## 8k basic

## INTRODUCTION

8 K BASIC is an interactive programming language with a variety of applications. It is used in s̈cientific and business environments to solve both simple and complex mathematical problems with a minimum of programming effort. It is used by educators and students as a problem-solving tool and as an aid to learning through programmed instruction and simulation.

In many respects the BASIC language is similar to other programming languages (such as FOCAL and FORTRAN), but BASIC is aimed at facilitating communication between the user and the computer. The BASIC user types in the computational procedure as a series of numbered statements, making use of common English words and familiar mathematical notations. Because of the small number of commands necessary and its easy application in solving problems, BASIC is one of the simplest computer languages to learn. With experience, the user can add the advanced techniques available in the language to perform more intricate manipulations or express a problem more efficiently and concisely.

8 K BASIC is an extended version of DEC's 4 K BASIC, ${ }^{1}$ but has additional features and requires 8 K of core. The user who has no familiarity with the BASIC language may wish to refer to the EduSystem Handbook for a background description of the language fundamentals, and for information pertaining to working with BASIC at the computer.

The minimum system configuration for 8 K BASIC is a PDP- 8

14 K BASIC, or EduSystem 10, is the most fundamental BASIC in DEC's series of EduSystems. This series is directed primarily for use in an educational environment. Information concerning the EduSystems may be obtained from DEC's PDP-8 Educational Marketing Department.
series computer with 8 K of core memory. Supported options include a high-speed reader and punch, and an LP08 line printer.

New features provided by 8 K BASIC include one and twodimensional subscripting, faster execution time, user-coded functions, use of the LP08 line printer and high-speed reader/punch, and specification of input and output devices from any part of a program.

Loading and operating instructions and a command summary are included at the end of the manual.

## NUMBERS

BASIC treats all numbers (real and integer) as decimal numbers -that is, it accepts any number containing a decimal point, and assumes a decimal point after an integer. The advantage of treating all numbers as decimal numbers is that the programmer can use any number or symbol in any mathematical expression without regard to its type.

In addition to integer and real formats, a third format is recognized and accepted by 8 K BASIC and is used to express numbers outside the range $.01<=x<=1,000,000$. This format is called exponential or E-type notation, and in this format, a number is expressed as a decimal number times some power of 10 . The form is:

## xxEn

where E represents "times 10 to the power of"; thus the number is read: "xx times 10 to the power of n." For example:

$$
23.4 \mathrm{E} 2=23.4 * 10^{2}=2340
$$

Data may be input in any one or all three of these forms. Results of computations are output as decimals if they are within the range previously stated; otherwise, they are output in E format. BASIC handles seven significant digits in normal operation and input/output, as illustrated below:

| Value Typed In | Value Output By BASIC |
| :---: | :---: |
| .01 | .01 |
| .0099 | $9.900000 \mathrm{E}-3$ |
| 999999 | 999999 |
| 1000000 | $1.000000 \mathrm{E}+6$ |

BASIC automatically suppresses the printing of leading and trailing zeros in integer and decimal numbers, and, as can be seen from the preceding examples, formats all exponential numbers in the form:

$$
(\operatorname{sign}) \operatorname{x.xxxxxx} E(+ \text { or }-) \mathrm{n}
$$

where x represents the number carried to six decimal places, E stands for "times 10 to the power of," and $n$ represents the exponential value. For example:

$$
-3.470218 \mathrm{E}+8 \text { is equal to }-347,021,800
$$

$7.260000 \mathrm{E}-4$ is equal to .000726

## VARIABLES

A variable in BASIC is an algebraic symbol representing a number, and is formed by a single letter or a letter followed by a digit. For example:

B3

X
$\frac{\text { Unacceptable Variables }}{2 \mathrm{C}-\mathrm{a} \text { digit cannot begin }} \begin{aligned} & \text { a variable }\end{aligned}$
AB - two or more letters cannot form a variable

The user may assign values to variables either by indicating the values in a LET statement, or by inputting the values as data; these operations are discussed further on in the manual.

## ARITHMETIC OPERATIONS

BASIC performs addition, subtraction, multiplication, division and exponentiation, as well as more complicated operations explained in detail later in the manual. The five operators used in writing most formulas are:

Symbol

| Operator |
| :---: |
| + |
| - |
| $/$ |
| $\uparrow$ |

| Meaning |  |
| :--- | ---: |
| Addition | Example |
| Subtraction | $A-B$ |
| Multiplication | $A * B$ |
| Division | $A / B$ |
| Exponentiation | A $\uparrow \mathrm{B}$ |
| (Raise A to the |  |
| Bth power) |  |

## Priority of Arithmetic Operations

In any given mathematical formula, BASIC performs the arithmetic operations in the following order of evaluation:

