

Alphanumeric Display Terminals - Basic Characteristics

The accompanying comparison charts summarize the characteristics of 184 commercially available alphanumeric display terminals from 74 vendors. Nearly all of the information was supplied by the manufacturers during the months of January and February 1976. Their cooperation is acknowledged and greatly appreciated.

Datapro sent repeated requests for information to more than 80 companies known or believed to be in the display terminal business. The 74 usable responses summarized in our charts provide a comprehensive picture of the commercial display terminals that are currently available in the United States and Canada. *The absence of any specific company from our charts means that the company either failed to respond to our repeated information requests or was unknown to us.*

The chart entries and their significance are explained in the following paragraphs.

Part 1 — Left hand page

Terminal Description

The industry trend toward "intelligent" terminals is indicated by the growing number of terminals with

A discussion of the important basic characteristics of display terminals plus a summary of the characteristics of 184 commercially available alphanumeric display terminals from 74 vendors. A two-page comparison chart format permits inclusion of extensive information on each product.

For a perspective of display terminals, including comprehensive user rating information, see Report C09-025-101 behind the Management/System Guides tab in Volume 1.

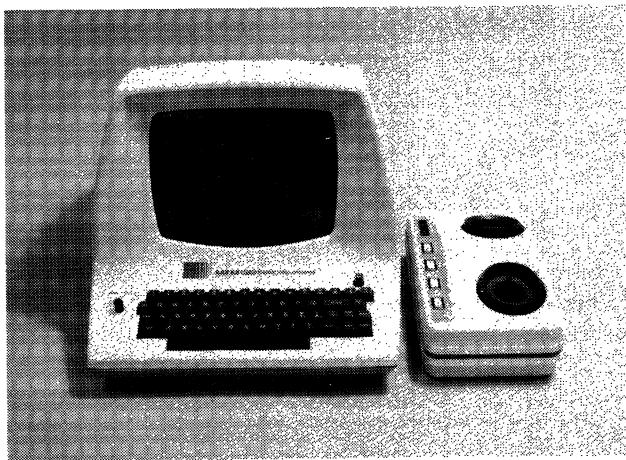

control and user functions implemented through some type of processor. The *processor control* entry includes a wide range of arrangements from simple microprocessor-based terminals to complex display-oriented minicomputer systems. (Terminals that do not contain a processor as their nucleus are hard-wired units that are often referred to as "dumb" terminals, because their functions cannot be changed and little flexibility is offered.)

Since all processors require memory for program and data storage, the *memory range* in bytes is provided to define ▷

Designed as a replacement for Teletype's Model 40, the microprocessor-based ICC 40+ has all the bells and whistles, and features a removable CRT that can be tilted and swiveled for operator viewing convenience. The manufacturer, ICC/Milgo, is a leading modem vendor.

Alphanumeric Display Terminals — Basic Characteristics

For just \$65 per month (on a one-year lease), you can get your "glass teleprinter" from Western Union Data Services. As WU's initial display terminal offering, the Video 100 (a Lear Siegler ADM-3) provides Teletype compatibility and features a 12-inch screen that can display 960 or 1920 characters. The Video 100 is available with an acoustic telephone coupler, teleprinter, and cassette tape drive.

- ▷ the minimum and maximum memory capacity of an expanded memory. In microprocessor-based terminals, memory is usually composed of read-only memory (ROM) and/or programmable read-only memory (PROM) for microprogram storage and random access memory (RAM) for data storage.

Display terminals are available in one of two basic terminal configurations: *stand-alone* and *cluster*. Stand-alone units are typically those that contain all components that support the operation of the terminal including display, keyboard, interface, and power supply within a single cabinet. Auxiliary units such as printers, cassette tape drives, etc., are usually external devices. Sometimes a stand-alone unit includes separate cabinets for terminal control and keyboard/display sections, and it may even include one or two separate displays. A cluster configuration typically includes a terminal control unit and a number of individual cable-connected keyboard/display units, which can often be located several thousand feet from the controller. In some cases, the vendor provides a multiplexer that accommodates a cluster of stand-alone terminals. A *local cluster* arrangement refers to a terminal that can be attached directly to a computer I/O channel and can operate as an on-line peripheral subsystem. A *remote cluster* arrangement refers to a terminal that is connected to the host computer via a communications facility. The size of a cluster arrangement is defined by the entries: *maximum number of displays per controller*, *maximum number of printers per controller*, and *maximum number of devices* (including displays and printers) *per controller*. In many cases displays and printers can be combined in any mix on the same controller. Cluster configurations that can accommodate *any mix of screen sizes* on the *same controller* are noted.

