE TO BE PROCESSED. UL=U1,U2 ...UN SET UNIT LIST AS SPECIFIED. UR=UU UNIT UU IS TO BE RECABLED WITH A NEW DRIVE. CURRENT EQUIPMENT CONFIGURATION. 034. DJ-1 CH05,07 UL=05 ST T REQUESTED EQUIPMENT CONFIGURATION. CH05,07 034. DJ-1 UL=05 --ST T - - -CHANGED UNITS IDLED EQUIPMENTS 027. DJ-1 CH26,32 UL=07 ST I

Figure 8-25. REDEFINE K Display (Left Screen)

3. Enter all of the valid parameters (refer to table 8-9) that define the reconfiguration characteristics for the specified device. Parameters are entered singly. Parameters are processed left to right; no terminator is necessary.

If you enter an incorrect parameter (for example, the wrong channel number), the error can be corrected by entering the correct parameter.

4. Enter

K.GO

to initiate processing of the parameters when all parameters and commands (refer to table 8-10) have been entered for the specific device. Enter this command after each set of parameters to signal the system to go ahead with the reconfiguration you have defined. If more devices remain to be reconfigured, repeat steps 3 and 4.

5. Enter

K.END

to end a reconfiguration run when there are no more devices to be processed.

Table 8-9. Reconfiguration Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CH=c1,c2                | Specifies the channel numbers ( $c_1$ and, optionally, $c_2$ ) to be used under the new device definition.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                         | Use this parameter when the entire device is to be redefined to alternate channel number(s). You can also use it to add or delete channels from an equipment definition. New channels can be added by specifying new channel numbers for a defined equipment. Channels can be deleted by specifying CH=. when deleting a unit. Acceptable values for $c_1$ and $c_2$ are from 0 to 13g for systems having 10 or less PPs; from 0 to 13g and from 20g to 33g for systems having more than 10 PPs. Leading zeros can be omitted.                   |
| EQ=est                  | Specifies the equipment with EST ordinal est is to be<br>processed. Enter this parameter when the processing of<br>equipments is order dependent; for example, when a device must<br>first be made available before it can replace a failing device.<br>The system ignores all parameters not processed before you ente<br>the EQ=est parameter. Parameters entered after EQ=est refer to<br>the specified equipment until you enter another EQ=est or a<br>command that causes the next equipment in the list to be<br>selected for processing. |
| $UL=u_1,u_2,\ldots,u_n$ | Specifies the unit list for the new configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                         | When a unit is to be replaced, added, or deleted, the entire<br>unit configuration must be entered with this parameter. The<br>equipment must be unloaded (multimainframe mode) or otherwise<br>have an unavailable status if a unit is to be added or deleted.<br>Any number of units can be changed. By specifying UL=. the<br>current unit configuration is deleted.                                                                                                                                                                          |
|                         | NOTE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                         | If the unit number specified in the UL=<br>parameter represents a unit that is not<br>defined in the EST, the unit number is<br>accepted without validation. Ensure that<br>the unit number entered represents a valid<br>device.                                                                                                                                                                                                                                                                                                                |
| UR=un                   | Specifies that the device with unit number un is to be<br>recabled. This parameter is used when a device is to be<br>physically replaced by a new device with the same unit number.<br>More than one device can be specified for recabling at the same<br>time.                                                                                                                                                                                                                                                                                  |

## Table 8-10. Reconfiguration Commands

| Command | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ABORT   | Discontinues processing of the current command. It is entered only<br>in response to a detected error condition and is used to initiate<br>error recovery procedures. This command cannot be followed<br>immediately by an END command.                                                                                                                                                                                                                                                                                                                              |
| CLEAR   | Clears the suspend and redefinition request status for the current<br>equipment. Label and read/write verification of the device is<br>performed. This command should be entered only when no further<br>processing is desired for the current equipment.                                                                                                                                                                                                                                                                                                            |
| END     | Terminates the reconfiguration processing. The K-display parameters<br>are set to the default values as control is returned. This command<br>cannot be entered immediately after an ABORT command.                                                                                                                                                                                                                                                                                                                                                                   |
| GO      | Initiates the processing of specified reconfiguration parameters previously entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IGNORE  | Informs the system on which the command was entered to ignore<br>processing on this device (multimainframe mode only). This command<br>should be entered during an add or delete unit reconfiguration run<br>on the machine(s) within the multimainframe complex which, for<br>control reasons, cannot add to or delete from the specified<br>equipment. Also, you can use this command to ignore an error<br>message pertaining to a marginally unacceptable servo timing check,<br>which is performed automatically when reconfiguring an 885-11/12<br>disk drive. |
| NEXT    | Enter this command in response to an 885-11/12 disk drive servo<br>timing check that meets requirements. This command causes<br>processing to continue with the next device or the next step of<br>processing. This command is valid only when reconfiguring 885-11/12<br>disk drives.                                                                                                                                                                                                                                                                               |
| RECHECK | Retries a verification/diagnostic process that previously gave an error. Only the commands RECHECK, ABORT, and IGNORE are accepted by the system when an error message is issued.                                                                                                                                                                                                                                                                                                                                                                                    |
| RERUN   | Sets the parameters to default values and updates the list of equipment to be reconfigured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| RESET   | Resets the parameters to default values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SUSPEND | Causes system processing on the specified device to be suspended<br>indefinitely while the device is in a not ready state. Only<br>diagnostic access to the device is allowed. All other jobs<br>accessing the device will be unable to continue until the device is<br>returned to a ready state. More than one equipment can be suspended<br>at the same time.                                                                                                                                                                                                     |

You can stop the reconfiguration procedure by entering either the K.ABORT command or the K.CLEAR command (depending on which command is posted in the list of valid commands on the K display). In either case, processing advances to the next device in the list of devices under IDLED EQUIPMENTS (see figure 8-25).

If the device specified is a shared device in a multimainframe environment and reconfiguration is not desirable on one or more of the mainframes, use the following procedure.

1. Enter

REDEFINE, est.

est EST ordinal of the shared device.

at the console of each mainframe for which reconfiguration of the shared device is not desired.

2. Enter

K,jsn.

jsn Job sequence name of the job requesting the K display.

3. Enter

K.IGNORE

and processing on the shared device in the list is ignored by that mainframe. The machine must wait until the shared device is done with its processing.

4. Enter

K.END

to end the reconfiguration procedure.

Enter either the RERUN or RESET command to clear the IGNORE command.

Figure 8-26 shows the output for a sample reconfiguration run.

| ORD | TYPE | CHANNELS | UNITS | STATUS |
|-----|------|----------|-------|--------|
| 06  | DJ-1 | CH26,32  | UL=06 | ST =   |
| 07  | DJ-1 | CH26,32  | UL=07 | ST =   |
| 10  | DJ-1 | CH32     | UL=01 | ST =   |
| 11  | DJ-1 | CH13     | UL=02 | ST =   |
| 12  | DI-1 | CH26     | UL=03 | ST =   |
| 13  | DI-1 | CH32     | UL=11 | ST =   |
| 14  | DI-1 | CH26,32  | UL=04 | ST = I |
|     |      | •        |       |        |

Following are examples of the reconfiguration of disk devices and how their status changes in the REDEFINE K display.

Example 1, returning a unit to the system:

Assume the unit of est ordinal 7, the system's spare disk drive, was used to replace a failing disk drive. Now that the defective unit has been repaired, it is to be returned as the unit of the spare disk drive.

Disk configuration before the REDEFINE:

| EST     | Equipment | Channel   | Unit          | Status |
|---------|-----------|-----------|---------------|--------|
| Ordinal | Type      | Number(s) | <u>Number</u> |        |
| 7       | DJ-0      | 00        |               | I      |

Enter the following commands:

| Command     | Description                                                                            |
|-------------|----------------------------------------------------------------------------------------|
| REDEFINE,7. | 7 is the EST ordinal of the shared device.                                             |
| K,jsn.      | jsn is the job sequence name of the job requesting the K display.                      |
| K.CH=32,26  | 32 and 26 are the channel numbers to be used by est ordinal 7.                         |
| K.UL=7      | 7 is the unit number of the device being returned.                                     |
| K.GO        | Initiates the processing of all the parameters and commands entered for EST ordinal 7. |

The system responds with the message:

EQ 7 PROCESSING COMPLETE.

To end the reconfiguration, enter:

K.END

Disk configuration after the REDEFINE:

| EST            | Equipment | Channe 1  | Unit   |        |
|----------------|-----------|-----------|--------|--------|
| <u>Ordinal</u> | Туре      | Number(s) | Number | Status |
| 7              | DJ-1      | 32, 26    | 7      |        |

Example 2, reconfiguring a failing unit:

Assume EST ordinal 10 and EST ordinal 11 are defined in the EST display. Equipment 10 is a spare unit currently not being used. Equipment 11 has a pack mounted and is the failing device. Before the failing device can be reconfigured, the spare unit must be removed from the EST. The following stipulations apply when deleting a unit from the EST:

- If the EST ordinal is defined in a single mainframe environment or if it is not shared in a multimainframe environment, then having device unavailable status (U status in the E,M display) for that EST ordinal is sufficient.
- If the EST ordinal is shared in a linked shared device multimainframe environment, then that EST ordinal must have device unavailable status and be globally unloaded (U and N status in the E,M display) before a reconfiguration can be performed.

Disk configuration before the REDEFINE:

| EST<br>Ordinal | Equipment<br>Type | Channel<br>Number(s) | Unit<br>Number | Status |
|----------------|-------------------|----------------------|----------------|--------|
| 10             | DJ-1              | 32                   | 1              | I      |
| 11             | DJ-1              | 13                   | 2              |        |

To perform the reconfiguration, enter the following commands:

| Command      | Description                                                                             |
|--------------|-----------------------------------------------------------------------------------------|
| REDEFINE,10. | 10 is the EST ordinal of the spare device.                                              |
| REDEFINE,11. | ll is the EST ordinal of the failing device.                                            |
| K,jsn.       | jsn is the job sequence name of the job requesting the K display.                       |
| K•CH=•       | Deletes the channel number(s) assigned to EST ordinal 10 from the EST.                  |
| K.UL=.       | Deletes the unit number of EST ordinal 10 from the EST.                                 |
| K.GO         | Initiates the processing of all the parameters and commands entered for EST ordinal 10. |

The system responds with:

EQ 10 PROCESSING COMPLETE.

Enter the reconfiguration commands for the failing device as follows:

| Command | Description                                                                             |
|---------|-----------------------------------------------------------------------------------------|
| K.CH=32 | 32 is the channel number that was assigned to EST ordinal 10.                           |
| K.UL=1  | l is the unit number that was assigned to EST ordinal 10.                               |
| K.GO    | Initiates the processing of all the parameters and commands entered for EST ordinal 11. |

The system responds with:

SPIN DOWN UNIT 02. 02 is the unit number of EST ordinal 11.

After the unit is spun down, the system responds with:

MOVE PACK FROM UNIT 02 TO UNIT 01 AND SPIN UP.

After the pack is moved and the new unit is spun up, the system responds with:

EQ 11 PROCESSING COMPLETE.

To end the reconfiguration, enter:

K.END

Disk configuration after the REDEFINE:

| EST            | Equipment | Channel   | Unit   | Status |
|----------------|-----------|-----------|--------|--------|
| <u>Ordinal</u> | Type      | Number(s) | Number |        |
| 10             | DJ-0      | 00        |        |        |
| 11             | DJ-1      | 32        | 1      |        |

#### Example 3, reconfiguring devices across channels:

Units may be reconfigured across channels with the REDEFINE command. Assume that EST ordinal 12 is the failing unit (or possibly the failing channel) and is on channel 26. EST ordinal 13 is the spare unit on channel 32. The following commands illustrate a reconfiguration across channels.

Disk configuration before the REDEFINE:

| EST<br>Ordinal | Equipment<br>Type | Channel<br>Number(s) | Unit<br><u>Number</u> | Status |
|----------------|-------------------|----------------------|-----------------------|--------|
| 12             | DI-1              | 26                   | 3                     |        |
| 13             | DI-1              | 32                   | 11                    |        |

Enter the following commands:

Command

## Description

REDEFINE, 12. 12 is the EST ordinal of the failing device.

REDEFINE, 13. 13 is the EST ordinal of the spare device.

K, jsn. jsn is the job sequence name of the job requesting the K display.

K.EQ=13 Selects the spare unit to be processed first.

K.SUSPEND Suspends the spare unit to clear it from the EST.

The system responds with:

SYSTEM USAGE OF EQ 13 SUSPENDED.

To continue with the reconfiguration on EST ordinal 12, enter:

| K.EQ=12 | Selects the failing unit for processing.                                                |
|---------|-----------------------------------------------------------------------------------------|
| K.CH=32 | Assigns the old channel number of EST ordinal 13 to EST ordinal 12.                     |
| K.UL=11 | Assigns the old unit number of EST ordinal 13 to EST ordinal 12.                        |
| K.GO    | Initiates the processing of all the parameters and commands entered for EST ordinal 12. |

The system responds with:

EQ 12 PROCESSING COMPLETE.

Disk configuration at this point in example 3.

| EST<br>Ordinal | Equipment<br>Type | Channel<br>Number(s) | Unit<br><u>Number</u> | <u>Status</u> |
|----------------|-------------------|----------------------|-----------------------|---------------|
| 12             | DI-1              | 32                   | 11                    | I             |
| 13             | DI-1              | 32                   | 11                    | IS            |

All SUSPEND status flags must be cleared before a reconfiguration run can be ended. The system therefore automatically selects EST ordinal 13 again for the next EST ordinal to be processed.

To continue with the reconfiguration, enter:

| Command | Description                                                                             |  |  |
|---------|-----------------------------------------------------------------------------------------|--|--|
| K.CH=26 | Assigns the old channel number of EST ordinal 12 to EST ordinal 13.                     |  |  |
| K.UL=3  | Assigns the old unit number of EST ordinal 12 to EST ordinal 13.                        |  |  |
| K.GO    | Initiates the processing of all the parameters and commands entered for EST ordinal 13. |  |  |

The system responds with:

EQ 13 PROCESSING COMPLETE.

To end the reconfiguration, enter:

K.END

Disk configuration after the REDEFINE:

| EST<br>Ordinal | Equipment<br>Type | Channel<br>Number(s) | Unit<br><u>Number</u> | Status |
|----------------|-------------------|----------------------|-----------------------|--------|
| 12             | DI-1              | 32                   | 11                    |        |
| 13             | DI-1              | 26                   | 3                     |        |

## **REMOTE BATCH FACILITY (RBF) K DISPLAY**

Whenever RBF is in operation, user connections and activity are shown in the RBF K display (refer to figure 8-27).

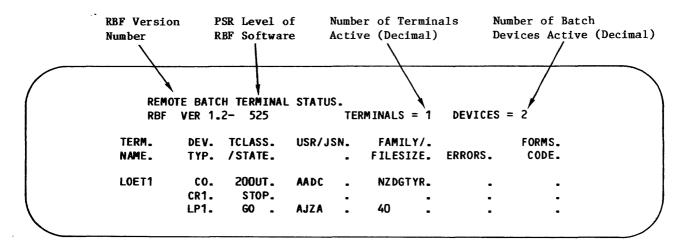

Figure 8-27. RBF K Display

Select the RBF K display with this DSD command:

K,RBF.

Data on the RBF display is updated periodically to reflect the current status of batch terminals connected to RBF.

Terminals are identified by termname, a unique name defined by the site. Terminals are displayed in alphabetical order. There are multiple lines on the K display per terminal; one line for the terminal console, and one line for each batch device (card reader, line printer, card punch, or plotter).

If there are more terminals and devices active than can be displayed on one screen, the message

MORE LINES FOLLOW.

appears at the lower left corner of the display. You can display additional screens by entering:

K.+

The K.+ command advances the display page-by-page and end-around from the last page to the first. All screens are displayed in a forward direction. Use of the console input K.- does not move the screen back to the previous display.

Entries in the display have the following format.

Header

| term | dev | tclass | usr/jsn | family/  |        | forms |
|------|-----|--------|---------|----------|--------|-------|
| name | typ | /state |         | filesize | errors | code  |

| term | Name of the terminal. A unique name, termname, assigned by the installation |
|------|-----------------------------------------------------------------------------|
| name | during network startup. This field is used for console devices only.        |

Description

dev Device type. The device type code is one of the following: typ

CodeDescriptionCOConsole device.CPiCard punch.CRiCard reader.LPiLine printer.PLiPlotter.

The ordinal number, i, of the device can range from 1 to 7.

tclass If this field is in the same line as the termname, the contents of the
/state field is the terminal class mnemonic (refer to the Remote Batch Facility
Reference Manual). If this field occurs in a line not containing a termname,
the device status code is one of the following:

#### Description Code ABRT File in transmission is to be discarded. CONN Device is connected (initial state). END Device stops transmission at EOI. ENDA File being aborted; device will stop at EOI. ENDC End connection. ENDI Device will stop at EOI; idle down requested. GO Device is ready for input.

The system input queue has reached its limit of jobs waiting to begin execution. QUEUE FULL

forms Forms code for output devices as specified by the user and defined by the code site.

## **REMOTE HOST FACILITY (RHF) K DISPLAY**

The Remote Host Facility (RHF) links NOS to a loosely coupled network (LCN) providing transfer of permanent files, queued files, and maintenance facilities for the LCN hardware. Each system in an LCN configuration is connected to one or more LCN trunks by network access devices (NADs). Several types of NADs are available, allowing the connection of various types of computer systems to an LCN. Each system has an RHF that provides some or all of the following capabilities.

RHF runs at a control point and contains an operator interface package, control tables, network application code, and the PP routines that drive the RHF network hardware.

The following applications are also available as part of RHF:

#### Application

#### Description

- PTF, PTFS Permanent File Transfer Facility (PTF) and Permanent File Transfer Facility Servicer (PTFS). PTF and PTFS provide users access to remote permanent files. A local user activates PTF with the MFLINK command (refer to the NOS 2 Reference Set, Volume 3). When a remote user enters the MFLINK command, RHF activates a PTFS application on the local host to service the remote request.
- MLTF Maintenance Logging Transfer Facility (MLTF). MLTF provides maintenance logging capabilities for local and remote mainframe NADs. All local NAD errors are logged to the binary maintenance log (BML). All remote mainframes that have error logging enabled (refer to the network path table display described later in this section) log errors. This application starts automatically when RHF is initiated.
- QTF, QTFS Queue File Transfer Facility (QTF) and Queue File Transfer Facility Servicer (QTFS). QTF and QTFS allow you to transfer input and output files to a remote system. When RHF is initiated, the system automatically activates QTF. When a remote host QTF application has a file to transfer, RHF initiates QTFS on the local host to service the remote request.

After initiation, both QTF and MLTF periodically roll in to check for files to transfer or to log NAD errors. You can change the time interval between periodic executions of either QTF or MLTF. For information on changing this time interval, refer to the NOS 2 Installation Handbook.

The following subsections describe the initiation, operation, control, and termination of the RHF.

## **RHF INITIATION**

Before network operation can begin, you must initiate RHF using the DSD RHFffff command (refer to section 5, DSD Commands).

When RHF is initiated, RHF generates jobs for loading NAD controlware for all local NADs that are defined in RHF's configuration and have an EST status of ON.

When RHF is initiated, it starts all enabled applications defined by the network configuration as autostart applications (refer to RHF - Configuration File Generation in the NOS 2 Installation Handbook). These applications are typically QTF and MLTF.

## **OPERATOR INTERFACE**

The operator interface for RHF consists of using the following displays.

| Display | Description |
|---------|-------------|
|         |             |

application table Lists all active applications.

network path table Shows how the remote hosts are connected to the local host.

An example of each display is shown later in this section. To understand how to use the information provided in the displays it is helpful to understand the sample LCN network shown in figure 8-28.

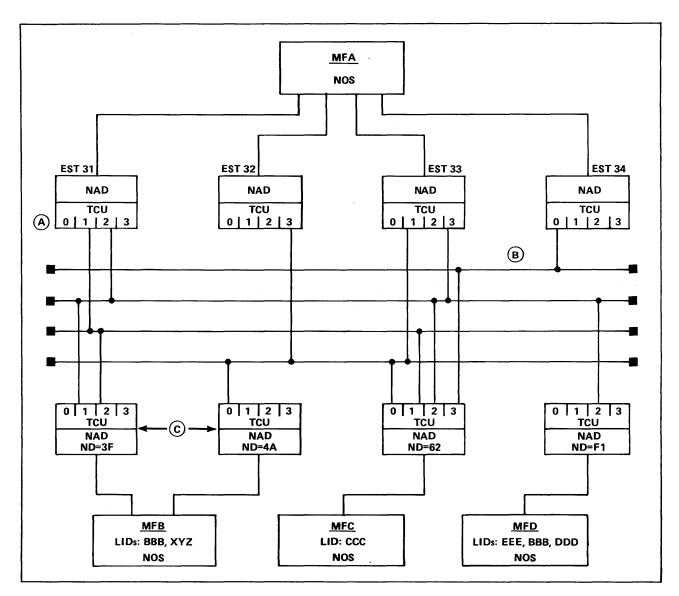

Figure 8-28. Sample LCN

MFA is the local NOS host and MFB, MFC, and MFD are the remote NOS hosts. MFA has four EST ordinals set up during installation (EST 31, 32, 33, and 34) to be used with the three remote hosts. Each NAD can connect to a maximum of four channels that can be used to communicate with NADs. These trunk control units (TCUs) are represented by the numbers 0, 1, 2, and 3 in the diagram (refer to A in figure 8-28).

The horizontal lines between the NADs of the local mainframe (MFA) and the NADs of the remote mainframes (MFB, MFC, and MFD) depict the connections between the NADs. For example, the top horizontal line shows the connections between the channels starting at TCU 0 of the local host and TCU 3 of the remote host (refer to B in figure 8-28).

Also during the installation process, each remote NAD is given a remote NAD address to uniquely identify that particular NAD. For example, the remote host MFB has two NADs associated with it. Their remote NAD addresses are 3F and 4A (refer to C in figure 8-28).

### **RHF Commands Under K Display**

Use the RHF K display to communicate with RHF. Bring up this display with this DSD command:

K,RHF.

Two K displays are available under RHF, the application table display (see figure 8-29) and the network path table display (see figure 8-30). When you first enter K,RHF, the application table display appears. The next time and subsequent times you enter K,RHF, the display that appears will be either the application table or the network path table, whichever was displayed last.

The following commands are available under the RHF K display:

| Command                                                     | Function                                                                     |
|-------------------------------------------------------------|------------------------------------------------------------------------------|
| APPL                                                        | Displays the application table (see figure 8-29).                            |
| IDLE                                                        | Begins the idle-down process of RHF and all its associated applications.     |
| PATH                                                        | Displays the network path table (see figure 8-30).                           |
| ord,ND=rna,AC=rnac,<br>DD=dd,RT=rteb,<br>LT=1teb,LOG=status | Modifies entries associated with the network path table display ordinal ord. |
| +                                                           | Pages the current display forward.                                           |
| -                                                           | Pages the current display backward.                                          |

## **Application Table Display**

:

The application table display (see figure 8-29) lists all active applications.

| ORD    | APPL      | ENABLED        | MAX<br>COPIES | ACTIVE<br>COPIES |        | MAX<br>NNECTS |
|--------|-----------|----------------|---------------|------------------|--------|---------------|
| OND    |           | LINDELD        | 001120        | 001 120          |        |               |
| 1      | QTF       | YES            | 1             | 1                |        | 4             |
| 2      | QTFS      | YES            | 4             | 3                |        | 1             |

| AAQT   | 31        | 1              | ACAL          |                  | 33     | 2             |
| ACXQ   | 24        | 0              |               |                  |        |               |

 $\ensuremath{^\dagger}\xspace$  USRAP represents an application written by the site.

Figure 8-29. Application Table Display

Each entry in the display appears in the following format.

| ord appl en  | nabled maxcopies activecopies maxconnects                                                 |
|--------------|-------------------------------------------------------------------------------------------|
| jobname jobo | ord connects                                                                              |
| Header       | Description                                                                               |
| ord          | Application table display ordinal.                                                        |
| appl         | Name of the application.                                                                  |
| enabled      | Specifies whether the application communicates with RHF.                                  |
| maxcopies    | Maximum number of copies of the application that can simultaneously communicate with RHF. |
| activecopies | Number of copies of the application that are currently communicating with RHF.            |
| maxconnects  | Maximum number of network connections allowed by each copy of the application.            |
| jobname      | Job sequence name of the application.                                                     |
| jobord       | Excecuting job table ordinal of the application.                                          |
| connects     | Number of network connections currently used by this copy of the application.             |

| 6   |     | 032 | 7  | NO      | 0001                       | 1000                        | 62                    | 0    | FOFO           | 0            | NO          |
| 7   |     | 033 | 10 | ) YES   | 0101                       | 1010                        | 62                    | 0    | FOFO           | 2            | NO          |
| 8   |     | 034 | 11 | YES     | 1000                       | 0001                        | 62                    | 0    | FOFO           | 0            | NO          |
| 9   | MFD | 031 | 6  | YES     | 0010                       | 0010                        | F1                    | 0    | FOFO           | 0            | NO          |
| 10  | _   | 033 | 10 | ) YES   | 0001                       | 0010                        | F1                    | 0    | FOFO           | 0            | NO          |

<sup>†</sup>A 1 means that a TCU is enabled. A 0 means that a TCU is not enabled. The leftmost digit of these entries corresponds with TCU 0, the next with TCU 1, and so forth. For example, if a NAD has TCUs 1 and 2 enabled, the corresponding entry should be 0110. Refer to figure 8-28.

Figure 8-30. Network Path Table Display

Each entry in the display appears in the following format.

| ord  | pid | est | ch | enabled | trunk | remote<br>trunk<br>enables | nad      | dest | _ | con<br>count | log<br>errs |  |
|------|-----|-----|----|---------|-------|----------------------------|----------|------|---|--------------|-------------|--|
| Head | er  |     |    |         |       | I                          | escripti | lon  |   |              |             |  |

ord Network path table display ordinal.

| pid | Physical | identifier | of | the | remote | mainframe | for | which | the | path | is |
|-----|----------|------------|----|-----|--------|-----------|-----|-------|-----|------|----|
|     | defined. |            |    |     |        |           |     |       |     |      |    |

est EST ordinal of the NAD that defines the local end of the path.

ch Channel number of the NAD that defines the local end of the path.

enabled Specifies whether RHF uses the path for starting new connections. For example, if a customer engineer wants to run diagnostics on a trunk connecting two NADs (local and remote), you would disable the appropriate path. When the connection count on that path falls to zero, the customer engineer can run concurrent diagnostics on that trunk without disturbing the operation of RHF.

| Header                     | Description                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local trunk<br>enables     | Bit pattern specifying which TCUs to use on the local NAD for communica-<br>tions with the remote NAD.                                                     |
| remote<br>trunk<br>enables | Bit pattern specifying which TCUs the remote NAD uses in returning communications to the local NAD.                                                        |
| remote nad<br>addr         | Hardware address (hexadecimal) of the remote NAD.                                                                                                          |
| dest                       | Destination device address (hexadecimal).                                                                                                                  |
| access code                | Access code of the remote NAD; the software access code is the two<br>leftmost characters and the hardware access code is the two rightmost<br>characters. |
| con count                  | Number of connections currently using this path.                                                                                                           |
| log errs                   | Specifies whether the MLTF application logs trunk errors (detected by the remote NAD) into the binary maintenance log (BML).                               |

When the network path table is displayed, you can enter the following command to make changes.

ord,ND=rna,AC=rnac,DD=dd,RT=rteb,LT=1teb,LOG=status.

| Parameter | Description                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ord       | Network path table display ordinal.                                                                                                                                                                                                                    |
| rna       | New remote NAD address in hexadecimal.                                                                                                                                                                                                                 |
| rnac      | New remote NAD access code in hexadecimal.                                                                                                                                                                                                             |
| dd        | New remote NAD destination device address in hexadecimal.                                                                                                                                                                                              |
| rteb      | New remote trunk enable bit pattern (nonzero 4-bit binary number with the leftmost bit representing TCU 0).                                                                                                                                            |
| lteb      | New local trunk enable bit pattern (nonzero 4-bit binary number with the<br>leftmost bit representing TCU 0). The same number of bits must be set<br>for both RT and LT or the command will be rejected.                                               |
| status    | Status of error logging for the specified remote NAD. Enter YES to have<br>MLTF periodically copy the trunk errors occurring on the specified<br>remote NAD to the binary maintenance log (BML). MLTF does not copy<br>trunk errors when you enter NO. |

ord is the only required parameter and it must come first. All other parameters are optional and can appear in any order, but at least one, besides ord, must be present.

## NOTE

Any change to rna, dd, or status for a given path results in an equivalent change for all paths using that remote NAD. This is because rna, dd, and status are associated with the remote NAD rather than the path to the remote NAD. When RHF determines a NAD or a NAD trunk control unit (TCU) on a path is bad, it turns off the NAD or path and notifies you with a message on the B,O display. It displays either

RHF, NAD ON EST est HAS BEEN TURNED OFF.

or

RHF, BAD TCU ON PATH xxx, PATH TURNED OFF.

## **RHF** Commands Available Under Application or Network Path Display

When the application table or network path table is displayed, you can enter the following commands to enable or disable the application or network path.

ENABLE, ord.

or

DISABLE, ord.

Parameter

ord

Ordinal of the application or network path on the current display.

Description

For example, if the application table display is up, ENABLE,ord enables the application specified by the display ordinal ord.

If an application is being enabled (whether currently enabled or disabled) and that application is defined as an autostart application, RHF initiates a copy of that application. This feature may be used, for example, if the MLTF application is normally disabled and you want to start logging NAD errors. It may also be used if the copy of the QTF application has been dropped accidentally and a new copy of the QTF application must be started.

## **RHF TERMINATION**

You can terminate an RHF operation using the IDLE command.

The command format is:

IDLE.

When you enter the IDLE command the system waits for applications to stop and the message IDLE-DOWN IN PROGRESS appears on the system status display. When activity stops, the system drops RHF and the message RHF ENDED appears. The IDLE command allows a gradual shutdown of RHF activities. No new connections are allowed.

## SCOPE 2 STATION FACILITY (SSF) K DISPLAYS

The following commands control operation of the SSF Subsystem.<sup>†</sup> Initiate the SSF Subsystem before issuing any commands. SSF can be initiated automatically when the system is brought up, either manually by entering an SSFffff command, or by entering the ENABLE,SSF command.

## **OPERATOR INTERFACE**

The SSF uses the K display for operator communications; therefore, the K display must be assigned to SSF before any other SSF Subsystem commands can be entered. Use the following command to assign the K display to SSF.

K,SSF.

### STATION LOGIN

After SSF is assigned to a control point, SSF searches the equipment status table (EST) for a SCOPE 2 communication coupler. If SSF finds an available coupler, it asks the SCOPE 2 mainframe to establish communications. If no coupler is found, a message appears at the console indicating that SSF is ready to log in to a SCOPE 2 mainframe. To log in, first enter an ON,est command (refer to section 5, DSD Commands, for a description of the ON,est command), then enter the following command.

K.LOGIN.

#### **ENABLING AND DISABLING FILE TRANSFERS**

File transfers between NOS and SCOPE 2 must be enabled before actual file transfers can begin; however, this occurs automatically when the SSF Subsystem is logged in. You can disable file transfers by entering the following command.

K.OFFSTAT,x.

Parameter

#### Description

x Specifies the SCOPE 2 mainframe PID.

When you enter a K.OFFSTAT command, file transfers in progress are completed, but no new file transfers are initiated. This command does not affect command, display, or message processing.

File transfers can be reenabled using the following command.

K.ONSTAT,x.

Parameter

Description

x

Specifies the SCOPE 2 mainframe PID.

<sup>&</sup>lt;sup>†</sup>Refer to appendix C for more information on the SSF Subsystem.

## STATION RECOVERY

If NOS fails, follow the SSF initiation procedure as described in section 5, DSD Commands, to recover the station. SSF does not require reinitiation if SCOPE 2 fails or if there is an FLPP failure that results in a reload of the FLPP.

## STATION DISCONNECTION AND LOGOUT

Station disconnection refers to the termination of communications between SSF and SCOPE 2 as a result of a hardware or software error or as a result of an operator command. When the disconnection occurs, all pending requests to the SCOPE 2 mainframe (such as screen refreshes, messages, and acknowledgements) are dropped.

Before entering an operator command to disconnect SCOPE 2, you should perform the following steps.

- 1. Idle down the file transfers by entering the K.OFFSTAT command. The station is idle when all staging SPOT jobs are finished and the spooling SPOT job has been swapped out.
- 2. If the system is in restricted or privileged mode, enter the CLROP command to relinquish operator control of SCOPE 2. Refer to the SCOPE 2.1 Operator's Guide for a description of the CLROP command.

To disconnect the SCOPE 2 mainframe, you can either drop the station control point by issuing a STOP or IDLE Subsystem command as described in section 5, DSD Commands, or you can log out of a specific SCOPE 2 mainframe by using the following command.

K.LOGOUT.

or

K.LOGOUT, pid.

#### Parameter

pid

## Description

PID of the mainframe you want to disconnect (required only in a multimainframe environment).

## FILE TRANSFER LIMIT COMMANDS

The following commands allow you to set limits on the number of file transfers that can be in progress concurrently for various types of file operations. The system default value for each of the following commands is 2; however, the default values can be changed, as an installation option, when SSF is installed. Refer to the NOS 2 Installation Handbook for more information on the default values for file transfer limit commands.

## **STAGED FILE TRANSFER COMMANDS**

The following commands control the number of concurrent SPOT jobs performing staged file operations:

| Command          | Description                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.PURGE,pid,n.   | Specifies the maximum number of concurrent SPOT jobs allowed to purge files from a NOS permanent file device. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of purge operations $(0 \le n \le 7)$ .                            |
| K.READTP,pid,n.  | Specifies the maximum number of concurrent SPOT jobs allowed to read tape files from NOS to SCOPE 2. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of read operations ( $0 \le n \le 7$ ).                                     |
| K.WRITETP,pid,n. | Specifies the maximum number of concurrent SPOT jobs allowed to write tape files from SCOPE 2 to NOS. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of write operations ( $0 \le n \le 7$ ).                                   |
| K.GETPF,pid,n.   | Specifies the maximum number of concurrent SPOT jobs allowed to read permanent files from NOS to SCOPE 2. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of permanent file read operations ( $0 \le n \le 7$ ).                 |
| K.SAVEPF,pid,n.  | Specifies the maximum number of concurrent SPOT jobs allowed to write files from SCOPE 2 to a NOS permanent file device. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of permanent file write operations ( $0 \le n \le 7$ ). |

## SPOOLED FILE TRANSFER COMMANDS

The following commands control the number of I/O files that the spooling SPOT job xSTA can transfer concurrently. Separate limits can be defined for both input and output files; however, the system limits the combined total of input and output files to four concurrent transfers.

| Command         | Description                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.INPUT,pid,n.  | Specifies the maximum number of concurrent input file transfers from NOS terminals to SCOPE 2. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of input files (0 $\leq$ n $\leq$ 4). |
| K.OUTPUT,pid,n. | Specifies the maximum number of concurrent output file transfers from SCOPE 2 to NOS terminals. pid is the PID of the SCOPE 2 mainframe. n is the maximum number of output files ( $0 \le n \le 4$ ). |

## TRANSACTION FACILITY (TAF) K DISPLAYS

The following commands control operation of the TAF Subsystem. Initiate the TAF Subsystem by using the TAFffff command before issuing these commands.

## **INITIATING TAF K DISPLAY**

When the transaction executive is brought to a control point, the message REQUEST \*K\* DISPLAY appears at the control point if a DISPLAY,ON command is specified in the TAF configuration file. Respond with the entry:

K, TAF.

Any of the following initialization commands can then be entered. If no values are to be changed, enter the command:

K.END.