1. Parentheses receive top priority. Any expression within parentheses is evaluated before an unparenthesized expression.
2. In absence of parentheses, the order of priority is:
a. Exponentiation
b. Multiplication and Division (of equal priority)
c. Addition and Subtraction (of equal priority)
3. If either 1 or 2 above does not clearly designate the order of priority, then the evaluation of expressions proceeds from left to right.
The expression $\mathrm{A} \uparrow \mathrm{B} \uparrow \mathrm{C}$ is evaluated from left to right as follows:
4. $\mathrm{A} \uparrow \mathrm{B}=$ step 1
5. (result of step 1) $\uparrow \mathrm{C}=$ answer

The expression $\mathrm{A} / \mathrm{B}^{*} \mathrm{C}$ is also evaluated from left to right since multiplication and division are of equal priority:

1. A/B $=$ step 1
2. (result of step 1 ) $* \mathrm{C} \quad=$ answer

## PARENTHESES

Parentheses may be used by the programmer to change the order of priority (as listed in rule 2 above), as expressions within parentheses are always evaluated first. Thus, by enclosing expressions appropriately, the programmer can control the order of evaluation. Parentheses may be nested, or enclosed by a second set (or more) of parentheses. In this case, the expression within the innermost parentheses is evaluated first, and then the next innermost, and so on, until all have been evaluated.

Consider the following example:
$A=7 *((B+2+4) / X)$
The order of priority is:

1. $\mathrm{B} \uparrow 2 \quad=$ step 1
2. (result of step 1$)+4=$ step 2
3. (result of step 2)/X $=$ step 3
4. $($ result of $\operatorname{step} 3) * 7=\mathrm{A}$

Parentheses also prevent any confusion or doubt as to how the expression is evaluated. For example:
$\mathrm{A} * \mathrm{~B}+2 / 7+\mathrm{B} / \mathrm{C}+\mathrm{D}+2$
$((A * B+2) / 7)+((B / C)+D+2)$
Both of these formulas will be executed in the same way. However, the inexperienced programmer or student may find that the second is easier to understand.

Spaces may be used in a similar manner. Since the BASIC compiler ignores spaces, the two statements:

```
10 LET B = Dt 2 + 1
10LETB=Dt2+1
```

are identical, but spaces in the first statement provide ease in reading.

## RELATIONAL OPERATORS

A program may require that two values be compared at some point to discover their relation to one another. To accomplish this, BASIC makes use of the following relational operators:

$$
\begin{array}{ll}
= & \text { equal to } \\
< & \text { less than } \\
<= & \text { less than or } \\
& \text { equal to }
\end{array} \quad \begin{aligned}
& \text { greater than } \\
& \text { greater than or } \\
& \\
&
\end{aligned}
$$

Depending upon the result of the comparison, control of program execution may be directed to another part of the program, or the validity of the relationship may cause a value of 0 to 1 to be associated with a variable (that is, if a condition is true, a value of 1 is assigned; if a condition is not true, then the value of 0 is returned). Relational operators are used in conjunction with IF and LET statements, both of which are discussed in greater detail later in the manual.

The meaning of the equal $(=)$ sign should be clarified. In algebraic notation, the formula $\mathbf{X}=\mathbf{X}+1$ is meaningless. However, in BASIC (and most computer languages), the equal sign designates replacement rather than equality. Thus, this formula is actually translated: "add one to the current value of $X$ and store
the new result back in the same variable X." Whatever value has previously been assigned to X will be combined with the value 1 . An expression such as $A=B+C$ instructs the computer to add the values of $B$ and $C$ and store the result in a third variable $A$. The variable A is not being evaluated in terms of any previously assigned value, but only in terms of $B$ and $C$. Therefore, if $A$ has been assigned any value prior to its use in this statement, the old value is lost; it is instead replaced by the value of $B+C$.

## IMMEDIATE MODE

There are two commands available which allow BASIC to act as a calculator-PRINT and LET. The user types in the algebraic expression which is to be calculated, and BASIC types back the result. This is called immediate mode since the user is not required to write a detailed program to calculate expressions and equations, but can use BASIC to produce results immediately.

## PRINT Command

The PRINT command is of the form:

## PRINT expression

and instructs BASIC to compute the value of the expression and print it on the Teletype. The expression may be made up of any decimal number, the arithmetic operators mentioned previously, and the functions which are discussed further on in the manual. (These may be used in conjunction with a string of text, as explained in the section concerning the PRINT statement.) For example:

```
PRINT 1/8!8
    5.960464E-08
```

## LET Command

Values may be assigned to variables by use of the LET command as follows:

$$
\text { LET variable }=\text { expression }
$$

The computer does not type anything in response to this command, but merely stores the information. This information may then be used in conjunction with a PRINT command to calculate results. For example:

LET P1 $=3.14159$
PRINT P1*4+2
50.26544

## BASIC STATEMENTS

## Example Program

The following example program is included at this point as an illustration of the format of a BASIC program, the ease in running it, and the type of output that may be produced. This program and its results are for the most part self-explanatory. Following sections cover the statements and commands used in BASIC programming.

```
10 REM - PROGRAM TO TAKE AUERAGE OF
15 REM - STUDENT GRADES AND CLASS GRADES
20 PRINT "HOW MANY STUDENTS, HOW MANY GRADES PER STUDENT";
30 INPUT A,B
40 LET I=\emptyset
50 FOR J=I TO A-1
55 LET V=0
60 PRINT "STUDENT NUMBER ='';
75 PRINT "ENTER GRADES"
76 LET D=J
80 FOR K=D TO D+(B-1)
81 INPUT G
8 2 ~ L E T ~ V = V + G
8 5 ~ N E X T ~ K
90 LET V=V/R
95 PRINT "AUERAGE GRADE ='';V
96 PFINT
9 9 ~ L E T ~ Q = Q + V ~
100 NEXT J
101 PRINT
102 PRINT
103 PRINT "CLASS AVERAGE =";Q/A
104 STOP
140 END
```

```
RUN
HOW MANY STULENTS, HOW MANY GRADES PER STULENT? 5,4
STULENT NUNBER = Ø
ENTER GRADES
?78
?86
?88
?74
AVERAGE GRADE = 81.5
STUDENT NUNEER = 1
ENTER GRADES
?59
?86
?70
?87
AUERAGE GRADE = 75.5
STUDENT NUMBER = 2
ENTER GRADES
?58
?64
?75
?80
AVERAGE GRADE = 69.25
STUDENT NUMBER = 3
ENTER GRADES
?88
?92
?85
?79
AVERAGE GRADE = 86
STUDENT NUMBER = 4
ENTER GRADES
?60
?78
?85
?80
AUERAGE GRADE = 75.75
CLASS AUERAGE = 77.6
READY.
```

## Statement Numbers

An integer number is placed at the beginning of each line in a BASIC program. BASIC executes the statements in a program in numerically consecutive order, regardless of the order in which they have been typed. A common practice is to number lines by
fives or tens, so that additional lines may be inserted in a program without the necessity of renumbering lines already present.

Multiple statements may be placed on a single line by seperating each statement from the preceding statement with a backslash (SHIFT/L). For example:

```
10 A=5\B=.2\C=3\PRINT "ENTER DATA"
```

All of the statements in line 10 will be executed before BASIC continues to the next line. Only one statement number at the beginning of the entire line is necessary. However, it should be remembered that program control cannot be transferred to a statement within a line, but only to the first statement of the line in which it is contained (see the section entitled Transfer of Control Statements).

## Commenting the Program

## REM

The REM or REMARK statement allows the programmer to insert comments or remarks into a program without these comments affecting execution. The BASIC compiler ignores everything following REM. The form is:

> (line number) REM (message)

In the Example Program, lines 10 and 15 are REMARK statements describing what the program does. It is often useful to put the name of the program and information relating to its use at the beginning where it is available for future reference. Remarks throughout the body of a long program will help later debugging by explaining the purpose of each section of code within the program.

## Terminating the Program

## END

The END statement (line 140 in the Example Program), if present, must be the last statement of the entire program. The form is:
(line number) END
This statement acts as a signal that the entire program has been executed. Use of the statement is optional. However, if the program contains an END statement, after execution, variables and
arrays are left in an undefined state, thereby losing any values they have been assigned during execution.

## STOP

The STOP statement is used synonymously with the END statement to terminate execution, but while END occurs only once at the end of a program, STOP may occur any number of times. The format of the STOP statement is:

> (line number) STOP

This statement signals that execution is to be terminated at that point in the program where it is encountered.

## The Arithmetic Statement

LET
The Arithmetic (LET) statement is probably the most commonly used BASIC statement and is used whenever a value is to be assigned to a variable. It is of the form:
(line number) (LET) $\mathrm{x}=$ expression
where x represents a variable, and the expression is either a number, another variable, or an arithmetic expression. The word 'LET' is optional; thus the following statements are treated the same:

```
100 LET A=A!B+10 110 LET C=F/G
1の0 A=A!B+1の 110 C=F/G
```

As mentioned earlier, relational operators may be used in a LET statement to assign a value of 0 (if false) or 1 (if true) to a variable depending upon the validity of a relationship. For example:

```
10\emptyset A=1\B=2
110 C=A=B
12\emptyset D=A>B
130 E=A <>B
140 PRINT C,D,E
150 END
```

Translated, this actually means "let $\mathrm{C}=1$ if $\mathrm{A}=\mathrm{B}$ ( 0 otherwise); let $\mathrm{D}=1$ if $\mathrm{A}>\mathrm{B}$ ( 0 otherwise)" and so on. Thus, the values of C , D , and E are printed as follows:

RUN
$\emptyset$

READY.

There is no limit to the number of relationships that may be tested in the statement.

## Input/Output Statements

Input/Output statements allow the user to bring data into a program and output results or data at any time during execution. The Teletype keyboard, low or high-speed reader/punch, and LP08 line printer are all available as $\mathrm{I} / \mathrm{O}$ devices in 8K BASIC. Statements which control their use are described next.

## READ AND DATA

READ and DATA statements are used to input data into a program. One statement is never used without the other. The form of the READ statement is:
(line number) READ $x 1, x 2, \ldots x n$
where $x 1$ through xn represent variable names. For example:

10 READ $A, B, C$
$\mathrm{A}, \mathrm{B}$, and C are variables to which values will be assigned. Variables in a READ statement must be separated by commas. READ statements are generally placed at the beginning of a program, but must at least logically occur before that point in the program where the value is required for some computation.