Local cluster arrangements must provide a *computer* interface to attach to the I/O channel of the host

computer. Because most terminals are equipped with an RS-232 interface, they can be directly attached to many minicomputers with such a serial I/O interface.

Terminals that are designed to be hand-carried in a suitcase-like enclosure are noted in the entry *portable case*.

Compatibility

Some terminals are designed as direct replacements for other terminals. In the alphanumeric display terminal market, replacement terminals fall into four principal categories: those designed to replace an IBM 3270 and/or 3275, those designed to replace an IBM 2260 and/or 2265, those designed to replace a Teletype Model 33 and 35 teleprinter, and those designed to replace a Teletype Model 40 display terminal. Some vendors provide compatibility with *other* terminals such as those produced by Burroughs, Honeywell, and UNIVAC. Datapro included these five entries to define the category of compatibility. Compatibility requirements include identical protocol, code and unit code structure, timing, asynchronous or synchronous operation, and transmission speed. Some vendors even provide identical cables, which is a cost-effective consideration in a local cluster environment. At least two vendors (Genesis One and Memorex) provide compatible replacements for only the display station in an IBM 3270 cluster environment.

Programmability

Programmability for processor-controlled terminals can be implemented via a combination of different techniques. The entry *user-created programs* defines the capability for the terminal to operate under the direction of a user-created application program stored within the terminal. This requires the provision of an assembly-like language at the very least. Programmability via *user-defined parameters* refers to the use of fixed programs, such as a data entry program where the user defines field length and type, duplication, skipping, etc. Microprocessor-based terminals are controlled via a microprogram (firmware), which is stored in the unit's ROM. Usually, the terminal operates under the control of *vendor-defined firmware*, but in some cases the vendor permits the user to define or create the microprograms, hence the entry *user-defined firmware*. Any *vendor-supplied software* is noted, such as assemblers, operating systems, emulators, etc. Minicomputer-based terminals are generally software-supported and usually provide at least an assembly language for users to create application programs. The entry *software pricing* identifies the vendor-supplied software as standard (supplied with the basic terminal at no extra cost) or extra cost.

Display Organization

Printed information is generally arranged according to an orderly format consisting of a maximum number of printed lines per page and characters per line. This orderly

Alphanumeric Display Terminals — Basic Characteristics

 arrangement is also used to characterize the arrangement of data display on the face of a CRT screen or other display device. The electronic circuitry that produces the display image is designed to a specified set of parameters that define the capacity (i.e., the maximum number of display positions) and the display format (i.e., the maximum number of displayable lines and displayable characters per line). Information is displayed in a rectangular area smaller than the total surface area of the display device. The factors that determine the required size of the display area are the display arrangement and the size of the displayable characters, which is normally a fixed parameter.

Symbol formation and the set of displayable symbols are functions of the character generator, which accepts coded characters (typically ASCII) from the computer and keyboard and converts them to a number of dots or strokes so that the form of the symbol or image can be displayed. In CRT's, characters are formed by a variety of techniques, including dots, strokes, starburst, or monoscope. The dot technique is by far the most popular. Each character is formed within a matrix of dots, and only those dots required to form the specific character are intensified. Typically, a dot matrix contains 35 dots arranged 7 dots high by 5 dots wide. Characters can be made clearer by increasing the number of dots within the matrix. The stroke technique forms characters by drawing short straight lines between specified points.

Solid-state display devices, such as plasma (gas) and LED (Light Emitting Diodes) are gaining popularity, but at present are generally limited to small display capacities consisting of a few characters. These typically form a character image in much the same way as a CRT display (i.e., via a dot matrix), though some form symbols through line segments.