Values are decimal unless otherwise indicated.

| Command  | Description                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| K.BFL=n. | Changes the starting and minimum field length allocated by TAF to CRM (200008 $\leq$ n $\leq$ 1000008). Default is 700008.                          |
| K.CMB=n. | Changes the maximum number of communication blocks allowed to the TAF Subsystem (7 $\leq$ n $\leq$ 40). Default is 40.                              |
| K.ECS=n. | Sets the extended memory field length to be used by the transaction executive; n is octal thousands of words. Default is $0$ .                      |
| K.EFL=n. | Changes the maximum additional central memory field length made available to CRM for buffers and capsules ( $0 \le n \le 100000_8$ ). Default is 0. |
| K.END.   | Ends input of the transaction executive initialization parameters.<br>Initialization is completed when the TAF K display appears.                   |

| Command           | Description                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.ERO=CRF,op.     | Specifies whether to override certain I/O and logic errors when processing the communication recovery files (CRF).                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                |
|                   | op                                                                                                                                                                                                                                                                                                                                                 | Description                                                                                                                                                                                                                    |
|                   | NO                                                                                                                                                                                                                                                                                                                                                 | Aborts if $I/0$ or logic errors are encountered while processing the communication recovery files. This is the default setting.                                                                                                |
|                   | YES                                                                                                                                                                                                                                                                                                                                                | I/O or logic errors encountered on a run unit header<br>record result in the loss of that run unit with no<br>indication to the terminal user. The loss is noted on<br>the recovery report.                                    |
|                   |                                                                                                                                                                                                                                                                                                                                                    | I/O or logic errors encountered on a message record<br>within a run unit result in a loss of that run unit. A<br>status field is set in the run unit header, allowing TAF<br>to inform the terminal user of the run unit loss. |
|                   |                                                                                                                                                                                                                                                                                                                                                    | I/O or logic errors encountered on the CRF header record result in an unconditional abort of the TAF Subsystem.                                                                                                                |
| K.GO.             | -                                                                                                                                                                                                                                                                                                                                                  | of the transaction executive initialization parameters.<br>tion is complete when the TAF K display appears.                                                                                                                    |
| K.INT=typ,fileid. | Specifies which communication recovery files (CRF) are to be<br>initialized. This is the only way to initialize a CRF. Files<br>specified on a RECOVER command in the TAF configuration file and<br>specified in this command are initialized. Files specified on a<br>RECOVER command but not specified in this command are used for<br>recovery. |                                                                                                                                                                                                                                |
|                   | base recove                                                                                                                                                                                                                                                                                                                                        | nd also specifies whether CYBER record manager (CRM) data<br>ery files are initialized or recovered. For CRM recovery<br>s command is valid regardless of TAF assembly parameters.                                             |
|                   | typ                                                                                                                                                                                                                                                                                                                                                | Description                                                                                                                                                                                                                    |

- CRF Communication recovery files. This parameter is valid only if the installation parameter IPTAR equals 1.
- CRM CYBER Record Manager after-image and before-image recovery files.

Command

## Description

fileid

## Description

- n A digit from 1 to 7 that defines a CRF to be initialized. The digit corresponds to the ID parameter on the RECOVER command in the TAF configuration file. This parameter is not valid for CRM recovery files.
- ALL If typ is CRF, all communication recovery files defined by RECOVER commands in the TAF configuration file are initialized. If typ is CRM, all CRM recovery files are initialized.

This parameter must be used with caution when typ is CRM since the CRM update history currently on the after-image recovery files is lost.

NOTE

- NONE If typ is CRF, communication recovery files are initialized; all communication recovery files specified in RECOVER commands in the TAF configuration file are recovered. If typ is CRM, all CRM data bases are recovered based on information in the existing recovery files. No CRM recovery files are initialized. This fileid is the default for both typ=CRF and typ=CRM.
- K.MFL=n. Sets the maximum field length to be used by the transaction executive ( $40000 \le n \le 376600$ ). Default is 376600.
- K.REC=a. Specifies whether to set the recovery bit in the user area of each terminal status table entry (YES or NO). If YES, the user recovery bit is set. If NO, the value of the user recovery bit is not changed from what it was before the command was issued. Default is NO.
- K.SCP=n. Changes the number of subcontrol points  $(2 \le n \le 31)$ . Default is 31.
- K.STOP. Aborts the TAF Subsystem initialization unconditionally.
- K.TFL=n. Changes the value used as the upper bound for TARGET. This is the amount of memory CRM uses for data and index blocks  $(10000_8 \le n \le 100000_8)$ . Default is 300008. For more information, refer to the CYBER Record Manager Advanced Access Methods Version 2 Reference Manual.

# K.TLF=filename. Changes the name of the system task library file (any valid file name). Default is TASKLIB.

## **RESTARTING TAF K DISPLAY**

On a level 3 recovery deadstart, or if the TAF Subsystem aborts, the TAF procedure file automatically restarts TAF by transferring control to the TAF automatic recovery program. The TAF automatic recovery program recovers the central memory pointers and variables defined during TAF initiation.

If a DISPLAY,ON command is in the TAF configuration file, the automatic recovery program brings up the K display on the left console screen. This display is identical to the initial K display, except that values specified in the TAF initiation replace any default values that were in the initial display.

## TAF K DISPLAY

When the TAF Subsystem is executing, the TAF K display indicates the:

- Latest transaction sequence number.
- Number of words of unused memory.
- Maximum field length.
- Global task dump limit.
- Subsystem default values for memory dump parameters.

The TAF K display appears on the system console as shown in figure 8-31.

The subsystem default values are used to control memory dumps when parameters are not included in the CMDUMP or DSDUMP command. Any of these default values can be changed by specifying the corresponding parameter in the K.DSDUMP command.

| TRANSACTION EXECUTIVE STATUS           | DISPLAY        | $\setminus$ |
|----------------------------------------|----------------|-------------|
| SEQUENCE NUMBER                        | 1              |             |
| UNUSED FL 3000                         | · · · · ·      |             |
| MAXIMUM FL 377700                      |                |             |

Figure 8-31. TAF K Display

The default parameter values for the CMDUMP and DSDUMP commands are given on the TAF K display shown in figure 8-31.

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| DB        | This parameter is not used. It is retained for compatibility with previous releases of NOS. |
| EP        | Exchange package:                                                                           |
|           | 0 Do not dump the exchange package.                                                         |
|           | 1 Dump the exchange package.                                                                |
| FW        | First word address of the task memory to be dumped.                                         |
| LW        | Last word address of the task memory to be dumped.                                          |
| OQ        | Output queue:                                                                               |
|           | BC Local batch.                                                                             |
|           | RB Remote batch.                                                                            |
|           | PF Permanent file.                                                                          |
| QD        | Queue destination:                                                                          |
|           | User name (if OQ=BC).                                                                       |
|           | Equipment identifier (if OQ=RB).                                                            |
|           | Permanent file name (if OQ=PF).                                                             |

## TAF K-DISPLAY COMMANDS

When the transaction executive is at its control point, the following commands can be entered from the system console or submitted from tasks using the KPOINT request. Any task can issue the K.DUMP command. Only tasks that reside on the system task library can issue the other K-display commands. (Refer to the TAF Reference Manual for additional information on the KPOINT request and the system task library.)

| Command            | Description                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.ASSIGN,est.      | Assigns a magnetic tape unit to be used for a journal file. est is the EST ordinal of the tape unit. The first form of the command                                                |
| or                 | makes unit est available for the transaction executive to assign to<br>the next tape journal file that encounters end of reel. Two tape                                           |
| K.ASSIGN,est,db,n. | units may be preassigned. If a tape has not been preassigned in<br>this manner, an end-of-reel on a journal file causes subsequent<br>entries for that file to be placed on disk. |

## Description Command The second form of the command forces journal file n (n=1, 2, or 3) for data base db, defined as a tape file, from disk to tape. The transaction executive copies the data from the disk journal file to tape est and places all subsequent entries for that file on the tape. This command is necessary after the transaction executive initialization to assign tape units to the tape journal files or after an end-of-reel on a tape journal file when no tape had been preassigned to the transaction executive. All data residing on the disk for the tape journal file must fit on the tape assigned by this command or the transaction executive will unload the tape and issue the message \*UNABLE TO USE TAPE\*. K.DEBUG. Turns on the application interface program (AIP) debug option, which logs all messages on trace file ZZZZZDN. Use this command only when TAF is installed with the DEBUG option. K.DROP.n. Drops an executing task at subcontrol point n. K.DSDUMP,FW=addr, Allows you to modify the standard system default parameters LW=addr,EP=pkg, controlling memory dumps. The command does not directly cause a OQ=outg,QD=qdest, dump. Rather, it sets default values to be used when a subsequent DB=db. CMDUMP request is received or when abort conditions occur. Refer to TAF K Display, earlier in this section, for explanations of the parameters. K.DUMP,fwa,1wa. Dumps all or part of the field length of the Transaction Facility from the first word address (fwa) to the last word address (1wa) of the area to be dumped. The default value for fwa is 0 and for lwa is 3777778. The default base is octal. If no parameters are specified, the entire field length is dumped. The output is routed to a printer that has an ID of 0. Unlike other K-display commands, the K.DUMP command can be issued from any task. Other K-display commands can be issued by tasks only if they are on the system task library (refer to the TAF Reference Manual). Since secure information may be contained in a dump of the Transaction Facility, the following safeguards have been set up to protect dumped information; however, the installation must take the ultimate responsibility for the protection of dumped information. The global task dump limit (GTDL) can be set by the K.DUMPLIM command to limit the number of times the K.DUMP command can be issued from tasks. The initial value of the GTDL is 0 (zero), so the K.DUMP command is disabled from use by a task by default. For all dumps of the Transaction Facility, whether you • initiated it or a task did, a one-page header precedes the dump. This header page indicates the output is secure and should be given only to the TAF central site systems analyst. When the Transaction Facility is dumped, the message TAF FIELD LENGTH DUMP RELEASED is issued to the system dayfile, the Transaction Facility dayfile, and line one of the

control point.

| Command                     | Description                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.DUMPLIM,n.                | Sets GTDL to value n (0 $\leq$ n $\leq$ 99999999). If n is not specified, the GTDL is set to 0.                                                                                                                                                                                                                                            |
|                             | The GTDL is the number of times the K.DUMP command can be issued<br>from tasks. This value is displayed on the TAF K display shown in<br>figure 8-31. The initial value of the GTDL is 0. When the GTDL is<br>0, no dumps of the Transaction Facility can occur from tasks. Thus,<br>the K.DUMP command is disabled from tasks by default. |
|                             | To enable the K.DUMP command for tasks, issue the K.DUMPLIM command<br>to set the GTDL to a value greater than zero. Each time a task<br>issues a K.DUMP command, the GTDL is decreased by one until it<br>equals zero. When the first K.DUMP command is issued from a task<br>with the GTDL equal to zero, the message                    |
|                             | GLOBAL TASK DUMP LIMIT EXHAUSTED                                                                                                                                                                                                                                                                                                           |
|                             | is issued to the Transaction Facility dayfile, the system dayfile, and line one of the control point. Also, the message                                                                                                                                                                                                                    |
|                             | DUMPS LOST                                                                                                                                                                                                                                                                                                                                 |
|                             | is displayed on the K display in place of the value of the GTDL.<br>This message remains until the value of GTDL is set to a value<br>greater than or equal to zero. The K.DUMPLIM command should be used<br>with care in system tasks, since this might allow unauthorized users<br>to alter the GTDL.                                    |
| K.IDLE.                     | Idles down the transaction control point. Once idle down has been initiated, no new transactions will be permitted but currently executing transactions will be allowed to finish.                                                                                                                                                         |
| K.JEND,db,n.                | Forces end-of-reel processing (writes an EOI and rewinds the file)<br>on tape journal file n of data base db. If n is not a tape journal<br>file, the command is ignored.                                                                                                                                                                  |
| K.MAXFL,n.                  | Alters the transaction executive maximum field length. The<br>transaction executive does not attempt to obtain more than n words<br>of storage. This command is rejected if the value for n is more<br>than 3766008 or less than the field length currently required for<br>TAF.                                                           |
| K.MESSAGE,TN=b.<br>message. | Directs the transaction executive to send message to a terminal specified by terminal name b.                                                                                                                                                                                                                                              |
| K.NODEBUG.                  | Turns off the application interface program (AIP) debug option,<br>which logs all messages on trace file ZZZZZDN. Use this command<br>only when TAF is installed with the DEBUG option.                                                                                                                                                    |
|                             |                                                                                                                                                                                                                                                                                                                                            |

| Command                                       | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.OFFTASK,a,db.                               | Disables the use of task a, where a is the task name in the data<br>base db task library directory (dbTASKL). The data base name db is<br>not specified for tasks in the system task library.                                                                                                                                                   |
| K.ONTASK.a,db.                                | Reverses the effect of a previous OFFTASK command for the specified<br>task a in the data base db task library directory (dbTASKL). The<br>data base name db is not specified for tasks in the system task<br>library (TASKLIB).                                                                                                                |
| K.ROLLTIM, nnnnnn.                            | Changes the amount of time that TAF will retain its field length<br>between communication input messages; nnnnnn is specified in units<br>of milliseconds. Refer to the installation parameter ITRTL in the<br>NOS 2 Installation Handbook.                                                                                                     |
| K.SWITCH.                                     | Causes the console K display to change to a display listing all<br>allowable console commands. When K.SWITCH is entered a second time,<br>the normal display returns. This command activates task KDIS and<br>forces TAF to remain rolled in.                                                                                                   |
| K.TBCON,nn.                                   | Changes the number of TAF/CRM batch concurrency users; nn is less<br>than or equal to the value specified on the TBCON command in TAF's<br>configuration file (TCF).                                                                                                                                                                            |
| K.TST,TN=a,DB=db,<br>U=nnnn,UL=mmmm,<br>NN=b. | Changes entries in the terminal status table for terminal a. The<br>following entries can be changed: data base name db, user area<br>upper 12 bits (nnnn), user area lower 12 bits (mmmm), and new<br>terminal name b. The changes do not affect the network and<br>simulation files. Do not use this command if the terminal is logged<br>in. |

# TAF/ CRM STATUS K DISPLAYS AND COMMANDS

You can use the K display to monitor the status of CRM, CRM data bases, or CRM data base permanent files while TAF/CRM is running if CRMTASK is present on the system task library. To get the CRM status K display enter:

#### K.DIS, CRMTASK.

After the K display is assigned to the task, the display in figure 8-32 is brought to the left screen.

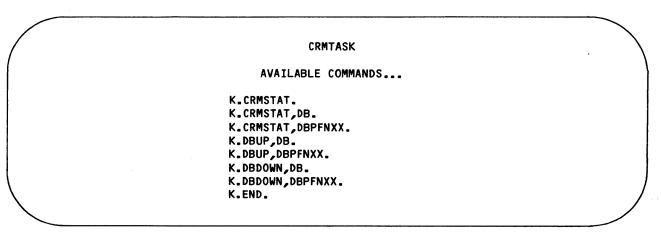

Figure 8-32. CRMTASK K Display

The following commands are available under CRMTASK.

| Command           | Description                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.CRMSTAT.        | Selects the CRM status K display (see figure 8-33). This display shows the status of all CRM data bases.                                                                                                        |
| K.CRMSTAT,db.     | Selects the CRM data base status K display (see figure 8-34). This display shows the status of the specific CRM data base with identifier db. It also shows the file name and status of the before-image files. |
| K.CRMSTAT,dbfile. | Selects the CRM file status K display (see figure 8-35). This<br>display shows the status of the specific permanent file in a CRM<br>data base with file name dbfile.                                           |
| K.DBDOWN,db.      | Makes a specific CRM data base with identifier db unavailable for processing. When this command executes, the CRMTASK command directory appears on the K display.                                               |

| Command          | Description                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.DBDOWN,dbfile. | Makes a specific permanent file in a CRM data base with file name<br>dbfile unavailable for processing. When this command executes, the<br>CRMTASK command directory appears on the K display. |
| K.DBUP,db.       | Makes a specific CRM data base with identifier db available for processing. When this command executes, the CRMTASK command directory appears on the K display.                                |
| K.DBUP,dbfile.   | Makes a specific permanent file in a CRM data base with file name<br>dbfile available for processing. When this command executes, the<br>CRMTASK command directory appears on the K display.   |

Figure 8-35. CRM File Status K Display

For the CRM status and CRM data base status displays, if all the information does not fit on one screen, you can bring up additional pages by entering the following command.

К.+.

To return to the first page of the display, enter the following command.

K.-.

At any time you can return to the initial CRMTASK K display (figure 8-32) by entering the following command.

K.MENU.

To end CRM status K-display processing, enter the following command.

K.END.

# **L-DISPLAY UTILITIES**

This section documents the following L displays and the utilities used to present them.

Description

| I dieplay i | s like the K display in that you must start the program by entering the pa                                            |
|-------------|-----------------------------------------------------------------------------------------------------------------------|
| SUBSYST     | Displays subsystem information.                                                                                       |
| SCTD        | Displays the contents of the service class control table, which shows the valid service classes for each origin type. |
| QDSPLAY     | Displays the contents of a file in the queued file table (QFT).                                                       |
| LIDOU       | Displays logical identifier table (LID).                                                                              |
| FOTD        | Displays family ordinal table (FOT).                                                                                  |

The L display is like the K display in that you must start the program by entering the name of the utility. When the L display is ready for use, DSD assigns it to the left screen automatically. Only one L-display program is active at a time. The program need not occupy a control point or memory while you are looking at the display.

Using the L display, you can run any utility program you have created. The L display is an interface between your program and DSD. This interface allows the site analyst to write CPU programs that show displays on the system console.

All entries must be prefixed by L period (L.). However, when pressing CR or NEXT after the first entry, everything but the L. is erased. This allows another command to be entered without entering L. first. All examples in this section show L., although you may not have to type it. If it becomes necessary to enter a DSD command during parameter entry, simply backspace to erase the L., enter the command, and then continue by typing L. and the entry.

After you call a specific utility, enter the first command in the following format.

L.commandstring.

Parameter

Utility

#### Description

commandstring

Any input (command, data, or parameter) that is defined by the job as valid input.

Execute your own L-display utility by entering the following command.

LDISopt.

Parameter

opt

One to three characters defining your utility.

Description

# FOTD L DISPLAY

The FOTD L-display utility displays all the family names known to the system and the corresponding family ordinal. To initiate the FOTD utility enter one of the following commands.

FOTD,L=outfile,LO=option.

or

FOTD, outfile, option.

#### Parameter

## Description

outfile Output file name. This parameter is valid only if a list option is specified. The default outfile is file OUTPUT.

option List option. Enter one or more of the following.

- D Formats the data for the DSD L display. This is the default list option if the parameters outfile and option are not specified.
- L Formats the data for a line printer.

If you do not specify outfile and option, the data is written to the L-display buffer once and the utility ends.

Figure 9-1 shows the FOTD L display.

FAMILY ORDINAL TABLE DISPLAY AVAILABLE ENTRIES = 638. DEFAULT FAMILY = FAMILY1 ORD. FAMILY ORD. FAMILY ORD. FAMILY ORD. FAMILY 1. FAMILY1 2. FAMILY2 3. FAMILY3 4. FAMILY4 7. FAMILY7 10. FAMILY8 5. FAMILY5 6. FAMILY6 11. FAMILY9 13. FAMIL11 14. FAMIL12 12. FAMIL10

Figure 9-1. FOTD L Display

The first line of the FOTD L display contains the default family name and the octal number of FOT entries that remain available for assignment. The rest of the display shows each family name and its corresponding family ordinal.

# LIDOU L DISPLAY

The LIDOU utility displays the LID table configuration and allows you to add or delete LIDs, LID attributes, and PID attributes in the LID table configuration. This modified configuration is retained across a level 1, 2, or 3 recovery deadstart. A level 0 deadstart causes a return to the configuration defined by the LID configuration file.

To initiate the LIDOU utility, enter one of the following commands.

LIDOU.

or

LID, I=infile, L=outfile.

The first command format can be entered only from the console under DSD control; also, all input and output is processed using the LIDOU L display. Figure 9-2 shows the initial LIDOU L display (LID display). From this display you can select the HELP display shown in figure 9-3. You can toggle between these two L displays as described at the bottom of each display.

The second command format can be entered under DIS control or by a system origin batch job. In either case, the I and L parameters must be specified.

#### Parameter

#### Description

I=infile

LIDOU reads input directives from file infile. Valid input directives are the same as the commands shown in the HELP L display (figure 9-3) without the L. prefix and without the BACK, HELP, +, or - commands.

L=outfile

LIDOU writes output to file outfile.

| PID | LID | ENABLED | ATTRIBUTE   | MFTYPE | NETWORK              |
|-----|-----|---------|-------------|--------|----------------------|
| MFB |     | YES     | HV          | NOS V2 | RHF - IN SERVICE     |
|     | MFB | YES     | ک جا و در ت |        | NAM - OUT OF SERVICE |

|     |     |         |             |        |                      |

Figure 9-2. LIDOU L Display (LID)

The information shown in figure 9-2 corresponds to the sample LCN shown in figure 8-28.

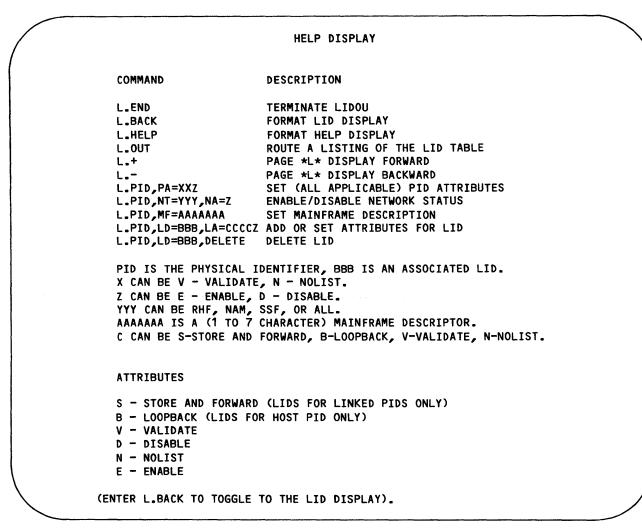

Figure 9-3. LIDOU L Display (HELP)

Although not shown in the HELP L display, some or all PID characteristics can be changed with one command by including all of the appropriate parameters on that command. For example, all PID characteristics for a given PID can be changed with the following command.

L.pid, PA=xxz, MF=aaaaaaaa, NT=yyy, NA=z.

# **QDSPLAY L DISPLAY**

The DSD utility QDSPLAY displays the content of a queued file listed in the queued file table (QFT).

# NOTE

On a secured system, the console must be in security unlock status to accept this command (refer to the UNLOCK,username,password command in section 5).

To bring the QDSPLAY L display to the left console screen, enter the following command.

QDSPLAY, jsn.

Parameter

Description

jsn

Job sequence name of the queued file you want to examine.

Figure 9-4 shows the initial QDSPLAY L display.

| THE FOLLOW | VING ARE VALID QUEUE DISPLAY COMMANDS -                                                           |  |

| SKIP LINE/ | PAGE COMMANDS ARE NOT ALLOWED FROM OCTAL DISPLAY.                                                 |  |

Figure 9-4. Initial QDSPLAY L Display

Valid QDSPLAY commands are:

| Command  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L.BOI.   | Positions the file to the beginning-of-information (BOI) and then displays the data from that point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| L.BR,r.  | Skips backward r records in the file and displays the data from the beginning of that record. If r is not specified, the default is one record. The record count, r, is decimal unless a B postradix is specified to make the number octal. The maximum skip count is 3777778. A BOI terminates the skip regardless of the number of records specified or skipped. This command is not allowed when the HELP display or system sector is being displayed.                                                                                                                                                            |
| L.DAY.   | Positions the print file to the beginning of the dayfile record and displays the data from that point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| L.DROP.  | Drops the file from the queue and terminates the QDSPLAY utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| L.END.   | Returns the file to the queue and terminates the QDSPLAY utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| L.HELP.  | Lists the L display commands for the QDSPLAY utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| L.LINE.  | Sets the file display mode to line format (not allowed when displaying the system sector).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| L.OCTAL. | Sets the file display mode to octal format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| L.SL,n.  | Skips n lines forward in the file and displays the data from the beginning of that line. If n is not specified, the default is one line. The line count, n, is decimal unless a B postradix is specified to make the number octal. The maximum skip count allowed is $377777_8$ . A line can be up to 14 words. An EOR, EOF, or EOI ends the skip regardless of the number of lines specified or skipped. This command is allowed only when displaying data in line format and is not allowed when the HELP display or system sector is being displayed.                                                             |
| L.SP,p.  | Skips forward p pages in the file and displays the data from the beginning<br>of that page. If p is not specified, the default is one page. The page<br>count, p, is decimal unless a B postradix is specified to make the number<br>octal. The maximum skip count allowed is 3777778. A page is based on a<br>carriage control l as the first character in a line. An EOR, EOF, or EOI<br>ends the skip regardless of the number of pages specified or skipped. The<br>command is allowed only when displaying data in line format and is not<br>allowed when the HELP display or system sector is being displayed. |
| L.SR,r.  | Skips forward r records in the file and displays the data from the beginning<br>of that record. If r is not specified, the default is one record. If an<br>asterisk (*) is specified for the record count, r, a skip forward to the EOI<br>occurs. The record count, r, is decimal unless a B postradix is specified<br>making the number octal. The maximum skip count allowed is 3777778. An<br>EOI ends the skip regardless of the number of records specified or skipped.                                                                                                                                        |

This command is not allowed when the HELP display or system sector is being

displayed.

| L.*.                      | Returns from the L.SS or L.HELP command displays and displays the contents<br>of the file at the current position. This command is ignored if you are<br>already displaying the contents of the file.                                                                               |  |  |  |  |  |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
| L.+.                      | Advances the display forward to the next screen of data. This command is<br>ignored under the L.HELP command where all information is presented on one<br>screen. For the L.SS command, after the last screen of data, the first<br>screen of the system sector is displayed again. |  |  |  |  |  |
| SCTD L DISPL              | SCTD L DISPLAY                                                                                                                                                                                                                                                                      |  |  |  |  |  |
|                           | ess control table L-display (SCTD) utility displays the contents of the control table (SCT). To begin the SCTD utility, enter one of the following                                                                                                                                  |  |  |  |  |  |
| SCTD,L=outfile,L0=option. |                                                                                                                                                                                                                                                                                     |  |  |  |  |  |
| or                        |                                                                                                                                                                                                                                                                                     |  |  |  |  |  |

| Parameter                 | Description                                                                                                                                                                                                                                                                         |  |  |  |  |  |
| outfile                   | Output file name. This parameter is valid only if a list option is specified. The default outfile is file OUTPUT.                                                                                                                                                                   |  |  |  |  |  |

Description

Displays the data from the beginning of the system sector in octal display

option List option. Enter one or more of the following.

- D Formats the data for the DSD L display. This is the default list option if the parameters outfile and option are not specified.
- L Formats the data for a line printer.

If you do not specify outfile and option, the data is written to the L-display buffer once and the utility ends.

•

Command

code format.

L.SS.

Figure 9-4 shows the SCTD L display.

SERVICE CLASS CONTROL TABLE DISPLAY. VALIDATED SERVICE CLASSES FOR EACH ORIGIN TYPE. SYSTEM ORIGIN SERVICE CLASS(ES). SY BC RB TS DI NS SS MA CT 10 11 12 13 LOCAL BATCH ORIGIN SERVICE CLASS(ES). BC REMOTE BATCH ORIGIN SERVICE CLASS(ES). RB INTERACTIVE ORIGIN SERVICE CLASS(ES). TS DI PRIORITY ORDERED SERVICE CLASSES. P0 P1 P2 Р3 P4 P5 P6 P7 12 10 TS 11 DI 13

Figure 9-4. SCTD L Display

The SCTD L display shows the various origin types along with the service classes valid for each origin type.

At the bottom of the screen, the display shows how the service classes are prioritized. The priority levels are PO through P7.

When entering the DSD CLASS or PCLASS command, use this utility to see the service classes for each origin type or the priority level. Refer to the DSD CLASS or PCLASS command in section 5 for further information.

# SUBSYST L DISPLAY

The SUBSYST L-display utility displays information about all the subsystems supported by NOS. To begin the SUBSYST utility enter one of the following commands.

SUBSYST,L=outfile,LO=option.

or

SUBSYST, outfile, option.

Parameter

outfile Output file name. This parameter is valid only if a list option is specified. The default outfile is file OUTPUT.

option List option. Enter one or more of the following.

D Formats the data for the DSD L display. This is the default list option if the parameters outfile and option are not specified.

Description

2

L Formats the data for a line printer.

If you do not specify outfile and option, the data is written to the L display.

Refer to the NOS 2 Operations Handbook for further information regarding the SUBSYST L display.

This section contains information about LID configuration files and RHF configuration files.

# LID CONFIGURATION FILE

You create a LID configuration file to define the physical and logical machines available for your system. After a level 0 deadstart, the system program CLDT searches for the LID configuration file on user index  $37777_8$ . It will use the information in this file to generate a logical identifier table (LDT) in central memory.

This section describes how to create and maintain the LID configuration file (LIDCMid). Specifically, how to:

- Create the LIDCMid file using NPID and NLID configuration statements.
- Specify the size of the LID table using the CMRDECK LDT entry.
- Build or rebuild the LID table using the X.CLDT command.
- List the current LID table using the LISTLID command.
- Change LIDs and LID attributes using the LIDOU display.

#### **CREATING THE LIDCMid FILE**

The first line of the LIDCMid file should be a 1- to 7-character name for the LID configuration file. Use this format for naming the file:

LIDCMid

id is a 2-character machine identifier for the mainframe.

You can place comment lines in the file by putting an asterisk in column 1 or by putting the word COMMENT beginning in column one. For example:

LIDCM64 \*LIDCMID FILE FOR MAINFRAME 64.

You should define each PID (physical identifier) and all the LIDs (logical identifiers) associated with the PID by using NPID and NLID statements.

# **NPID Statement**

Use one NPID statement to define each physical mainframe available to your system. Use this format for the NPID statement:

NPID,PID=pid,ENABLED=status,MFTYPE=type,AT=at,NETDIS=sub.

| Parameter      |                                                                                                                                                                                                                      | Description                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PID=pid        | -                                                                                                                                                                                                                    | ifier; pid is the 3-character physical identifier ame. Required.                                                                                                                               |
| ENABLED=status |                                                                                                                                                                                                                      | her the mainframe identified by PID is available.<br>YES or NO. Default is YES.                                                                                                                |
| MFTYPE=type    | the mainframe (                                                                                                                                                                                                      | ; type is any l- to 7-character string specifying<br>type or mainframe identifier (for example, NOSBE,<br>SMF2, CLSH1). Required.                                                              |
| AT=at          | Specifies the attribute associated with the mainframe identified<br>by PID. You can specify multiple attributes by using a slant<br>separator (AT=VALID/NLIST) or by repeating the parameter<br>(AT=VALID,AT=NLIST). |                                                                                                                                                                                                |
|                | at                                                                                                                                                                                                                   | Description                                                                                                                                                                                    |
|                | VALID                                                                                                                                                                                                                | Specifies that USER command prevalidation is required.                                                                                                                                         |

|                | RHF                                                                                                                                                                                                                  | Remote Host Facility.                                                                                                                                                                          |
|                | SSF                                                                                                                                                                                                                  | SCOPE Station Facility.                                                                                                                                                                        |

# **NLID Statement**

Use NLID statements after each NPID statement to define the relationship between each PID and its associated LIDs and the attributes of the LIDs. Use this format for the NLID statement:

NLID,LID=1id,ENABLED=status,AT=at.

| Parameter      |                 | Description                                                                                                                                                                                       |
|----------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LID=1id        | for the mainfra | fier; lid is the 3-character logical identifier<br>ame identified by the last NPID statement. lid<br>e as the last pid. Required.                                                                 |
| ENABLED=status |                 | ner the mainframe identified by LID is available.<br>YES or NO. Default is YES.                                                                                                                   |
| AT=at          | by LID. You ca  | attribute associated with the mainframe identified<br>an specify multiple attributes by using a slant<br>STOREF/VALID) or by repeating the parameter<br>VALID).                                   |
|                | at              | Description                                                                                                                                                                                       |
|                | LOOPB           | Loopback capability for RHF testing. This<br>testing can be performed on one mainframe with<br>one NAD. The attribute of LOOPB is valid only<br>for LIDs defined for the host (local) mainframe.  |
|                |                 | You should not specify the LOOPB attribute if the STOREF attribute is specified.                                                                                                                  |
|                | STOREF          | Store and forward capability indicating that the<br>specified mainframe will act as part of the<br>network in store and forward mode. Data will<br>pass through the machine and into the network. |
|                |                 | You should not specify the STOREF attribute if the LOOPB attribute is specified.                                                                                                                  |
|                | VALID           | Specifies that USER command prevalidation is<br>required and can be specified only if the STOREF<br>attribute is specified.                                                                       |
|                | NVALID          | Specifies that USER command prevalidation is not<br>required and can be specified only if the STOREF<br>attribute is specified.                                                                   |
|                | NLIST           | Specifies that this LID is not available to the<br>end user through the LISTLID command. LIDs with<br>this attribute might be reserved for onsite<br>maintenance purposes.                        |

## Example

Figure 10-1 shows an equipment configuration consisting of six mainframes. Following the figure are the LIDCMid files for the three NOS mainframes in the configuration: LIDCM64, LIDCM42, and LIDCM05.

LIDCM05 LIDCMID FILE FOR MAINFRAME O5. AGAIN, NOTE THAT \*LIDCMO5 LID=NBE IS DEFINED AS A STORE AND FORWARD LID FOR THE NOS/BE MAINFRAME. NPID,PID=M05,MFTYPE=M05. NLID,LID=M05. NLID,LID=LBK,AT=LOOPB. NLID, LID=M64, AT=STOREF. NLID,LID=CCC,AT=STOREF. NLID,LID=NBE,AT=STOREF. NPID, PID=NBE, MFTYPE=NOSBE, AT=NVALID. NLID,LID=CCC. NLID, LID=NBE. NPID, PID=M64, MFTYPE=NOS64. NLID, LID=M64.

#### SPECIFYING THE SIZE OF THE LID TABLE

You should specify the size of the LID table (LDT) in central memory with this CMRDECK entry:

LDT=nnnn.

nnnn is the number of central memory words allocated to the LDT (default=1, minimum=0, maximum=11008). You can calculate the value for nnnn by using this formula:

(3+lid)\*pid

lid is the maximum number of LIDs allowed per PID. pid is the total number of PIDs in all networks.

#### **BUILDING OR REBUILDING THE LID TABLE**

When you deadstart the system, the system program CDLT automatically looks for the LIDCMid file under user index 3777778. It will use the file to automatically create the LID table in central memory.

If the system cannot find the file, or if there are errors in the file, an error message will be displayed in the dayfile. You can then create or correct your LIDCMid file and execute the X.CLDT command to build or rebuild the LID table in central memory.

To build or rebuild the LID table in central memory, follow these steps:

- 1. Create or correct your LIDCMid file and ensure that the file is stored as an indirect access file on user index  $377777_8$ .
- 2. Ensure that all subsystems that access the LID table (NAM, RHF, and SSF) are not active.
- 3. Enter this command:

X.CLDT

The system will build or rebuild the LID table in central memory.

LIDCM64 LIDCMID FILE FOR MAINFRAME 64. NOTE THAT LID=LBK IS \*LIDCM64 DEFINED AS A LOOPBACK LID AND THAT THE NAM NETWORK IS \* DISABLED TO NOS PID=M42. \* NPID,PID=M64,MFTYPE=NOSHOST,AT=VALID. NLID,LID=M64. NLID, LID=AAA. NLID,LID=AAB. NLID,LID=LBK,AT=LOOPB. NPID,PID=M42,MFTYPE=NOS42,NETDIS=NAM. NLID,LID=M42. NLID,LID=BBB. NLID,LID=BBC. NLID,LID=NBE,AT=STOREF/NLIST. NLID,LID=CCC,AT=STOREF. NPID,PID=MF2,MFTYPE=SCOPE2,AT=NVALID. NLID\_LID=MF2. NLID,LID=SC2. NPID,PID=120,MFTYPE=C120,AT=NVALID. NLID, LID=120. NPID,PID=M05,MFTYPE=NOS05. NLID, LID=DDD. NLID,LID=NBE,AT=STOREF. NLID,LID=CCC,AT=STOREF. LIDCM42 LIDCMID FILE FOR MAINFRAME 42. NOTE THAT LID=NBE IS \*LIDCM42 DEFINED AS A STORE AND FORWARD LID FOR THE NOS/BE MAINFRAME. \* NPID,PID=M42,MFTYPE=NOSHOST. NLID,LID=M42. NLID,LID=BBB. NLID,LID=BBC. NLID,LID=M64,AT=STOREF. NLID,LID=CCC,AT=STOREF. NLID,LID=NBE,AT=STOREF. NLID, LID=LBK, AT=LOOPB. NPID,PID=M64,MFTYPE=NOS64,NETDIS=NAM. NLID,LID=M64. NLID, LID=AAA. NLID, LID=AAB. NPID,PID=NBE,MFTYPE=NOSBE,AT=NVALID. NLID, LID=NBE. NLID,LID=CCC. NPID, PID=120, MFTYPE=C120, AT=NVALID. NLID, LID=120.