Values which will be assigned to the variables in a READ statement are supplied in a DATA statement of the form:
(line number) DATA $\mathrm{x} 1, \mathrm{x} 2, \ldots \mathrm{xn}$
where x 1 through xn represent values. The values must be separated by commas and occur in the same order as the variables which are listed in the corresponding READ statement. A DATA statement appropriate for the preceding READ statement is:

7 D DATA $1,2,3$

Thus, at execution time $\mathrm{A}=1, \mathrm{~B}=2$, and $\mathrm{C}=3$.
The DATA statement is usually placed at the end of a program (before the END statement) where it is easily accessible to the programmer should he wish to change the values.

A READ statement may have more or fewer variables than there are values in any one DATA statement. The READ statement causes BASIC to search all available DATA statements in the order of their line numbers until values are found for each variable in the READ. A second READ statement will begin reading values where the first stopped. If at some point in the program an attempt is made to read data which is not present or if the data is not separated by commas, BASIC will stop and print the following message at the console:

DATA ERROR AT LINE XXXX
where XXXX indicates the line which caused the error.

## RESTORE

If it should become necessary to use the same data more than once in a program, the RESTORE statement will make it possible to recycle through the DATA statements beginning with the lowest numbered DATA statement. The RESTORE statement is of the form:

## (line number) RESTORE

An example of its use follows:

```
15 READ B,C,D
•
55 RESTORE
60 READ E,F,G
\bullet
\bullet
8\emptyset DATA 6,3,4,7,9,2
•
100 END
```

The READ statements in lines 15 and 60 will both read the first three data values provided in line 80 . (If the RESTORE statement
had not been inserted before line 60 , then the second READ would pick up data in line 80 starting with the fourth value.)

The programmer may use the same variable names the second time through the data, or not, as he chooses, since the values are being read as though for the first time. In order to skip unwanted values, the programmer may insert replacement, or dummy, variables. Consider :

```
1 REM - PROGRAM TO ILLUSTRATE USE OF RESTORE
20 READ N
25 PRINT "UALUES OF X ARE:"
30 FOR I=1 TO N
40 READ X
50 PRINT X,
60 NEXT I
70 RESTORE
185 PRINT
190 PRINT "SECOND LIST OF X VALUES"'
2\emptyset\emptyset PRINT "FOLLOWING RESTORE STATEMENT:"
210 FOR I=1 TO N
220 READ X
230 PRINT X,
240 NEXT I
250 DATA 4,1,2
251 DATA 3,4
300 END
```

```
RUN
VALUES OF X ARE:
    1 2 3 4
SECOND LIST OF X VALUES
FOLLOWING RESTORE STATEMENT:
    4 1 2 3
READY.
```

The second time the data values are read, the first X picks up the value originally assigned to N in line 20 , and as a result, BASIC prints:

To circumvent this, the programmer could insert a dummy variable which would pick up and store the first value, but would not be represented in the PRINT statement, in which case the output would be the same each time through the list.

## INPUT

The INPUT statement is used when data is to be supplied by the user from the Teletype keyboard while a program is executing, and is of the form:
(line number) INPUT $\mathrm{x} 1, \mathrm{x} 2, \ldots \mathrm{xn}$
where x 1 through xn represent variable names. For example:

25 INPUT A,B,C

This statement will cause the program to pause during execution, print a question mark on the Teletype console, and wait for the user to type in three numerical values. The user must separate the values by commas; they are entered into the computer by his pressing the RETURN key at the end of the list.

If the user does not insert enough values to satisfy the INPUT statement, BASIC prints another question mark and waits for more values to be input. When the correct number has been entered, execution continues. If two many values are input, BASIC ignores those in excess of the required number. The values are entered when the user types the RETURN key.

## PTR

A PTR statement is used when data is to be input from the highspeed paper tape reader. The format of the data on the paper tape must be the same as it would be if it were input from the Teletype keyboard. If more than one value is to be input at a time, the values must be separated by commas. The tape must be positioned in the reader before it is called by the program; while it is reading, there is no echo (type out) on the Teletype. The form is:
(line number) PTR
The PTR statement is most useful for inputting large amounts of data in conjunction with the INPUT command. The following program accepts 20 data values from the high-speed reader, prints a heading, the value input, and its sine on the Teletype:

```
50 PTR
60 PRINT "SINE TABLE"
10\emptyset FOR J=1 TO 2\emptyset
110 INPUT A
120 LET B=SIN(A)
130 PRINT A,B
140 NEXT J
150 END
RUN
SINE TABLE
-.97
    -.8248857
-.911 -.7901171
-.872 -.7656171
-.723 -.6616371
-.719 -.6586325
-.61 -.5728675
-.502 -.4811798
-.346 -. 3391376
-.33 -. 324043
-.283 -. 2792376
-.175 -.1741081
-.155 -. 1543801
-.02 -.01999867
    .03 .0299955
    .093 -092866
    .127 -1266589
    .13 •1296341
    .42 .4077605
    .529 . 5046703
    .632 .5907596
READY.
```

## PRINT

The PRINT statement is used to output results of computations, comments, values of variables, or plot points of a graph on the Teletype. The format is:

## (line number) PRINT expression

When used without an expression, a blank line will be output on the Teletype. For more complicated formats, the type of expression and the type of format control characters following the word PRINT determines which formats will be created.