Display Features

Attention can be drawn to vital information and different types of significant data can be visually separated by the use of the following display features:

- Color—characters or fields can be separated by color, which can also be used to identify conditions or types of data. Few display terminals offer color, primarily due to cost, but the few that do offer up to eight colors.
- Reverse video—displays a *negative* image of data, i.e., data normally displayed in white on a dark background is displayed in black on a white background. Characters or fields can be displayed in reverse video.
- Programmable brightness levels—visually separates different kinds of displayed information by displaying each type of a different intensity level, such as a fixed format and the entered data.

- Character and/or field blinking—vital information consisting of a single character or an entire field is blinked to attract attention.

Some terminals offer several of these display features, which can be combined to produce even more effective results.

Some applications require viewing more data than can be displayed at one time. The following features satisfy this need:

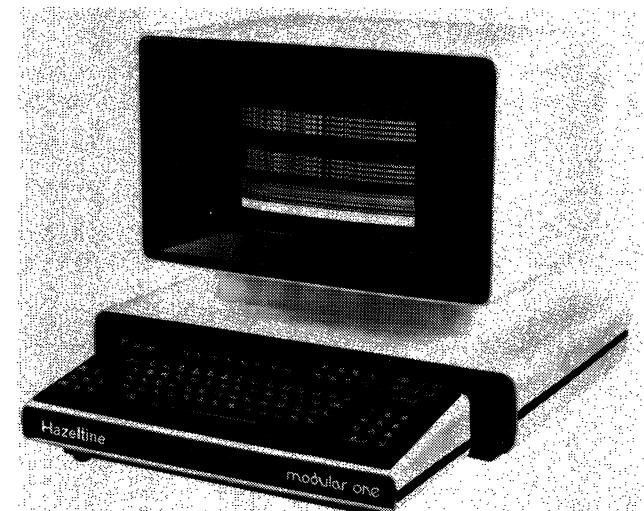

- Roll (or scroll)—this feature moves all displayed lines of data up or down by one line as a new line is added and an existing one removed. In some cases, the first line is linked with the last so that the data is rolled but not lost. Typically, data is lost as it rolls off the screen. This feature permits the user to scan through a volume of data to locate key information.
- Paging—this feature stores two or more frames or *pages* of data and displays any selected page.

Although roll and paging features can be software implemented in the host computer, the comparison chart entry applied to *only* those terminals that implement the features via hardware or firmware.

Many terminals provide the roll feature, but few provide paging. Some provide both features.

Cursor Control

The cursor marks the position on the screen where the next character will be read or written from memory. Cursor controls enable the operator to maneuver the cursor on the screen and facilitate the input and output of data. Typical cursor controls include:

Brand new from Hazeltine is the microprocessor-based Modular One. Priced at a startlingly low \$1,420 (base price for 1 to 50 units), with quantity discounts available, the terminal has a standard 1920-character screen and offers a host of options, including a polling feature with user-defined protocol.

Alphanumeric Display Terminals — Basic Characteristics

Control Data's new, microprocessor-based Model 92451 Conversational Display provides Teletype Model 33/35 compatibility and features a 960- or 1920-character screen and a host of options. Auxiliary devices include a single- or dual-drive diskette or cassette tape unit and a 180-cps impact or 30-cps non-impact printer. The OEM base price is \$2,000; quantity discounts are available.

- ▷ • Move left (L)—moves the cursor one space to the left, which can be from the initial character position of a line to the last character position of the previous line if the terminal features wraparound.
- Move right (R)—moves the cursor one space to the right, which can be from the last character position of a line to the first character position of the next line if the terminal features wraparound.
- Move up (U)—moves the cursor to the same position on the previous line, which can be from the first line to the last line if the terminal features wraparound.
- Move down (D)—moves the cursor to the same position on the following line, which can be from the last line to the first line if the terminal features wraparound.
- Home top (H)—moves the cursor to the initial character position of the first line.
- Home bottom—moves the cursor to the initial character position of the last line.
- Tab—moves the cursor forward to the next tab stop or backward to the previous tab stop (backtab).
- Return (RT)—moves the cursor to the initial character position of the next line; this is identical to the carriage return function of a typewriter.
- Backspace—moves the cursor one space to the left.

- Line Feed—moves the cursor to the same position on the following line.

Some cursors blink, others keep moving as long as the control key remains depressed. All cursors should be of the nondestructive type. Different manufacturers use a variety of symbols to indicate the cursor position on the screen. Some terminals also have *addressable/readable cursors*, which enable the position of the cursor to be written or read by the host computer under program control.