(Continued)

LIDCM05 LIDCMID FILE FOR MAINFRAME 05. AGAIN, NOTE THAT \*LIDCM05 LID=NBE IS DEFINED AS A STORE AND FORWARD LID FOR THE NOS/BE MAINFRAME. NPID,PID=M05,MFTYPE=M05. NLID,LID=M05. NLID, LID=LBK, AT=LOOPB. NLID, LID=M64, AT=STOREF. NLID,LID=CCC,AT=STOREF. NLID, LID=NBE, AT=STOREF. NPID,PID=NBE,MFTYPE=NOSBE,AT=NVALID. NLID,LID=CCC. NLID, LID=NBE. NPID,PID=M64,MFTYPE=N0S64. NLID,LID=M64.

## SPECIFYING THE SIZE OF THE LID TABLE

You should specify the size of the LID table (LDT) in central memory with this CMRDECK entry:

LDT=nnnn.

nnnn is the number of central memory words allocated to the LDT (default=1, minimum=0, maximum=11008). You can calculate the value for nnnn by using this formula:

(3+1id)\*pid

lid is the maximum number of LIDs allowed per PID. pid is the total number of PIDs in all networks.

#### **BUILDING OR REBUILDING THE LID TABLE**

When you deadstart the system, the system program CDLT automatically looks for the LIDCMid file under user index 3777778. It will use the file to automatically create the LID table in central memory.

If the system cannot find the file, or if there are errors in the file, an error message will be displayed in the dayfile. You can then create or correct your LIDCMid file and execute the X.CLDT command to build or rebuild the LID table in central memory.

To build or rebuild the LID table in central memory, follow these steps:

- Create or correct your LIDCMid file and ensure that the file is stored as an indirect access file on user index 3777778.
- 2. Ensure that all subsystems that access the LID table (NAM, RHF, and SSF) are not active.
- 3. Enter this command:

X.CLDT

The system will build or rebuild the LID table in central memory.

# LISTING THE LID TABLE

You can use the LISTLID command to list the configuration of the LID table. The LISTLID command can be executed through an interactive or batch environment. Use this format for the command:

LISTLID,LID=1id,PID=pid,L=1ist.

| Parameter | Description                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LID=lid   | List the attributes of PIDs in which LID lid exists. LID lid must<br>be enabled and it must be a listable LID. If the LID keyword is<br>specified, a LID value lid must also be specified. If the LID<br>keyword is omitted, the default is to list all listable LIDs. |
| PID       | List the attributes of a given LID (LID=1id specified) or all LIDs                                                                                                                                                                                                     |
| or        | (LID omitted) under a given PID (PID=pid specified) or all PIDs<br>(PID specified). If the PID keyword is omitted, the default is to                                                                                                                                   |
| PID=pid   | list all listable LIDs specified by the LID parameter.                                                                                                                                                                                                                 |
| L=list    | Specifies the local file to which all listable output is to be written. If the L keyword is omitted, the default is file OUTPUT.                                                                                                                                       |

# CHANGING THE LIDS USING THE LIDOU DISPLAY

You can change LIDs by using the LIDOU display. Refer to section 9, L-Display Utilities, for information about the LIDOU display.

# **RHF CONFIGURATION FILES**

You must define the RHF configurations including all NADs, applications, and physical identifiers (PIDs) to be used by or accessible to RHF. You may define multiple configurations. Each RHF in the network must have its own definition of the configuration; each definition will be different from the definition of the configuration for other RHFs in the network. Use the RCFGEN utility to define these configurations.

The RCFGEN utility reads network configuration statements to create a direct access permanent file under user name SYSTEMX. RHF then uses the permanent file as the network description and can properly access the network.

When RHF is started, it expects to find a local configuration file named RCFILE. If it does not find this file, RHF will attach the RHF configuration file using file name RCFMid, where id is the machine identifier.

The following command calls the RCFGEN utility.

RCFGEN, I=input, L=list, O=output.

The parameters are order independent and optional; if omitted, the defaults are used.

| Parameter | Description                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| I=input   | Specifies the local file from which the network configuration statements are to be read. The default is file INPUT. |
| L=list    | Specifies the local file to which all listable output is to be written. The default is file OUTPUT.                 |
| 0=output  | Specifies the local file to which the configuration tables are to be written. The default is file RCFILE.           |

The input to RCFGEN consists of network configuration statements. The syntax of these statements conforms to COMPASS statements. Configuration statements (except LNAD and RNAD statements) must not start before character position 3.

Use the following network configuration statements.

| Statement | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| LNDR      | Defines the maximum number of local NAD drivers (NDRs) allowed to execute at one time. |
| APPL      | Defines application programs that are allowed to access RHF.                           |
| NPID      | Defines the physical identifier of a remote mainframe.                                 |
| PATH      | Defines the paths to a remote mainframe through the LCN network.                       |
| LNAD      | Defines information necessary to address local NADs.                                   |
| RNAD      | Defines the addressing information necessary to access a remote NAD.                   |
| DEBUG     | Defines debug parameters.                                                              |
| CHARGE    | Defines the charge that is transferred to a user control point for each RHF call.      |

Network configuration statements must be specified in the following order to properly define a network.

- 1. LNDR statement (if necessary).
- 2. APPL statement to define application programs.
- 3. Sets of NPID and PATH statements that define all portions of the network. The PATH statement must be associated with a given physical mainframe (NPID statement). The following structure is required of these statements when defining a network:
  - NPID statement.
  - All paths (PATH statement) associated with the preceding NPID.
- 4. LNAD statements to define local NADs.
- 5. RNAD statements to define hardware addressing of remote NADs.
- 6. DEBUG and CHARGE statements (order independent).

At least one of each configuration statement is required in the configuration file with the exceptions of the LNDR, DEBUG, and CHARGE statements. Defaults are specified in the individual statement descriptions.

#### **NETWORK CONFIGURATION STATEMENTS**

The network configuration statements are described in the order that they must be specified to define a network.

### **LNDR** Statement

The maximum number of NAD drivers is the maximum number of PPs that may contain a NAD driver at one time, regardless of the number of NADs and the number of drivers allowed per NAD.

To define the maximum NDRs allowed for all NADs, enter:

LNDR MAXNDRS=nn

Parameter

#### Description

MAXNDRS=nn Maximum number of PPs that may contain NDRs at any one time. Default is 4. The maximum value is the number of PPs available for NAD drivers. nn must not be less than the largest value specified for MAXNDRS on any LNAD statement.

#### **APPL Statement**

Each application definition uses additional RHF field length. This additional field length is equal to mxcopys\*(5+3\*mxcons) central memory words (mxcopys and mxcons are defined below). To define an RHF application, enter:

APPL NAME=name, ENABLED=status, MXCONS=mxcons, MXCOPYS=mxcopys, SVR=status, ASTART=status

| Parameter       | Description                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME=name       | Application name; name is 1- to 7-alphanumeric characters, where the first character must be alphabetic. Required.                                                                                                                                                                                                                  |
| ENABLED=status  | Availability of the application when RHF is initiated. status may be YES or NO. Default is YES.                                                                                                                                                                                                                                     |
| MXCONS=mxcons   | Maximum simultaneous connections that are allowed for this application. The maximum value for mxcons is 127. Default is 1.                                                                                                                                                                                                          |
| MXCOPYS=mxcopys | Maximum number of simultaneously active copies of this application that are allowed. The maximum value for mxcopys is 127. Default is 1.                                                                                                                                                                                            |
| SVR=status      | Servicer program status; specifi'es if the application is a servicer,<br>that is, an application program that is started automatically by RHF<br>upon request of an application program on another host. status may<br>be YES or NO. Default is NO.                                                                                 |
| ASTART=status   | Application startup status; specifies whether the application is<br>started when RHF is initiated or when the operator enables the<br>application. status may be YES or NO. If NO is specified, the<br>application is started by the user, or for a servicer application,<br>by a request from a remote application. Default is NO. |

In determining the number of allowed connections and copies of an application, note that each NAD has a maximum of 127 active connections. This number is restricted to 35 during NAD controlware loading but may be increased by modifying the appropriate NAD controlware load parameters in LOADBC.

When defining the APPL statements you must follow certain restrictions for system-supplied applications QTF, QTFS, PTF, PTFS, ITF, and MLTF. The maximum simultaneous connections should be set to one (default) for QTFS, PTF, PTFS, and MLTF. The maximum number of simultaneously active copies should be set to one (default) for QTF, ITF, and MLTF. The maximum simultaneous connections for QTF should be set to four unless installation parameters ACNMAXC for QTF and MAXFILEXFR for FIP are changed. The SVR=YES parameter must be specified for QTFS and PTFS and must not be specified for QTF, PTF, ITF, or MLTF. ASTART=YES should be specified for both QTF and MLTF.

For ITF, the maximum simultaneous connections should be equal to the value of the PI parameter on the ITF command in the JOBITF record on the NAMI startup master file. The released default is 2.

# **NPID Statement**

Each remote mainframe definition requires three words in RHF's field length. To define a remote mainframe, enter:

NPID PID=pid, ENABLED=status, MFTYPE=type

| Parameter      | Description                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PID=pid        | Physical identifier of the remote mainframe; pid must be a unique<br>3-character physical identifier. Required.                                                                |
| ENABLED=status | Availability of the mainframe identified by PID. status may be YES or NO. Default is YES.                                                                                      |
| MFTYPE=type    | Mainframe type; type is any l- to 7-character string specifying the mainframe type or mainframe identifier. For example, you could use NOS1, NOS2, NOS/BE, or CY200. Required. |

### **PATH Statement**

Every path defined for a remote mainframe requires two words in RHF's field length. To define a path for a remote mainframe, enter:

PATH ENABLED=status,LT=tttt,RT=rrrr,RNAD=raddr,LNAD=laddr,AC=aaaa

| Parameter      | Description                                                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENABLED=status | Availability of the path when RHF is initialized. status may be YES or NO. Default is YES.                                                                    |
| LT=tttt        | Local trunk control units (TCUs) enabled; tttt is a 4-digit nonzero<br>binary number indicating the network trunk connections for the local<br>NAD. Required. |
| RT=rrrr        | Remote TCUs enabled; rrrr is a 4-digit nonzero binary number<br>indicating the network trunk connections for the remote NAD.<br>Required.                     |
| RNAD=raddr     | Symbolic address of the remote NAD entry for this path referenced in the RNAD statement. Required.                                                            |
| LNAD=1addr     | Symbolic address of the local NAD entry for this path referenced in the LNAD statement. Required.                                                             |
| AC=aaaa        | Access code; aaaa is a 4-digit hexadecimal access code for the remote NAD. Default is 0.                                                                      |

At least one PATH statement is required for each PID defined.

## **LNAD Statement**

Each local NAD definition requires two words in RHF's field length. To define a local NAD, enter:

| laddr LNAD             | CH=ch,MAXNDRS=n,DEDICATE=status,CMPATHS=nn,CMBUFFS=nn.                                                                                                                                                                                                                                                          |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter              | Description                                                                                                                                                                                                                                                                                                     |
| laddr                  | Symbolic address referenced in a preceding PATH statement. This parameter is required and must begin in character position 1 or 2.                                                                                                                                                                              |
| CH=ch                  | Channel number; ch is a 2-digit octal number of the channel to which the NAD is connected.                                                                                                                                                                                                                      |
| MAXNDRS=n              | Maximum number of NAD drivers that may be assigned at one time to this NAD. $n$ can be from 1 to 3. Default is 1.                                                                                                                                                                                               |
| <b>DEDICATE=status</b> | Dedicated channel status; specifies whether the driver will<br>always hold the NAD channel reservation between consecutive<br>blocks of one I/O request. status may be YES or NO. Default is<br>YES. YES should be specified unless some non-CDC driver<br>requires high-performance access to the NAD channel. |
| CMPATHS=nn             | Maximum number of convert mode paths. You can specify a number<br>from 0 to 63. The default is 0. If nn is 0, then code<br>conversion is done in the CPU. Refer to table 10-1 for<br>additional information.                                                                                                    |
| CMBUFFS=nn             | Maximum number of convert mode buffers. You can specify a number from 0 to 63. The default is 0. Refer to table 10-1 for                                                                                                                                                                                        |

The software relies on the NAD to determine the actual number of paths and buffers reserved for code and conversion. The algorithm used by the NAM is Buffers Reserved = (the smaller of paths requested) or (buffers reserved  $\frac{2}{3}$ ).

The code conversion parameters should be adjusted according to the average number of concurrently active connections doing code conversion and the average size of the files being converted. Table 10-1 gives some suggested values for the code conversion parameters. In this table, the term average connection implies four conversion connections. The term average file size is a file approximately 500 PRUs long.

additional information.

|                                                       | 96K-Byte NAD         | 128K-Byte NAD         |
|-------------------------------------------------------|----------------------|-----------------------|
| Less than average connections, average file size      | 2 paths<br>3 buffers | 2 paths<br>3 buffers  |
| Less than average connections,<br>large file sizes    | 2 paths<br>5 buffers | 2 paths<br>5 buffers  |
| Average connections, average file sizes               | 4 paths<br>6 buffers | 5 paths<br>8 buffers  |
| Greater than average connections, average file sizes  | 6 paths<br>9 buffers | 7 paths<br>11 buffers |
| Greater than average connections,<br>large file sizes | 5 paths<br>9 buffers | 6 paths<br>13 buffers |

Table 10-1. Suggested Code Conversion Parameters

# **RNAD Statement**

Every remote NAD defined requires one word in RHF's field length. To define a remote NAD, enter:

| raddr      | RNAD | ND=nn,DD=d,LOG=status                                                                                                                                             |
|------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter  |      | Description                                                                                                                                                       |
| raddr      |      | Symbolic address referenced in a preceding PATH statement. This parameter is required and must begin in character position 1 or 2.                                |
| ND=nn      |      | Remote NAD address; nn is a 2-digit hexadecimal address of the remote NAD. Default is 0.                                                                          |
| DD=d       |      | Remote NAD exit port; d is a l-digit hexadecimal address of the exit port of the remote NAD. Default is 0.                                                        |
| LOG=statu: | S    | Error logging status; specifies if remote NAD trunk errors are<br>to be recorded by MLTF in the mainframe´s error log. status may<br>be YES or NO. Default is NO. |

#### **DEBUG Statement**

The DEBUG statement controls the manner in which RHF uses queue entries.

DEBUG TRACE=status

Description Parameter RHF trace status; specifies whether the RHF trace is on or off. TRACE=status status may be YES or NO. Default is NO. NO specifies that RHF trace is off and queue entries freed by RHF are placed at the top of the empty queue and reused immediately. RHF uses a slightly smaller amount of processing time when the RHF trace is off. Default is NO. YES specifies that RHF trace is on and a queue entry is reused only after all queue entries ahead of it have been used. Also, when the RHF trace is on, you can use it for analysis of an RHF dump and resolution of the associated RHF problem.

## **CHARGE** Statement

The CHARGE statement specifies the amount of system resources a user control point is charged for an RHF call. RHF distinguishes two different types of calls; those that require a large amount of processing time and those that require a small amount of processing time.

| CHARGE TYPE=type,CPA=cpa,CPB=cpb,IO=io,CMFL=cm,PP=pp |                                                                                                                                                            |  |  |  |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| Parameter                                            | Description                                                                                                                                                |  |  |  |
| TYPE=type                                            | Type of call for which the charge is being specified.                                                                                                      |  |  |  |
|                                                      | type Description                                                                                                                                           |  |  |  |
|                                                      | l Requires small amount of RHF processing time.                                                                                                            |  |  |  |
|                                                      | 2 Requires large amount of RHF processing time.                                                                                                            |  |  |  |
| CPA=cpa                                              | Time to be charged for central processor cpa (decimal<br>milliseconds). Default is 2 milliseconds for a type 1 call; 10<br>milliseconds for a type 2 call. |  |  |  |
| СРВ=срЪ                                              | Time to be charged for central processor cpb (decimal milliseconds). Default is 0.                                                                         |  |  |  |
| 10=io                                                | Input/output time to be charged (decimal milliseconds). Default is 0.                                                                                      |  |  |  |
| CMFL=cm                                              | Central memory field length to be charged. cm is the field length in octal divided by $100_8$ . Default is 108.                                            |  |  |  |
| PP=pp                                                | PP time to be charged (decimal milliseconds). Default is 0.                                                                                                |  |  |  |

A CHARGE statement is not required. You may, however, enter two CHARGE statements: one for type 1 calls, a second for type 2 calls.

# Examples

Figure 10-2 illustrates a sample LCN network and is the basis of the network configuration statements in examples 1 and 2.

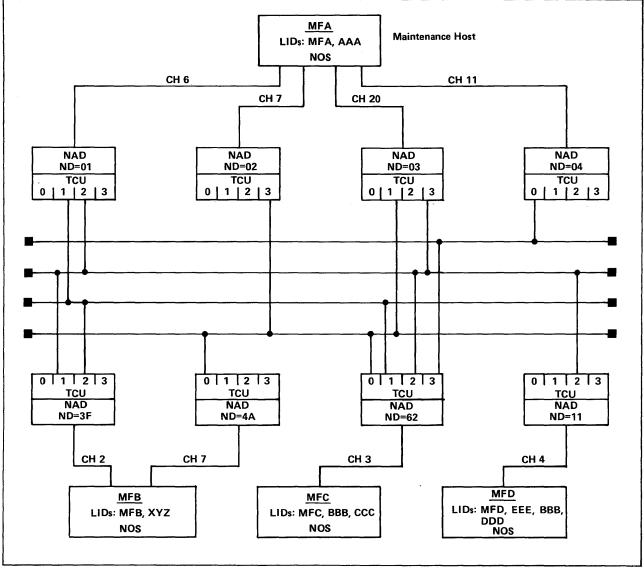

Figure 10-2. Sample LCN Network

# Example 1.

# INTRODUCTION

The Mass Storage Archival Subsystem (MSAS) is the product consisting of the 7990 hardware, the channel interface, the diagnostics, and the operational software.

The 7990 hardware is a large-capacity online mass storage device, which is a cost-effective extension to the disk file storage system and an alternative to conventional magnetic tape storage. Storing files on the 7990 retains the security, data integrity, and online access capabilities provided by disk and reduces the operational and data integrity problems caused by storing, retrieving, and mounting tape volumes. You can use both the 7990 and magnetic tapes to protect files from hardware and system failures.

The 7990 hardware is composed of the following components.

| Component                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |  |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| Cartridge                   | A plastic housing that encloses magnetic tape on which data is<br>stored under program control. This cartridge is compatible with an<br>IBM 3850 cartridge.                                                                                                                                                                                                                                                                                           |  |  |  |
| 7991 Storage<br>Module (SM) | The hardware unit that houses up to $312$ usable data cartridges. The SM also consists of the cartridge accessor unit, which picks cartridges from and puts cartridges in their cubicles, and one or two data recording drives (DRD), which read data from and write data to the cartridges. The cubicles are assigned coordinate locations that are identified by the ordered pair (y,z), where the z axis is horizontal and the y axis is vertical. |  |  |  |
| 7990 Control<br>Unit (CU)   | The hardware unit that is the controller for up to four 7991 SMs.<br>The CU acts like a tape controller for up to four IBM channel<br>interfaces and includes one or two data recording controllers<br>(DRCs). The MSAS software supports up to two IBM channel interfaces<br>per CYBER mainframe.                                                                                                                                                    |  |  |  |

The basic function of MSAS is to store data on the 7990 and move it to disk upon request for access by an authorized user. Control of file movement between a disk and a 7990 is transparent to the applications programmer; however, there are operational changes and additions that site personnel should note. These include modifications to operational procedures in the areas of permanent file backup, permanent file recovery, and disk space management. In addition, new MSAS utilities are introduced. Detailed information about the call and operation of each MSAS utility, listed next, is included in this section.

| Utility | Description                                                                           |  |  |
|---------|---------------------------------------------------------------------------------------|--|--|
| SSDEF   | Creates the system files (SM maps and 7990 catalogs) necessary for MSAS processing.   |  |  |
| SSLABEL | Manages allocation of cubicles and assignment of cartridges in the SM.                |  |  |
| SSMOVE  | Controls the destaging of files (creating 7990 images) and the release of disk space. |  |  |

| Utility | Description                                                                                                                                                   |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSVAL   | Controls the release of 7990 space and analyzes the SM maps, 7990 catalogs, and PFC entries to identify and flag discrepancies within these three components. |
| SSUSE   | Provides reports on the assignment and availability of cartridges and cubicles within an SM.                                                                  |
| SSDEBUG | Corrects error conditions detected by SSVAL and recovers data from 7990 cartridges.                                                                           |
| SSBLD   | Builds the unit device table (UDT) for SSEXEC. The UDT describes the 7990 hardware configuration.                                                             |
| SSALTER | Provides dynamic modification of the 7990 hardware configuration.                                                                                             |

## UTILITY DESCRIPTION TERMINOLOGY

Review the following terms; they are defined as used in the descriptions of the MSAS utilities later in this section.

## Cartridge

A cartridge is the 7990 storage component consisting of magnetic tape. The 7990 hardware always writes or reads 6652 8-bit byte records, called stripes, to or from the magnetic tape. Each cartridge has 27,087 stripes. The first 20 stripes contain a manufacturer's label. The second 20 stripes contain a 7990 cartridge label written by the SSLABEL utility. The remaining 27,047 stripes are organized into software-defined allocation units (AUs) of 14 stripes each for a total of 1931 AUs per cartridge.

An allocation unit is the smallest allocatable portion of a cartridge. One or more AUs may be allocated to contain data for a single file. The allocated AUs for each file are organized into volumes (definition follows), which are chained together in the 7990 catalog to identify the sequence of AUs that must be accessed in order to read a file. A head-ofchain (HOC) flag identifies the first volume in the chain, a link field identifies the next volume in the chain, and an end-of-chain (EOC) flag identifies the last volume in the chain.

The addition, removal, and reassignment of cartridges are managed by the MSAS utilities. The cartridge labels, and also the 7990 catalogs and SM maps (definitions following), contain information concerning the location and content of the cartridges. The descriptions of the MSAS utilities later in this section contain further information on cartridge management.

#### SM Map

An SM map is a direct access permanent file that contains information indicating how cubicles in an SM are assigned to a family and identifying the cartridges that reside in the SM. There is one SM map for each SM in the configuration. The permanent file name of the SM map is SMMAPi, where i is the SM identifier (a letter from A to H); its user index is 377760<sub>8</sub>; and its family is the default family on the mainframe on which SSEXEC executes (refer to the definition of SSEXEC later in this section).

An SM map contains an entry for each possible coordinate pair (y,z) that identifies a cubicle in the SM, from (0,0), which is bottom left, to (21,15), which is upper right. Certain coordinate pairs are reserved for customer engineering use, system use, and diagnostic purposes.

Each entry in an SM map has this format:

| 59   | 53             | 47  | 41  |            | 0 |
|------|----------------|-----|-----|------------|---|
| code |                | ord |     | familyname |   |
| 2/// | sub-<br>family | id  |     | unused     |   |
| cm   |                |     | csn |            |   |

**Field** 

code

Number from 0 to 6 indicating how the cubicle is assigned.

Description

|            | code                               | Description                                                                                                                                                                           |
|------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | 0                                  | Unassigned.                                                                                                                                                                           |
|            | 1                                  | Reserved for customer engineer.                                                                                                                                                       |
|            | 2                                  | Reserved for system use.                                                                                                                                                              |
|            | 3                                  | Reserved for a different SM map.                                                                                                                                                      |
|            | 4                                  | Assigned to the cartridge scratch pool. $\dagger$                                                                                                                                     |
|            | 5                                  | Assigned to a subfamily.                                                                                                                                                              |
|            | 6                                  | No cubicle exists at these coordinates.                                                                                                                                               |
| ord        | which the cubic<br>FCT ordinal (re | s cubicle in the 7990 catalog of the subfamily to<br>le is assigned. This ordinal is referred to as the<br>fer to the definition of 7990 catalog, next). This<br>gful only if code=5. |
| familyname |                                    | name, in 6-bit display code, of the family to which<br>assigned. This field is meaningful only if code=5.                                                                             |
| ٤          |                                    | lag that is set by the SSVAL utility when an SM map<br>cle assigned to a family has no corresponding entry<br>alog.                                                                   |
| subfamily  |                                    | o 7 identifying the subfamily to which the cubicle is field is meaningful only if code=5.                                                                                             |
| id         | Letter from A t                    | o H identifying the SM.                                                                                                                                                               |

<sup>&</sup>lt;sup>†</sup>The pool is an area of the SM that stores scratch cartridges managed by the SSLABEL utility.

#### Description

<u>Field</u> cm

Cartridge manufacturer code.

 $\mathbf{cm}$ 

#### Description

A- Cartridge manufacturer is IBM.

B- Reserved for future cartridge manufacturer.

csn

The 8-character cartridge serial number of the cartridge assigned to the cubicle. If no cartridge is assigned, this field contains spaces.

The zero entry in the SM map is the map header entry. In this entry the code field is 6, the leftmost 6 bits of the second word contain the SM identifier, and the remaining bits contain the permanent file name of the SM map.

The SM map is updated whenever the SSLABEL, SSVAL, or SSDEBUG utility causes a change in cubicle or cartridge assignment. It is recommended that the SM map be backed up after every update to avoid problems such as:

- Mismatches between SM map and 7990 catalog entries
- Lost SM maps because of a disk failure or other problem
- Attempts to access cartridges that are no longer available
- Attempts to store cartridges in cubicles that are no longer empty

Thus, you should make a copy of the SM map on tape or another device or family in order to retain the latest version of the SM map. If a device containing SM maps is reloaded, the latest version of the SM maps should be recovered from the backup copy after the reload is completed. After recovering the SM maps, you should run the SSVAL utility to check that the entries in the SM maps and 7990 catalogs match. If there are inconsistencies, corrective action should be taken as described under Error Conditions and Corrective Actions later in this section.

#### 7990 Catalog

A 7990 catalog is a disk-resident direct access permanent file that contains information describing which allocation units of each cartridge assigned to a particular subfamily are allocated to 7990 files and which AUs are available for allocation. There is one 7990 catalog for each subfamily of a family that can have 7990-resident files, and it resides on the master device for the subfamily. The permanent file name of the 7990 catalog file is SFMCATi and its user index is 37776i<sub>8</sub>, where i is the subfamily identifier (a number from 0 to 7). For example, file SFMCAT3 and user index 377763<sub>8</sub> identify the 7990 catalog for subfamily 3.

A 7990 catalog is partitioned into subcatalogs, one subcatalog for each SM used by the subfamily. The maximum number of subcatalogs in a 7990 catalog is eight (the maximum number of SMs in a configuration). Each subcatalog consists of two parts, the file and cartridge table (FCT) and the allocation summary table (AST). The FCT has an entry for each cartridge assigned to the subfamily from the given SM. The maximum number of FCT entries in a subcatalog is 312 (the maximum number of cartridges in an SM). The AST contains information used by the allocation algorithm to select the cartridges on which a file will reside.

The first part of the 7990 catalog contains a header and at most eight subcatalog entries. The header identifies the family and subfamily of the 7990 catalog. Each subcatalog entry contains the length and location of its FCT and AST, the SM identifier, unallocated AUs available for small and large files, and the date and time of the last SSVAL run that resulted in the release of 7990 space assigned to orphan files. The format of the header is:

| 59 |            | 17             | 11    | 20 |
|----|------------|----------------|-------|----|
|    | familyname | sub-<br>family | .V/// | id |
|    | unused     |                |       |    |
|    | unused     |                |       |    |

FieldDescriptionfamilynameThe 7-character name, in 6-bit display code, of the family for this<br/>7990 catalog.subfamilyNumber from 0 to 7 identifying the subfamily for this 7990 catalog.idNumber identifying this file as a 7990 catalog file. id is set to 1.

The format of the subcatalog entry is:

| 59    | 53            | 47                                          | 41                                                                | 35                                                                               | 26       | 17      | 11         | 0                             |  |

Each cubicle from the given SM assigned to the subfamily has an entry in the FCT of the subcatalog. This entry contains the coordinates (y,z) of the assigned cubicle. If a cartridge has been assigned to the cubicle, the FCT entry also contains the csn of the cartridge, usage information, status flags, and information about each of the AUs of the assigned cartridge. The format of each FCT entry is:

This flag is set or cleared by a<br>directive to the SSLABEL utility. |  |  |  |

#### Description

#### Description

- 16 Lost cartridge flag indicating that the cartridge assigned to this cubicle was not there the last time SSEXEC tried to pick it. This flag can be cleared by a directive to the SSLABEL utility.
- 15 Excessive write parity error flag set by SSEXEC when an error threshold has been passed. Space from this cartridge is not to be allocated. This flag can be cleared by a directive to the SSDEBUG utility.
- 14 Linkage error flag indicating that the SM map entry for the location (y,z) is inconsistent with the FCT entry. This flag is set by the SSVAL utility and cleared by the SSDEBUG utility.
- 13 Free cartridge flag. When this flag is set, SSEXEC inhibits further allocation. Files can be removed by running the SSVAL utility. This flag is set or cleared by a directive to the SSLABEL utility.

12 Reserved.

Bit

ord

Ordinal of the FCT entry in the subcatalog.

ocli

Off-cartridge link specifying the ordinal of the FCT entry for the cubicle containing the next cartridge on which the file on the cartridge assigned to this cubicle resides. If a file does reside on multiple cartridges, the entire file must be contained within a l6-cartridge group. Also, since there are only three off-cartridge link fields, if a cartridge contains several files, only three can be contained on other cartridges.

first stripe First usable stripe following the cartridge label. This field is set to 40.

stripe Number of stripes in each AU. This field is set to 14.

pru Number of PRUs that can be written on each stripe. This field is set to 13.

max AUs Maximum number of AUs in a cartridge. This field is set to 1931.

cdp Cartridge division point between small and large files kept on the same cartridge. The cartridge division point is defined with the B=n parameter to an SSLABEL directive. The default is B=600, specifying that the first 600 AUs of a cartridge are available for small files.

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25     | Start of fragment flag indicating this AU is the beginning of a chain fragment.                                                                                                                                                                                                                                                                                                                                                                                             |
| 24     | Flawed AU flag indicating this AU is not to be allocated to a file.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23     | Continuation AU flag indicating whether or not this<br>AU is the first AU of a volume. If this flag is<br>clear, the AU is the first AU of the volume; if<br>set, the AU is not the first AU of the volume.                                                                                                                                                                                                                                                                 |
| 22-21  | Off-cartridge link field indicating that the next volume of the file is on another cartridge. The next cartridge is identified by one of the $ocl_i$ fields. The value of the off-cartridge link flag (1, 2, or 3) specifies which $ocl_i$ field to use. The link field specifies the number of the first AU on the next volume of the file. This field is meaningful only if the chain control field indicates that this volume is the first or middle volume of the file. |
| 20-19  | Chain control field indicating whether this volume<br>is the first (1), last (2), only (3), or middle (0)<br>volume of the file.                                                                                                                                                                                                                                                                                                                                            |
| 18-12  | File length field indicating the number of AUs in the file following the first accessed AU.                                                                                                                                                                                                                                                                                                                                                                                 |
| 11-0   | Link field indicating the first AU on the next                                                                                                                                                                                                                                                                                                                                                                                                                              |

volume of the file. If the continuation AU flag is clear, this field contains the ordinal of the first AU of the volume. If the continuation AU flag is set, this field contains the ordinal of the first AU within the volume.

The 7990 catalog is updated whenever the SSLABEL, SSMOVE, SSVAL, or SSDEBUG utility causes a change in cartridge or cubicle assignment that affects the subfamily. Because the 7990 catalog for a subfamily resides on its master device, it will be backed up by PFDUMP whenever the master device for the subfamily is dumped. Consequently, when PFLOAD reloads all files, the 7990 catalogs are automatically recovered and all 7990-resident files as indicated in a recovered PFC will also have entries in the recovered 7990 catalog. Thus, no special operational procedures are needed to back up a 7990 catalog. It is possible, however, that the 7990 catalog will be inconsistent with the SM maps or cartridge labels. If such inconsistencies do exist, corrective action will have to be taken as described under Error Conditions and Corrective Actions later in this section.

Field

## 7990 Files

In an MSAS environment, permanent files can be categorized according to whether or not they reside on 7990. A disk file is a permanent file that resides on disk but not on 7990. A 7990 file is a permanent file that resides on 7990 and may or may not also reside on disk, depending on how the disk space is managed (refer to Disk Space Management later in this section). Depending on backup requirements (BR parameters), both disk and 7990 files can also have backup images on tape (refer to the NOS 2 Reference Set, Volume 3).

When a user defines a direct access file, initially it is a disk file. A disk file becomes a 7990 file when it is destaged to 7990; that is, an image of the file is created on 7990. Files are destaged through use of the SSMOVE utility, which is run periodically to manage disk space. When SSMOVE is run, files are destaged to 7990 and/or their disk space released depending on certain file characteristics (refer to SSMOVE later in this section). Thus, after an SSMOVE run a file can reside on disk, on 7990, or on both. If the file does have a 7990 image, the asa field in the PFC entry for the file indicates the location of the 7990 copy.

When a user attaches a 7990 file, it is staged to disk from 7990 (that is, a disk image is created) if the file is not on disk. If a direct access file is attached in write mode, the AFOBS flag is set in the PFC entry for that file. The current version of the file resides on disk only. If an indirect access file is replaced or appended to, the asa field is cleared in the PFC entry for that file. Setting the AFOBS flag or clearing the asa in the PFC ensures that the current version of the file will be copied to 7990 when that file is again selected for being released from disk.

If the file is purged, its disk space, but not its 7990 space, is immediately released. The SSVAL utility must be run to release 7990 space allocated to purged files. Thus, because a purged file has no PFC entry linking to its 7990 catalog entry, the 7990 image that still exists before SSVAL is run is called an orphan file. However, a user can never access an orphan file.

When a file is destaged to 7990, control information is written on each stripe to which the file data is written. This information is sufficient to identify the file.

#### SSEXEC

SSEXEC is the main processing program that is responsible for controlling MSAS activities. The MSAS utilities issue requests to SSEXEC to destage files from disk to 7990, purge unneeded 7990 files, label or relabel cartridges, update SM maps and 7990 catalogs, and so forth. In a multimainframe environment, two versions of this program exist: the mainframe to which the 7990 device is physically connected (the master mainframe) has a program called SSEXEC, and all other mainframes (the slave mainframes) have a program called SSSLV. Refer to section 13, Multimainframe Operations, for more information.

#### Subfamily

Each permanent file family consists of eight subfamilies, subfamily 0 through subfamily 7. The lower 3 bits of the user index identify the subfamily to which a user belongs. For example, a user whose index ends in 3 (or 011 in bit notation) belongs to subfamily 3. When the SSDEF utility is run to create MSAS system files, the SM maps are created on the master device under user index  $377760_8$  (subfamily 0) and one 7990 catalog is created under each user index  $377761_8$  (subfamily i), i=0,1,2,...,7. When the SSLABEL utility is used to assign an SM, cubicle, or cartridge to a family, it is possible to specify assignment to particular subfamilies of the family.

#### Group

A group is a software-defined structure for allocating cartridges within a subfamily. A group of cartridges is a number of cartridges (up to 16) in which files belonging to a subfamily can reside. Any file can overflow from one cartridge in a group to any other cartridge in the same group. However, no file can overflow from a cartridge in one group to any cartridge in another group. Cartridges are placed in or removed from specific groups by using the SSLABEL utility. The SSVAL utility compares the 7990 catalogs (for each subfamily) with the same information obtained from the PFC entries.

#### Volume

A volume is a software-defined structure used to simplify the allocation and access of large 7990 files. Up to 128 consecutive AUs in a cartridge that have the same status (either allocated or not allocated) are considered to belong to the same volume. These consecutive AUs are composed of stripes that all have the same volume serial number (a physical identifier that is written to the tape on the cartridge). The MSAS software fills cartridges (unallocated volumes) from the beginning to the end with no rewinding. This action minimizes repositioning of the tape in a cartridge for multivolume files.

When a file is staged back to disk, the control information on each stripe is verified. If a discrepancy is detected, an error message is issued, the file stage is aborted, an error flag is set in the PFC entry to indicate that the 7990 file could not be accessed, and the AU conflict flag is set in the 7990 catalog entry for the particular cartridge(s) and AU(s).

# **MSAS UTILITIES**

MSAS utilities are described next. All of these utilities must be run from system origin jobs. In a multimainframe environment, the SSDEF, SSUSE, and SSBLD utilities can be run on any mainframe that has access to the family being processed. However, the remaining utilities must be run on the mainframe on which SSEXEC executes.

# SSDEF

SSDEF creates the system files (SM maps and 7990 catalogs) that are necessary for MSAS processing. If an SM is added to the 7990 hardware configuration, SSDEF is used to create the SM map for that SM. If a family is to be permitted to have 7990-resident files, SSDEF is used to create the eight 7990 catalogs for that family (one catalog for each subfamily).