In order to have the computer print out the results of a computation, or the value of a variable at any point in the program, the
user types the line number, PRINT, and the variable name(s) separated by a format control character, in this case, commas:

```
5 A=1 5\B=5\C=4
10 PRINT A,C+R,SQR(A)
```

In BASIC, a Teletype line is formatted into five fixed columns (called print zones) of 14 spaces each. In the above example, the values of $A, C+B$, and the square root of $A$ will be printed in the first three of these zones as follows:

```
RUN
    16 9
READY.
```

A statement such as:

```
5 A=2.3\R=21\C=156.75\D=1.134\E=23.4
10 PRINT A,B,C,D,E
```

will cause the values of the variables to be printed in the same format using all five columns:

| RUN    <br> 2.3 21 156.75 1.134 | 23.4 |
| :---: | :---: | :---: | :---: | :---: |

READY.
When more than five variables are listed in the PRINT statement, the sixth value begins a new line of output.

The PRINT statement may also be used to output a message or line of text. The desired message is simply placed in quotation marks in the PRINT statement as follows:

10 PRINT "THIS IS A TEST"

When line 10 is encountered during execution, the following will be printed:

```
THIS IS A TEST
```

A message may be combined with the result of a calculation or a variable as follows:

```
8\emptyset PRINT "AMOUNT PER PAYMENT =''R
```

Assuming $\mathrm{R}=344.9617$, when line 80 is encountered during execution, this will be output as:

RUN
AMOUNT PER PAYMENT $=344.9617$

READY.
It is not necessary to use the standard five zone format for output. The control character semicolon (;) causes the text or data to be output immediately after the last character printed (separated by one space.) If neither a comma nor a semicolon is used, BASIC assumes a semicolon. Thus both of the following:

```
80 PRINT "AMOUNT PER PAYMENT ='R
8\emptyset PRINT "AMOUNT PER PAYMENT ='';R
```

will result in:

```
AMOUNT PER PAYMENT = 344.9617
```

The PRINT statement can also cause a constant to be printed on the console. (This is similar to the PRINT command used in Immediate Mode.) For example:

10 PRINT 1.234, SQR(10014)
will cause the following to be output at execution time:
$1.234 \quad 100.07$

Any algebraic expression in a PRINT statement will be evaluated using the current value of the variables. Numbers will be printed according to the format previously specified.

The following example program illustrates the use of the control characters ${ }^{2}$ in PRINT statements:

[^0]```
10 READ A,B,C
20 PRINT A,B,C,A+2,B+2,C+2
30 PRINT
40 PRINT A;B;C;A!2;B!2;C!2
50 DATA 4,5,6
60 END
```

```
RUN
```

RUN
4 5
4 5
36
36
4
4
READY.

```
READY.
```

As this example illustrates, if a number should be too long to be printed on the end of a single line, BASIC automatically moves the entire number to the beginning of the next line.

Another use of the PRINT statement is to combine it with an INPUT statement so as to identify the data expected to be entered. As an example, consider the following program:

```
10 REM - PROGRAM TO COMPUTE INTEREST PAYMENTS
20 PRINT 'INTEREST IN PERCENT';
25 INPUT J
26 LET J=J/100
3g PRINT "AMOUNT OF LOAN";
35 INPUT A
4\emptyset PRINT "NUMBER OF YEARS";
4 5 ~ I N P U T ~ N
50 PRINT 'NUMEER OF PAYMENTS PER YEAR';
55 INPUT M
60 LET N=N*M
65 LET I=J/M
70 LET B=1+I
75 LET R=A*I/(1-1/BiN)
78 PRINT
80 PRINT "AMOUNT PER PAYMENT =";R
85 PRINT "TOTAL INTEREST ='";R*N-A
8 PRINT
90 LET B=A
9 5 ~ P R I N T ~ " ~ I N T E R E S T ~ A P P ~ T O ~ P R I N ~ B A L A N C E " '
10\emptyset LET L=B*I
110 LET P=R-L
120 LET B=B-P
130 PRINT L,P,B
140 IF B>=RGC TO 100
150 PRINT B*I,R-B*I
160 PRINT "LAST PAYMENT =''B*I+B
2Ø0 END
```