Format Control

Most businesses use printed forms for daily activities such as billing, ordering, payroll, etc. Some CRT terminals can duplicate the printed form on the face of the screen, and data can be keyed into the blank spaces just as the typist enters data into a printed form. This "fill-in-the-blanks" approach to data entry requires a *protected format* capability. Display terminals that incorporate this feature treat the fixed format differently from keyed data. Field identifiers such as "name" or "salesman number" are protected from inadvertent key entry, and data entry is confined to the variable fields (blank spaces) following the field identifiers. Some terminals automatically *tab* to the beginning of the next variable field immediately following the entry of the character that completes each field. The tab key is used where a field is partially filled.

Some terminals permit *format creation via the keyboard*; i.e., the fixed format can be keyed and *edited* on the screen before it is *stored* in the terminal's memory or on cassette tape, diskette, or hard disk. Depending on memory size, multiple formats can be stored. Of course, format storage on magnetic media is virtually unlimited. ▷

Plantronics's VuSet, available from the Bell System for \$35 per month, provides a 3-inch CRT that displays any of 64 characters in up to 64 display positions. It's intended for applications that involve short messages such as account status, sales statistics, customer balances, etc. The VuSet attaches to any Touch-Tone telephone, which is used to call the computer and to enter data; a VuSet modem is required at the computer end.

Alphanumeric Display Terminals — Basic Characteristics

Designed for the traveler, Digi-Log's TeleComputer is an attache-enclosed terminal that includes a 5-inch display, keyboard, and acoustic telephone coupler. It's Teletype-compatible, weighs less than 25 pounds, and sells for \$1,470, with a 14 percent discount for 100-unit quantities. A 12-inch monitor is also available.

- ▷ Having completed entry into the fixed format, the operator transmits the data to the central computer. A feature called *partial screen transmit* promotes line economies by transmitting only the keyed data; the fixed format remains displayed and the "blanks" are erased for the next entry. This feature is also useful for transmitting only a portion of the displayed data such as a field, line, or block.

Editing features in a display terminal can consist of any combination of the functions listed below, although the best terminal for editing purposes would include all of them. Each function is performed with respect to the current position of the cursor. The desirable editing functions are:

- Character insert—the capability to insert a character into an existing line of displayed text; the remaining characters shift to the right or "spread" to accommodate the added character. The spreading capability may terminate at the last character position of the line or at the last displayable position on the screen. Data is lost when it is spread beyond the termination point.
- Character delete—the capability to delete a character from an existing line of displayed text; the remaining text closes up when the character is deleted.
- Line insert—the capability to insert a line of text into existing text; the text spreads to accommodate the added line.
- Line delete—the capability to delete a line of text from existing text; the remaining text closes up when the line is deleted.

- Erase—the capability to erase a character, line of text, message, field, or the complete screen. Most terminals include character erase and some form of display erase, which may erase the entire contents of the display, just that portion following the cursor location, or a combination of both functions. *Line* erase is optional in many terminals.
- Character repeat—enters a continuous sequence of symbols as long as the appropriate key remains depressed.

Keyboard

Keyboard *style* defines the general arrangement of keys; e.g., typewriter or data entry style. The *character/code set* refers to the set of symbols that appear on the keytops and, in many cases, to the actual character codes generated for each key depression, such as ASCII, EBCDIC, APL, etc. Some terminals are available with more than one keyboard style to satisfy particular user needs.

Keyboards that can either fit flush against the display or be located some distance away via cable connection are referred to as *detachable keyboards*. This feature provides increased configuration flexibility and operator convenience.

Some terminals are available with program function keys. These are special keys whose character codes are interpreted by the user's program. A function key is used to reduce the number of required input keystrokes to save time and reduce the number of input errors. Depressing one key could instruct the system to "sell one seat" or "call Chart A," for example.

Most keyboards are equipped with *cursor control keys* and *edit function keys* to permit the operator to manipulate the cursor and edit keyed data before it is transmitted and/or recorded.

A *numeric keypad* is a special keyboard feature that includes a set or block of 10 numeric keys, usually located to the right of the main keygroup. These numeric keys are arranged in an adding-machine format and are particularly useful for applications that require a high volume of numeric entries or arithmetic calculations.