# NOTE

If the SM parameter is specified, SSDEF will create an SM map for the specified SM (refer to the definition of SM map earlier in this section). It is recommended that the SM map be copied on tape or on another device or family immediately after it is created.

The format of the SSDEF command is:

SSDEF, p1, p2.

| <u>p</u> i    | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| FM=familyname | Family for which 7990 catalogs are to be created, one catalog for each subfamily.         |
| FM            | Same as FM=system default family.                                                         |
| FM omitted    | No 7990 catalogs are to be created. SM=id or SM must be specified.                        |
| SM=id         | SM identifier of the SM for which an SM map is to be created; id is a letter from A to H. |
| SM            | Same as SM=A.                                                                             |
| SM omitted    | No SM map is to be created. FM=familyname or FM must be specified.                        |

## Example:

SSDEF,SM=B.

SMMAPB, the SM map for SM B, is created, and its entries are as described in the definition of SM map earlier in this section. However, since SSDEF does not assign cubicles, the entries for cubicles available for use initially indicate that the cubicles are unassigned.

## SSLABEL

SSLABEL manages cartridge assignment and cubicle allocation in an SM. The following functions are performed through use of directives to SSLABEL.

- Add an SM to a subfamily (AS directive).
- Remove an SM from a subfamily (RS directive).
- Add cubicles to a subfamily, the pool, or the reserved area (AB directive).
- Remove cubicles from a subfamily, the pool, or the reserved area (RB directive).
- Add cartridges to a subfamily or the pool (AM directive).
- Remove cartridges from a subfamily or the pool (RM directive).
- Restore an abnormally removed cartridge (RC directive).
- Repair a cartridge label or overwrite a family label (FX directive).
- Inhibit or allow further allocation of files to a cartridge (IB directive).
- Initiate freeing all files from an existing cartridge (FC directive).

Input to SSLABEL is via a directive file. SSLABEL reads the appropriate SM maps and 7990 catalogs to determine how to process each directive and then issues requests to SSEXEC to read and/or write cartridge labels and to update the SM maps and 7990 catalogs. SSLABEL generates a report detailing the action taken for each input directive. If the assignment information or cartridge label is not appropriate or conflicts with data in the SM map or 7990 catalog, the cartridge label information is included on this report and the cartridge is put into the exit tray. It may be possible to restore such a cartridge, as described under Cartridge Restoration and Reuse later in this section.

# NOTE

SSLABEL updates the SM map for the specified SM (refer to the definition of SM map earlier in this section). It is recommended that the SM map be copied on tape or on another device or family immediately after each update.

Decemintion

The format of the SSLABEL command is:

SSLABEL, p1, p2.

\_

| $\frac{\mathbf{p_i}}{\mathbf{i}}$ | Description                                |
|-----------------------------------|--------------------------------------------|
| I=filename                        | File containing the directives to SSLABEL. |
| I                                 | Same as I=INPUT.                           |
| I omitted                         | Same as I=INPUT.                           |

# Description

| L=filename | File on which listable output is to be written.                              |
|------------|------------------------------------------------------------------------------|
| L          | Same as L=OUTPUT.                                                            |
| L=0        | No output file is to be generated.                                           |
| L omitted  | Same as L=OUTPUT.                                                            |
| Z          | Directives are contained on the SSLABEL command. The I parameter is ignored. |
| Z omitted  | Directives are contained on the file specified by the I parameter.           |

# **SSLABEL** Directives

Pi

The directives to SSLABEL can be specified on a separate file (specified by the I parameter) or after the SSLABEL command (Z specified). If on the input file, each directive must be specified on a separate line using the OP=directive option. Parameters for a directive are on the same line, are separated by commas, and end with a period:

OP=directive,  $p_1, p_2, \ldots, p_n$ .

Example:

SSLABEL, I=DIRFILE.

DIRFILE is the directive file; it contains the following directives.

OP=AM, N=4, PK=D. OP=RM, CN=44455566, FM, SB=1, PK=F.

Two directives to SSLABEL are specified. OP=AM adds four cartridges to the pool of SM A (SM parameter not specified). OP=RM removes the cartridge whose csn is 44455566 from subfamily l of the default family. (Refer to the following descriptions of directives and parameters.)

If the directives are contained on the command, they follow the command terminator. The first character following the terminator is the separator. Any character that does not appear in any of the directives can be used as the separator character. Each directive must be preceded by the separator and terminated by a period.

Example:

SSLABEL,Z./OP=AM, N=4, PK=D./OP=RM, CN=44455566, FM, SB=1, PK=F.

The slant is used as the separator. This command performs the same functions as those in the preceding example.

The following directives are available with SSLABEL. Some of these directives cause cartridges to be physically moved to and from cubicles and the input or exit tray (refer to OP=AM, OP=RM, OP=RC, and OP=FX in the following paragraphs). The remaining directives cause only logical operations to occur, updating the MSAS system files. Descriptions of the parameters for these directives follow the directives.

## OP=AS - Add SMs

OP=AS adds an SM to a subfamily. The 7990 catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily can reside on the specified SM. This directive, however, does not manipulate cartridges or cubicles.

## OP=RS - Remove SMs

OP=RS removes an SM from a subfamily. The 7990 catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily cannot reside on the specified SM. Before OP=RS can be specified, all cubicles in the specified SM must have been removed previously from the family (refer to the OP=RB directive). This directive, however, does not manipulate cartridges or cubicles.

#### OP=AB - Add Cubicles

OP=AB adds an unassigned cubicle within an SM to a subfamily (PT=F), the pool (PT=P), or the reserved area of the SM (PT=R). More than one cubicle (N=n) can be added at a time. Specific cubicles (YI and ZI parameters) can be added, but they must be currently unassigned. For PT=R, YI and ZI must be used to add multiple cubicles; N=n is not valid. The SM map is updated to reflect the new assignment of cubicles. When PT=R is specified, the cubicle is reserved to a different SM map. Cubicles reserved for system use, storage module maintenance, or customer engineering use are reserved at compile time. Cubicles assigned to the pool are not assigned to a family or subfamily.

## OP=RB - Remove Cubicles

OP=RB removes an assigned empty cubicle from a subfamily (PK=F), the pool (PK=P), or the reserved area of the SM (PK=R). More than one cubicle (N=n) can be removed at a time. SSLABEL reads the SM map and selects the first empty cubicle assigned to the subfamily, pool, or reserved area to be removed. Specific cubicles (YI and ZI parameters) can be removed, but they must be empty. The SM map is updated to reflect that the cubicles are unassigned.

## OP=AM - Add Cartridges

OP=AM adds a cartridge to either a specific subfamily (PT=F) or the pool (PT=P). SSLABEL selects the first empty cubicle assigned to the subfamily or pool as the new location for the cartridge. More than one cartridge (N=n) can be added at a time or a specific cartridge (CN=csn) from the pool can be added to a subfamily. The SM map, 7990 catalog, and cartridge label are updated to reflect the new assignment of the cartridge. Cartridges added to a subfamily may be added to a specific group using the GR=n parameter. If cartridges are added to the pool, the GR=n parameter is not valid. The small and large boundaries for file size are specified by the B=n parameter with the OP=AM option. Default is B=600, implying that the first 600 AUs of the cartridge are available for small files. Cartridges added to the pool are not assigned to a family or subfamily. A customer engineer cartridge can be stored into location (0,0) or (0,15) by using the CC=loc parameter.

## OP=RM - Remove Cartridges

OP=RM either removes an empty cartridge from a subfamily (PK=F) and moves the cartridge to the pool (PT=P) or the exit tray (PT=D), or it removes any cartridge from the pool (PK=P) and moves it to the exit tray (PT=D). Any cartridge currently assigned to a subfamily cannot be removed unless it is empty; that is, all AUs must be unallocated. To remove a cartridge that is not empty, first use the OP=FC directive to free up the cartridge.

If the cartridge specified by the CN=csn parameter is lost (does not reside in its assigned cubicle) and if the cartridge is assigned to a family, the LT parameter should be specified. This allows the appropriate entries in the SM map and 7990 catalog to be deleted even though the cartridge is not available to have its label updated. If LT is not specified, an error message is issued and SSLABEL aborts. SSLABEL will not update the SM map and 7990 catalog with the LT parameter unless the lost cartridge flag is set in the 7990 catalog. SSLABEL will set the lost cartridge flag if SSLABEL is run to remove a cartridge that is not present.

If the cartridge specified by the CN=csn parameter is lost and it is in the pool, then the LT parameter should not be used. Rather, SSDEBUG must be run to remove the SM map entry and SSLABEL must be run to reassign the cartridge to the pool.

A specified number (N=n) of cartridges may be removed from a group of a subfamily by using the GR=n parameter.

#### OP=RC - Restore Lost Cartridges

OP=RC restores to its proper cubicle a cartridge that was inadvertently removed from an SM. If restoration is successful, the lost flag in the 7990 catalog is cleared. If data recorded on the cartridge label does not agree with the information in the 7990 catalog and the SM map entry for the cubicle to which the cartridge is to be restored, the cartridge label information is reported and the cartridge is put into the exit tray for use in further processing of the cartridge.

Not more than one lost cartridge can be restored at a time using the OP=RC directive. Also, since customer engineer cartridges do not exist in the SM map, OP=RC will not restore a cartridge to a customer engineer cartridge cubicle.

## OP=FX - Fix Cartridge Labels

OP=FX writes a scratch label on a cartridge identified by the CN=csn parameter and adds the cartridge to the pool. This directive is intended for use when a cartridge label has been destroyed, but the cartridge itself is not physically damaged and can be reused. It can also be used when a cartridge with a family label is to be assigned to a different subfamily using the OP=AM directive, but it is not feasible to first remove the cartridge normally using the OP=RM directive. For example, if SSLABEL is run to add a cartridge to a subfamily, and a system failure occurs before the 7990 catalog and SM map are updated but after the cartridge is relabeled, then the cartridge label does not match the corresponding entries in the 7990 catalog and SM map. Hence, OP=RM cannot be used to remove the cartridge from the subfamily, but OP=FX can be used to rewrite the cartridge label and then OP=AM can be used to add the cartridge to a subfamily. However, if a family label is to be overwritten, the FM=familyname and SB=subfamily parameters must identify the family and subfamily to which the cartridge was assigned. The SM map and 7990 catalog are updated to reflect the new cartridge label.

OP=RM cannot be used with the LT parameter to remove pool cartridges. SSLABEL sets the SM map error flag because no 7990 catalog entries exist for pool cartridges. Use SSDEBUG to remove pool cartridges.

#### OP=IB - Control Cartridge Allocation

OP=IB sets or clears the inhibit allocation flag in the 7990 catalog entry for the specific cartridge (CN=csn). If the flag is set (ON), SSEXEC does not allocate new 7990 files to this cartridge. If the flag is cleared (OF), allocation of files to this cartridge is enabled.

## OP=FC - Free Cartridge Files

OP=FC sets or clears the free cartridge flag in the 7990 catalog entry for the specified cartridge (CN=csn). If the flag is set (ON), SSEXEC will inhibit further allocation. Files can be removed by running the SSVAL utility. Refer to the free cartridge discussion under SSVAL later in this section. If the SM map entry is missing, SSDEBUG must be used to set the free cartridge flag. Refer to the discussion under SSDEBUG later in this section.

## Parameters for SSLABEL Directives

The descriptions of the parameters to the SSLABEL directives follow. Not all parameters are valid with all directives, as indicated.

# P<sub>i</sub>

Description

B≃n

Number of AUs on this cartridge to be used to store small files. The remaining AUs (1931-n) are reserved for large files. The distinction between small and large files is controlled by an assembly parameter. B=n is valid only with OP=AM.

B omitted

Same as B=600.

# Description

| <sup>p</sup> i | Description                                                                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CC=loc         | Location into which the cartridge is to be stored.                                                                                                                                       |
|                | loc Description                                                                                                                                                                          |
|                | A Store cartridge into location (0,0).                                                                                                                                                   |
|                | B Store cartridge into location (0,15).                                                                                                                                                  |
|                | Any value of CC other than A or B is not accepted.                                                                                                                                       |
| CM=A-          | Cartridge manufacturer code is A-, indicating IBM.                                                                                                                                       |
| CM             | Same as CM=A                                                                                                                                                                             |
| CM omitted     | Same as CM=A                                                                                                                                                                             |
| CN=csn         | Cartridge serial number of the cartridge to be added, removed, or<br>repaired; not valid if PK=pkloc is specified. If CN=csn is<br>specified, n must be l if N=n is specified.           |
| CN             | Cartridge serial number of the cartridge is not specified.                                                                                                                               |
| CN omitted     | Same as CN.                                                                                                                                                                              |
| FM=familyname  | Family to which SSLABEL adds or from which it removes a cartridge or SM. With OP=FX, this parameter specifies the family to which the cartridge was assigned.                            |
| FM             | Same as FM=system default family.                                                                                                                                                        |
| FM omitted     | Same as FM=system default family.                                                                                                                                                        |
| GR=n           | Group to which SSLABEL adds or from which it removes a cartridge; $1 \le n \le 20$ . With OP=AM, this parameter is ignored if PT=P is specified. GR=n is valid only with OP=AM or OP=RM. |
| GR             | Not permitted.                                                                                                                                                                           |
| GR omitted     | Default groups are chosen sequentially. SSVAL runs most efficiently if SSLABEL chooses the default groups.                                                                               |
| LT             | SM map and 7990 catalog entries are to be updated, even though the cartridge is lost and its label cannot be updated; valid only with OP=RM.                                             |
| LT omitted     | If the cartridge is lost and OP=RM is specified, an error message is issued and SSLABEL aborts.                                                                                          |
| N=n            | Number of cartridges or cubicles to be added, removed, or repaired; $l \leq n \leq 100$ ; not valid if PT=R is specified. If CN=csn is specified, n must be l.                           |
| N              | Same as N=1.                                                                                                                                                                             |
| N omitted      | Same as N=1.                                                                                                                                                                             |

11-18

| ₽ <sub>i</sub> |              | Description                                                                                                                                             |

## SSLABEL Update Sequence

Each directive to SSLABEL updates SM maps, 7990 catalogs, and cartridge labels, whichever are appropriate, to reflect the changes in cartridge, cubicle, or SM assignment. Because the 7990 catalog is a disk-resident permanent file, it will be backed up on a dump tape whenever PFDUMP dumps the master device for its particular subfamily. Thus, it is not necessary for the analyst to back up the 7990 catalogs immediately after an SSLABEL run. However, the backup and recovery of SM maps do require special operational procedures, which should be performed immediately after an SSLABEL run (refer to the definition of SM map earlier in this section).

When SSLABEL is run to change the assignment of a cartridge, the update sequence consists of a series of steps to delete the old assignment information from the MSAS system files, relabel the cartridge, and add the new assignment information to the MSAS system files. If an interruption such as a system failure, SSLABEL abort, or SSEXEC abort prevents SSLABEL from completing the update sequence, the location of the affected cartridge and the status of the SM maps and 7990 catalogs depend on the point of interruption, as follows:

- If the cartridge label, 7990 catalog, and SM map do not all match, then the cartridge is put into the exit tray. The OP=RC directive cannot be used to restore the cartridge because of the inconsistency. However, OP=FX can be used to overwrite the cartridge label and add the cartridge to the pool, if the FM and SB parameters specify the family and the subfamily on the cartridge label.
- If the cartridge label, 7990 catalog, and SM map do match, then the cartridge may be returned to its original location, the new location, or the exit tray, depending on the exact point of interruption. If the cartridge is in the input tray, OP=RC can be used to restore the cartridge to the location indicated on the cartridge label.

Cartridge Restoration and Reuse, later in this section, describes the procedure for restoring cartridges found in the exit tray.

#### **Restrictions to SSLABEL**

The following restrictions apply to the SSLABEL utility.

- SSEXEC must be running when SSLABEL is run.
- Only one copy of SSLABEL can be run at a time.
- SSLABEL, SSVAL, and SSDEBUG cannot be run at the same time.

#### Example

The following output shows the format of an SSLABEL report. The cartridge label information is included on the report because of a mismatch with the SM map. An error message is issued for the first directive on the command (in this case, the only directive).

SSLABEL REPORT FILE

SSLABEL,Z./OP=RC,PK=D,SM=B.