```
RUN
INTEREST IN PERCENT?9
AMOUNT OF LOAN?250ø
NUMEER OF YEARS?2
NUMBER OF PAYMENTS PER YEAR?4
AMOUNT PER PAYMENT = 344.9617
TOTAL INTEREST = 259.6932
    INTEREST APP TO PRIN BALANCE
    56.25 288.7117 2211.288
    49.75399 295.2077 1916.081
    43.11182 301.8498 1614.231
    36.32019 308.6415 1305.589
    29.37576 315.5859 990.0035
    22.27508 322.6866 667.317
    15.01463 329.947 337.3699
    7.590824 337.3708
LAST PAYMENT = 344.9608
READY.
```

As can be noticed in this example, the question mark is grammatically useful in a program in which several values are to be input by allowing the programmer to formulate a verbal question which the input value will answer.

## LPT

The LPT statement is used to generate output on the LP08 line printer, and is of the form:

## (line number) LPT

By inserting this statement anywhere in a program, all subsequent output, with the exception of error messages, will be printed on the line printer. The LPT statement is particularly advantageous for outputting large amounts of calculated data, as can be seen from this and following examples:

```
100 LPT
110 FOR F=30 TO 60 STEP 3
120 PRINT F,F!2
130 NEXT F
140 END
```

| 30 | 926 |
| :--- | :--- |
| 33 | 1009 |
| 36 | 1296 |
| 39 | 1521 |
| 42 | 1764 |
| 45 | 2025 |
| 48 | 2304 |
| 51 | 2601 |
| 54 | 2916 |
| 57 | 3249 |
| 60 | 3600 |

When the END statement is encountered in the program, the output device is reset to the Teletype.

PTP
The high-speed paper tape punch is also available as an output device in 8 K BASIC, permitting users to save data or output files quickly on paper tape. When the statement is encountered, all output is diverted from the Teletype to the high-speed punch. Control automatically returns to the Teletype when the END statement is encountered. The form is:

## (line number) PTP

By substituting this statement in line 100 of the previous program, all output, with the exception of error messages, will be sent to the high-speed paper tape punch instead of the line printer.

## TTY IN AND TTY OUT

The Teletype may be placed under program control so that, during execution of a program, I/O may be obtained or sent alternately between any available device. By issuing the statement:
(line number) TTY IN
control of input is returned to the Teletype if it has been previously set to another device. Similarly, the statement:
(line number) TTY OUT
returns output control to the Teletype.

The following program makes use of most all the available I/O devices. The output, with the exception of paper tape, is also included.

```
1Ø0 LPT
110 PRINT "FIRST DEGREE EQUATION CALCULATION"
120 TTY IN
130 TTY OUT
135 PRINT "TYPE X1 Y1 THEN X2 YZ"
140 INPUT X1,Y1,X2,Y2
150 X=X2-X1
160 Y=Y2-Y1
170 M=Y/X
180 B=Y2-M*X2
190 IF B>=\emptyset THEN 30\emptyset
2\emptyset\emptyset PRINT "Y=''M"X'B
210 LPT
220 PRINT ''Y=''M''X''B
230 GO TO 40\emptyset
30\emptyset PRINT "Y='M"X+"'B
310 LPT
320 PRINT "Y=''M"X+''B
400 FOR Y=0 T0 10 STEP 2
4 1 0 ~ F O R ~ X = \emptyset ~ T O ~ 1 0 ~ S T E P ~ . ~ 5 ~
420 LET T=M*X+B-Y
430 IF T<>\emptyset THEN 480
4 4 0 ~ P R I N T ~ X , Y ~
4 5 0 ~ P T P
4 6 0 ~ P R I N T ~ X , Y ~
4 7 0 ~ L P T
4 8 0 ~ N E X T ~ X ~
4 9 0 ~ N E X T ~ Y ~
500 END
RUN
TYPE X1 Y1 THEN X2 Y2
?-3,-4,-1,0
Y= 2 X+ 2
READY.
```

The line printer output is the following:

```
FIRST OEGREE CALCULATION
y=2 x+2
    0
    1 4
    2 6
    4 - 
```

## NOTE

The Teletype low-speed reader and punch may be used as I/O devices at any time. No special statement is required. To read in data from the low-speed reader, position the tape over the sprocket wheel and set the reader to START when input is required. The tape will begin reading in. To punch a tape, set the low-speed punch to ON and all ouput will be punched on the low-speed punch.
Using the low-speed I/O devices is, in effect, the same as using the Teletype keyboard. Characters will be typed on the Teletype keyboard as tapes are being read in or punched.

## Loops

FOR, NEXT, AND STEP
FOR and NEXT statements define the beginning and end of a loop. A loop is a set of instructions which are repeated over and over again, each time being modified in some way until a terminal condition is reached. The FOR statement is of the form:
(line number) FOR $\mathrm{v}=\mathrm{x} 1$ TO x 2 STEP x 3
where v represents a variable name, and $\mathrm{x} 1, \mathrm{x} 2$, and x 3 all represent formulas (a formula in this case means a numerical value, variable name, or mathematical expression). v is termed the index, x 1 the initial value, x 2 the terminal value, and x 3 the incremental value. For example:

15 FOR K=2 TO 20 STEP 2

This means that the loop will be repeated as long as $K$ is less than or equal to 20 . Each time through the loop, $K$ is incremented by 2, so the loop will be repeated a total of 10 times.

A variable used as an index in a FOR statement must not be subscripted, although a common use of loops is to deal with subscripted variables, using the value of the index as the subscript of
a previously defined variable (this is illustrated in the section concerning Subscripted Variables).

The NEXT statement is of the form:

## (line number) NEXT

and signals the end of the loop. When execution of the loop reaches the NEXT statement, the computer adds the STEP value to the index and checks to see if the index is less than or equal to the terminal value. If so, the loop is executed again. If the value of the index exceeds the terminal value, control falls through the loop to the following statement, with the value of the index equaling the value it was assigned the final time through the loop. ${ }^{3}$

If the STEP value is omitted, a value of +1 is assumed. Since +1 is the usual STEP value, that portion of the statement is frequently omitted. The STEP value may also be a negative number.

The following example illustrates the use of loops. This loop is executed 10 times: the value of $I$ is 10 when control leaves the loop. +1 is the assumed STEP value.