Part 2—Right hand page**Operator Features**

Special operator oriented features are provided by some terminals, especially those that emulate the IBM 3270, which has all of the following:

- Numeric lock—locks the keyboard in numeric mode so that only numerics can be entered.

Alphanumeric Display Terminals — Basic Characteristics

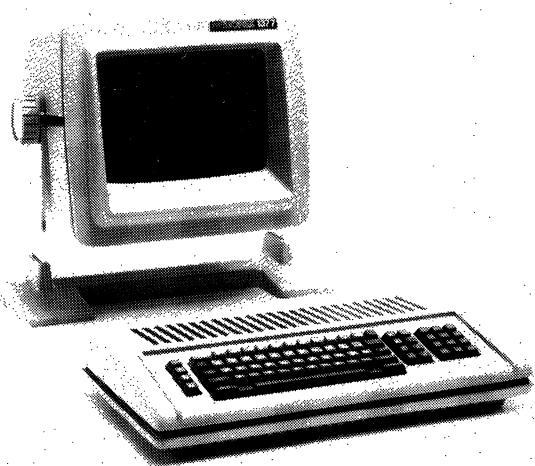

- ▷ ● Audible alarm—alerts an operator absent from the terminal to a pending message.
- Keylock—electronically locks the terminal to prevent operator control.
- Operator I.D. card reader—a device that reads magnetic stripe identification cards (similar to a plastic storage card) to insure proper user identification for security purposes.
- Light pen—a hand-held device similar to a pen that permits the user to initiate commands or to “call for” a page of data by pointing the pen at a displayed entry.

Ancillary Devices

External I/O devices can add considerable flexibility to the applications possibilities for display terminals. A cassette tape drive or diskette drive can be used to store display formats, data to be transmitted, or user programs in the case of intelligent terminals. A serial printer provides hard copy when required.

These devices can usually be added to a terminal by the user via the terminal's RS-232 serial interface. The device is attached between the terminal and the external modem.

Although the above I/O devices are the most common, other devices can be and are used, such as industry-compatible 7- or 9-track magnetic tape drives, disk drives (cartridge or pack type), line printers, card readers, etc.

Memorex recently announced its presence with its new 1377, an attractive plug-to-plug replacement for the IBM 3272-2 Display Station. The Memorex 1377 plugs into an IBM local or remote (BSC or SDLC) control unit, can use existing IBM cables, and displays up to 1920 characters. Features include a non-glare tiltable screen, a detachable 78-key typewriter or operator console keyboard, upper and lower case alphabetics, and a selector light pen in addition to all IBM features. The Memorex 1377 can be used in both the IBM 3270 and 3790 systems. It weighs just 49 pounds including keyboard.

Transmission Parameters

The display terminal contains a communications interface that enables communications between the terminal and the central computer site. Mode and technique define the operating mode and the method in which data is transmitted. There are three operating modes: simplex (transmission in one direction only), half duplex (transmission both directions, but not simultaneously), and full duplex (simultaneous transmission in both directions).

Data is transmitted synchronously or asynchronously. Asynchronous transmission is characterized by the transmission of data in irregular spurts, where the duration of time can vary between successive transmitted characters; the transmission from an unbuffered teletypewriter is a good example. Synchronous transmission implies the transmission of data in a steady stream. The time interval between successive characters is always precisely the same. The communications interface either provides clocking or accepts external clocking signals from the data set.

Communications protocol refers to the type of line discipline (control code sequence and control characters) that the terminal employs. The two most commonly used protocols are ASCII and IBM's Binary Synchronous Communications (BSC) technique. IBM's latest protocol, Synchronous Data Line Control (SDLC), will be widely used in the future. Other large mainframe vendors such as Burroughs, Honeywell, and Digital Equipment Corporation (DEC) have produced their own communications protocols.

The *transmission code* refers to the bit pattern of the transmitted characters. Two codes are prominent: EBCDIC and ASCII. The latter has been accepted as an industry and government standard, and is now the most commonly used code by display terminals.

The *unit code structure* specifies the total number of bits transmitted for each character. Asynchronous operating conventions require a single start bit and one or two stop bits to be combined with the character code for each transmitted character; therefore, an 8-level code such as ASCII is transmitted as a 10- or 11-unit code. Following Teletype's lead, the 11-unit code structure has been generally adopted for transmission at 10 characters per second; 10-unit codes are typically used at higher operating speeds.