- 1 OP=RC,PK=D,SM=B.
- 1 OP=RC,PK=D,SM=B.

```
CM=A-

CSN = 66157234

FAMILY = SYSTST

SUBFAMILY = 0

SM = B

Y = 2

Z = 6

# SSMOVE

SSMOVE manages disk and 7990 residence. That is, SSMOVE determines which files should be left on disk, which files should be released from disk and moved to 7990, and which files should be resident both on disk and on 7990.

The selection process includes algorithms that weigh certain file characteristics, as follows:

- Files are selected for destaging to 7990 based on file length, time since the last update, and the preferred residence specified by the user.
- Files are selected for release from disk based on time since the last access and the backup requirement specified by the user.

SSMOVE reads the PFC entries for a particular family and calculates release and destage values (refer to Selection Algorithms later in this section) for each file to determine its residence. If a file has both disk and 7990 images but is to reside only on 7990, SSMOVE releases the disk space for the file. For files that do not have a 7990 image, SSMOVE creates entries on the SSMOVE/SSEXEC communication file, MV0COM, to identify the files to be destaged and to specify whether or not the file's disk space is to be released upon completion of the destage. SSEXEC then processes each destage and destage/release request on MV0COM.

SSMOVE generates an output report that includes a list of input directives to SSMOVE, site-defined values used in the destage/release decision-making process, files selected for processing, and a summary of the number of files expected to reside on each device after destage/release processing. The format of the SSMOVE command is:

 $ssmove, p_1, p_2, \ldots, p_n$ .

| <sup>p</sup> i | Description                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|
| DN=device      | Device number of the only disk from which files are to be destaged/released.                                 |
| DN             | SSMOVE destages and releases files from all devices in a specified family.                                   |
| DN omitted     | Same as DN.                                                                                                  |
| FM=familyname  | Family to be used by SSMOVE.                                                                                 |
| FM             | Same as FM=system default family.                                                                            |
| FM omitted     | Same as FM=system default family.                                                                            |
| I=filename     | File containing the directives to SSMOVE.                                                                    |
| I              | Same as I=INPUT.                                                                                             |
| I=0            | No input directives file exists. SSMOVE uses the default parameters.                                         |
| I omitted      | Same as I=INPUT.                                                                                             |
| L=filename     | File on which listable output is to be written.                                                              |
| L              | Same as L=OUTPUT.                                                                                            |
| L=0            | No output file is to be generated.                                                                           |
| L omitted      | Same as L=OUTPUT.                                                                                            |
| LB=n           | Large file boundary is used when sorting files for destaging. All files smaller than n PRUs are small files. |
| LB             | Same as LB=365.                                                                                              |
| LB omitted     | Same as LB=365.                                                                                              |
| LO=F           | All files selected for staging, destaging, or releasing are to be included in the report file.               |
| LO=P           | Only files actually processed are listed in the report file. Refer to the PX parameter.                      |
| LO             | Individual files are not to be listed in the report file.                                                    |
| LO omitted     | Same as LO.                                                                                                  |

| <sup>p</sup> i | Description                                                                                   |                                                                                                                                                             |  |

# **SSMOVE** Directives

The directives to SSMOVE are specified on a separate file. Each directive must be specified on a separate line. Three types of input directives can be included in an SSMOVE directive file. They are: comment directives, specific file directives, and value specifier directives.

Comment directives have an asterisk (\*) in the first column followed by any message or comment the user wishes to enter.

The specific file and value specifier directives are described in the following paragraphs.

.

## Specific File (SF) Directives

SSMOVE uses SF directives to select a given file or set of files on which to perform the specified processing action. The format of the SF directive is:

SF,FN=filename,UI=userindex,PO=process.

| Parameter           |                                                                                         | Description                                                                               |  |  |
|---------------------|-----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|--|--|
| FN=filename         |                                                                                         | cters that specify a permanent file or set of<br>Asterisks in the file name are wild card |  |  |
| <b>UI=userindex</b> | User index of the file specified by the FN=filename parameter.                          |                                                                                           |  |  |
| P0=process          | Processing action to be performed on the file specified by the $FN=filename$ parameter. |                                                                                           |  |  |
|                     | process                                                                                 | Description                                                                               |  |  |
|                     | A                                                                                       | Archive the specified file.                                                               |  |  |
|                     | В                                                                                       | Create a backup copy by destaging the specified file from disk to the 7990.               |  |  |
|                     | F                                                                                       | Free the specified file from the 7990 by clearing its asa value in the file's PFC entry.  |  |  |
|                     | S                                                                                       | Stage the specified file from the 7990 to disk.                                           |  |  |

For example, the following SF directive selects all permanent files with a 2-character permanent filename beginning with Z from user index 0026228 to be staged to disk.

SF,FN=Z\*,UI=2622,PO=S.

The SF directive can be used without specifying the FN parameter to establish default values for the UI and/or PO parameters. These default values will be used for subsequent SF, FN=filename directives that are missing UI and/or PO parameters. Default values for UI and/or PO parameters can be redefined by using another SF directive without specifying the FN parameter.

## Value Specifier Directives

SSMOVE uses the value specifier directives to redefine the values of the weight factors or thresholds (installation parameters) used in the algorithms that select files to be destaged or released. The site analyst uses these value specifiers to increase or decrease the importance of certain file characteristics used to determine which files are to be destaged and/or released. For example, specifying a large MN parameter prohibits SSMOVE from selecting small files for destage/release processing.

# The general format of a value specifier directive statement is:

directive,qualifier(s),parameter(s).

| directive | Description                                            |  |  |  |  |
|-----------|--------------------------------------------------------|--|--|--|--|
|           | Enter a 2-character value specifier directive keyword. |  |  |  |  |
| BR        | Keyword for backup requirement directive.              |  |  |  |  |
| FR        | Keyword for file requirement directive.                |  |  |  |  |
| PR        | Keyword for preferred residence directive.             |  |  |  |  |
| SM        | Keyword for site management directive.                 |  |  |  |  |
| WA        | Keyword for weight adder directive.                    |  |  |  |  |
| WM        | Keyword for weight multiplier directive.               |  |  |  |  |

#### qualifier(s)

## Description

Enter one or more qualifier keywords that specify the file type (direct/indirect access) and decision type (destage/release) to be used in the selection process. If all qualifier keywords are omitted, all four combinations of file types and decision types are used in the selection process.

IA Keyword for indirect access files.

DA Keyword for direct access files.

DS Keyword for destage decisions.

RL Keyword for release decisions.

#### parameter(s)

#### Description

Enter a parameter keyword and a value (positive integer) for the specified directive keyword. Multiple parameter=value combinations can be entered in the same value specifier directive statement.

#### BR Directive Parameters

| τ. | aı | a | шç | • | C. | L | Э |
|----|----|---|----|---|----|---|---|
| _  | _  | _ | _  | _ | -  | - |   |

| N=wf  | wf is the weight factor to be used as the backup requirement value for decisions involving files with a BR=N attribute (no backup).†            |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Y=wf  | wf is the weight factor to be used as the backup requirement value for decisions involving files with a BR=Y attribute (tape backup). $\dagger$ |
| MD=wf | wf is the weight factor to be used as the backup requirement value                                                                              |

for decisions involving files with a BR=MD attribute (media dependent, tape, or 7990 backup).†

<sup>†</sup>The file owner specifies the backup requirement attribute using the BR parameter on the DEFINE or CHANGE command (refer to the NOS 2 Reference Set, Volume 3).

| P2                         | Available for site use.                                                                                                                                                                                                                                                                                                                                      |
| WA Directive<br>Parameters |                                                                                                                                                                                                                                                                                                                                                              |
| AG=wa                      | wa is the weight adder to be added to the weighted file age.                                                                                                                                                                                                                                                                                                 |
| LN=wa                      | wa is the weight adder to be added to the weighted file length.                                                                                                                                                                                                                                                                                              |
| AC=wa                      | wa is the weight adder to be added to the weighted file access count.                                                                                                                                                                                                                                                                                        |
| DV=sf                      | sf is the scaling factor given to the divisor when calculating destage and release values.                                                                                                                                                                                                                                                                   |
|                            |                                                                                                                                                                                                                                                                                                                                                              |

<sup>&</sup>lt;sup>†</sup>The file owner specifies the preferred residence attribute using the PR parameter on the DEFINE or CHANGE command (refer to the NOS 2 Reference Set, Volume 3).

## parameter(s)

#### Description

WM Directive Parameters

AG=wf wf is the weight factor given to the file age (days since the file was last accessed or updated).

LN=wf wf is the weight factor given to the file length.

AC=wf wf is the weight factor given to the file access count.

For example, the following value specifier directive specifies that the minimum size for an indirect access file to be destaged is three disk PRUs.

FR, IA, DS, MN=3.

The following value specifier directive requires that all files to be destaged or released must be less than 98765 PRUs long.

FR, MX=98765.

If a directive error is detected on the directive input file, SSMOVE ignores the incorrect directive and continues to run in report mode. A message is issued to the job dayfile and no processing is done.

#### Excluding Destage/Release Processing

SSMOVE uses FR directives to select candidates for destage and release processing. After selecting the candidates and making the final processing decisions, SSMOVE checks the PX parameter to determine if any processing should be excluded.

If FR,RL,MN=99999999 is specified, all files less than 9999999 PRUs will be given a negative release value. Any file less than 9999999 PRUs will not be released unless the file has been specifically selected for releasing with an SF directive.

IF PX=A is specified, SSMOVE selects files for processing without considering that release processing is prohibited. When the final processing decisions have been made, any files selected for releasing will not be processed. That is, files selected for releasing only will not be processed; and files selected for both destaging and releasing will not be processed.

If PX=B is specified, destage processing is excluded just as release processing was in the previous description.

Destaging cannot be excluded with an FR,DS,MN=99999999 directive as releasing can. Even though all files less than 9999999 PRUs will be given a negative destage value and not selected for destaging, they will be made candidates for destaging in case any of them are selected for releasing. When the final processing decisions are made, any file that is a candidate for destaging and has been selected for releasing will be destaged and released. However, any destaging candidate not selected for releasing will not be destaged.

#### **Selection Algorithms**

SSMOVE determines which files to destage and/or release according to the following algorithms. Files that reside only on 7990 are not considered because they have been destaged and released previously. For all other files, SSMOVE checks the file length and excludes from further consideration any file whose length in PRUs is less than the minimum length threshold (refer back to the MN parameter) or greater than the maximum length threshold (refer back to the MX parameter).

If the current image of the file resides on both disk and 7990, SSMOVE uses the release algorithm to determine whether or not to release disk space; the destage algorithm is not used. If the current file resides on disk only, SSMOVE uses the destage algorithm to determine whether or not to destage the file. If the file is to be destaged to 7990, SSMOVE also determines via the release algorithm whether or not to release the file's disk space.

# Destage and Release Algorithms

An analyst uses the FR directive to establish file requirements on files that are to be eligible for destage and/or release processing. These requirements include file length (minimum and maximum) and file age. A file's age is the number of days since the file was last updated (for destaging) or accessed (for releasing). Separate requirements can be established for the various combinations of file types (direct/indirect) and decision types (destage/release).

Files that meet the eligibility requirements are assigned separate destage and release values. SSMOVE calculates these values for each eligible file according to the following equation, which considers various file attributes from the file's PFC entry (length, age, access count, preferred residence, and backup requirements). These file attributes are weighted according to site-defined values (refer to Value Specifier Directives earlier in this section).

| value = $\frac{(a_1+a_2*1e_1)}{(a_1+a_2*1e_1)}$ | ngth)*(b1+b2*age)*(res)*(bkup)                                                                                                                                                    |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                 | $(c_1+c_2*access)*sf$                                                                                                                                                             |
| Variable                                        | Description                                                                                                                                                                       |
| al                                              | Site-defined length weight adder specified by the LN parameter of the WA directive.                                                                                               |
| a2                                              | Site-defined length weight factor specified by the LN parameter of the WM directive.                                                                                              |
| length                                          | Length of the file in PRUs.                                                                                                                                                       |
| ъ1                                              | Site-defined age weight adder specified by the AG parameter of the WA directive.                                                                                                  |
| b2                                              | Site-defined age weight factor specified by the AG parameter of the WM directive.                                                                                                 |
| age                                             | Number of days since the file was last updated (for destage) or accessed (for release).                                                                                           |
| res                                             | Site-defined preferred residence weight factor specified by the PR directive. The PR directive parameter depends on which preferred residence attribute the file owner specified. |

| Variable       | Description                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bkup           | Site-defined backup requirement weight factor specified by the BR<br>directive. The BR directive parameter depends on which backup<br>requirement attribute the file owner specified. |
| cl             | Site-defined access count weight adder specified by the AC parameter of the WA directive.                                                                                             |
| c <sub>2</sub> | Site-defined access count weight factor specified by the AC parameter of the WM directive.                                                                                            |
| access         | Number of times the file was accessed.                                                                                                                                                |
| sf             | Site-defined scaling factor specified by the DV parameter of the WA directive.                                                                                                        |

If a file's destage/release value exceeds a site-defined threshold (TH parameter of the FR directive), the file is selected for destage/release processing. Conversely, if the file's destage/release value does not exceed the threshold, the file is not considered for destage/release processing.

Files eligible for releasing are sorted according to their release values. The files on each disk with the greatest release values are selected to be released. When enough files have been selected and released, the site-defined disk space availability goals will be achieved.

#### Decision Algorithm Hierarchy

Several different functions of SSMOVE can lead to apparent contradictory processing decisions. The decisions are made using the following rules, which are listed in order of precedence.

- SSMOVE does not consider any files for processing if they are excluded by the PX=I, PX=D, or UI parameters to SSMOVE or if the file has a PR=L attribute.
- Files identified for specific processing using the SF directive are selected for the specified processing regardless of the file requirements controlled by the FR directive.
- 3. If DN=0, all files that meet the destage requirements are selected to be destaged. Otherwise, only files on the specified device are destaged.
- 4. No file with a BR=Y attribute will be selected to be released (including files specified for processing with an SF directive) if the file data has not been included in a full or incremental dump using PFDUMP.
- 5. If DN=0, all files that meet the release requirements are selected to be released, if needed, to meet the disk space availability goals. Otherwise, only files on the specified device are released.
- 6. If a file is selected for a specific processing action (such as destage) and the corresponding action is precluded by a PX parameter (in this case, PX=B), then the selected action is not performed. In all cases, however, the SSMOVE device status report is based on which files were selected for processing rather than whether the PX parameter actually allowed the selected processing to occur.

#### **Disk Space/Dump Tape Management**

As more disk-resident files are created and more 7990-resident files are staged to disk, it will be necessary to monitor the availability of disk space. It is recommended that SSMOVE be used as a periodic disk space management procedure to avoid frequent disk-full conditions (refer to Disk Space Management later in this section). SSMOVE can also be used to reduce the amount of data written on dump tapes and thereby avoid maintaining large numbers of dump tapes. This is accomplished by destaging to 7990 and/or releasing disk space of files that need not be on the dump tape (refer to Dump Tape Management later in this section).

An analyst can specify what percent of disk space is to contain indirect access files and what percent is to contain direct access files. For direct access files, the analyst can further specify the percent of master device and/or secondary device disk space. These percent values are applied to all devices in the family on which SSMOVE is run or a specific device can be managed by using the DN parameter to SSMOVE. The specified percentages of disk space are considered to be goals in that other site-defined constraints and file-busy conditions may make it impossible to achieve these goals.

# **Restrictions to SSMOVE**

Only one copy of SSMOVE per family can be run at a time. A second SSMOVE aborts if the first one has not completed.

SSMOVE and PFDUMP should not be run at the same time. The concurrent execution of PFDUMP and SSMOVE to destage files may result in errors in the PFC entries.

#### **Output Example**

The SSMOVE report consists of the following five sections.

- A list of directives from the input directive file plus any diagnostic messages.
- A list of run-time parameter values used in the release and destage decision-making process. These values consist of the site-defined, assembly-time values as modified by the value specifier directives.
- An optional list of the files selected for processing. This list shows the file name, file type, user index, length, date, access count, processing action, and destage and release values.
- A device status report that includes a summary of the number of files and total file length expected to reside on each device as a result of release processing. Also, a subfamily report that includes a summary (for each subfamily) of the number of files and file length for files to be destaged, files that reside only on 7990, and files that reside on 7990 and disk.
- A destage abandonment report that is not produced if the NW parameter is specified. This report provides a list of the number of files not destaged and an optional list of the abandoned files. It also provides an updated device status report reflecting only the files that were destaged.

#### SSVAL

SSVAL either performs release processing or reports on problems with the current MSAS system files. When release processing, SSVAL makes 7990 space available that is presently allocated to files that are no longer needed, or flags files to be staged to disk in order to free up cartridges. When problem reporting, SSVAL reports on irregularities or discrepancies found in the current 7990 catalogs and PFC entries for the specified family and, optionally, in certain SM maps. The function to be performed is determined by whether or not the RF parameter is specified, as described next.

# NOTE

SSVAL updates the SM map for the specified SM. (Refer to the definition of SM map earlier in this section.) It is recommended that the SM map be copied on tape or on another device or family immediately after every update of the SM map.

The format of the SSVAL command is:

 $SSVAL, p_1, p_2, \ldots, p_n$ .

| P <sub>i</sub> | Description                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AM             | The SM map for the SM specified by the SM=id parameter is to be analyzed in addition to the 7990 catalogs; not valid if RF=filename or RF is specified.    |
| AM omitted     | SM maps are not to be analyzed.                                                                                                                            |
| FM=familyname  | Family to be analyzed; not valid if the RF parameter is specified.                                                                                         |
| FM             | Same as FM=system default family; not valid if the RF parameter is specified.                                                                              |
| FM omitted     | Same as FM=system default family if the RF parameter is not<br>specified. The family on the release data file is used if the RF<br>parameter is specified. |
| FX=n           | Error threshold. If the total error count is greater than n, neither release processing nor problem fixing is performed.                                   |
| FX             | Same as FX=0.                                                                                                                                              |
| FX omitted     | Same as $FX=0$ .                                                                                                                                           |
| L=filename     | File on which listable output is to be written.                                                                                                            |
| L              | Same as L=OUTPUT.                                                                                                                                          |
| L=0            | No output file is to be generated.                                                                                                                         |
| L omitted      | Same as L=OUTPUT.                                                                                                                                          |

## Description

| <sup>p</sup> i | Description                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RF=filename    | File that contains the release data file.                                                                                                                      |
| RF             | Same as RF=ZZZZRDF.                                                                                                                                            |
| RF omitted     | Current versions of the 7990 catalogs are to be analyzed.                                                                                                      |
| RL             | Release processing is to be performed; valid only if the RF parameter is specified.                                                                            |
| RL omitted     | No release processing is to be performed.                                                                                                                      |
| SB=subfamily   | Subfamily to be processed. Up to eight subfamilies can be selected<br>by the numbers 0 through 7. For example, SB=723 selects subfamilies<br>2, 3, and 7.      |
| SB             | Same as SB=01234567.                                                                                                                                           |
| SB omitted     | Same as SB=01234567.                                                                                                                                           |
| SM=id          | SM identifier of the SM to be used. Up to 8 SMs can be selected by the letters A through H. For example, SM=ACG selects SM A, C, and G.                        |
| SM             | Same as SM=ABCDEFGH.                                                                                                                                           |
| SM omitted     | Same as SM=ABCDEFGH.                                                                                                                                           |
| ST=n           | Scattered file criterion. Files are indicated as scattered if they are contained on at least n more cartridges than the minimum number needed to contain them. |
| ST             | Same as ST=1. That is, files are scattered if they are contained on more than the minimum number of cartridges needed to contain them.                         |
| ST omitted     | Same as ST=1.                                                                                                                                                  |

#### **Release Processing**

If RF=filename or RF is specified, SSVAL determines which 7990 files are no longer needed and issues a request to SSEXEC to purge these files so their 7990 space can be reused. The procedure is for SSVAL to analyze copies of the 7990 catalogs and PFC entries for the specified family that are contained on the release data file (RDF) specified by the RF parameter. Those 7990 files described in a 7990 catalog but not having a PFC entry (that is, orphans) can be purged. During the analysis (refer to both 7990 Catalog Analysis and PFC Analysis later in this section), SSVAL keeps track of the error conditions it discovers, and if the error count is less than or equal to the threshold specified by the FX parameter, release processing is performed if RL is specified. That is, trouble-free orphans are purged and their 7990 space is made available for reuse. The current 7990 catalog is updated to reflect that these files no longer exist. A validation report is issued that lists the errors encountered, the number of trouble-free orphans, and the amount of released 7990 space. If RL is not specified, no release processing is performed but the validation report is issued, which lists the errors encountered, the number of trouble-free orphans, and the amount of releasable 7990 space.

The RDF used for this analysis is a file produced during a previous PFDUMP run and it contains versions of the 7990 catalogs and PFC entries that were current at the time of the dump. The site analyst chooses which RDF to use depending on how long after a file was purged he/she wants to wait before releasing 7990 space. For example, the site analyst might run SSVAL every week for release processing purposes and use the RDF from the previous week's full dump. There are some restrictions as to which RDFs can be used (refer to 7990 Space Management later in this section).

Unlike the purging of disk-only files, where the file space on disk is immediately made available for reassignment, the MSAS software will not immediately free up a permanent file's 7990 space following a purge of the associated disk copy of the permanent file (assuming both a 7990 and a disk permanent file image). The reason for not freeing up the subject 7990 space is that a subsequent PFLOAD, following a disk failure, could reload the PFC entry for the associated permanent file. Therefore, 7990 space for purged permanent files that were resident on the 7990 must not be made available for reuse until the possibility of such a recovery action cannot occur.

The site analyst determines which dump tapes can and cannot be used for reloading files and PFC entries following a disk failure. When a PFDUMP is taken, two files are normally produced: the actual dump file used with PFLOAD to perform a recovery, and the RDF file to be used with SSVAL to make 7990 space available after purging files.

Using an RDF file allows the corresponding dump tape to be used (later dump tapes are also allowable), but earlier dump tapes are not allowed. Because the MSAS software cannot control which dump tapes actually are used in reloading, it is the site analyst's responsibility to observe the above restriction.

The concurrent execution of PFDUMP with OP=S not specified and SSVAL with RL specified causes SSVAL to run very slowly. PFDUMP acquires and keeps the PF utility interlock for its duration, and this gives the appearance that SSVAL is hung, when it is actually just waiting. Therefore, operations personnel should not attempt to run both of these utilities with the above options at the same time.

If the RF parameter is not specified, SSVAL will set the free file flag for all files that totally or partially reside on all cartridges on which the free cartridge flag is set.

#### **Problem Reporting**

If RF=filename or RF is not specified, SSVAL reports on problems with the current 7990 catalogs and PFC entries for the specified family. If AM is specified, problems with SM maps are also included in the report. SSVAL examines the MSAS system files and PFC entries and searches for problem chains and fragments, problem asa values, and SM map/7990 catalog mismatches. The procedures SSVAL uses to detect and classify inconsistencies and discrepancies are described next, under Error Detection and Classification. SSVAL keeps track of the error conditions, if any, and if the error count is less than or equal to the threshold specified by the FX parameter, problem fixing is performed. That is, SSVAL sets flags in the appropriate entries of the SM map, 7990 catalog, and/or PFC entries to prevent propagation of errors due to the inconsistencies or discrepancies found and to permit error recovery by the SSDEBUG utility. A count of the errors is recorded in the job dayfile. A validation report is issued, which lists the errors encountered, the number of trouble-free orphans, and the amount of releasable 7990 space.

# NOTE

For release processing or problem fixing, SSVAL predicts what it expects to happen (if no problems occur) prior to doing the releasing or fixing. If SSVAL encounters problems, the reports may not reflect the actual status of the cartridges. In this case, run SSVAL in report mode following the release processing or problem fixing to verify the actual status of the 7990 catalogs and cartridges.

# **Error Detection and Classification**

SSVAL detects and classifies errors according to the following procedures. During the SM map analysis, SSVAL detects and classifies errors in the SM map. During the 7990 catalog analysis, SSVAL detects errors with chains of AUs; during the PFC analysis, SSVAL classifies these errors. Whenever an error is encountered, the total error count is increased by 1. The action taken for each type of error is discussed under Release Processing and Problem Fixing later in this section.

#### SM Map Analysis

If the AM option is specified, SSVAL attempts to locate problems with SM map entries by comparing the 7990 catalogs and the SM map. For each coordinate pair (y,z) in a 7990 catalog entry, SSVAL locates the corresponding SM map entry. A type l error exists if the code field in the SM map entry is not 5 (assigned to a subfamily), or if the family, subfamily, or csn fields in the SM map entry do not match those in the corresponding 7990 catalog entry. SSVAL also scans the SM map for all other entries assigned to the subfamily and reports as a type 2 error any of these entries that does not have a corresponding 7990 catalog entry.

## 7990 Catalog Analysis

The 7990 catalog analysis locates problems with chains of AUs (refer to the definition of cartridge earlier in this section) and identifies on each HOC whether any of the following problems exist or whether any part of the 7990 files resides on a cartridge that is lost or has excessive write parity errors.

SSVAL scans the 7990 catalog for HOC entries that are allocated and follows each chain until it terminates. Normal termination occurs with an EOC entry. Abnormal termination occurs when no EOC is found, an AU links to an unallocated AU, or an AU links to an AU previously found in the chain being followed (looping chain). During the chain scans, the following types of chains can be encountered; they are linkage problems that are identified on the HOC entry.

Chain

# Description

Intersecting More than one chain links to the same AU.

Scattered file The number of cartridges used for the file exceeds the value specified by the ST parameter.

SSVAL also locates any AUs that are allocated but were not on any chain being followed. Such AUs are linked together to form partial chains without an HOC. These partial chains are called fragments and the first AU in a fragment is designated as the start of fragment. Each fragment chain is followed until it terminates. The abnormal termination conditions previously listed can also occur with fragments. Intersections can occur, but a fragment chain that intersects the start of another fragment chain is not an intersection; rather, one is the tail end of the other.

#### PFC Analysis

The PFC analysis is performed to classify the errors encountered on chains during the 7990 catalog analysis. For each PFC entry with  $asa\neq 0$  (the file has a 7990 image and the asa value identifies the first AU in the chain containing the file), SSVAL classifies the following errors. Error type 3 exists if the asa value is invalid. Error type 4 exists for any of the following reasons.

- The AU specified by the asa value is not allocated or is not an HOC entry.
- The chain does not terminate normally.
- The chain intersects with another chain or fragment.
- More than one PFC entry points to the chain.
- The chain includes a cartridge for which the lost or excessive parity error flag is set.

SSVAL also classifies the following error conditions.

- Error type 5 exists if an orphan chain terminates abnormally or intersects with other chains or fragments. Trouble-free orphans (chains without a PFC entry pointing to them and without linkage problems) are not classified as errors.
- Error type 6 exists if an orphan is a fragment.
- Error type 7 exists if a chain or fragment points to an unallocated AU.

SSVAL generates informational report messages if either of the following conditions is true.

- The system error flag is set in the PFC.
- The read error flag is set in the PFC.

#### **Release Processing and Problem Fixing**

If the total error count calculated during the analyses described previously exceeds the value specified by the FX parameter, then neither release processing nor action to flag or fix the detected error conditions is performed. The validation report, however, is produced. Otherwise, action taken depends on the parameter specified and the type of errors found, as follows.

If SSVAL was run for release processing purposes (RF=filename or RF specified), SSVAL issues a request to SSEXEC to release trouble-free orphans if RL was specified. If RL was not specified, no release processing is performed. If SSVAL was run for problem reporting purposes (RF omitted and FX=n, where n is greater than the number of validation errors), the following action is taken.

- For error type 1, the linkage error flag is set in the 7990 catalog entry.
- For error type 2, the linkage error flag is set in the SM map entry.
- For error type 3, there are three alternatives:
  - If the file also has a disk image, the asa field in the PFC entry is cleared. Thus, the good disk image will not be released and the file is accessible even if the 7990 image cannot be retrieved.
  - If the file does not have a disk image, no action is taken.
  - However, if the disk image can be reloaded from tape, it is recommended that the file be reloaded using PFLOAD with OP=Z so that the asa field will be cleared.
- For error type 4, the action taken is both that taken for error type 3 and that taken for error type 5, 6, or 7.
- For error type 5, 6, or 7, the frozen flag is set in the 7990 catalog entry for the initial AU on the problem chain or fragment. This enables the problem chain/fragment/AU to be made available to the SSDEBUG utility, but prevents these AUs from being overwritten until then. Thus, the SSDEBUG utility can be used to inspect or save data from the corresponding AUs or cartridges. If the AUs are not allocated, the inhibit flag is also set in the 7990 catalog for that cartridge so that no new files will overwrite any data that might be on the cartridge.

## **Validation Report**

The validation report consists of a report heading and a series of report groups for each subfamily and SM being reported on. The heading identifies the subfamily, the SM, whether or not there are any problems, and the last purge date and time for the SM (the last time orphans on this SM were released). There is one report group for each error detected, and the actual information recorded in a report group depends on the type of error, as described next. Each report group, however, contains the following items.

- Error type (a number from 1 to 7).
- Identification (refer to the particular error type, described next).
- Chain information (7990 catalog ordinal, AU number, A or U designation for allocated or unallocated, H or E designation for HOC or EOC).
- Error description.

After the last report group, the validation report lists the number of trouble-free orphans, the amount of released or releasable 7990 space, the total number of errors detected, and whether or not the MSAS system files were updated.

#### Error Types 1 and 2

Error types 1 and 2 identify mismatches between the SM map and the 7990 catalog. In the validation report, the identification field lists the 7990 catalog ordinal, the y and z coordinates, and the csn of the cartridge in error. The chain field is blank because problem chains are not identified as either error type 1 or 2. The analyst should run the SSUSE utility to produce a detailed report of the appropriate SM map and 7990 catalog entries to determine the exact problem.

## Error Types 3 and 4

Error types 3 and 4 identify problem chains and problem as avalues. In the validation report, the identification field lists the permanent file name and user index of the affected file; the dump control date and time (from the PFC entry for the file) to identify the backup file, if any; and the letter N (no) or Y (yes) to indicate whether or not the file has a disk image. The chain field lists the 7990 catalog ordinal and volume number for all AUs in the affected chain. An A or U indicates whether each AU is allocated or unallocated, and an H or E identifies the HOC or EOC. An error description is printed for each error detected; one chain can have several errors.

# Error Types 5, 6, and 7

Error types 5, 6, and 7 identify problem orphans, fragments, and problem unallocated AUs. In the validation report, the information reported is the same as for error types 3 and 4, except for the identification field. Instead of the permanent file identification, the word ORPHAN (error type 5), FRAGMENT (error type 6), or UNALLOCATED (error type 7) is printed. Error type 7 is an unallocated AU that is pointed to by a chain or fragment. Each such AU is also reported with the chain for the corresponding orphan or fragment.

## Intersections

Intersections occur when more than one chain links to the same AU; they are classified as either error type 4 or 5. Thus, they are reported as explained previously. Intersections are also reported in a separate entry consisting of a heading and additional information identifying the 7990 catalog ordinals and AU numbers of the intersecting chains. Therefore, when intersections are reported, there are two entries for the affected subfamily and SM: one lists only the intersections and the other lists all the errors encountered.

#### Validation Report Example

The following output shows the format of a validation report. SSVAL was run for problem reporting purposes (RF not specified), and no errors were detected.

SSVAL - VALIDATION REPORT

FAMILY = SYSTST

SSVAL, FM=SYSTST, SB=0, SM=A.

# **Typical SSVAL Runs**

As described previously, SSVAL is run either to make 7990 space available for reuse or to report on problems with the current MSAS system files and/or PFC entries. The following examples show typical SSVAL runs that may be used periodically for these purposes.

# Example:

The following SSVAL command causes 7990 space to be made available for reuse.

#### SSVAL, RF=DUMP1, RL.

DUMP1 is the release data file produced by a previous PFDUMP run from which SSVAL can identify all the 7990 files that were orphans at the time of the dump. If no error conditions are detected in the 7990 catalog and PFC entries contained on file DUMP1 (FX=0 by default), the orphans are purged and the 7990 space assigned to them is released. The last purge date and time field in the subcatalog (in the 7990 catalog) for each SM for each subfamily is updated to the time of the SSVAL run if any file from that SM is purged. This is to ensure that a subsequent SSVAL run does not release the same space a second time, as the 7990 space may be reallocated to a new file. If errors were detected, they are listed on the validation report and release processing is not performed. This is indicated by the CATALOGS NOT MODIFIED message at the end of the validation report. The analyst can rerun SSVAL with the following command to ensure that release processing is performed (n is the number of errors detected during the previous SSVAL run).

SSVAL, RF=DUMP1, RL, FX=n.

After this SSVAL run has completed, an analysis of the current version of the SM map, 7990 catalog, and PFC entries should be made to determine whether or not the errors detected in the first SSVAL run exist in the current MSAS system files and PFC entries. This is accomplished using the command:

SSVAL,FM=familyname,AM.

familyname is that on the release data file, DUMPl.

Example:

Upon completion of any device reload that includes recovery of a 7990 catalog and/or SM map, SSVAL should be run to determine whether any SM map/7990 catalog mismatches exist. The following call accomplishes this.

SSVAL,FM=familyname,SB=n<sub>1</sub>,n<sub>2</sub>,...,n<sub>h</sub>,AM.

familyname is that for which recovery was done;  $n_1, n_2, \ldots, n_h$  are the affected subfamilies if just some of the devices of the family were reloaded.

SSVAL analyzes the SM map, 7990 catalog, and PFC entries for the subfamilies specified by the SB parameter and reports any discrepancies or inconsistencies. For example, if the recovery was not scheduled and SSLABEL was run to add or remove cartridges or cubicles from one of the affected subfamilies after the last incremental or full dump for these subfamilies, then the SM map will reflect the results of the SSLABEL run but the 7990 catalog will not. Such mismatches will be reported on the validation report.

If the following SSVAL command is then made, the errors detected during the previous run will be flagged, as described previously under Release Processing and Problem Fixing.

SSVAL,FM=familyname,SB=n1,n2,...,nh,AM,FX=n.

familyname and  $n_1, n_2, \ldots, n_h$  are the same as in the previous SSVAL run; n is the number of errors detected during the previous run. After investigating the cause of these errors, the analyst can run the SSDEBUG utility to correct the error conditions (refer to SSDEBUG later in this section).

If a device reload includes recovery of all SM maps (default family, user index= $377760_8$ ), the latest SM maps should be recovered from backup copies. Then each family that has 7990-resident files should be analyzed using the following command to detect SM map/7990 catalog mismatches.

SSVAL,FM=familyname,AM.

It is recommended that the previous SSVAL run be made periodically to check whether any unexpected error conditions exist. As the site analyst becomes more familiar with MSAS processing, these periodic SSVAL runs can be done less frequently.

# **Restrictions to SSVAL**

- Only one copy of SSVAL can be run at a time.
- SSVAL, SSLABEL, and SSDEBUG cannot be run at the same time.

# SSUSE

SSUSE reads data in the 7990 catalogs and SM maps and produces reports on the availability of space on 7990 cartridges and the allocation of cubicle space within an SM. The reports may not be completely up to date because the 7990 catalogs and SM maps can be updated while the reports are being generated.

The types of reports that SSUSE generates are:

| Report             | Description                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Basic usage report | Usage report that lists general information about the use of each SM in a subfamily.                                                                                                                                |
| Optional report A  | SM map report that lists the contents of an SM as described in the SM map.                                                                                                                                          |
| Optional report B  | Cartridge summary report that lists general status information<br>for each cartridge entry in the 7990 catalog. The report<br>identifies the available AUs and flags set for each cartridge<br>in the 7990 catalog. |
| Optional report C  | Detailed cartridge report that lists cartridge usage information for each cartridge entry in the 7990 catalog.                                                                                                      |
| Optional report D  | Detailed AU status report that lists AU status information for each entry in the 7990 catalog plus cartridge usage information.                                                                                     |

The format of the SSUSE command is:

 $SSUSE, p_1, p_2, \ldots, p_n$ .

| $\frac{p_{i}}{1}$ | Description                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| CM=A-             | Cartridge manufacturer code is A-, indicating IBM.                                                                      |
| СМ                | Same as CM=A                                                                                                            |
| CM omitted        | Same as CM=A                                                                                                            |
| CN=csn            | Cartridge serial number of a specific cartridge. The CN=csn parameter is valid only if the OP=D parameter is specified. |
| CN                | Cartridge serial number is not specified.                                                                               |
| CN omitted        | Same as CN.                                                                                                             |
| FM=familyname     | Family to be reported on.                                                                                               |
| FM                | Same as FM=system default family.                                                                                       |
| FM omitted        | Same as FM=system default family.                                                                                       |

| <sup>p</sup> i | Description                                                                                                                                               |  |  |  |  |  |  |  |  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|--|--|
| L=filename     | File on which listable output is to be written.                                                                                                           |  |  |  |  |  |  |  |  |

|                | A Optional report A and basic usage report.                                                                                                               |  |  |  |  |  |  |  |  |
|                | B Optional report B and basic usage report.                                                                                                               |  |  |  |  |  |  |  |  |
|                | C Optional report C and basic usage report.                                                                                                               |  |  |  |  |  |  |  |  |
|                | D Optional report D and basic usage report.                                                                                                               |  |  |  |  |  |  |  |  |
| OP             | Basic usage report only is to be generated.                                                                                                               |  |  |  |  |  |  |  |  |
| OP omitted     | Same as OP.                                                                                                                                               |  |  |  |  |  |  |  |  |
| SB=subfamily   | Subfamily to be reported on. Up to eight subfamilies can be selected by the numbers 0 through 7. For example, SB=0273 selects subfamilies 0, 2, 3, and 7. |  |  |  |  |  |  |  |  |
| SB             | Same as SB=01234567.                                                                                                                                      |  |  |  |  |  |  |  |  |
| SB omitted     | Same as SB=01234567.                                                                                                                                      |  |  |  |  |  |  |  |  |
| SM=id          | SM identifier of the SM to be used. Up to eight SMs can be selected<br>by the letters A through H. For example, SM=AGC selects SM A, C,<br>and G.         |  |  |  |  |  |  |  |  |
| SM             | Same as SM=A.                                                                                                                                             |  |  |  |  |  |  |  |  |
| SM omitted     | Same as SM=A.                                                                                                                                             |  |  |  |  |  |  |  |  |

# **Basic Usage Report**

The basic usage report includes a title line, which identifies the family and SM being reported on. The statistics in this report contain data for each group followed by totals for SMs and subfamilies. The following items are listed.

- Number of cubicles reserved for each subfamily. .
- Number of cartridges in each subfamily.
- Number of unassigned and unflagged AUs for small files.
- Number of unassigned and unflagged AUs for large files. .
- Number of flagged cartridges. ٠
- Number of flagged AUs.
- If any empty cubicles are assigned, they are listed first for each subfamily. This . line shows a hyphen (-) as the group designator since groups are assigned only to cartridges.

The following output shows the format of a basic usage report.

# **Optional Report A**

Optional report A includes a title line that identifies the SM being reported on. This report is made up of 15 pages, each page describing the SM map for specific y and z coordinates. Each page describes 22 y coordinates (rows) and 1 z coordinate (column). Column 6 (z=6) is not reported on because it contains the data recording drives. The information listed in optional report A includes the following items.

- y and z coordinates.
- Cartridge manufacturer code and CSN of the cartridge.
- Family and subfamily.
- Group and ordinal in group.
- Flags.

SSUSE REPORT FILE

The following output shows the format of optional report A.

# **Optional Report B**

Optional report B includes a title line identifying the subfamily, family, and SM being reported on. There is one line of output per cartridge within a subfamily and storage module. The report includes the following cartridge information about entries in the 7990 catalog.

- Group and ordinal in group.
- y and z coordinates.
- Cartridge manufacturer code and CSN of the cartridge.
- Free AUs for small and large files.
- Cartridge flags.
- Error conditions.

The following output shows the format of optional report B.

# **Optional Report C**

Optional report C is the detailed cartridge report. It lists the group and FCT ordinal for each 7990 catalog entry and the y and z coordinates and CSN for each cartridge. The report also includes the AU numbers of the first AUs for small and large files and the division point for each cartridge.

The following output shows the format of optional report C.

## **Optional Report D**

Optional report D is the detailed AU status report. It lists the group and FCT ordinal of the cartridge, the CSN, the y and z coordinates of the cartridge, and the number of available off-cartridge links. The report also includes the octal numbers of the AUs with flawed AU, start of volume, and error flags noted. This report also specifically notes when a cartridge is empty (for use in determining the status of a cartridge that is to be made available).

The following output shows the format of optional report D.

SSUSE REPORT FILE

yy/mm/dd. hh.mm.ss. PAGE 6

SSUSE OPTIONAL REPORT D - DETAILED AU STATUS REPORT SM = A SUBFAMILY = 1 FAMILY = MTST

F = FLAWED AU (DEMARK FAILURE)

V = START OF VOLUME

E = ONE OF THE ERROR FLAGS SET (AU CONFLICT, FROZEN CHAIN, START OF FRAGMENT)

## SSDEBUG

SSDEBUG allows the analyst to update appropriate entries in the SM maps and/or 7990 catalogs and thereby resolve inconsistencies reported by the SSVAL utility. SSDEBUG can also copy data from selected 7990 files or cartridges to disk. This function of SSDEBUG is intended for use when errors such as unrecoverable read errors do not allow successful staging of a 7990 file.

# NOTE

SSDEBUG updates the SM map for the specified SM. (Refer to the definition of SM map earlier in this section.) It is recommended that the SM map is copied on tape or on another device or family immediately after every update of the SM map.

Input to SSDEBUG is via a directive file. Refer to SSLABEL, earlier in this section, for a description of the directive file format.

The format of the SSDEBUG command is:

SSDEBUG, p1, p2, p3.

| <sup>p</sup> i | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| I=filename     | File on which directives are written.                                        |
| I              | Same as I=INPUT.                                                             |
| I omitted      | Same as I=INPUT.                                                             |
| L=filename     | File on which listable output is to be written.                              |
| L              | Same as L=OUTPUT.                                                            |
| L=0            | No output file is to be generated.                                           |
| L omitted      | Same as L=OUTPUT.                                                            |
| Ζ              | Directives are contained on the SSDEBUG command. The I parameter is ignored. |
| Z omitted      | Directives are contained on the file specified by the I parameter.           |

# **SSDEBUG Directives**

The following directives are available with SSDEBUG. The descriptions of the parameters for these directives follow this listing of directives.

# OP=RS - Read AUs

OP=RS reads selected AUs of a cartridge identified by its csn (CN=csn) or y and z coordinates (YI and ZI parameters). The SM parameter specifies the SM where the cartridge resides. The range of AUs to be read is specified by the SL and SU parameters. The AUs are written to the file specified by the PF parameter. All CYBER data plus 7990 and CRC data, including header and trailer information, is returned. The analyst can write an application program to reconstruct the permanent file by stripping off all CYBER or 7990 related control information. Refer to Format of Disk Files Read From 7990 by SSDEBUG later in this section for a description of the control information written to disk along with the disk file contents.

# OP=RF - Read File

OP=RF reads the file whose alternate storage address is specified by the FO, SB, SM, and ST parameters. The file is written to the file specified by the PF parameter. All data, including header and trailer information, is returned (refer to Format of Disk Files Read From 7990 by SSDEBUG later in this section).

## OP=RP - Release Frozen Chain Space

OP=RP clears flags in the 7990 catalog and releases 7990 space for the chain whose alternate storage address is specified by the FO, SB, SM, and ST parameters.

# OP=RL - Remove Cartridge Entry From 7990 Catalog

OP=RL removes a 7990 catalog entry that is not linked properly to the SM map. The FO, SB, and SM parameters identify the 7990 catalog entry to be removed.

# OP=RC - Remove Cartridge Entry From SM Map

OP=RC removes an SM map entry that does not have a corresponding FCT entry in the 7990 catalog. The SM, YI, and ZI parameters identify the SM map entry to be removed. The cartridge at the particular location (y,z) is put into the exit tray and the SM map entry is changed to unassigned. The SM map should be backed up immediately after the SSDEBUG run to ensure consistency with cartridge labels and 7990 catalogs (refer to the definition of SM map earlier in this section).

A scratch label is written on the cartridge prior to it being replaced in the exit tray, but the cartridge history information remains intact.

## OP=CF - Change Flag in SM Map or 7990 Catalog

OP=CF sets or clears flags in the SM map or 7990 catalog. The FL and ON or OF parameters indicate the flag type and the action to be taken. The appropriate FCT entry or SM map entry is determined from the CN, FO, or YI and ZI parameters. For FCT flags (FL=AC, FC, or SF), the analyst can specify either a single AU using the ST parameter or a range of AUs using the SL and SU parameters.

## **Parameters for the SSDEBUG Directives**

The descriptions of the parameters to the SSDEBUG directives follow. Not all parameters are valid with all directives, as indicated.

| P <sub>i</sub> | Description                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CM=A-          | Cartridge manufacturer code is A-; indicating IBM.                                                                                                                    |
| СМ             | Same as CM=A                                                                                                                                                          |
| CM omitted     | Same as CM=A                                                                                                                                                          |
| CN=csn         | Cartridge serial number of the cartridge to be used; not valid for OP=RS if YI=y or ZI=z is specified; and not valid for OP=CF if FO=ord, YI=y, or ZI=z is specified. |

| <sup>p</sup> i     | Description                                                                                                                                                      |  |  |  |  |  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
| CN omitted         | YI=y and ZI=z must be specified for OP=RS. FO=ord or YI=y and ZI=z must be specified for OP=CF.                                                                  |  |  |  |  |  |
| FL=flag            | Name of flag in SM map or 7990 catalog to be set or cleared. Valid only for OP=CF.                                                                               |  |  |  |  |  |
|                    | flag Description                                                                                                                                                 |  |  |  |  |  |
|                    | AC AU conflict flag.                                                                                                                                             |  |  |  |  |  |
|                    | EW Excessive write parity error flag.                                                                                                                            |  |  |  |  |  |
|                    | FC Frozen chain flag.                                                                                                                                            |  |  |  |  |  |
|                    | FE Linkage error flag (in 7990 catalog FCT).                                                                                                                     |  |  |  |  |  |
|                    | IB Inhibit allocation flag.                                                                                                                                      |  |  |  |  |  |
|                    | LC Lost cartridge flag.                                                                                                                                          |  |  |  |  |  |
|                    | ME Linkage error flag (in SM map).                                                                                                                               |  |  |  |  |  |
|                    | SF Start of fragment flag.                                                                                                                                       |  |  |  |  |  |
| FL omitted         | FL=flag must be specified for OP=CF.                                                                                                                             |  |  |  |  |  |
| FM=familyname      | Family to be processed.                                                                                                                                          |  |  |  |  |  |
| FM                 | Same as FM=system default family.                                                                                                                                |  |  |  |  |  |
| FM omitted         | Same as FM=system default family.                                                                                                                                |  |  |  |  |  |
| F0=ord             | 7990 catalog ordinal indicating the file to be read or the chain<br>whose space is to be released. Not valid for OP=CF if CN=csn, YI=y,<br>or ZI=z is specified. |  |  |  |  |  |
| FO omitted         | FO=ord must be specified for OP=RF, OP=RP, and OP=RL. CN=csn or YI=y and ZI=z must be specified for OP=CF.                                                       |  |  |  |  |  |
| OF                 | Flag specified by FL=flag is to be cleared. Valid only with OP=CF.                                                                                               |  |  |  |  |  |
| ON                 | Flag specified by FL=flag is to be set. Valid only with $OP=CF$ .                                                                                                |  |  |  |  |  |
| <b>PF=filename</b> | File to which the 7990 image is to be copied. This file is defined under the user's current family and user index.                                               |  |  |  |  |  |
| PF                 | Same as PF=MMMBUG.                                                                                                                                               |  |  |  |  |  |
| PF omitted         | Same as PF=MMMBUG.                                                                                                                                               |  |  |  |  |  |
| SB=subfamily       | Subfamily to be used; $0 \leq $ subfamily $\leq 7$ .                                                                                                             |  |  |  |  |  |

# Description

| P <sub>i</sub> | Description                                                                                                                                                                                                                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SB             | Same as SB=0.                                                                                                                                                                                                                                                                                                                                            |
| SB omitted     | Same as SB=0.                                                                                                                                                                                                                                                                                                                                            |
| SL=i           | AU where OP=RS begins copying or OP=CF begins changing flags; $1 \le i \le 1931$ ; $i \le j$ (refer to SU=j).                                                                                                                                                                                                                                            |
| SL             | Same as SL=1.                                                                                                                                                                                                                                                                                                                                            |
| SL omitted     | Same as SL=1.                                                                                                                                                                                                                                                                                                                                            |
| SM=id          | SM identifier of the SM to be used by SSDEBUG; id is a letter from A to H.                                                                                                                                                                                                                                                                               |
| SM             | Same as SM=A.                                                                                                                                                                                                                                                                                                                                            |
| SM omitted     | Same as SM=A.                                                                                                                                                                                                                                                                                                                                            |
| ST=s           | AU where OP=RF begins reading files or fragments or OP=RP begins<br>releasing frozen chain space. If specified with OP=CF, ST=s<br>specifies the AU number of an FCT flag to be changed and takes<br>precedence over the range of AUs specified by the SL and SU<br>parameters. AU numbers are meaningful with OP=CF only for flags<br>FL=AC, FC, or SF. |
| ST omitted     | ST=s must be specified for OP=RF and OP=RP.                                                                                                                                                                                                                                                                                                              |
| SU=j           | AU where OP=RS ends copying or OP=CF ends changing flags; $1 \le j \le 1931$ ; $i \le j$ (refer to SL=i).                                                                                                                                                                                                                                                |
| SU             | Same as SU=1.                                                                                                                                                                                                                                                                                                                                            |
| SU omitted     | Same as SU=1.                                                                                                                                                                                                                                                                                                                                            |
| YI=y           | y coordinate of the cubicle where the cartidge to be read resides; $0 \leq y \leq 21$ . ZI=z must also be specified. CN=csn must not be specified with OP=RS. # **Restrictions to SSDEBUG**

The following restrictions apply to the SSDEBUG utility.

- SSEXEC must be running when SSDEBUG is run.
- Only one copy of SSDEBUG can be run at one time.
- SSDEBUG, SSVAL, and SSLABEL cannot be run at the same time.

# y,z Relationship With SM Map Ordinal

A one to one functional mapping exists between coordinate (y,z) pairs and the ordinal entries within the SM map. To determine the coordinate pair (y,z) from the SM map ordinal (ord), use the following equations.

$$y = \frac{(352 - \text{ord})}{16}$$

z = 352 - ord - 16y

To determine the SM map ordinal (ord) from the coordinate pair (y,z), use the following equation.

ord = 352 - z - 16y

# Format of Disk Files Read From 7990 by SSDEBUG

Γ

A local disk file created by SSDEBUG with the OP=RS or OP=RF option includes all CYBER and 7990 header and trailer information. Figure 11-1 shows the format of a disk file created when SSDEBUG reads a full stripe; figure 11-2 shows the format of a disk file created when SSDEBUG reads a partial stripe.

Figure 11-1. Full Stripe Disk File Format

٦

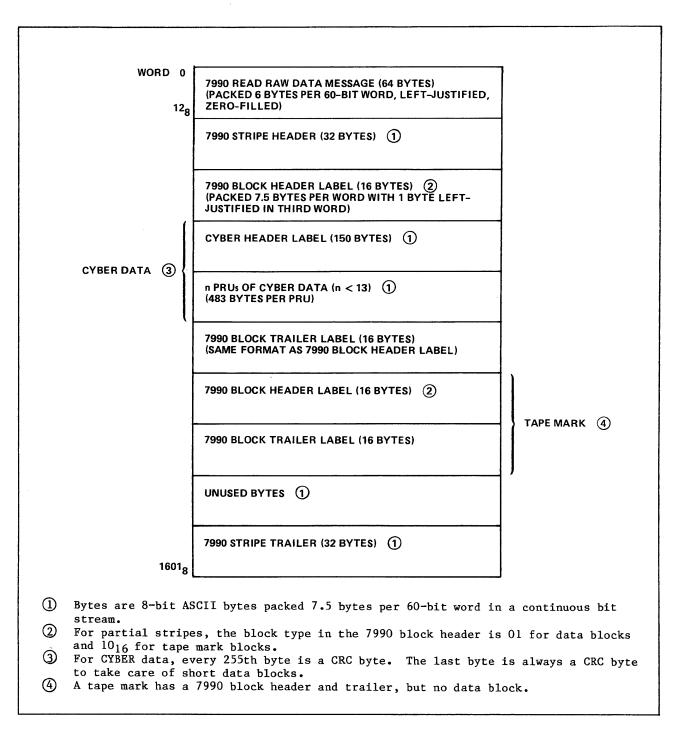

Figure 11-2. Partial Stripe Disk File Format

# 7990 Stripe Header and Trailer

The 7990 stripe header is a 32-byte block that occupies the first 32 bytes of the stripe; the 7990 stripe trailer occupies the last 32 bytes. The 7990 stripe header and trailer have the same format.

| Bytes | Description                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-5   | Volume serial number. A 6-character string specifying the volume serial number of the stripe.                                                                               |
| 6-7   | Version number. Two characters specifying the version number associated with the volume serial number.                                                                      |
| 8-9   | File number. Two characters specifying the number of the file within the volume.                                                                                            |
| А-В   | Logical stripe number. Relative stripe number within the volume.<br>The logical stripe number may not correlate with the physical stripe<br>number due to demarked stripes. |
| C-D   | Address of last block trailer. Byte number, within the stripe, of the first byte of the last block trailer.                                                                 |
| E-1D  | Reserved.                                                                                                                                                                   |
| 1E-1F | Checksum. Chosen such that the sum, modulo 65536, of all bytes in the header equals zero.                                                                                   |

# 7990 Block Header and Trailer

Each 7990 block has a 16-byte header that precedes each block and a 16-byte trailer that follows each block, or partial block, of data on the stripe. The 7990 block header and trailer have the same format.

Byte(s) Description 0-1 Block type. The following block types are valid. Block type Description 01 A complete block is contained in this stripe. 02 First block segment of a multistripe block. 04 Intermediate block segment of a multistripe block. 80 Last block segment of a multistripe block. 1016 Tape mark. 2-3 Block length. The number of bytes in a data block excluding the block header and trailer. The block length of a tape mark is zero. 4-7 Block sequence number. The number of a given data block within a file.

| Byte(s) | Description                                                                                                                                                                              |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8–9     | Block segment number. For complete blocks, the segment number is 0 (zero). For multistripe blocks, the segment number is the sequence number of the block segment within the data block. |
| A-E     | Reserved.                                                                                                                                                                                |
| F       | Checksum. Chosen such that the sum, modulo 256, of all bytes in the header equals zero.                                                                                                  |

# SSBLD

SSBLD reads a specified direct access permanent file that contains SSBLD statements. These statements consist of 7990 component-oriented mnemonics that define the logical mapping from component to component within the 7990 configuration. SSBLD processes these statements and generates a direct access permanent file which SSEXEC uses as its unit device table (UDT).

The format of the SSBLD command is:

SSBLD, CF=confile, BF=bldfile.

| Parameter  | Description                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------|
| CF=confile | Configuration file on which SSBLD statements are written under user index $377760_8$ .              |
| CF         | Same as CF=SUDT.                                                                                    |
| CF omitted | Same as CF=SUDT.                                                                                    |
| BF=bldfile | Build file on which SSBLD generates the UDT for SSEXEC. The build file is under user index 3777608. |
| BF         | Same as BF=BUDT.                                                                                    |
| BF omitted | Same as BF=BUDT.                                                                                    |

#### SSBLD Statements

The 7990 hardware consists of a number of 7990 control units (CU) and a number of 7991 storage modules (SM). SSBLD uses two types of statements: those that link individually controllable nodes and paths within each CU, and those that link SMs to CUs. SSBLD statements must be processed in the following sequence or SSBLD aborts.

- 1. Statements that define the linkage between nodes and paths within each CU.
- 2. Statements that define the linkage between SMs and CUs.

#### Node/Path Linkage Statements

These SSBLD statements are order dependent. There are seven types of statements for a given CU and they must appear together in the following sequence and format.

1. CUest=da,CH01=st,CH02=st,CH03=st,CH04=st.

est is the EST ordinal of the CU. da is the device address of CUest. st is the channel status (ON or OFF).

The CYBER channel number is associated with the 7990 channel interface (CIF) number. The position (first, second, and so on) of the channel in the CU statement minus 1 defines the CIF number wired to that channel. For example, CHO2 is wired to CIF1. Also, if a single digit channel is used to connect to a 7990, it must have a leading 0 in the CU statement. For example, channel 3 is entered as CHO3.

2. CIFn=DTIO=st,DTI1=st,DTO0=st,DTO1=st.

n is the device address of CIF (0 through 3). DTI is the data transfer input. DTO is the data transfer output. st is the data transfer status (ON or OFF).

3. DTIn=DIFO=st,DIF1=st.

n is the device address of DTI (0 or 1). DIF is the device interface. st is the specified device interface status (ON or OFF).

4. DTOn=DIF0=st,DIF1=st.

n is the device address of DTO (0 or 1). st is the device interface status (ON or OFF).

5. DIFn=DRCO=st,DRC1=st.

n is the device address of DIF (0 or 1). DRC is the data recording controller. st is the data recording controller status (ON or OFF).

6. DRCn=DRDO=st,...,DRD7=st.

n is the device address of DRC (0 or 1). DRD is the data recording driver. st is the data recording driver status (ON or OFF).

7. AIFn=ACO=st,AC1=st,AC2=st,AC3=st.

AIF is the accessor interface. n is the device address of AIF. AC is the accessor. st is the accessor status (ON or OFF).

## SM/CU Linkage Statements

The SM statement defines the linkage between SMs and CUs; its format is:

SMid=st,ACn,CUest,CUest,DRDa=st,DRDa=st.

id is the SM identifier (A through H).
st is the status (ON or OFF).
n is the device address of AC (0 through 3).
est is the EST ordinal of the CU(s) connected to SMid.
a is the device address of the DRD(s) connected to ACn.

SSBLD and SSEXEC use the common deck COMBUDT to define the amount of memory to reserve within SSEXEC for the unit device tables. Any attempt to change the number of SMs or CUs specified in the common deck will cause SSBLD to abort.

## Example of SSBLD Statements

The first two SSBLD statements specify the total number of CUs and SMs in the following configuration. The first statement specifies CUs and the second statement specifies SMs. The rest of the statements define the 7990 configuration.

```
1

1

CU41=0,,CH23=ON,..

CIF1=DTIO=ON,,DTOO=ON,.

DTIO=DIFO=ON,DIF1=ON.

DTOO=DIFO-ON,DIF1=ON.

DIF0=DRCO=ON,DRC1=ON.

DIF1=DRCO=ON,DRC1=ON.

DRC0=DRDO=ON,DRD1=ON,...

AIF0=ACO=ON,...

SMA=ON,ACO,,CU41,DRDO=ON,DRD1=ON.

*COMMENT.
```

An asterisk (\*) in the first column of an SSBLD statement specifies a comment statement. Comment statements are not sent to the dayfile.

## 7990 Equipment Configuration Constraints

Controls paths and data paths within the 7990 configuration have certain constraints placed upon the allowable device addresses of the accessors and DRDs. The accessor numbers and corresponding DRD numbers are:

| Accessor Number | DRD Numbers |
|-----------------|-------------|
| 0               | 0 or 1      |
| 1               | 2 or 3      |
| 2               | 4 or 5      |
| 3               | 6 or 7      |

Accessors and DRDs that are to be coupled to two controllers must have the same path numbers assigned from each controller. For example, if an accessor is plugged into accessor path 2 of CU1, then a DRD on the same storage module must be coupled to a DRC path of 4 or 5 from CU1. If a second controller is to be attached to this same storage module, then the other accessor port must also be plugged into accessor path 2 of CU2 and a DRD must be coupled to a DRC path of 4 or 5 from CU2.

## SSALTER

SSALTER displays the current 7990 hardware configuration and allows an analyst to change the status of certain elements in the 7990 configuration. SSALTER works with SSEXEC to make the specified changes to the existing 7990 configuration.

The initial 7990 configuration file is built by the SSBLD utility and stored as a permanent file (default file name is BUDT) under user index  $377760_8$  on the default family. This configuration file is the unit device table read by SSEXEC during initialization.

SSALTER can be run at SSEXEC initialization time or at any time after SSEXEC has been initialized. SSALTER aborts if SSEXEC is not executing.

#### **Console Input**

SSALTER can be executed only from the system console. Input from the console requires the following sequence of entries and responses.

1. Call SSALTER by entering:

X.SSALTER.

The B,O display indicates the job sequence name (jsn) of SSALTER. To the right of the entry appears the message:

REQUEST \*K\* DISPLAY

- 2. Activate the K display for that control point by entering:
  - K,jsn. (jsn is the job sequence name of SSALTER as specified on the B,O display)
- 3. Select the desired K display by entering

K.SM=id. (id is the SM identifier, A through H)

to select the SM K display (figure 11-3), which shows the 7990 configuration of the storage module and DRDs complete with status information; or

K.CUest. (est is the EST ordinal of the CU)

to select the CU K display (figure 11-4), which shows the status of various paths/nodes in the specified control unit.

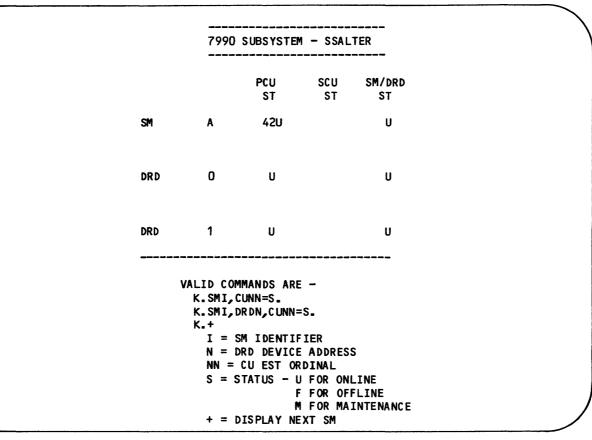

Figure 11-3. SM K Display

When a DRD's status is changed to online, any cartridges in the DRD are placed in service cells if space is available; otherwise, they are ejected from the storage module. A clear cartridge is then loaded into the DRD, its cartridge label and CSN are checked, and it is unloaded. The same cartridge is reloaded, its label and CSN are checked again, and the cartridge is returned to its cubicle. The service cells are then checked for cartridges. If a cartridge is found, it is either returned to the cubicle matrix or ejected from the storage module, depending on the cartridge label's contents.

When a SM's status is changed to online, the accessor is first cleared of any cartridge it may contain. The cartridge is stored in a service cell if one is empty; otherwise, the cartridge is ejected from the storage module. The accessor then picks a clear cartridge from its cubicle, and immediately puts it back. If the SM's status is changed to online after SSEXEC has been initialized, the service cells are then checked for cartridges. Any cartridges found are ejected from the storage module.

|      |            |    | ORD   | CU<br>ST |       |       |      |       |

# **MSAS OPERATIONAL PROCEDURES**

Next is a summary of the operational procedures used in an MSAS environment. These procedures include modifications to existing procedures and new MSAS procedures, especially in the areas of permanent file backup and reloading and disk space management. Refer to the descriptions of the appropriate utilities for details about these operational procedures.

## INITIALIZATION

MSAS processing is initiated when the SSDEF utility is run to create the system files necessary to allow storage of files on 7990. SSDEF creates both an SM map for each SM that is to store file data on cartridges and eight 7990 catalogs (one for each subfamily) for each family that is to have 7990-resident files. Once these system files have been created, the SSLABEL utility can then be run to allocate portions of the SM to each subfamily and to initialize cartridges for use by files belonging to these subfamilies. Note that SSEAEC need not be executing when SSDEF is run, but SSEXEC must be executing when SSLABEL is run.

When permanent files are defined, they reside on disk until the SSMOVE utility is run. Depending on the parameters specified, SSMOVE can destage files to 7990 and release the disk space assigned to files so that it is available for general use.

#### DISK SPACE MANAGEMENT

The availability of disk space must be managed more frequently in an MSAS environment than in a non-MSAS environment. This is necessary because 7990-resident files must be staged to disk before a user can access them, and their disk space is not immediately released upon completion of the jobs that attached the files. Consequently, disks are apt to approach a disk-full condition unless the SSMOVE utility is used periodically to release disk space.

The SSMOVE utility destages selected files to 7990 and optionally releases their disk space. It is recommended that the site analyst use SSMOVE as part of a periodic disk space management procedure and also just prior to a full dump to reduce the amount of data dumped to tape. (Refer to Dump Tape Management later in this section.)

The E,M display can be used to monitor the tracks on a device or set of devices. When too few tracks (as defined by the installation) are available on the direct access devices for a family or subfamily, the SSMOVE utility should be run. SSMOVE reads the PFC entries for the specified family, selects certain files to reside on 7990, and decides which files should be released from disk.

Files can be destaged to 7990 without their disk space being released. This destage-only feature can be used prior to a routine backup dump to create 7990 images for files with the BR=MD attribute and thereby eliminate the need to include them on a backup dump tape. (Refer to Dump Tape Management later in this section.) Having a 7990 image also provides backup for the file in special cases where the permanent file is being updated at the same time PFDUMP is being run.

The destage-only feature can also be used to allow disk space to become available immediately when SSMOVE is run again. That is, SSMOVE can directly release disk space of files that have both disk and 7990 images but are to reside on 7990 only. However, for files that have no 7990 image, there is a delay before the disk space can be released because these files must first be destaged to 7990.

#### **7990 SPACE MANAGEMENT**

The availability of 7990 space must be managed because 7990 space is not automatically released when a permanent file is purged. This allows you to perform a permanent file recovery to a time prior to the purging of the file. On a typical dump tape, the entry for a 7990-resident file includes the PFC and permit entries, but not the file data. A subsequent reload operation recovers only what was dumped; the PFC and permit information, but not the file data. Thus, 7990 space for a purged permanent file cannot be released until you no longer need to recover the file data, because the file data resides on 7990 only and typically not on any dump tape.

A 7990-resident file is stored only on the cartridges within the cubicles of SMs assigned to a subfamily. When destaging a file to 7990, SSEXEC selects the SM with the most space available. If no SM has enough free space to store the file being destaged, SSEXEC abandons that destage request, issues a message to the dayfile, and continues to destage other files that fit on the available 7990 space. To avoid this problem, use the SSVAL utility periodically to release 7990 space for purged files, thereby making it available for reuse.

When you want to reuse 7990 space currently allocated to files that have been purged, run SSVAL with the RF and RL parameters specified. The RF parameter specifies an RDF, which is an auxiliary file produced by the permanent file utility PFDUMP and which contains versions of the 7990 catalogs and PFC entries that were current at the time of the dump. SSVAL examines the RDF to identify unneeded 7990 files (those without PFC entries) and their 7990 space is released. Choose which RDF to use based on the date and time of the dump that produced it. That is, a particular RDF is used only if there is no need for a permanent file recovery to a time prior to the dump that produced the RDF.

Once an RDF is used by SSVAL to release 7990 space, you should discard it and any other RDFs for the same set of devices. These RDFs cannot be used as input to SSVAL in any future run. The MSAS software does not permit an RDF to be specified by the RF parameter on an SSVAL call, unless it was produced by PFDUMP after the last SSVAL run that released 7990 space was completed. This prevents the inadvertent release of 7990 space that was previously released and reassigned to a file.

Example 1:

Assume that two PFDUMPs were run a week apart producing two release data files, RDF1 and RDF2. Assume, also, that according to both RDF1 and RDF2, file AFILE is an orphan (it has been purged but still resides on 7990). If the following call to SSVAL is made, the 7990 space assigned to AFILE is released and made available for reuse, if no errors were encountered.

## SSVAL, RF=RDF1, RL.

Now, suppose that a new file, BFILE, which did not exist when RDF1 and RDF2 were produced, is assigned to the 7990 space on which AFILE has resided. If SSVAL were to accept either RDF1 or RDF2 on a subsequent SSVAL call, the 7990 space allocated to file AFILE (which is now the space where BFILE resides) is released. However, any RDF created after the SSVAL run that purged AFILE would not have an entry for AFILE and, hence, SSVAL would not inadvertently release the 7990 space presently allocated to BFILE.

After SSVAL uses a release data file to release 7990 space, the corresponding backup tape from PFDUMP is the oldest tape that should be used for the first reel of a future incremental load. The first reel determines which files are to be reloaded according to the CIR on the tape (refer to PFLOAD in section 17, Permanent File Utilities). Use of an older tape as the first reel can allow the PFC entry for a purged file to be restored even though its 7990 space may have been reassigned. The MSAS software does not prevent loading from the wrong dump tape, but does detect as an error an attempt to stage a file whose data was overwritten (see Example 2).

60459300 D

#### Example 2:

Assume that RDF1 and RDF2 are as in the previous example, and that file CFILE is an orphan according to RDF2, but not according to RDF1. The following SSVAL call releases 7990 space allocated to CFILE.

SSVAL, RF=RDF2, RL.

Now, suppose that the dump tape created by the PFDUMP run that produced RDF1 is used as the first reel of an incremental PFLOAD. Then the PFC and permit entries for file CFILE are reloaded, but, in fact, file CFILE does not exist on 7990. This will be detected as an error when a user attempts to attach CFILE.

## **BACKUP AND RECOVERY**

Permanent file backup and recovery methods in an MSAS environment are similar to those in a non-MSAS environment. It is assumed that most sites with disk-resident permanent files have a file backup procedure consisting of a full dump followed by a series of incremental dumps. The assumed reload procedure is to load from tapes starting with the most recent incremental dump tape and continuing through older incremental dump tapes until the most recent full dump tape is processed. These procedures can be modified as follows to accommodate 7990-resident files.

## **File Dumping**

The normal backup dump procedure is to dump files based on the modification date field in the PFC entries for the files. New parameters to PFDUMP provide the capability to dump files that have been modified during a certain interval, which is useful in recycling old dump tapes (refer to Dump Tape Management later in this section). For files that reside only on 7990, you can either stage the file to disk and thereby include it in the dump or suppress staging and include only the file's PFC and permit information on the dump tape. If the device or family being dumped has 7990-resident files, the following procedures should be included with the normal dumping procedures.

#### Full Dumps

Full dumps should be performed as usual, but OP=S should be specified on the call to PFDUMP to suppress staging. Thus, all files on disk are dumped but only the PFC and permit entries for 7990 files without disk images are included in the dump. It is unnecessary and not feasible to dump the files that reside only on 7990. Specify OP=S and SD on the call to PFDUMP; use the RD=filename parameter at your own discretion.

| Parameter   | Description                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP=S        | Selects no staging. If the SD option was inadvertently used on any previous nonincremental dump, an incremental dump should be taken prior to the full dump.                                                                            |
| SD          | Updates the dump date/time field on each master device dumped to<br>permit files created or modified prior to this dump to be released<br>when SSMOVE is run again. Refer to Destage and Release Algorithms<br>earlier in this section. |
| RD=filename | Specifies that PFDUMP is to write a release data file to be used<br>later by SSVAL. RD=filename is included or excluded on a call to<br>PFDUMP depending on how often you want to purge unneeded 7990 files.                            |

#### Incremental Dumps

Incremental dumps should be performed as usual. No staging should occur because any files that were created or modified since the last dump will still be on disk if a tape backup is required. The following parameters should be specified on the call to PFDUMP.

| Parameter  | Description                                                                                       |
|------------|---------------------------------------------------------------------------------------------------|
| OP=M       | Selects incremental dumps.                                                                        |
| SD         | Updates the date/time field on each master device dumped, as previously described for full dumps. |
| AD=y ymmdd | Selects the date and time just prior to the previous incremental or                               |
| and        | full dump of the device. Hence, all files not included in the last dump are dumped.               |
| AT=hhmmss  | • •                                                                                               |

The following parameters should be used with caution.

| Parameter   | Description                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP=S        | Selects no staging. If the SD option was inadvertently used on any<br>recent partial dump, OP=S should not be specified so any file with a<br>BR=Y attribute that had its disk space inadvertently released will<br>be included in the dump. |
| RD=filename | Specifies that PFDUMP is to write a release data file to be used later by SSVAL, as previously described for full dumps.                                                                                                                     |

#### Dump Tape Management

In a non-MSAS environment, it is possible to make all previous dump tapes available for use after a full dump is completed. However, in an MSAS environment, such dump tape recycling cannot occur because files that have resided only on 7990 for some time are probably not included on any recent dump tape. When a low percentage of files on a tape are active files, it is possible to redump any remaining files in order to recycle the tape by running PFDUMP and specifying the OP=M, BD, and BT parameters, but not specifying the OP=S parameter.<sup>†</sup> This performs a dump of all files that were last dumped before the date and time specified on the PFDUMP call. If necessary, files will be staged in from 7990; after the dump is completed, the disk space for these staged files is released. Thus, files that might not be on any dump tape made after the date specified by the BD parameter are dumped and tapes created before this date can be recycled.

The number of dump tapes created can be reduced by using SSMOVE to reduce the amount of data written on these dump tapes. If SSMOVE is run prior to an incremental dump, files with the BR=MD attribute can be destaged to 7990 and excluded from the dump. That is, the incremental dump will exclude the files with a BR=MD attribute that are on both 7990 and disk. If SSMOVE is run prior to a full dump, disk space for files that do not have to be on disk can be released and these files are not written on the dump tape. The following procedure involving dumps and SSMOVE runs can be used for efficiency.

- 1. Run SSMOVE to destage files with the BR=MD attribute.
- 2. Take an incremental dump to back up files with the BR=Y attribute.
- 3. Run SSMOVE to release the disk images of files backed up in step 2.
- 4. Take a full dump to reduce the number of dump tapes involved if a reload is required.

## SM Map/7990 Catalog Backup

An SM map is created for each SM in an MSAS environment and is updated by the SSLABEL, SSVAL, and SSDEBUG utilities. (Refer to the definition of SM map earlier in this section.) It is recommended that the SM map be copied on tape or on another device or family immediately after every update of the SM map. PFDUMP can be used to do this by dumping user index 3777608 with FM equal the default system family name, but only if SSEXEC is not running. When SSEXEC is executing, it has the SM map files attached in modify mode; hence, PFDUMP will not dump the SM maps.

If the device containing subfamily 0 of the default family is reloaded, the latest SM maps should be recovered from the backup copies. After recovering the SM maps, run the SSVAL utility with the AM and FM parameters specified to ensure that the SM map and 7990 catalog entries match. If they do not, corrective action should be taken as described in Error Conditions and Corrective Actions later in this section. Failure to retain or recover the latest SM maps can cause problems with future SSLABEL runs (refer to the definition of SM map earlier in this section).

<sup>&</sup>lt;sup>†</sup>It is possible to specify the AD and AT parameters also, thereby dumping files that were dumped during an interval after the date and time specified by AD and AT and before the date and time specified by BD and BT (refer to parameters for PFDUMP). This performs a dump of all files last dumped during the interval specified (including 7990-resident files) and allows your site to recycle all dump tapes created during this interval.

## Full Dumps

Full dumps should be performed as usual, but OP=S should be specified on the call to PFDUMP to suppress staging. Thus, all files on disk are dumped but only the PFC and permit entries for 7990 files without disk images are included in the dump. It is unnecessary and not feasible to dump the files that reside only on 7990. Specify OP=S and SD on the call to PFDUMP; use the RD=filename parameter at your own discretion.

| Parameter   | Description                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP=S        | Selects no staging. If the SD option was inadvertently used on any previous nonincremental dump, an incremental dump should be taken prior to the full dump.                                                                            |
| SD          | Updates the dump date/time field on each master device dumped to<br>permit files created or modified prior to this dump to be released<br>when SSMOVE is run again. Refer to Destage and Release Algorithms<br>earlier in this section. |
| RD=filename | Specifies that PFDUMP is to write a release data file to be used<br>later by SSVAL. RD=filename is included or excluded on a call to<br>PFDUMP depending on how often you want to purge unneeded 7990 files.                            |

## Incremental Dumps

Incremental dumps should be performed as usual. No staging should occur because any files that were created or modified since the last dump will still be on disk if a tape backup is required. The following parameters should be specified on the call to PFDUMP.

| Parameter | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| OP=M      | Selects incremental dumps.                                                                        |
| SD        | Updates the date/time field on each master device dumped, as previously described for full dumps. |
| AD=yymmdd | Selects the date and time just prior to the previous incremental or                               |
| and       | full dump of the device. Hence, all files not included in the last dump are dumped.               |
| AT=hhmmss |                                                                                                   |

The following parameters should be used with caution.

#### Parameter

## Description

- 0P=S
  - Selects no staging. If the SD option was inadvertently used on any recent partial dump, OP=S should not be specified so any file with a BR=Y attribute that had its disk space inadvertently released will be included in the dump.

RD=filename Specifies that PFDUMP is to write a release data file to be used later by SSVAL, as previously described for full dumps.

#### Dump Tape Management

In a non-MSAS environment, it is possible to make all previous dump tapes available for use after a full dump is completed. However, in an MSAS environment, such dump tape recycling cannot occur because files that have resided only on 7990 for some time are probably not included on any recent dump tape. When a low percentage of files on a tape are active files, it is possible to redump any remaining files in order to recycle the tape by running PFDUMP and specifying the OP=M, BD, and BT parameters, but not specifying the OP=S parameter.<sup>†</sup> This performs a dump of all files that were last dumped before the date and time specified on the PFDUMP call. If necessary, files will be staged in from 7990; after the dump is completed, the disk space for these staged files is released. Thus, files that might not be on any dump tape made after the date specified by the BD parameter are dumped and tapes created before this date can be recycled.

The number of dump tapes created can be reduced by using SSMOVE to reduce the amount of data written on these dump tapes. If SSMOVE is run prior to an incremental dump, files with the BR=MD attribute can be destaged to 7990 and excluded from the dump. That is, the incremental dump will exclude the files with a BR=MD attribute that are on both 7990 and disk. If SSMOVE is run prior to a full dump, disk space for files that do not have to be on disk can be released and these files are not written on the dump tape. The following procedure involving dumps and SSMOVE runs can be used for efficiency.

- 1. Run SSMOVE to destage files with the BR=MD attribute.
- 2. Take an incremental dump to back up files with the BR=Y attribute.
- 3. Run SSMOVE to release the disk images of files backed up in step 2.
- 4. Take a full dump to reduce the number of dump tapes involved if a reload is required.

## SM Map/7990 Catalog Backup

An SM map is created for each SM in an MSAS environment and is updated by the SSLABEL, SSVAL, and SSDEBUG utilities. (Refer to the definition of SM map earlier in this section.) It is recommended that the SM map be copied on tape or on another device or family immediately after every update of the SM map. PFDUMP can be used to do this by dumping user index 377760g with FM equal the default system family name, but only if SSEXEC is not running. When SSEXEC is executing, it has the SM map files attached in modify mode; hence, PFDUMP will not dump the SM maps.

If the device containing subfamily 0 of the default family is reloaded, the latest SM maps should be recovered from the backup copies. After recovering the SM maps, run the SSVAL utility with the AM and FM parameters specified to ensure that the SM map and 7990 catalog entries match. If they do not, corrective action should be taken as described in Error Conditions and Corrective Actions later in this section. Failure to retain or recover the latest SM maps can cause problems with future SSLABEL runs (refer to the definition of SM map earlier in this section).

<sup>&</sup>lt;sup>†</sup>It is possible to specify the AD and AT parameters also, thereby dumping files that were dumped during an interval after the date and time specified by AD and AT and before the date and time specified by BD and BT (refer to parameters for PFDUMP). This performs a dump of all files last dumped during the interval specified (including 7990-resident files) and allows your site to recycle all dump tapes created during this interval.

A 7990 catalog is created for each subfamily of a family that can have 7990-resident files and is updated by the SSLABEL, SSMOVE, SSVAL, and SSDEBUG utilities. When PFDUMP copies permanent files to tape for a master device or all devices in a family, it ensures that corresponding 7990 catalogs are also dumped. (If SSEXEC has a 7990 catalog attached in modify mode, PFDUMP interfaces with SSEXEC so that the 7990 catalog is included on the dump tape. While PFDUMP is accessing the 7990 catalog, any file destage requests for that subfamily are delayed.) Consequently, if PFLOAD is used to reload all files, the 7990 catalogs are automatically recovered and entries for all 7990-resident files reflected in recovered PFC entries will exist in the recovered 7990 catalog.

If PFLOAD is run after the SSLABEL utility has updated the 7990 catalog and SM map but before the 7990 catalog has been backed up, the recovered 7990 catalog will not match exactly the corresponding SM map. In this case, recovery procedures (as described in 7990 Catalog/SM Map Mismatch later in this section) must be taken to bring the SM map, 7990 catalog, and cartridge label information into agreement.

## **File Reloading**

PFLOAD runs should be made as usual. PFLOAD reads the CIR records from the most recent incremental dump tape to control loading of file data and PFC and permit information. For 7990-resident only files, PFLOAD reloads only the PFC and permit information (if PFDUMP dumped only this information). The following situations involve PFLOAD in an MSAS environment.

- If one device needs to be reloaded, the DN or TD parameter specifies the device. The OP=Z and UD parameters should not be specified.
- If PFLOAD is used for other than a device recovery, both OP=Z and UD should be specified. The OP=Z parameter ensures that the PFC entry does not link to a 7990 file that may no longer exist, and UD ensures that the file is included in the next incremental or full dump.
- If a file has a nonzero as a value in its PFC entry (indicating that the file has a 7990 image), the SSCVER flag in the PFC entry will be set when the PFC and permit information are reloaded. If the file is successfully staged to disk when it is attached, this flag is cleared. Otherwise, the flag remains set. This can be used to indicate the possibility of an operational error, such as omitting OP=Z when a file or set of files is reloaded from an obsolete dump tape.
- If any unscheduled device reload that includes recovery of a 7990 catalog and/or SM map is made, SSVAL should be run with the AM and FM parameters specified. SSVAL examines the PFC entries for 7990-resident files, the 7990 catalog, and the SM map to detect any error conditions that exist.

## ERROR CONDITIONS AND CORRECTIVE ACTIONS

It is possible for operational, hardware, or software malfunctions to cause a variety of error conditions to exist or appear to exist in the 7990 catalogs, SM maps, PFC entries, or cartridge labels. The SSVAL utility can analyze the 7990 catalogs, SM maps, and PFC entries to detect these errors, and the SSLABEL utility can identify problems with cartridge labels. The following paragraphs describe some specific error conditions and the actions that should be taken to correct them. Most of the errors are caused either by incorrect operational procedures that result in the recovery of the wrong version of an MSAS system file, or by abnormal termination of SSEXEC or MSAS utility processing, which can interrupt the updating of an MSAS system file.

## **Clearing Permanent File Error Flags**

The permanent file error flags that have been set by SSEXEC in the PFC can be cleared by the CE parameter of the CHANGE command. The job must be of system origin.

## Permanent File Recovery

If a permanent file cannot be accessed or is included by SSVAL on the validation report, try the following procedures to recover a copy of the file.

- 1. Attach the file. If the file has a disk image or can be staged in from 7990, the file data will be available on disk and can be copied to another file. SSVAL should then be run as described in step 2.
- 2. If the file cannot be attached, reload the file from a dump tape using PFLOAD with OP=Z. To identify the PFDUMP run that saved a backup copy of the file, check the output from SSVAL or PFCAT, which includes date and time fields from the PFC entry for the file. Depending on the BR attribute (backup requirement) of the file, a backup copy on a dump tape may not exist.

If the file can be reloaded to disk, SSVAL should be run as follows:

SSVAL, FM=familyname, SB=subfamily, FX=n, AM.

familyname and subfamily identify the family and subfamily of the recovered file and n is sufficiently large that the fixing/flagging will be done. SSVAL sets the obsolete flag in the PFC entry because the file now has a disk image; thus the file is disassociated from the error condition. The error condition may still exist in the 7990 catalog or SM map, but you can analize and then correct the error by using the SSDEBUG utility. Before using SSDEBUG to correct the error, you should take an incremental dump so the old PFC entry with an asa value pointing to a problem 7990-resident file will not be reloaded if a device reload occurs before the next scheduled backup dump.

- 3. If steps 1 and 2 fail, try to regenerate the file. Depending on the particular problem and status of the cartridges to which the file was destaged, the OP=RF or OP=RS directive to SSDEBUG might recover the file data.
- 4. If the file cannot be recovered, purge it so there is no PFC entry pointing to a problem 7990-resident file.

#### Cartridge Restoration and Reuse

If a cartridge is unexpectedly found anywhere outside its assigned cubicle, follow these steps to restore the cartridge so it can be used again:

- 1. Put the cartridge in the input tray of the SM to which it is assumed to belong and run SSLABEL with the OP=RS directive. If the cartridge label information agrees with the SM map entry for the cubicle with the coordinates (y,z) written on the cartridge label, the cartridge will be restored to that cubicle and the 7990 catalog entry for the cartridge is updated to clear the lost flag. Otherwise, the cartridge is put in the exit tray and the cartridge label information is included in the output from SSLABEL.
- 2. If the cartridge was not restored to its SM cubicle, examine the label information reported by SSLABEL. If the cartridge is assigned to a different SM, repeat step 1 using the correct SM. If the family name is blank, the cartridge has a scratch label and can be assigned normally with the OP=AM directive to SSLABEL.
- 3. If steps 1 and 2 fail, examine the SM map entry for the cubicle with the coordinates (y,z) written on the cartridge label to see how the cubicle is assigned. Examine the cartridge, if any, in this cubicle. Also, it might be useful to run SSVAL to ensure the SM map and 7990 catalog entries for the cartridge match or to identify affected permanent files, if any, if they do not match.
- 4. If step 3 does not produce any useful information and the cartridge cannot be restored, use the OP=FX directive to SSLABEL to rewrite the cartridge label and thereby make a scratch cartridge. It might be useful to first run SSDEBUG with the OP=RS directive to preserve the data on the cartridge.

## **Removal of Faulty or Missing Cartridges**

Follow these steps to remove a cartridge that has unrecoverable errors, or to release the SM map entry for a cartridge that is missing.

For unallocated cartridges:

- 1. Attempt to remove the cartridge with the SSLABEL OP=RM directive.
- 2. If CARTRIDGE NOT FOUND is reported, repeat step 1 specifying the LT parameter.
- 3. If CARTRIDGE NOT EMPTY is reported, at least one AU on the cartridge is still allocated.

For allocated cartridges:

- 1. Use the SSLABEL OP=FC directive to inhibit further allocation of the cartridge.
- 2. Run SSVAL specifying the AM parameter. Examine the report for possible discrepancies between the SM map, 7990 catalog, and PFC entries related to this cartridge.
- 3. If no 7990 catalog entry corresponds to the SM map entry, use the OP=RC directive to SSDEBUG to remove the map entry.
- 4. If no discrepancy is reported by SSVAL, the affected files should be attached in write mode (if possible), reloaded using PFLOAD with the OP=Z parameter, or purged. Then SSVAL release processing should be done to release the 7990 space on the cartridge, and the cartridge can be removed with the SSLABEL OP=RM directive.

## 7990 Catalog/SM Map/PFC Problems

If error conditions exist in the 7990 catalogs or SM maps, the recovery procedure is to correct the appropriate entry rather than reload the entire file. Reloading other than the latest copy of the SM map is not feasible because it can contain entries for several families and these entries would not be up to date. Reloading an old copy of the 7990 catalog is not desirable because any permanent file that was destaged and released from disk since the last incremental dump will be lost. The following paragraphs describe corrective action for specific problems with 7990 catalogs, SM maps, or PFC entries.

#### 7990 Catalog/SM Map Mismatch

The following examples of 7990 catalog/SM map mismatches can appear as error type 1 or 2 on the SSVAL output report, which identifies the mismatch and the permanent files or orphans affected. Before taking any corrective action, the analyst should ensure that operational errors did not result in loading the wrong version of the SM map or 7990 catalog.

- If a cartridge has a 7990 catalog entry indicating that all AUs on the cartridge are available for allocation but is not identified in any SM map entry (type 1 mismatch), use the OP=RL directive to SSDEBUG to remove the 7990 catalog entry for the cartridge.
- If a cartridge is identified in an SM map entry but has no 7990 catalog entry (type 2 mismatch), use the OP=RC directive to SSDEBUG to update the SM map entry to unassigned and empty status. This directive will write a scratch label for the cartridge, if any, and place the cartridge in the exit tray.
- If a cartridge has a 7990 catalog entry indicating that at least one AU on the cartridge is allocated, recover the disk space for the affected permanent file, if any, or purge the file. Run SSVAL to purge unneeded 7990 files and thereby make the cartridge unallocated. Use the OP=RL directive to SSDEBUG to remove the 7990 catalog entry for the cartridge.

NOTE

It sometimes takes two SSVAL/SSDEBUG runs to completely clear up type 1 or type 2 errors. Therefore, it is recommended that SSVAL be rerun with the AM parameter after an SSDEBUG run using OP=RC or OP=RL.

#### 7990 Catalog Chain Problems

AUs that are allocated to a 7990-resident file are chained together in the 7990 catalog to identify the sequence of AUs that contain the file. (Refer to the definition of cartridge earlier in this section.) For most files, the AUs in the chain reside on the same cartridge. Hence, one disk access is sufficient to update information for the entire chain at one time. However, a 7990-resident file can reside on several cartridges, and several disk accesses may be necessary to update its chain. If SSEXEC is interrupted during such an update, the resultant chain will be incomplete. SSVAL identifies incomplete chains as error type 4, 5, or 6 on the validation report. The following are types of incomplete chains.

- If an incomplete chain is produced while a 7990-resident file is being purged, it is a chain fragment (one without an HOC entry).
- If an incomplete chain is produced while a file is being destaged to 7990, it is an ill-formed chain (one without an EOC entry).
- If an ill-formed chain is not corrected, the AU that should have been linked to it may be reused and become part of a good chain. Although the ill-formed chain may appear to be complete, the ill-formed chain and the good chain are intersecting.

The corrective action for any of these bad chain conditions is:

- 1. Run SSVAL with the FM parameter specified and use a sufficiently large FX=n value so that SSVAL updates the 7990 catalog entries affected by the problem chains.
- Recover the permanent files, if any, that have 7990 images potentially affected by these error conditions. (The SSVAL report identifies these files.) Use the procedure described under Permanent File Recovery earlier in this section.
- 3. Take an incremental or full backup dump. This prevents PFC entries with inaccurate as a values or problem 7990 chains from being recovered if a device reload is necessary.
- 4. Run SSDEBUG with the OP=RP directive to make each AU on the problem chain available for allocation. Thus, the AUs can be included in a new chain without any problems. In the case of intersecting chains, all chains that have an AU in common with another chain should be released before any further destage attempts; otherwise, errors will occur when a user tries to attach a file that is contained on an intersecting chain.

#### PFC/7990 Catalog Mismatch

It is possible that an old version of a 7990 catalog can be reloaded because of incorrect operational procedures. If so, the asa value in the PFC entry for a file can be invalid according to the obsolete 7990 catalog or can point to a problem chain. If the correct version of the 7990 catalog is available on tape, it should be reloaded. If it is not available, the following action is appropriate. If the file also has a disk image, SSVAL should be run to clear the asa field in the PFC entry. If there is no disk image, the analyst should reload the file from tape, if possible, and then run SSVAL to clear the asa value.

.

# INTRODUCTION

The MSF hardware product is a large-capacity online mass storage device, which is a costeffective extension to the disk file storage system and an alternative to conventional magnetic tape storage. Storing files on MSF retains the security, data integrity, and online access capabilities provided by disk and reduces the operational and data integrity problems caused by storing, retrieving, and mounting tape volumes. You can use both MSF and magnetic tapes to protect files from hardware and system failures.

MSF is composed of the following components.

| Component | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cartridge | A plastic housing that encloses 2540 mm (100 in) of magnetic tape on which data is stored under program control.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Coupler   | The interface between the peripheral processor (PP) and the mass<br>storage adapter (MSA), which includes a buffer that contains data<br>going to or coming from the mass storage transport.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CSU       | Cartridge storage unit (CSU), which includes storage cells<br>(cubicles) for 2052 cartridges <sup>†</sup> and a selector that moves cartridges<br>among the mass storage transport, the cubicles, and the input/output<br>(I/O) drawers of the CSU. Each CSU has two I/O drawers; the top one<br>is the input drawer and the bottom one is the output drawer. Each<br>drawer has eight vertically aligned drawer slots, numbered from O<br>(top slot) to 7 (bottom slot). There can be up to 13 CSUs in an MSS<br>configuration. Each CSU in a configuration is associated with a<br>letter from A to M, which is the CSU identifier. |
| MSA       | Mass storage adapter, which interfaces between the coupler and the mass storage transport or the CSU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| MST       | Mass storage transport, which includes storage positions for five<br>cartridges: one being read or written, two queued for reading or<br>writing, and two queued for storage by the selector into the CSU.                                                                                                                                                                                                                                                                                                                                                                                                                            |

The MSS is the product consisting of the MSF hardware, the CYBER coupler, the diagnostics, and the operational software. The basic function of MSS is to store data on MSF and move it to disk upon request for access by an authorized user. Control of file movement between disk and MSF is transparent to the applications programmer; however, there are operational changes and additions that site personnel should note. These include modifications to operational procedures in the areas of permanent file backup, permanent file recovery, and disk space management. In addition, new MSS utilities are introduced.

<sup>&</sup>lt;sup>†</sup>2000 cartridges are available for file data storage and the rest are reserved for customer engineer and system use.

Detailed information about the call and operation of each MSS utility is included in this section.

| <b>Utility</b> | Description                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ASDEF          | Creates the system files (CSU maps and MSF catalogs) necessary for MSS processing.                                                                           |
| ASLABEL        | Manages allocation of cubicles and assignment of cartridges in the CSU.                                                                                      |
| ASMOVE         | Controls the destaging of files (creating MSF images) and the release of disk space.                                                                         |
| ASVAL          | Controls the release of MSF space and analyzes the CSU maps, MSF catalogs, and PFC entries to identify and flag discrepancies within these three components. |
| ASUSE          | Provides reports on the assignment and availability of cartridges and cubicles within a CSU.                                                                 |
| ASDEBUG        | Corrects error conditions detected by ASVAL and recovers data from MSF cartridges.                                                                           |

## UTILITY DESCRIPTION TERMINOLOGY

Review the following terms; they are defined as used in the descriptions of the MSAS utilities later in this section.

#### Cartridge

A cartridge is the MSS data storage component consisting of 16 streams, called allocation units (AUs). Streams that have data written on them (allocated streams) are chained together in the MSF catalog (definition following) to identify the sequence of streams that must be accessed in order to read a file on MSF. A head-of-chain (HOC) flag identifies the first AU in the chain, a link field identifies the next AU in the chain, and an end-of-chain (EOC) flag identifies the last AU in the chain.

The cartridge label contains information that characterizes one of the three types of cartridges that can be used in an MSS environment. Cartridges having label types other than the following cannot be processed by MSS except by the ASLABEL utility, which can rewrite the cartridge label, or by the ASDEBUG utility, which can write the data on the cartridge to a permanent file.

- A manufacturer's label contains the volume serial number (vsn) of the cartridge in a machine-readable format. A cartridge with a manufacturer's label can be added to a CSU and assigned to a subfamily or pool (refer to the ASLABEL utility later in this section).
- A scratch label contains the vsn of the cartridge and additional system information indicating that the cartridge is available for assignment by the ASLABEL utility. A scratch label also contains the usage record of the cartridge. A cartridge with a scratch label is called a scratch cartridge.
- A family label contains the vsn of the cartridge and additional system information indicating that the cartridge is assigned to a particular subfamily. It also indicates the CSU identifier and the coordinates x and y of the cubicle where the cartridge resides when it is not in use.

The addition, removal, and reassignment of cartridges are managed by the MSS utilities. The cartridge labels, and also the MSF catalogs and CSU maps (definitions following), contain information concerning the location and content of the cartridges. When a cartridge is labeled and assigned to a subfamily, a label is written on each stream of the cartridge, which contains the cartridge vsn, the CSU id, x and y coordinates, family, and subfamily to which it was assigned, and the stream number of the particular stream. If such a cartridge is accessed for relabeling or for reading or writing an MSF file, the stream label verification procedure is used to verify this stream label information against the data in the MSF catalogs and CSU maps. If a discrepancy is detected, an error message is issued and corrective action must be taken to update the cartridge labels and/or system files as described in a later section. Whenever the cartridge location or content is changed, the cartridge. The descriptions of the MSS utilities later in this section contain further information on cartridge management.

# CSU Map

A CSU map is a direct access permanent file that contains information indicating how cubicles in a CSU are assigned to a family and identifying the cartridges that reside in the CSU. There is one CSU map for each CSU in the configuration. The permanent file name of the CSU map is CSMAPi, where i is the CSU identifier (a letter from A to M); its user index is 377760<sub>8</sub>; and its family is the default family on the mainframe on which MSSEXEC executes (refer to the definition of MSSEXEC later in this section).

A CSU map contains an entry for each possible coordinate pair (x,y) that identifies a cubicle in the CSU, from (0,0), which is bottom right, to (57,36), which is upper left. There are no cubicles at the positions where x=30 or y=18, but there are entries in the CSU map for such coordinate pairs and these entries indicate that no cubicle exists there. Thirty-one cubicles are reserved for customer engineer use; they have these coordinates: (57,36), (0,36), (57,0), and (26 through 0,0). Twenty-one cubicles are reserved for system use; they have these coordinates: (48 through 31,0), (29,0), (28,0), and (27,0). In all, there are 2146 entries in a CSU map and they are ordered (assigned a map entry ordinal) according to the positions in the CSU of the corresponding cubicles. That is, the following scheme is used to relate the coordinate pairs (x,y) and the map entry ordinals.

- Given the coordinates x and y, the ordinal is 2146-x-(y\*58).
- Given the ordinal, y is the whole number quotient of (2146-ordinal)/58 and x is the remainder.
- Ordinal 0 does not represent a coordinate pair; it is used as a map header entry.

Thus, in a CSU map the zero entry is the map header entry; the first entry describes the cubicle at coordinates (57,36); the second entry describes the cubicle at coordinates (56,36); and so forth.

Each entry in a CSU map has this format:

| <u>Field</u> | Description                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| code         | Number from 1 to 7 indicating how the cubicle is assigned.                                                                                                                                                                                            |