The CRT terminal is a high-speed device that is usually capable of transmitting and receiving several thousand characters per second; however, it must run at a speed that is compatible with the communications system in which it used. Most terminals are used on voice-grade facilities, which limit the *transmission speed* to a practical maximum of 4800 bits per second over the dial network and 9600 bits per second over leased or private lines.

Alphanumeric Display Terminals — Basic Characteristics

- ▷ Terminals that are capable of operating at more than one transmission speed typically feature *operator selectable speeds* via switch selection.

Message format refers to the way data is transmitted, e.g., by block or by character. Terminals that are designed to be transmission-compatible with a Teletype unit transmit a character for each key depression. Buffered terminals transmit data in multi-character blocks. The line or block mode permits data to be composed and edited prior to each transmission and generally permits more efficient utilization of the communications facility. Some terminals offer manual selection between the modes.

Transmission Features

Multipoint operation characterizes terminals that are capable of operating in a multiple-terminals-per-line environment such as that employed by the IBM 3270 and 2260/2265 display terminals. Basic to implementing this capability is the ability of a terminal to distinguish a control message intended for it alone. Polling invites the terminals to send data. Addressing informs the terminal that a message from the central computer is coming, so that it will be conditioned to receive. Central control of the message traffic is maintained by the central computer.

Automatic answer refers to the facility for unattended operation on the dial network whereby incoming calls are automatically answered and messages are received without human intervention.

Auto call refers to the facility for unattended operation on the dial network whereby outgoing calls are automatically "dialed" and messages are transmitted without human intervention.

Terminal Interface

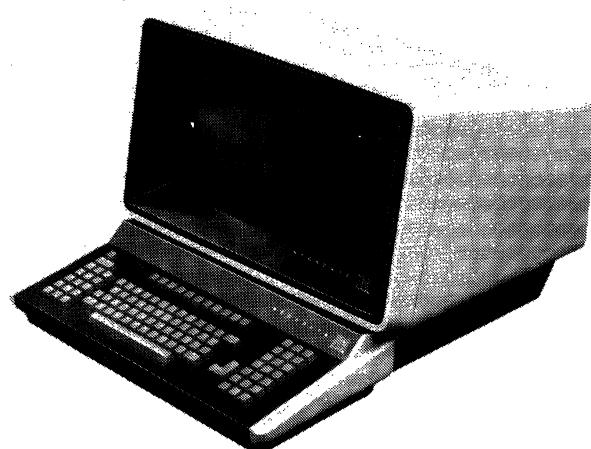

Display terminals usually have interfaces meeting the standards of the EIA RS-232B/C specification and connect to an external modem or acoustic telephone coupler.

Line Interface

Some terminals contain an *integral modem* that can be connected directly to a communications line. In some cases the vendor provides an *acoustic telephone coupler*, so that the terminal can be connected to a conventional telephone handset, or makes available a separate *external modem*.

Diagnostics

The entry *self diagnostics* denotes the terminal's capability to identify failures via self-generated test procedures. Failures are typically indicated by displayed test patterns or by indicator lamps. Self-diagnostics are typically performed while the terminal is in the off-line mode.

The new Megadata System 700 is a user-programmable terminal that incorporates a 12-bit minicomputer (similar to the DEC PDP-8E) with up to 64K bytes of user memory. Programming is performed in assembly language. The standard 1920-character screen displays 64 to 256 different characters via a programmable character generator. A host of peripherals is available, and all are program-controlled. The base price is \$2,995, with quantity discounts available.

On-line diagnostics denotes failure analysis of the terminal via diagnostic procedures generated by an external source, such as the host computer.

Off-line diagnostics denotes failure analysis of the terminal performed via diagnostic procedures while the terminal is in the off-line mode.

Pricing

Terminal pricing is provided for unit quantities (one terminal) unless otherwise specified. One, two, and three year leases (where applicable) and purchase prices are shown for the display station, serial printer, and terminal controller. Purchase prices are also provided for optional software. Quantity discounts are noted when available.