|              | code Description                                                                                                                                                                                                                                      |
|              | 1 Reserved for customer engineer.                                                                                                                                                                                                                     |
|              | 2 Reserved for system use.                                                                                                                                                                                                                            |
|              | 3 Reserved for a different CSU map.                                                                                                                                                                                                                   |
|              | 4 Assigned to the cartridge scratch pool. <sup>†</sup>                                                                                                                                                                                                |
|              | 5 Assigned to a subfamily.                                                                                                                                                                                                                            |
|              | 6 Unassigned.                                                                                                                                                                                                                                         |
|              | 7 No cubicle exists at these coordinates $(x=30 \text{ or } y=18)$ .                                                                                                                                                                                  |
| ord          | Ordinal for this cubicle in the MSF catalog of the subfamily to<br>which the cubicle is assigned. This ordinal is referred to as the<br>FCT ordinal (refer to the definition of MSF catalog later, next).<br>This field is meaningful only if code=5. |
| familyname   | The 7-character name, in 6-bit display code, of the family to which the cubicle is assigned. This field is meaningful only if code=5.                                                                                                                 |
| ٤            | Linkage error flag that is set by the ASVAL utility when a CSU map<br>entry of a cubicle assigned to a family has no corresponding entry<br>in the MSF catalog.                                                                                       |
| subfamily    | Number from 0 to 7 identifying the subfamily to which the cubicle is assigned. This field is meaningful only if code=5.                                                                                                                               |
| vsn          | The 6-character volume serial number of the cartridge assigned to the cubicle. If no cartridge is assigned, this field contains spaces.                                                                                                               |
|              |                                                                                                                                                                                                                                                       |

The zero entry in the CSU map is the map header entry. In this entry the code field is 7, the leftmost 6 bits of the second word contain the CSU identifier, and the remaining bits are unused.

The CSU map is updated whenever the ASLABEL, ASVAL, or ASDEBUG utility causes a change in cubicle or cartridge assignment. It is recommended that the CSU map be backed up after every update to avoid problems such as:

- Mismatches between CSU map and MSF catalog entries.
- Lost CSU maps because of a disk failure or other problem.
- Attempts to access cartridges that are no longer available.
- Attempts to store cartridges in cubicles that are no longer empty.

<sup>&</sup>lt;sup>†</sup>The pool is an area of the CSU that stores scratch cartridges that are managed by the ASLABEL utility.

Thus, you should make a copy of the CSU map on tape or another device or family in order to retain the latest version of the CSU map. If a device containing CSU maps is reloaded, the latest version of the CSU maps should be recovered from the backup copy after the reload is completed. After recovering the CSU maps, the analyst should run the ASVAL utility to check that the entries in the CSU maps and MSF catalogs match. If there are inconsistencies, corrective action should be taken as described under Error Conditions and Corrective Actions later in this section.

## **MSF** Catalog

An MSF catalog is a disk-resident direct access permanent file that contains information describing which streams of each cartridge assigned to a particular subfamily are allocated to MSF files and which streams are available for allocation. There is one MSF catalog for each subfamily of a family that can have MSF-resident files, and it resides on the master device for the subfamily. The permanent file name of the MSF catalog file is MSFCATi and its user index is 3777618, where i is the subfamily identifier (a number from 0 to 7). For example, file MSFCAT3 and user index 3777638 identify the MSF catalog for subfamily 3.

An MSF catalog is partitioned into subcatalogs, one subcatalog for each CSU used by the subfamily. The maximum number of subcatalogs in an MSF catalog is 13 (the maximum number of CSUs in a configuration). Each subcatalog consists of two parts: the file and cartridge table (FCT) and the available stream table (AST). The FCT has an entry for each cubicle assigned to the subfamily from the given CSU. The maximum number of FCT entries in a subcatalog is 2000 (the maximum number of user cartridges in a CSU). The AST contains information used by the allocation algorithm to select the cartridges on which a file will reside.

The first part of the MSF catalog contains a header and at most 13 subcatalog entries. The header identifies the family and subfamily of the MSF catalog. Each subcatalog entry contains the length and location of its FCT and AST, the CSU identifier, unallocated stream count, and date of the last ASVAL run that resulted in the releasing of MSF space assigned to the particular CSU or the setting of flags in entries for cubicles in the CSU. The format of the header is:

| i9 |            | 17 11          |        |
|----|------------|----------------|--------|
|    | familyname | sub-<br>family | unused |
|    | unused     |                |        |

Field

Description

familyname

The 7-character name in 6-bit display code of the family for this MSF catalog.

subfamily Number from 0 to 7 identifying the subfamily for this MSF catalog.

# The format of the subcatalog entry is:

| 59        | 53     | 41                                                                                                                                                                                 | 35  | 29      | 17       | 0   |
|-----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------|----------|-----|
| id        | length | FCT                                                                                                                                                                                | loc | AST loc | streams  |     |
|           | unused |                                                                                                                                                                                    |     | date    | time     |     |

| id        |        | CSU identifier for the subcatalog (a letter from A to M).                                                                                                                          |     |         |          |     |
| length    |        | Number of FCT (and AST) entries in the subcatalog.                                                                                                                                 |     |         |          |     |
| FCT loc   |        | Location (beginning PRU number) of the FCT.                                                                                                                                        |     |         |          |     |
| AST loc   |        | Location (beginning PRU number) of the AST.                                                                                                                                        |     |         |          |     |
| streams   |        | Number of unallocated streams for this subcatalog.                                                                                                                                 |     |         |          |     |
| date time | :      | Date and time of the last releasing of orphan files on the CSU<br>identified by id, or the last time flags were set for cartridges or<br>cubicles in the CSU (whichever is later). |     |         |          |     |

The header and subcatalog information is arranged in this order:

- 1. First word of the header.
- 2. First word of each of the subcatalog entries.
- 3. Second word of the header.
- 4. Second word of each of the subcatalog entries.

Each cubicle from the given CSU assigned to the subfamily has an entry in the FCT of the subcatalog. This entry contains the coordinates (x,y) of the assigned cubicle. If a cartridge has been assigned to the cubicle, the FCT entry also contains the vsn of the cartridge, usage information, status flags, and information about each of the 16 streams of the assigned cartridge. The format of each FCT entry is:

| 57         | 53                                        | 47                                                                     | 41                                                                                                                                                                           | 35 33                                                                                                                                                                                            | 29                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 27                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 20                                                                                                                                                                                                                                                               | C                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| bps               | Number of blocks per stream on the cartridge assigned to this cubicle.                                                                                                                                                                                                                                                                                                                        |  |  |
| flagsl            | One of the following flags.                                                                                                                                                                                                                                                                                                                                                                   |  |  |
|                   | Bit Description                                                                                                                                                                                                                                                                                                                                                                               |  |  |
|                   | 53 Inhibit allocation flag indicating that space from the<br>cartridge assigned to this cubicle is not to be allocated<br>to a file. This flag is set by a directive to the<br>ASLABEL utility.                                                                                                                                                                                               |  |  |
|                   | 52 Lost cartridge flag indicating that the cartridge<br>assigned to this cubicle was not there the last time<br>MSSEXEC tried to pick it. This flag can be cleared by a<br>directive to the ASLABEL utility.                                                                                                                                                                                  |  |  |
|                   | 51 Excessive write parity error flag. Space from such a cartridge will not be allocated. This flag can be cleared by a directive to the ASDEBUG utility.                                                                                                                                                                                                                                      |  |  |
|                   | 50 Reserved.                                                                                                                                                                                                                                                                                                                                                                                  |  |  |
|                   | 49 Linkage error flag indicating that the CSU map entry for<br>the location (x,y) is inconsistent with this FCT entry.                                                                                                                                                                                                                                                                        |  |  |
|                   | 48 Reserved.                                                                                                                                                                                                                                                                                                                                                                                  |  |  |
| x                 | x coordinate of this cubicle.                                                                                                                                                                                                                                                                                                                                                                 |  |  |
| у                 | y coordinate of this cubicle.                                                                                                                                                                                                                                                                                                                                                                 |  |  |
| vsn               | The 6-character volume serial number of the cartridge assigned to this cubicle. If no cartridge is assigned, this field contains spaces.                                                                                                                                                                                                                                                      |  |  |
| link <sub>i</sub> | Ordinal of the FCT entry for the cubicle containing the next car-<br>tridge n which the file on the cartridge assigned to this cubicle<br>resides. If a file does reside on multiple cartridges, the entire<br>file must be contained in one CSU. Also, since there are only three<br>link fields, if a cartridge contains several files, only three can be<br>contained on other cartridges. |  |  |
| load threshold    | If the number of loads of the cartridge exceeds this threshold value, streams from this cartridge will not be allocated to new files.                                                                                                                                                                                                                                                         |  |  |
| load count        | Number of times the cartridge assigned to this cubicle has been loaded to a mass storage transport read/write station.                                                                                                                                                                                                                                                                        |  |  |
| pass threshold    | If the number of passes across the read/write heads exceeds this threshold value, streams from this cartridge will not be allocated to new files.                                                                                                                                                                                                                                             |  |  |
| pass count        | Number of times the cartridge assigned to this cubicle has been passed across a read/write head.                                                                                                                                                                                                                                                                                              |  |  |
| error threshold   | If the number of errors recorded exceeds this threshold value, streams from this cartridge will not be allocated to new files.                                                                                                                                                                                                                                                                |  |  |

|                    | 41-40                                          | Off-cartridge link flag indicating that the next stream of the file is on another cartridge. The next cartridge is identified by one of the link <sub>i</sub> fields. The value of the off-cartridge link flag $(1, 2, \text{ or } 3)$ specifies which link <sub>i</sub> to use. The chain field specifies the stream number on the next cartridge. Only 3 of the 16 streams of a cartridge can have this flag set at any one time. This field is meaningful only if the chain control field indicates that this stream is the first or middle stream of the file. |  |  |
|                    | 39-38                                          | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |  |
|                    | 37-36                                          | Chain control indicating whether the stream is a<br>first (1), last (2), only (3), or middle (0) stream<br>of the file. This field is meaningful only if the<br>stream is allocated to a file.                                                                                                                                                                                                                                                                                                                                                                     |  |  |

35-34 Unused.

60459300 D

| Field                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| chain                      | Next stream number, if any, containing file data for the file. This field is meaningful only if the stream is allocated to a file.                                                                                                                                                                                                                                                                                                                   |
| stream <sub>l</sub> detail | PRU, flag, and chain control information about stream 1. The upper<br>30 bits of this word contain information about stream 0. The lower<br>30 bits are divided into the same fields, and contain information<br>about stream 1. The next seven words are divided similarly: the<br>upper 30 bits contain information about stream 2, 4, 6, 8, 10, 12,<br>or 14 and the lower 30 bits contain information about stream 3, 5,<br>7, 9, 11, 13, or 15. |

The MSF catalog is updated whenever the ASLABEL, ASMOVE, ASVAL, or ASDEBUG utility causes a change in cartridge or cubicle assignment that affects the subfamily. Because the MSF catalog for a subfamily resides on its master device, it will be backed up by PFDUMP whenever the master device for the subfamily is dumped. Consequently, when PFLOAD reloads all files, the MSF catalogs are automatically recovered and all MSF-resident files as indicated in a recovered PFC will also have entries in the recovered MSF catalog. Thus, no special operational procedures are needed to back up an MSF catalog. It is possible, however, that the MSF catalog will be inconsistent with the CSU maps or cartridge labels. If such inconsistencies do exist, corrective action will have to be taken as described under Error Conditions and Corrective Actions later in this section.

#### **MSF** Files

In an MSS environment, permanent files can be categorized according to whether or not they reside on MSF. A disk file is a permanent file that resides on disk but not on MSF. An MSF file is a permanent file that resides on MSF and may or may not also reside on disk, depending on how the disk space is managed (refer to Disk Space Management later in this section). Depending on backup requirements (BR parameters), both disk and MSF files can also have backup images on tape (refer to the NOS 2 Reference Set, Volume 3).

When a user defines a direct access file, initially it is a disk file. A disk file becomes an MSF file when it is destaged to MSF; that is, an image of the file is created on MSF. You can destage files through the ASMOVE utility, which is run periodically to manage disk space. When ASMOVE is run, files are destaged to MSF and/or their disk space released depending on certain file characteristics (refer to ASMOVE later in this section). Thus, after an ASMOVE run a file can reside on disk, on MSF, or on both. If the file does have an MSF image, the asa field in the PFC entry for the file indicates the location of the MSF copy. The obsolete (AFOBS) flag in the PFC entry indicates whether or not the MSF image is a current version of the file.

When a user attaches an MSF file, it is staged to disk from MSF (that is, a disk image is created) if the current version of the file is not on disk. If the file is attached in write mode, the MSF image is marked obsolete; that is, the AFOBS flag in the PFC entry for the file is set. This is because the disk image is immediately updated when the user makes changes to the file, but the MSF image is not updated until the ASMOVE utility is run again. Hence, the current version of the file resides on disk only. Setting the AFOBS flag ensures that the current version of the file will be copied to MSF and will replace the obsolete MSF file the next time ASMOVE is run. When a user attaches a file, however, it is always the current version of the file that the user accesses; an obsolete file cannot be accessed.

If the file is purged, its disk space, but not its MSF space, is immediately released. The ASVAL utility must be run to release MSF space allocated to purged files. Thus, because a purged file has no PFC entry linking to its MSF catalog entry, the MSF image that still exists before ASVAL is run is called an orphan file. However, a user can never access an orphan file.

When a file is destaged to MSF, information is written on each stream to which the file data is written. This information includes the file's creation date and time and user index from the PFC entry, the identity of the first stream to which the file is written, the identity of the stream immediately preceding this one, and the number of disk PRUs of data recorded on previous streams (for all but the first stream of multistream files).

When a file is staged back to disk, the file label verification procedure is used to verify this file label information against the stream label information (refer to the definition of cartridge earlier in this section) for each stream of the file. If a discrepancy is detected, an error message is issued, the file stage is aborted, an error flag is set in the PFC entry to indicate that the MSF file could not be accessed, and the stream conflict error flag is set in the MSF catalog entry for the particular cartridge(s) and stream(s).

## MSSEXEC

MSSEXEC is the main processing program that is responsible for controlling MSS activities. The MSS utilities issue requests to MSSEXEC to destage files from disk to MSF, purge unneeded MSF files, label or relabel cartridges, update CSU maps and MSF catalogs, and so forth. In a multimainframe environment, two versions of this program exist: the mainframe to which the MSF device is physically connected (the master mainframe) has a program called MSSEXEC, and all other mainframes (the slave mainframes) have a program called MSSELV. Refer to section 13, Multimainframe Operations, for more information.

## Subfamily

Each permanent file family consists of eight subfamilies, subfamily 0 through subfamily 7. The lower 3 bits of the user index identify the subfamily to which a user belongs. For example, a user whose index ends in 3 (or 011 in bit notation) belongs to subfamily 3. When the ASDEF utility is run to create MSS system files, the CSU maps are created under user index 377760g (subfamily 0) and one MSF catalog is created under each user index 377761g (subfamily i), i=0,1,2,...,7. When the ASLABEL utility is used to assign a CSU, cubicle, or cartridge to a family, it is possible to specify assignment to particular subfamilies of the family.

# **MSS UTILITIES**

MSS utilities are described next. All of these utilities must be run from system origin jobs. In a multimainframe environment, the ASDEF and ASUSE utilities can be run on any mainframe that has access to the family being processed. However, the remaining utilities must be run on the mainframe on which MSSEXEC executes.

## ASDEF

ASDEF creates the system files (CSU maps and MSF catalogs) that are necessary for MSS processing. If a CSU is added to the MSF hardware configuration, ASDEF is used to create the CSU map for that CSU. If a family is to be permitted to have MSF-resident files, ASDEF is used to create the eight MSF catalogs for that family (one catalog for each subfamily).

# NOTE

If the CS parameter is specified, ASDEF will create a CSU map for the specified CSU (refer to the definition of CSU map earlier in this section). It is recommended that the CSU map be copied on tape or on another device or family immediately after it is created.

The format of the ASDEF command is:

ASDEF, p1, p2.

| $\frac{p_i}{i}$ | Description                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------|
| CS=id           | CSU identifier of the CSU for which a CSU map is to be created; id is a letter from A to M. |
| CS              | Same as CS=A.                                                                               |
| CS omitted      | No CSU map is to be created. FM=familyname or FM must be specified.                         |
| FM=familyname   | Family for which MSF catalogs are to be created, one catalog for each subfamily.            |
| FM              | Same as FM=system default family.                                                           |
| FM omitted      | No MSF catalogs are to be created. CS=id or CS must be specified.                           |

#### Example:

ASDEF,CS=B.

CSMAPB, the CSU map for CSU B, is created, and its entries are as described in the definition of CSU map earlier in this section. However, since ASDEF does not assign cubicles, the entries for cubicles available for use initially have zeros or spaces in all but the code field, which indicates the cubicles are unassigned.

## ASLABEL

ASLABEL manages cartridge assignment and cubicle allocation in a CSU. The following functions are performed through the use of directives to ASLABEL.

- Add a CSU to a subfamily (AC directive).
- Remove a CSU from a subfamily (RC directive).
- Add cubicles to a subfamily, the pool, or the reserved area (AB directive).
- Remove cubicles from a subfamily, the pool, or the reserved area (RB directive).
- Add cartridges to a subfamily or the pool (AM directive).
- Remove cartridges from a subfamily or the pool (RM directive).
- Restore an abnormally removed cartridge (RS directive).
- Repair a cartridge label or overwrite a family label (FX directive).
- Inhibit or allow further allocation of files to a cartridge (IB directive).

Input to ASLABEL is via a directive file. ASLABEL reads the appropriate CSU maps and MSF catalogs to determine how to process each directive and then issues requests to MSSEXEC to read and/or write cartridge labels and to update the CSU maps and MSF catalogs. ASLABEL generates a report detailing the action taken for each input directive. If the assignment information or cartridge label is not appropriate or conflicts with data in the CSU map or MSF catalog, the cartridge label information is included on this report and the cartridge is put into the output drawer. It may be possible to restore such a cartridge as described under Cartridge Restoration and Reuse later in this section.

## NOTE

ASLABEL updates the CSU map for the specified CSU (refer to the definition of CSU map earlier in this section). It is recommended that the CSU map be copied on tape or on another device or family immediately after each update.

The format of the ASLABEL command is:

ASLABEL, p1, p2.

 Pi
 Description

 I=filename
 File containing the directives to ASLABEL.

 I
 Same as I=COMPILE.

 I omitted
 Same as I=INPUT.

| <sup>p</sup> i | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| L=filename     | File on which listable output is to be written.                              |
| L              | Same as L=OUTPUT.                                                            |
| L=0            | No output file is to be generated.                                           |
| L omitted      | Same as L=OUTPUT.                                                            |
| Z              | Directives are contained on the ASLABEL command. The I parameter is ignored. |
| Z omitted      | Directives are contained on the file specified by the I parameter.           |

## **ASLABEL** Directives

The directives to ASLABEL can be specified on a separate file (specified by the I parameter) or after the ASLABEL command (Z specified). If on the input file, each directive must be specified on a separate line via the OP=directive option. Parameters for a directive are on the same line, are separated by commas, and end with a period:

OP=directive,p1,p2,...,pn.

Example:

ASLABEL, I=DIRFILE.

DIRFILE is the directive file; it contains the following directives.

OP=AM,N=4,PK=D. OP=RM,V=VSN444,FM,SB=1.

Two directives to ASLABEL are specified. OP=AM adds four cartridges to the pool of CSU A (CS parameter not specified). OP=RM removes the cartridge whose vsn is VSN444 from subfamily 1 of the default family. (Refer to the following descriptions of directives and parameters.)

If the directives are contained on the command, they follow the command terminator. The first character following the terminator is the separator. Any character that does not appear in any of the directives can be used as the separator character. Each directive must be preceded by the separator and terminated by a period.

Example:

ASLABEL,Z./OP=AM,N=4,PK=D./OP=RM,V=VSN444,FM,SB=1.

The slant is used as the separator. This command performs the same functions as those in the preceding example.

The following directives are available with ASLABEL. Some of these directives cause cartridges to be physically moved to and from cubicles and the input or output drawer (refer to OP=AM, OP=RM, OP=RS, and OP=FX). The remaining directives cause only logical operations to occur, updating the MSS system files. Descriptions of the parameters for these directives follow the directives.

#### **OP=PC** - **Add CSUs**

OP=AC adds a CSU to a subfamily. The MSF catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily can reside on the specified CSU. This directive, however, does not manipulate cartridges or cubicles.

## **OP=RC - Remove CSUs**

OP=RC removes a CSU from a subfamily. The MSF catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily cannot reside on the specified CSU. Before OP=RC can be specified, all cubicles in the specified CSU must have been removed previously from the family (refer to the OP=RB directive). This directive, however, does not manipulate cartridges or cubicles.

## OP=AB - Add Cubicles

OP=AB adds an unassigned cubicle within a CSU to a subfamily (PT=F), the pool (PT=P), or the reserved area of the CSU (PT=R). More than one cubicle (N=n) can be added at a time. Specific cubicles (XI and YI parameters) can be added, but they must be currently unassigned. For PT=R, XI and YI must be used to add multiple cubicles; N=n is not valid. If cubicles are to be assigned to a subfamily, ASLABEL selects available cubicles closest to the top of the CSU. If cubicles are to be assigned to the pool, ASLABEL selects available cubicles cubicles closest to the bottom of the CSU. The CSU map is updated to reflect the new assignment of cubicles.

#### OP=RB - Remove Cubicles

OP=RB removes an assigned empty cubicle from a subfamily (PK=F), the pool (PK=P), or the reserved area of the CSU (PK=R). More than one cubicle (N=n) can be removed at a time. ASLABEL reads the CSU map and selects the first empty cubicle assigned to the subfamily, pool, or reserved area to be removed. Specific cubicles (XI and YI parameters) can be removed, but they must be empty. The CSU map is updated to reflect that the cubicles are unassigned.

## OP=AM - Add Cartridges

OP=AM adds a cartridge with a manufacturer's label or a scratch label to either a specific subfamily (PT=F) or the pool (PT=P). ASLABEL selects the first empty cubicle assigned to the subfamily or pool as the new location for the cartridge. More than one cartridge (N=n) can be added at a time or a specific cartridge (V=vsn) from the pool can be added to a subfamily. The CSU map, MSF catalog, and cartridge label are updated to reflect the new assignment of the cartridge.

| <u>p</u> i | Description                                                                  |
|------------|------------------------------------------------------------------------------|
| L=filename | File on which listable output is to be written.                              |
| L          | Same as L=OUTPUT.                                                            |
| L=0        | No output file is to be generated.                                           |
| L omitted  | Same as L=OUTPUT.                                                            |
| Z          | Directives are contained on the ASLABEL command. The I parameter is ignored. |
| Z omitted  | Directives are contained on the file specified by the I parameter.           |

## **ASLABEL Directives**

The directives to ASLABEL can be specified on a separate file (specified by the I parameter) or after the ASLABEL command (Z specified). If on the input file, each directive must be specified on a separate line via the OP=directive option. Parameters for a directive are on the same line, are separated by commas, and end with a period:

OP=directive,p1,p2,...,pn.

Example:

ASLABEL, I=DIRFILE.

DIRFILE is the directive file; it contains the following directives.

OP=AM,N=4,PK=D. OP=RM,V=VSN444,FM,SB=1.

Two directives to ASLABEL are specified. OP=AM adds four cartridges to the pool of CSU A (CS parameter not specified). OP=RM removes the cartridge whose vsn is VSN444 from subfamily l of the default family. (Refer to the following descriptions of directives and parameters.)

If the directives are contained on the command, they follow the command terminator. The first character following the terminator is the separator. Any character that does not appear in any of the directives can be used as the separator character. Each directive must be preceded by the separator and terminated by a period.

Example:

ASLABEL,Z./OP=AM,N=4,PK=D./OP=RM,V=VSN444,FM,SB=1.

The slant is used as the separator. This command performs the same functions as those in the preceding example.

The following directives are available with ASLABEL. Some of these directives cause cartridges to be physically moved to and from cubicles and the input or output drawer (refer to OP=AM, OP=RM, OP=RS, and OP=FX). The remaining directives cause only logical operations to occur, updating the MSS system files. Descriptions of the parameters for these directives follow the directives.

#### **OP=PC** - Add CSUs

OP=AC adds a CSU to a subfamily. The MSF catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily can reside on the specified CSU. This directive, however, does not manipulate cartridges or cubicles.

#### OP=RC - Remove CSUs

OP=RC removes a CSU from a subfamily. The MSF catalog for the specified subfamily is updated to reflect that cartridges and permanent files for the subfamily cannot reside on the specified CSU. Before OP=RC can be specified, all cubicles in the specified CSU must have been removed previously from the family (refer to the OP=RB directive). This directive, however, does not manipulate cartridges or cubicles.

#### **OP=AB - Add Cubicles**

OP=AB adds an unassigned cubicle within a CSU to a subfamily (PT=F), the pool (PT=P), or the reserved area of the CSU (PT=R). More than one cubicle (N=n) can be added at a time. Specific cubicles (XI and YI parameters) can be added, but they must be currently unassigned. For PT=R, XI and YI must be used to add multiple cubicles; N=n is not valid. If cubicles are to be assigned to a subfamily, ASLABEL selects available cubicles closest to the top of the CSU. If cubicles are to be assigned to the pool, ASLABEL selects available cubicles cubicles closest to the bottom of the CSU. The CSU map is updated to reflect the new assignment of cubicles.

#### **OP=RB** - Remove Cubicles

OP=RB removes an assigned empty cubicle from a subfamily (PK=F), the pool (PK=P), or the reserved area of the CSU (PK=R). More than one cubicle (N=n) can be removed at a time. ASLABEL reads the CSU map and selects the first empty cubicle assigned to the subfamily, pool, or reserved area to be removed. Specific cubicles (XI and YI parameters) can be removed, but they must be empty. The CSU map is updated to reflect that the cubicles are unassigned.

#### OP=AM - Add Cartridges

OP=AM adds a cartridge with a manufacturer's label or a scratch label to either a specific subfamily (PT=F) or the pool (PT=P). ASLABEL selects the first empty cubicle assigned to the subfamily or pool as the new location for the cartridge. More than one cartridge (N=n) can be added at a time or a specific cartridge (V=vsn) from the pool can be added to a subfamily. The CSU map, MSF catalog, and cartridge label are updated to reflect the new assignment of the cartridge.

#### OP=RM - Remove Cartridges

OP=RM either removes an empty cartridge from a subfamily (PK=F) and moves the cartridge to the pool (PT=P) or the output drawer (PT=D), or it removes any cartridge from the pool (PK=P) and moves it to the output drawer (PT=D). Any cartridge currently assigned to a subfamily cannot be removed unless it is empty; that is, all 16 streams must be unallocated. More than one cartridge (N=n) can be removed or a specific cartridge (V=vsn) from the pool can be removed to the output drawer. The CSU map, MSF catalog, and cartridge label are updated to reflect the change in location of the cartridge. The removed cartridge then has a scratch label, which allows it to be reassigned via the OP=AM directive.

If the cartridge specified by the V parameter is lost (does not reside in its assigned cubicle), the LT parameter should be specified. This allows the appropriate entries in the CSU map and MSF catalog to be deleted even though the cartridge is not available to have its label updated. If LT is not specified, an error message is issued and ASLABEL aborts.

#### OP=RS - Restore Lost Cartridges

OP=RS restores to its proper cubicle a cartridge that was inadvertently removed from a CSU. If restoration is successful, the lost flag in the MSF catalog is cleared. If data recorded on the cartridge label does not agree with the information in the MSF catalog and the CSU map entry for the cubicle to which the cartridge is to be restored, the cartridge label information is reported and the cartridge is put into the output drawer for use in further processing of the cartridge.

#### OP=FX - Fix Cartridge Labels

OP=FX writes a scratch label on a cartridge and adds the cartridge to the pool. This directive is intended for use when a cartridge label has been destroyed, but the cartridge itself is not physically damaged and can be reused. It can also be used when a cartridge with a family label is to be assigned to a different subfamily via the OP=AM directive, but it is not feasible to first remove the cartridge normally via the OP=RM directive. For example, if ASLABEL is run to add a cartridge to a subfamily, and a system failure occurs before the MSF catalog and CSU map are updated but after the cartridge is relabeled, then the cartridge label does not match the corresponding entries in the MSF catalog and CSU map. Hence, OP=RM cannot be used to remove the cartridge from the subfamily, but OP=FX can be used to rewrite the cartridge label and then OP=AM can be used to add the cartridge to a subfamily. However, if a family label is to be overwritten, the FM and SB parameters must identify the family and subfamily to which the cartridge was assigned. The CSU map and MSF catalog are updated to reflect the new cartridge label.

# OP=IB - Control Cartridge Allocation

OP=IB sets or clears the inhibit allocation flag in the MSF catalog entry for the specific cartridge (V=vsn must be specified). If the flag is set (ON), MSSEXEC does not allocate new MSF files to this cartridge. If the flag is cleared (OF), allocation of files to this cartridge is enabled.

# Parameters for ASLABEL Directives

The descriptions of the parameters to the ASLABEL directives follow. Not all parameters are valid with all directives, as indicated.

| <sup>p</sup> i | Description                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CS=id          | CSU identifier of the CSU to be used by ASLABEL; id is a letter from A to M.                                                                                    |
| CS             | Same as CS=A.                                                                                                                                                   |
| CS omitted     | Same as CS=A.                                                                                                                                                   |
| D=d            | Input drawer slot from which ASLABEL picks the cartridge; valid only with OP=AM, OP=RS, or OP=FX.                                                               |
| D              | First nonempty input drawer slot is to be used; valid only with OP=AM, OP=RS, or OP=FX.                                                                         |
| D omitted      | Same as D.                                                                                                                                                      |
| FM=familyname  | Family to which ASLABEL adds or from which it removes a cartridge or CSU. With OP=FX, this parameter specifies the family to which the cartridge was assigned.  |
| FM             | Same as FM=system default family.                                                                                                                               |
| FM omitted     | Same as FM=system default family.                                                                                                                               |
| LT             | CSU map and MSF catalog entries are to be updated, even though the cartridge is lost and its label cannot be updated; valid only with OP=RM.                    |
| LT omitted     | If the cartridge is lost and OP=RM is specified, an error message is issued and ASLABEL aborts.                                                                 |
| N=n            | Number of cartridges or cubicles to be added, removed, or repaired; l $\leq$ n $\leq$ 2000; not valid if PT=R is specified. If V=vsn is specified, n must be l. |
| N              | Same as N=1.                                                                                                                                                    |
| N omitted      | Same as N=1.                                                                                                                                                    |
| OF             | Inhibit allocation flag in the MSF catalog is to be cleared; valid only with OP=IB.                                                                             |
| ON             | Inhibit allocation flag in the MSF catalog is to be set; valid only with OP=IB.                                                                                 |

| <sup>p</sup> i   | Description                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
|------------------|------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| PK=pkloc         | Location from which the cartridge or cubicle is to be picked; not valid if V=vsn is specified. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |

#### ASLABEL Update Sequence

The general result of each directive to ASLABEL is an update of the CSU maps, MSF catalogs, and cartridge labels, whichever are appropriate, to reflect the changes in cartridge, cubicle, or CSU assignment. Because the MSF catalog is a disk-resident permanent file, it will be backed up on a dump tape whenever PFDUMP dumps the master device for its particular subfamily. Thus, it is not necessary for the analyst to back up the MSF catalogs immediately after an ASLABEL run. However, the backup and recovery of CSU maps do require special operational procedures, which should be performed immediately after an ASLABEL run (refer to the definition of CSU map earlier in this section). When ASLABEL is run to change the assignment of a cartridge, the update sequence consists of a series of steps to delete the old assignment information from the MSS system files, relabel the cartridge, and add the new assignment information to the MSS system files. If an interruption such as a system failure, ASLABEL abort, or MSSEXEC abort prevents ASLABEL from completing the update sequence, the location of the affected cartridge and the status of the CSU maps and MSF catalogs depend on the point of interruption, as follows:

- If the cartridge label, MSF catalog, and CSU map do not all match, then the cartridge is put into the output drawer. The OP=RS directive cannot be used to restore the cartridge because of the inconsistency. However, OP=FX can be used to overwrite the cartridge label and add the cartridge to the pool, if the FM and SB parameters specify the family and the subfamily on the cartridge label.
- If the cartridge label, MSF catalog, and CSU map do match, then the cartridge may be returned to its original location, the new location, or the output drawer, depending on the exact point of interruption. If the cartridge is in the output drawer, OP=RS can be used to restore the cartridge to the location indicated on the cartridge label.

Cartridge Restoration and Reuse later in this section describes the procedure for restoring cartridges found in the output drawer.

# **Restrictions to ASLABEL**

The following restrictions apply to the ASLABEL utility.

- MSSEXEC must be running when ASLABEL is run.
- Only one copy of ASLABEL can be run at a time.
- ASLABEL, ASVAL, and ASDEBUG cannot be run at the same time.

### Example

The following output shows the format of an ASLABEL report. The cartridge label information is included on the report because of a mismatch with the CSU map. An error message is issued for the first directive on the command (in this case, the only directive).

ASLABEL REPORT FILE

ASLABEL,Z./OP=RS,PK=D,CS=B.

- 1 OP=RS, PK=D, CS=B.
- 1 OP=RS,PK=D,CS=B.

```
VSN = P66157

FAMILY = SYSTST

SUBFAMILY = 0

CSU = B

X = 2

Y = 6

*** ERROR 8 DIRECTIVE 1

UNEXPECTED CSU, X, Y, FAMILY OR SUBFAM.***
```

# ASMOVE

ASMOVE manages disk and MSF residence. That is, ASMOVE determines which files should be left on disk, which files should be released from disk and moved to MSF, and which files should be resident both on disk and on MSF. The ASVAL utility, not ASMOVE, controls the release of MSF space.

The selection process includes these two algorithms that weigh certain file characteristics as follows:

- Files are selected for destaging to MSF based on file length, time since the last update, and the preferred residence specified by the user.
- Files are selected for release from disk based on time since the last access and the backup requirement specified by the user.

ASMOVE reads the PFC entries for a particular family and calculates release and destage values (refer to Selection Algorithms later in this section) for each file to determine its residence. If a file has both disk and MSF images but is to reside only on MSF, ASMOVE releases the disk space for the file. For files that do not have an MSF image, ASMOVE creates entries on the ASMOVE/MSSEXEC communication file, MOVCOM, to identify the files to be destaged and to specify whether or not the file's disk space is to be released upon completion of the destage. MSSEXEC then processes each destage and destage/release request on MOVCOM.

ASMOVE generates an output report that lists the files released by ASMOVE and the files contained on MOVCOM. A report on the use of disk space before and after the ASMOVE run is included in the output file and the dayfile.

The format of the ASMOVE command is:

```
ASMOVE, p1, p2,..., pn.
```

P<u>i</u> FM=familyname

FM omitted

L=filename

FM

Family to be used by ASMOVE. Same as FM=system default family. Same as FM=system default family. File on which listable output is to be written.

Description

L Same as L=OUTPUT.

L=0 No output file is to be generated.

L omitted Same as L=OUTPUT.

NW No wait. ASMOVE will not wait for completion of destage and release processing by MSSEXEC.

NW omitted ASMOVE will wait for completion of destage and release processing by MSSEXEC.

RD=yymmdd Last access date. All files not accessed after yymmdd are to be released from disk.

| <b>UI</b> omitted | All user indexes are processed.                                                                                                                                                                                                                                                                          |  |  |

The following parameters for ASMOVE redefine the values of the weight factors or thresholds (installation parameters) used in the algorithms that select files to be destaged or released. Use these parameters to increase or decrease the importance of certain file characteristics used to determine which files are to be destaged and/or released. For example, specifying a large MN parameter prohibits ASMOVE from selecting small files for destaging to MSF. Unless otherwise stated, each of these parameters causes the installation-defined value to be multiplied by the integer value n; n  $\leq 0$ .

| Parameter  | Description                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB=n       | n times the installation-defined DB weight factor is to be used as the preferred residence value for destage decisions involving files with a PR=M attribute. <sup>†</sup> |
| DB         | Same as DB=1.                                                                                                                                                              |
| DB omitted | Same as DB=1.                                                                                                                                                              |
| DC=n       | n times the installation-defined weight factor is to be used as the preferred residence value for destage decisions involving files with a PR=N attribute. <sup>†</sup>    |
| DC         | Same as DC=1.                                                                                                                                                              |
| DC omitted | Same as DC=1.                                                                                                                                                              |
| DL=n       | n times the installation-defined length weight factor is to be used as the length weight factor for destage decisions.                                                     |
| DL         | Same as DL=1.                                                                                                                                                              |
| DL omitted | Same as DL=1.                                                                                                                                                              |
| DT=n       | n times the installation-defined time weight factor is to be used as the time weight factor for destage decisions.                                                         |
| DT         | Same as DT=1.                                                                                                                                                              |
| DT omitted | Same as DT=1.                                                                                                                                                              |
| DV=n       | n times the installation-defined destage control value is to be used as the destage control value.                                                                         |
| DV         | Same as DV=1.                                                                                                                                                              |
| DV omitted | Same as DV=1.                                                                                                                                                              |
| MN=n       | n times the installation-defined minimum length threshold is to be<br>used as the minimum allowable size in disk PRUs (64 words) for MSF<br>files.                         |

<sup>&</sup>lt;sup>†</sup>The file owner specifies the preferred residence attribute via the PR parameter on the DEFINE or CHANGE command (refer to of the NOS 2 Reference Set, Volume 3).

| Parameter  | Description                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------|
| MN         | Same as MN=1.                                                                                                                        |
| MN omitted | Same as MN=1.                                                                                                                        |
| MX=n       | n times the installation-defined maximum length threshold is to be<br>used as the maximum allowable size in disk PRUs for MSF files. |
| MX         | Same as MX=1.                                                                                                                        |
| MX omitted | Same as MX=1.                                                                                                                        |

#### **Selection Algorithms**

ASMOVE determines which files to destage and/or release according to the following algorithms. Files that reside only on MSF are not considered because they have been destaged and released previously. Also, indirect access files are excluded from consideration because they cannot reside on MSF. For all other files, ASMOVE checks the file length and excludes from further consideration any file whose length in PRUs is less than the minimum length threshold (refer back to the MN parameter) or greater than the maximum length threshold (refer back to the MX parameter).

If the current image of the file resides on both disk and MSF, ASMOVE uses the release algorithm to determine whether or not to release disk space; the destage algorithm is not used. If the current file resides on disk only, ASMOVE uses the destage algorithm to determine whether or not to destage the file. If the file is to be destaged to MSF, ASMOVE also determines via the release algorithm whether or not to release the file's disk space.

#### Destage Algorithm

The destage algorithm is used to select for destaging certain files that do not have current MSF images. ASMOVE calculates the destage value for each eligible file according to the following equation. If the destage value exceeds the destage control value (refer back to the DV parameter), ASMOVE selects the file for destaging. Otherwise, the file remains on disk only.

destage value = (l+t\*time)\*(l+l\*length)\*(res)

#### Variable

# Description

- t Installation-defined time weight factor.
- time Number of days since the file was last modified.
- l Installation-defined length weight factor.
- length Length of the file in PRUs.
- res Installation-defined preferred residence value. This value depends on whether the file owner specified no preferred residence or MSF residence preferred for the file. Refer back to the DB and DC parameters.

#### Release Algorithm

The release algorithm is used to select files whose disk space is to be released. Any file with a backup required (BR=Y)<sup>†</sup> attribute and whose master device has not been dumped since the file was last modified is not considered for disk space release. The date and time the master device was last dumped was set by the SD parameter on PFDUMP. For all other files, ASMOVE checks the last access date and time in the PFC entry for each file. If the file was last accessed before the date and time specified by the RD and RT parameters, its disk space is to be released. If the file to be released has a current MSF image, ASMOVE releases the disk space. If the file to be released does not have a current MSF image, MSSEXEC creates one before releasing the disk space.

#### Disk Space/Dump Tape Management

As more disk-resident files are created and more MSF-resident files are staged to disk, it will be necessary to monitor the availability of disk space. It is recommended that ASMOVE be used as a periodic disk space management procedure to avoid frequent disk full conditions (refer to Disk Space Management later in this section). ASMOVE can also be used to reduce the amount of data written on dump tapes and thereby avoid maintaining large numbers of dump tapes. This is accomplished by destaging to MSF and/or releasing disk space of files that need not be on the dump tape (refer to Dump Tape Management later in this section).

### Restriction to ASMOVE

Only one copy of ASMOVE per family can be run at a time. A second ASMOVE aborts if the first one has not completed.

#### Example

The following output shows the format of an ASMOVE report. The files that are to be destaged and destaged/released are listed. An account of the disk space and the destage for backup, release date, and release time values is given.

<sup>&</sup>lt;sup>†</sup>The file owner specifies the backup requirement using the BR parameter on the DEFINE or CHANGE command (refer to the NOS 2 Reference Set, Volume 3).

ASMOVE REPORT.

4

# ASVAL

ASVAL either performs release processing or reports on problems with the current MSS system files. That is, it either makes available MSF space presently allocated to files that are no longer needed, or reports on irregularities or discrepancies found in the current MSF catalogs and PFC entries for the specified family and, optionally, in certain CSU maps. The function to be performed is determined by whether or not the RF option is specified, as described in the following paragraphs.

# NOTE

ASVAL updates the CSU map for the specified CSU. (Refer to the definition of CSU map earlier in this section.) It is recommended that the CSU map be copied on tape or on another device or family immediately after every update of the CSU map.

The format of the ASVAL command is:

| ASVAL,p1,p2,,Pn | •                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <sup>p</sup> i  | Description                                                                                                                                            |
| AM              | The CSU map for the CSU specified by the CS parameter is to be analyzed in addition to the MSF catalogs; not valid if RF=filename or RF is specified.  |
| AM=             | Same as AM.                                                                                                                                            |
| AM omitted      | CSU maps are not to be analyzed.                                                                                                                       |
| CS=id           | CSU identifier of the CSU to be used. Up to 13 CSUs can be selected<br>by the letters A through M. For example, CS=ACJG selects CSU A, C,<br>G, and J. |
| CS              | Same as CS=ABCDEFGHIJKLM.                                                                                                                              |
| CS omitted      | Same as CS=ABCDEFGHIJKLM.                                                                                                                              |
| FM=familyname   | Family to be analyzed; not valid if the RF option is specified.                                                                                        |
| FM              | Same as FM=system default family; not valid if the RF option is specified.                                                                             |
| FM omitted      | Same as FM=system default family if the RF option is not specified.<br>The family on the release data file is used if the RF option is specified.      |
| FX=n            | Error threshold. If the total error count is greater than n, neither release processing nor problem fixing is performed.                               |
| FX              | Same as FX=0.                                                                                                                                          |

| <sup>p</sup> i | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FX omitted     | Same as FX=0.                                                                                                                                                                                                                                                                                                                                                                                                      |
| L=filename     | File on which listable output is to be written.                                                                                                                                                                                                                                                                                                                                                                    |
| L              | Same as L=OUTPUT.                                                                                                                                                                                                                                                                                                                                                                                                  |
| L=0            | No output file is to be generated.                                                                                                                                                                                                                                                                                                                                                                                 |
| L omitted      | Same as L=OUTPUT.                                                                                                                                                                                                                                                                                                                                                                                                  |
| RF=filename    | File that contains the release data file.                                                                                                                                                                                                                                                                                                                                                                          |
| RF             | Same as RF=ZZZZRDF.                                                                                                                                                                                                                                                                                                                                                                                                |
| RF omitted     | Current versions of the MSF catalogs are to be analyzed.                                                                                                                                                                                                                                                                                                                                                           |
| RL             | Release processing is to be performed; valid only if the RF parameter is specified.                                                                                                                                                                                                                                                                                                                                |
| RL omitted     | No release processing is to be performed.                                                                                                                                                                                                                                                                                                                                                                          |
| SB=subfamily   | Subfamily to be processed. Up to eight subfamilies can be selected<br>by the numbers 0 through 7. For example, SB=723 selects subfamilies<br>2, 3, and 7.                                                                                                                                                                                                                                                          |
| SB             | Same as SB=01234567.                                                                                                                                                                                                                                                                                                                                                                                               |
| SB omitted     | Same as SB=01234567.                                                                                                                                                                                                                                                                                                                                                                                               |
| ST=n           | Scattered file criterion. Files are indicated as scattered if they<br>are contained on at least n more cartridges than the minimum number<br>needed to contain them. The minimum number of cartridges is the<br>quotient of (number of streams+15)/16; the remainder is ignored.<br>For example, if the file is contained on 100 streams and 10<br>cartridges, it is scattered if n=1 but is not scattered if n=5. |
| ST             | Same as ST=0. That is, files are scattered if they are contained on more than the minimum number of cartridges needed to contain them.                                                                                                                                                                                                                                                                             |
| ST omitted     | Same as ST=0.                                                                                                                                                                                                                                                                                                                                                                                                      |

#### Release Processing

If RF=filename or RF is specified, ASVAL determines which MSF files are no longer needed and issues a request to MSSEXEC to purge these files so their MSF space can be reused. The procedure is for ASVAL to analyze copies of the MSF catalogs and PFC entries for the specified family that are contained on the release data file (RDF) specified by the RF parameter. Those MSF files described in an MSF catalog but not having a PFC entry (that is, orphans) can be purged. During the analysis (refer to both MSF Catalog Analysis and PFC Analysis later in this section), ASVAL keeps track of the error conditions it discovers, and if the error count is less than or equal to the threshold specified by the FX parameter, release processing is performed if RL is specified and the last purge date in the MSF catalog is prior to the RDF file dump date. That is, trouble-free orphans are purged and their MSF space is made available for reuse. The current MSF catalog is updated to reflect that these files no longer exist. A validation report is issued that lists the errors encountered, the number of trouble-free orphans, and the amount of released MSF space. If RL is not specified or the last purge date in the MSF catalog follows the RDF file dump date, no release processing is performed but the validation report is issued, which lists the errors encountered, the number of trouble-free orphans, and the amount of releasable MSF space.

The RDF used for this analysis is a file produced during a previous PFDUMP run and it contains versions of the MSF catalogs and PFC entries that were current at the time of the dump. The site analyst chooses which RDF to use depending on how long after a file was purged he/she wants to wait before releasing MSF space. For example, the analyst might run ASVAL every week for release processing purposes and use the RDF from the previous week's full dump. There are some restrictions as to which RDFs can be used (refer to MSF Space Management later in this section). The capability to release trouble-free orphans by analyzing the current MSF catalogs and PFC entries is not provided in order to ensure that an MSF file is released from MSF only after it is no longer needed.

### **Problem Reporting**

If RF=filename or RF is not specified, ASVAL reports on problems with the current MSF catalogs and PFC entries for the specified family. If AM is specified, problems with CSU maps are also included in the report. ASVAL examines the MSS system files and PFC entries and searches for problem chains and fragments, problem asa values, and CSU map/MSF catalog mismatches. The procedures ASVAL uses to detect and classify inconsistencies and discrepancies are described later in this section under Error Detection and Classification. ASVAL keeps track of the error conditions, if any, it discovers, and if the error count is less than or equal to the threshold specified by the FX parameter, problem fixing is performed. That is, ASVAL sets flags in the appropriate entries of the CSU map, MSF catalog, and/or PFC entries to prevent propagation of errors due to the inconsistencies or discrepancies found and to permit error recovery by the ASDEBUG utility. A count of the errors is recorded in the dayfile. A validation report is issued that lists the errors encountered, the number of trouble-free orphans, and the amount of releasable MSF space.

## **Error Detection and Classification**

ASVAL detects and classifies errors according to the following procedures. During the CSU map analysis, ASVAL detects and classifies errors in the CSU map. During the MSF catalog analysis, ASVAL detects errors with chains of AUs; during the PFC analysis, ASVAL classifies these errors. Whenever an error is encountered, the total error count is increased by 1. The action taken for each type of error is discussed under Release Processing and Problem Fixing later in this section.

#### CSU Map Analysis

If the AM option is specified, ASVAL attempts to locate problems with CSU map entries by comparing the MSF catalogs and the CSU map. For each coordinate pair (x,y) in an MSF catalog entry, ASVAL locates the corresponding CSU map entry. A type 1 error exists if the code field in the CSU map entry is not 5 (assigned to a subfamily), or if the family, subfamily, or vsn fields in the CSU map entry do not match those in the corresponding MSF catalog entry. ASVAL also scans the CSU map for all other entries assigned to the subfamily and reports as a type 2 error any of these entries that does not have a corresponding MSF catalog entry.

#### MSF Catalog Analysis

The MSF catalog analysis locates problems with chains of AUs (refer to the definition of cartridge earlier in this section) and identifies on each HOC whether any of the following problems exist or whether any part of the MSF files resides on a cartridge that is lost or has excessive write parity errors.

ASVAL scans the MSF catalog for HOC entries that are allocated and follows each chain until it terminates. Normal termination occurs with an EOC entry. Abnormal termination occurs when no EOC is found, but rather an incorrect link value exists, an AU links to an unallocated stream, or an AU links to an AU previously found in the chain being followed (looping chain).

During the chain scans, the following types of chains can be encountered; they are linkage problems that are identified on the HOC entry.

### Chain

#### Description

Intersecting More than one chain links to the same AU.

Scattered file The number of cartridges used for the file exceeds the value specified by the ST parameter plus the minimum number of cartridges needed for the file.

ASVAL also locates any AUs that are allocated but were not on any chain being followed. Such AUs are linked together to form partial chains without an HOC. These partial chains are called fragments and the first AU in a fragment is designated as the start of fragment. Each fragment chain is followed until it terminates. The abnormal termination conditions previously listed can also occur with fragments. Intersections can occur, but a fragment chain that intersects the start of another fragment chain is not an intersection; rather, one is the tail end of the other.

### PFC Analysis

The PFC analysis is performed to classify the errors encountered on chains during the MSF catalog analysis. For each PFC entry with  $asa \neq 0$  (the file has an MSF image and the asa value identifies the first AU in the chain containing the file), ASVAL classifies the following errors. Error type 3 exists if the asa value is incorrect. Error type 4 exists for any of the following reasons.

- The AU specified by the asa value is not allocated or is not an HOC entry.
- The chain does not terminate normally.
- The chain intersects with another chain or fragment.
- More than one PFC entry points to the chain.
- The chain includes a cartridge for which the lost or excessive parity error flag is set.

ASVAL also classifies the following error conditions.

- Error type 5 exists if an orphan chain terminates abnormally or intersects with other chains or fragments. Trouble-free orphans (chains without a PFC entry pointing to them and without linkage problems) are not classified as errors.
- Error type 6 exists if an orphan is a fragment.
- Error type 7 exists if a chain or fragment points to an unallocated AU.

ASVAL generates informational report messages if either of the following conditions is true.

- The system error flag is set in the PFC.
- The read error flag is set in the PFC.

### **Release Processing and Problem Fixing**

If the total error count calculated during the analyses described previously exceeds the value specified by the FX parameter, then neither release processing nor action to flag or fix the detected error conditions is performed. The validation report, however, is produced. Otherwise, action taken depends on the parameter specified and the type of errors found, as follows.

If ASVAL was run for release processing purposes (RF=filename or RF specified), ASVAL issues a request to MSSEXEC to release trouble-free orphans if RL was specified. If RL was not specified, no release processing is performed. If ASVAL was run for problem reporting purposes (RF omitted), the following action is taken.

- For error type 1, the linkage error flag is set in the MSF catalog entry.
- For error type 2, the linkage error flag is set in the CSU map entry.
- For error type 3, there are two alternatives. If the file also has a disk image, the asa field in the PFC entry is cleared. Thus, the good disk image will not be released and the file is accessible even if the MSF image cannot be retrieved. If the file does not have a disk image, no action is taken. However, if the disk image can be reloaded from tape, it is recommended that the file be reloaded and that ASVAL then be rerun to clear the asa field in preparation for other corrective action.
- For error type 4, the action taken is both that taken for error type 3 and that taken for error type 5, 6, or 7.
- For error type 5, 6, or 7, the frozen flag is set in the MSF catalog entry for the initial AU on the problem chain or fragment. This enables the problem chain/fragment/AU to be made available to the ASDEBUG utility, but prevents these AUs from being overwritten until then. Thus, the ASDEBUG utility can be used to inspect or save data from the corresponding streams or cartridges.

#### **Validation Report**

The validation report consists of a report heading and a series of report groups for each subfamily and CSU being reported on. The heading identifies the subfamily, the CSU, whether or not there are any problems, and the last purge date and time for the CSU (the last time orphans on this CSU were released). There is one report group for each error detected, and the actual information recorded in a report group depends on the type of error as described in the following paragraphs. Each report group, however, contains the following items.

- Error type (a number from 1 to 7).
- Identification (refer to the particular error type described in the following paragraphs).
- Chain information (MSF catalog ordinal, stream number, A or U designation for allocated or unallocated, H or E designation for HOC or EOC).
- Error description.

After the last report group, the validation report lists the number of trouble-free orphans, the amount of released or releasable MSF space, the total number of errors detected, and whether or not the MSS system files were updated.

#### Error Types 1 and 2

Error types 1 and 2 identify mismatches between the CSU map and the MSF catalog. In the validation report, the identification field lists the MSF catalog ordinal, the x and y coordinates, and the vsn of the cartridge in error. The chain field is blank because problem chains are not identified as either error type 1 or 2. The analyst should run the ASUSE utility to produce a detailed report of the appropriate CSU map and MSF catalog entries to determine the exact problem.

#### Error Types 3 and 4

Error types 3 and 4 identify problem chains and problem as values. In the validation report, the identification field lists the permanent file name and user index of the affected file; the dump control date and time (from the PFC entry for the file) to identify the backup file, if any; and the letter N (no) or Y (yes) to indicate whether or not the file has a disk image. The chain field lists the MSF catalog ordinal and stream number for all AUs in the affected chain. An A or U indicates whether each AU is allocated or unallocated, and an H or E identifies the HOC or EOC. An error description is printed for each error detected; one chain can have several errors.

#### Error Types 5, 6, and 7

Error types 5, 6, and 7 identify problem orphans, fragments, and problem unallocated AUs. In the validation report, the information reported is the same as for error types 3 and 4, except for the identification field. Instead of the permanent file identification, the word ORPHAN (error type 5), FRAGMENT (error type 6), or UNALLOCATED (error type 7) is printed. Error type 7 is an unallocated AU that is pointed to by a chain or fragment. Each such AU is also reported with the chain for the corresponding orphan or fragment.

#### Intersections

Intersections occur when more than one chain links to the same AU; they are classified as either error type 4 or 5. Thus, they are reported as explained previously. Intersections are also reported in a separate entry consisting of a heading and additional information identifying the MSF catalog ordinals and stream numbers of the intersecting chains. Therefore, when intersections are reported, there are two entries for the affected subfamily and CSU: one lists only the intersections and the other lists all the errors encountered.

The following output shows the format of a validation report. ASVAL was run for problem reporting purposes (RF not specified), and no errors were detected.

#### ASVAL - VALIDATION REPORT

\*\*REPORT COMPLETE\*\*

#### **Typical ASVAL Runs**

As described previously, ASVAL is run either to make MSF space available for reuse or to report on problems with the current MSS system files and/or PFC entries. The following examples show typical ASVAL runs that may be used periodically for these purposes.

Example:

The following ASVAL command causes MSF space to be made available for reuse.

ASVAL, RF=DUMP1, RL.

DUMP1 is the release data file produced by a previous PFDUMP run from which ASVAL can identify all the MSF files that were orphans at the time of the dump. If no error conditions are detected in the MSF catalog and PFC entries contained on file DUMP1 (FX=0 by default), the orphans are purged and the MSF space assigned to them is released. The last purge date and time field in the subcatalog (in the MSF catalog) for each CSU for each subfamily is updated to the time of the ASVAL run if any file from that CSU is purged. This is to ensure that a subsequent ASVAL run does not release the same space a second time, since the MSF space may be reallocated to a new file.

If errors were detected, they are listed on the validation report and release processing is not performed. This is indicated by the CATALOGS NOT MODIFIED message at the end of the validation report. The analyst can rerun ASVAL with the following command to ensure that release processing is performed (n is the number of errors detected during the previous ASVAL run).

ASVAL, RF=DUMP1, RL, FX=n.

After this ASVAL run has completed, an analysis of the current version of the CSU map, MSF catalog, and PFC entries should be made to determine whether or not the errors detected in the first ASVAL run exist in the current MSS system files and PFC entries. This is accomplished through the following command.

ASVAL, FM=familyname, AM.

familyname is that on the release data file, DUMP1.

Example:

Upon completion of any device reload that includes recovery of an MSF catalog and/or CSU map, ASVAL should be run to determine whether any CSU map/MSF catalog mismatches exist. The following call accomplishes this.

ASVAL, FM=familyname, SB=n1, n2, ..., nh, AM.

familyname is that for which recovery was done and  $n_1, n_2, \ldots, n_h$  are the affected subfamilies if just some of the devices of the family were reloaded.

ASVAL analyzes the CSU map, MSF catalog, and PFC entries for the subfamilies specified by the SB parameter and reports any discrepancies or inconsistencies. For example, if the recovery was not scheduled and ASLABEL was run to add or remove cartridges or cubicles from one of the affected subfamilies after the last incremental or full dump for these subfamilies, then the CSU map will reflect the results of the ASLABEL run but the MSF catalog will not. Such mismatches will be reported on the validation report. If the following ASVAL command is then made, the errors detected during the previous run will be flagged as described previously under Release Processing and Problem Fixing.

ASVAL, FM=familyname, SB=n1, n2,...,nh, AM, FX=n.

familyname and  $n_1, n_2, \ldots, n_h$  are the same as in the previous ASVAL run and n is the number of errors detected during the previous run. After investigating the cause of these errors, the analyst can run the ASDEBUG utility to correct the error conditions (refer to ASDEBUG later in this section).

If a device reload includes recovery of all CSU maps (default family, user index= $377760_8$ ), the latest CSU maps should be recovered from backup copies. Then each family that has MSF-resident files should be analyzed via the following command to detect CSU map/MSF catalog mismatches.

ASVAL, FM=familyname, AM.

It is recommended that the previous ASVAL run be made periodically to check whether any unexpected error conditions exist. As the site analyst becomes more familiar with MSS processing, these periodic ASVAL runs can be done less frequently.

#### **Restrictions to ASVAL**

- Only one copy of ASVAL can be run at a time.
- ASVAL, ASLABEL, and ASDEBUG cannot be run at the same time.

# ASUSE

ASUSE reads data in the MSF catalogs and CSU maps and produces reports on the availability of space on MSF cartridges and the allocation of cubicle space within a CSU. The reports may not be completely up to date because the MSF catalogs and CSU maps can be updated while the reports are being generated.

The types of reports that ASUSE generates are:

| Report             | Description                                                                         |
|--------------------|-------------------------------------------------------------------------------------|
| Basic usage report | Lists general information about the use of each CSU in a subfamily.                 |
| Optional report A  | Identifies cartridges with a specified number of streams available for assignment.† |
| Optional report B  | Identifies cartridges with flags set in the MSF catalog.                            |
| Optional report C  | Lists the contents of a CSU as described in the CSU map.                            |

<sup>†</sup> A cartridge that has the lost cartridge flag, inhibit allocation flag, or excessive write parity errors flag set is considered to have zero streams available for allocation regardless of the number of unallocated streams on the cartridge.

| Report                  | Description                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Optional report D       | Lists detailed cartridge status information on each entry in the MSF catalog.                                                                    |
| Optional report E       | Lists detailed cartridge and stream status information on each entry in the MSF catalog.                                                         |
| The format of the ASUSE | command is:                                                                                                                                      |
| ASUSE,p1,p2,,Pn.        |                                                                                                                                                  |
| °,                      | Description                                                                                                                                      |
| CS=id                   | CSU identifier of the CSU to be used. Up to 13 CSUs can be selected by the letters A through M. For example, CS=ACJG selects CSU A, C, G, and J. |
| CS                      | Same as CS=ABCDEFGHIJKLM.                                                                                                                        |
| CS omitted              | Same as CS=ABCDEFGHIJKLM.                                                                                                                        |
| FM=familyname           | Family to be reported on.                                                                                                                        |
| FM                      | Same as FM=system default family.                                                                                                                |
| FM omitted              | Same as FM=system default family.                                                                                                                |
| L=filename              | File on which listable output is to be written.                                                                                                  |
| L                       | Same as L=OUTPUT.                                                                                                                                |
| L=0                     | No output file is to be generated.                                                                                                               |
| L omitted               | Same as L=OUTPUT.                                                                                                                                |
| 0P=op                   | Type of report to be generated. Multiple options can be specified (for example, OP=AB).                                                          |
|                         | op Description                                                                                                                                   |
|                         | A Optional report A and basic usage report.                                                                                                      |
|                         | B Optional report B and basic usage report.                                                                                                      |
|                         | C Optional report C and basic usage report.                                                                                                      |
|                         | D Optional report D and basic usage report.                                                                                                      |
|                         | E Optional report E and basic usage report.                                                                                                      |
| OP                      | Basic usage report only is to be generated.                                                                                                      |
| OP omitted              | Same as OP.                                                                                                                                      |

| <sup>p</sup> i | Description                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SB=subfamily   | Subfamily to be reported on. Up to eight subfamilies can be selected by the numbers 0 through 7. For example, SB=0273 selects subfamilies 0, 2, 3, and 7.                                      |
| SB             | Same as SB=01234567.                                                                                                                                                                           |
| SB omitted     | Same as SB=01234567.                                                                                                                                                                           |
| SL=n           | Minimum number of streams available for assignment; valid only with optional report A. Cartridges with n or more streams available are reported. $0 \le n \le 16$ , $n \le m$ (refer to SU=m). |
| SL             | Same as SL=0.                                                                                                                                                                                  |
| SL omitted     | Same as SL=0.                                                                                                                                                                                  |
| SU=m           | Maximum number of streams available for assignment; valid only with optional report A. Cartridges with m or less streams available are reported. $0 \le m \le 16$ , $n \le m$ (refer to SL=n). |
| SU             | Same as SU=16.                                                                                                                                                                                 |
| SU omitted     | Same as SU=16.                                                                                                                                                                                 |

#### **Basic Usage Report**

The basic usage report includes a title line, which identifies the subfamily, family, and CSU being reported on. The statistics in this report contain separate totals for CSUs and subfamilies. The following items are listed.

- Number of CSU locations reserved for the subfamily.
- Number of cartridges in the subfamily.
- Number of cartridges with 0 streams available for assignment.
- Number of cartridges with 1 stream available for assignment.
- Number of cartridges with 16 streams available for assignment.
- Number of unassigned and unflagged streams.
- Number of assigned and unflagged streams.
- Number of flagged streams.
- Number of cartridges with the inhibit allocation flag set.
- Number of available off-cartridge links.
- Number of cartridges with available streams and no off-cartridge links.

The following output shows the format of a basic usage report.

#### **Optional Reports A and B**

Optional reports A and B both include a title line, which identifies the subfamily, family, and CSU being reported on, and list the following information about cartridges. Optional report A includes a cartridge only if the number of streams available for assignment is within the range specified by the SL and SU parameters. Optional report B includes only those cartridges for which flags are set in the MSF catalog.

- Volume serial number of the cartridge.
- x and y coordinates of the cartridge location.
- Number of streams available on the cartridge.
- Number of off-cartridge links available on the cartridge.

In addition to the preceding items, optional report B lists one or more of the following messages depending on the flags set in the MSF catalog. Refer to the definition of MSF catalog earlier in this section for more information about these flags.

- EXCESSIVE PARITY ERRORS.
- . LOST.
- INHIBIT SET.
- STREAM n START OF FRAGMENT.
- STREAM n FROZEN CHAIN.
- STREAM n STREAM CONFLICT.

The following output shows the format of optional report A.

ASUSE REPORT FILE SUBFAMILY = 3 CSU = J FM = SYSTST OPTIONAL REPORT(S) AB VSN = V9900445 X = Y = 36 AVAILABLE STREAMS = 0 OFF CARTRIDGE LINKS = 0 VSN = V99005 X = 44 36 Y = AVAILABLE STREAMS = 0 OFF CARTRIDGE LINKS = 0 VSN = V99006X = 43 Y = 36 AVAILABLE STREAMS = 0 **OFF CARTRIDGE LINKS =** 0 VSN = V99007X = 42 Y = 36 AVAILABLE STREAMS = 0 OFF CARTRIDGE LINKS = 3 END OF REPORT(S) AB

# **Optional Report C**

Optional report C includes a title line, which identifies the CSU being reported on. The CSU number and y coordinate are printed at the top of the page. There is a new y coordinate on each page, from y=36 to y=0. x coordinates are written two to a line, from x=57 to x=0. The information listed in this report includes the following items.

- x coordinate
- code
- vsn
- family
- subfamily
- FCT link
- flags

### Optional Reports D and E

Optional reports D and E both include a title line, which identifies the subfamily, family, and CSU being reported on. Both reports list the following cartridge information about entries in the MSF catalog.

- FCT ordinal of the MSF catalog entry.
- x and y coordinates of the location of the cartridge in the cubicle described by this entry.
- Volume serial number of the cartridge in the cubicle described by this entry.

In addition to the preceding information, optional report E lists the following information about the streams on the cartridges previously described.

- Off-cartridge links. Also referred to as Off-MSC (mass storage cartridge) links.
- Two words reserved for site use.
- Stream detail in octal.

Refer to the definition of MSF catalog earlier in this section for more information about the catalog entries.

The following output shows the format of optional report E.

# ASDEBUG

ASDEBUG allows the analyst to update appropriate entries in the CSU maps and/or MSF catalogs and thereby resolve inconsistencies reported by the ASVAL utility. ASDEBUG can also copy data from selected MSF files or cartridges to disk. This function of ASDEBUG is intended for use when errors such as unrecoverable read errors do not allow successful staging of an MSF file.

# NOTE

ASDEBUG updates the CSU map for the specified CSU. (Refer to the definition of CSU map earlier in this section.) It is recommended that the CSU map be copied on tape or on another device or family immediately after every update of the CSU map. Input to ASDEBUG is via a directive file. Refer to the ASLABEL utility earlier in this section for a description of the directive file format.

The format of the ASDEBUG command is:

ASDEBUG, p1, p2, p3.

| <sup>p</sup> i | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| I=filename     | File on which directives are written.                                        |
| I              | Same as I=COMPILE.                                                           |
| I omitted      | Same as I=INPUT.                                                             |
| L=filename     | File on which listable output is to be written.                              |
| L              | Same as L=OUTPUT.                                                            |
| L=0            | No output file is to be generated.                                           |
| L omitted      | Same as L=OUTPUT.                                                            |
| Z              | Directives are contained on the ASDEBUG command. The I parameter is ignored. |
| Z omitted      | Directives are contained on the file specified by the I parameter.           |

# **ASDEBUG** Directives

The following directives are available with ASDEBUG. The descriptions of the parameters for these directives follow this section.

#### OP=RS - Read Streams

OP=RS reads selected streams of a cartridge in a specified drawer (D=d) or a cartridge identified by its vsn (V=vsn) or x and y coordinates (XI and YI parameters). The CS parameter specifies the CSU where the cartridge resides. The range of streams to be read is specified by the SL and SU parameters. The streams are written to the file specified by the PF parameter.

#### OP=RF - Read File

OP=RF reads the file whose alternate storage address is specified by the CS, FO, and ST parameters. The file is written to the file specified by the PF parameter.

## OP=RP - Release Frozen Chain Space

OP=RP clears flags in the MSF catalog and releases MSF space for the chain whose alternate storage address is specified by the CS, FO, and ST parameters.

# OP=RL - Remove Cartridge Entry from MSF Catalog

OP=RL removes an MSF catalog entry that is not linked properly to the CSU map. The CS and FO parameters identify the MSF catalog entry to be removed.

#### OP=RC - Remove Cartridge Entry from CSU Map

OP=RC removes a CSU map entry that does not have a corresponding FCT entry in the MSF catalog. The CS, XI, and YI parameters identify the CSU map entry to be removed. The cartridge at the particular location (x,y) is put into the output drawer and the CSU map entry is changed to unassigned. The CSU map should be backed up immediately after the ASDEBUG run to ensure consistency with cartridge labels and MSF catalogs (refer to the definition of CSU map earlier in this section).

# OP=CF - Change Flag in CSU Map or MSF Catalog