Single entries generally indicate the price of the basic unit without options; price ranges show the price of the basic unit and the price of an expanded unit with all options. In some cases, the terminal vendor offers a lease term other than those shown, such as a 4- or 5-year lease or a 30- or 60-day, short-term rental. In such cases, the lease prices and terms appear in the Comments at the bottom of the charts.

Many terminal vendors do not lease their equipment, and in these cases you'll find dashes in the lease price entries. Also, a number of terminal makers sell their wares on an OEM basis only, for incorporation into systems supplied by other vendors.

Availability

Date of first production delivery indicates when the first production model of each terminal was delivered (or is scheduled to be delivered) to a customer.

Alphanumeric Display Terminals — Basic Characteristics

Here's an example of the use of partial reverse video (dark characters on light background) and formatted operation. The Tektronix 4023 is a general-purpose alphanumeric terminal with a 12-inch CRT, capable of displaying up to 1920 characters. Options include the Ruling Character Set (shown above as the solid horizontal and vertical lines), a hard-copy unit (Model 4023), and a cartridge tape drive (Model 4923). Tektronix is a leading vendor of graphic display terminals.

► **Display units installed to date** shows how many display units of each type has been delivered to customers as of approximately June 1, 1976. All figures were supplied by the vendors themselves, and a number of companies chose not to release this information.

Serviced by specifies the party responsible for maintaining the terminal. In some cases the vendor provides total service; in others a national service organization is responsible. Service is sometimes rendered under the combined efforts of both the vendor and an independent service organization; usually in this situation, the vendor handles those areas close to his headquarters or where it has a multiplicity of installations, and the service company handles other geographical areas.

Number of service locations specifies the total number of service points nationwide that provide customer service for the terminal.

Comments

Comments at the bottom of the charts describe significant or unusual features, capabilities, or applications which are not reflected in the standard entries. □

Manufacturers

Listed below, for your convenience in obtaining additional information, are the full names and addresses of the 74 vendors whose products are summarized in the comparison charts.

Ann Arbor Terminals, Inc., 6107 Jackson Road, Ann Arbor, Michigan 48103. Telephone (313) 769-0926.

Applied Digital Data Systems, Inc., 100 Marcus Boulevard, Hauppauge, New York 11787. Telephone (516) 231-5400.

Beehive Terminals, 870 West 2600 South, PO Box 19244, Salt Lake City, Utah 84119. Telephone (801) 487-0741.

Bunker Ramo Corporation, Trumbull Industrial Park, Trumbull, Connecticut 06609. Telephone (203) 377-4141.

Burroughs Corporation, Business Machines Group, Room 2A38, Burroughs Place, Detroit, Michigan 48232. Telephone (313) 972-9115.

Computek, Inc., 143 Albany Street, Cambridge, Massachusetts 02139. Telephone (617) 864-5140.

Computer Communications, Inc., 2610 Columbia Street, Torrance, California 90503. Telephone (213) 320-9101.

Computer Optics, Inc., Berkshire Industrial Park, Bethel, Connecticut 06801. Telephone (203) 744-6720.

Conrac Corporation, Conrac Division, 600 N. Rimsdale Avenue, Covina, California. Telephone (213) 966-3511.

Control Data Corporation, 8100 34th Avenue South, Minneapolis, Minnesota 55420. Telephone (612) 853-4656.

Courier Terminal Systems, Inc., 2202 E. University Drive, Phoenix, Arizona 85034. Telephone (602) 244-1392.

Data General Corporation, Route 9, Southboro, Massachusetts, 01770. Telephone (617) 485-9100.

Data 100 Corporation, 7725 Washington Avenue South, Minneapolis, Minnesota 55435. Telephone (612) 941-6500.

Display units installed to date	1,650	5,700	—	3000/200	150
Serviced by	Ann Arbor	Ann Arbor	NCR	NCR	ADDS
No. of service locations	—	—	—	—	—
COMMENTS	Terminals are available in a total of 6 display formats: 16 x 32, 24 x 40, 16 x 80, 20 x 50, 24 x 80, and 40 x 80. DESIGN III uses same circuitry as Series 200, but is housed in attractive casework. Series 200 is available as circuit boards with monitor in desk or rack mounting			Also available from NCR as Model 796-101; MRD 380 is rack-mount controller priced at \$1,195