```
10 FOR I=1 TO 10
20 NEXT I
30 PRINT I
4 0 ~ E N D
```

## RUN

10
READY.

If line 10 had been:

10 FOR $I=10$ TO 1 STEP - 1
the value printed by the computer would be 1 .
As indicated earlier, the numbers used in the FOR statement
${ }^{3}$ The user should note that this method of handling loops varies among different versions of BASIC.
are formulas; these formulas are evaluated upon first encountering the loop. While the index, initial, terminal and STEP values may be changed within the loop, the value assigned to the initial formula remains as originally defined until the terminal condition is reached. To illustrate this point, consider the last example program. The value of I (in line 10) can be successfully changed as follows:

```
10 FOR I=1 TO 10
15 LET I=10
2\emptyset NEXT I
```

The loop will only be executed once since the value 10 has been reached by the variable I and the terminal condition is satisfied.

If the value of the counter variable is originally set equal to the terminal value, the loop will execute once, regardless of the STEP value. If the starting value is beyond the terminal value, the loop will also execute only once.

It is possible to exit from a FOR-NEXT loop without the index reaching the terminal value. (This is known as a conditional transfer and is explained in the section entitled Transfer of Control Statements.) Control may only transfer into a loop which has been left earlier without being completed, ensuring that the terminal and STEP values are assigned.

## Nesting Loops

It is often useful to have one or more loops within a loop. This technique is called nesting, and is allowed as long as the field of one loop (the numbered lines from the FOR statement to the corresponding NEXT statement, inclusive) does not cross the field of another loop. A diagram is the best way to illustrate acceptable nesting procedures:

## ACCEPTABLE NESTING UNACCEPTABLE NESTING TECHNIQUES TECHNIQUES

A maximum of eight (8) levels of nesting is permitted. Exceeding that limit will result in the error message:

FOR ERROR AT LINE XXXX
where XXXX is the number of the line in which the error occurred.

## Subscripted Variables

In addition to single variable names, BASIC accepts another class of variables called subscripted variables. Subscripted variables provide the programmer with additional computing capabilities for handling lists, tables, matrices, or any set of related variables. Variables are allowed one or two subscripts. A single letter forms the name of the variable; this is followed by one or two integers in parentheses and separated by commas, indicating the place of that variable in the list. Up to 26 arrays are possible in any program (corresponding to the letters of the alphabet), subject only to the amount of core space available for data storage. For example, a list might be described as $\mathrm{A}(\mathrm{I})$ where I goes from 1 to 5 , as follows:

This allows the programmer to reference each of the five elements in the list A. A two dimensional matrix $\mathbf{A}(\mathrm{I}, \mathrm{J})$ can be defined in a similar manner, but the subscripted variable A can only be used once (i.e., $A(I)$ and $A(I, J)$ cannot be used in the same program). It is possible however, to use the same variable name as both a subscripted and an unsubscripted variable. Both $A$ and $A(I)$ are valid variable names and can be used in the same program.

Subscripted variables allow data to be input quickly and easily, as illustrated in the following program (the index of the FOR statement in lines 20,42 , and 44 is used as the subscript) :

```
10 REM - PROGRAM DEMONSTRAT ING READING
11 REM - OF SUBSCRIPTED VARIABLES
15 DIM A(5),B(2,3)
18 PRINT "A(I) WHERE A=1 T0 5;"
2\emptyset FOR I=1 TO 5
25 READ A(I)
3Ø PRINT A(I);
35 NEXT I
3 8 ~ P R I N T
39 PRINT
4\emptyset PRINT "B(I,J) WHERE I=1 TO 2:"
41 PRINT " AND J=1 TO 3:"
4 2 ~ F O R ~ I = 1 ~ T O ~ 2 ~
4 3 ~ P R I N T
4 4 ~ F O R ~ J = 1 ~ T O ~ 3 ~
4 8 ~ R E A D ~ B ( I , J )
50 PRINT B(I,J);
5 5 ~ N E X T ~ J ~ J
56 NEXT I
60 DATA 1,2,3,4,5,6,7,8
61 DATA 8,7,6,5,4,3,2,1
65 END
RUN
A(I) WHERE A=1 TO 5;
    1 2 3 4 5
B(I,J) WHERE I=1 TO 2:
        AND J=1 TO 3:
    6 7 8
    8 7 6
READY.
```

## DIM

From the preceding example, it can be seen that the use of subscripts requires a dimension (DIM) statement to define the maximum number of elements in the array. The DIM statement is of the form:

$$
\text { (line number) DIM } \mathrm{v}_{1}\left(\mathrm{n}_{1}\right), \mathrm{v}_{\cdot 2}\left(\mathrm{n}_{2}, \mathrm{~m}_{\cdot 2}\right)
$$

where $v *$ indicates an array variable name and $n$ and $m$ are integer numbers indicating the largest subscript value required during the program. For example:
$15 \operatorname{DIM} A(6,10)$

The first element of every array is automatically assumed to have a subscript of zero. Dimensioning $A(6,10)$ sets up room for an array with 7 rows and 11 columns. This matrix can be thought of as existing in the following form:

and is illustrated in the following program:

```
10 REM - MATRIX CHECK PROGRAM
15 DIM A (6,10)
2\emptyset FOR I=\emptyset TO 6
22 LET A (I,0)=I
25 FOR J=\emptyset TO 10
28 LET A (Ø,J)=J
3\varnothing PRINT A(I,J);
35 NEXT J
4 0 ~ P R I N T
4 5 ~ N E X T ~ I ~
50 END
```

| RUN |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 2 | 3 | 4 | 5 | 0 | 7 | 8 | 9 | 10 |
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 5 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 6 | $\emptyset$ | $\emptyset$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

READY.

Notice that a variable assumes a value of zero until another value has been assigned. If the user wishes to conserve core space by not making use of the extra variables set up within the array, he should set his DIM statement to one less than necessary, DIM $\mathbf{A}(5,9)$. This results in a 6 by 10 array which may then be referenced beginning with the $\mathrm{A}(0,0)$ element.

More than one array can be defined in a single DIM statement:
$10 \operatorname{DIM} \mathrm{~A}(20), \mathrm{B}(4,7)$

This dimensions both the list $A$ and the matrix $B$.
A number must be used to define the maximum size of the array. A variable inside the parentheses is not acceptable and will result in an error message by BASIC at run time. The amount of user core not filled by the program will determine the amount of data the computer can accept as input to the program at any one time. In some programs a TOO-BIG ERROR may occur, indicating that core will not hold an array of the size requested. In that event,
the user should change his program to process part of the data in one run and the rest later.

## Transfer of Control Statements

Certain control statements cause the execution of a program to jump to a different line either unconditionally or depending upon some condition within the program. Looping is one method of jumping to a designated point until a condition is met. The following statements give the programmer added capabilities in this area.

## UNCONDITIONAL TRANSFER-GOTO

The GOTO (or GO TO) statement is an unconditional statement used to direct program control either forward or back in a program. The form of the GOTO statement is:

## (line number) GOTO n

where n represents a statement number. When the logic of the program reaches the GOTO statement, the statement(s) immediately following will not be executed; instead execution is transferred to the statement beginning with the line number indicated.

The following program never ends; it does a READ, prints something, and jumps back to the READ via a GOTO statement. It attempts to do this over and over until it runs out of data, which is sometimes an acceptable, though not advisable, way to end a program.

```
10 REM - PROGRAM ENDING WITH ERROR
11 REM - MESSAGE WHEN OUT OF DATA
2\emptyset READ X
25 PRINT "X='"X,"X+2="X!2
30 GO TO 20
35 DATA 1,5,10,15,20,25
40 END
```

```
RUN
X= 1 X!2=1
X=5 X+2=25
x=10 }x+2=10
x=15 x+2= 225
X=20 }x+2=40
x=25 X+2=625
DATA ERROR AT LINE 20
```

CONDITIONAL TRANSFER-IF-THEN AND IF-GOTO
If a program requires that two values be compared at some point, control of program execution may be directed to different procedures depending upon the result of the comparison. In computing, values are logically tested to see whether they are equal, greater than, less than another value, or possibly a combination of the three. This is accomplished by use of the relational operators discussed earlier.

IF-THEN and IF-GOTO statements allow the programmer to test the relationship between two formulas (variables, numbers, or expressions). Providing the relationship described in the IF statement is true at the point it is tested, control will transfer to the line number specified, or perform the indicated operation. The statements are of the form:
(line number) IF v1 <relation> v2 $\left\{\begin{array}{l}\text { GOTO } \\ \text { THEN }\end{array}\right\} x$ or expression
where v 1 and v 2 represent variable names or expressions, x represents a line number, and expression represents an operation to be performed. The use of either THEN or GOTO is acceptable.

The following two examples are equivalent (the value of the variable $A$ is changed or remains the same depending upon A's relation to B ) :

```
10日 IF A>B THEN 12Ø
110 A=ATB-1
120 C=A/D
10\emptyset IF A<=B THEN A}=A+B-
110 C=A/D
```

## Subroutines

## GOSUB AND RETURN

A subroutine is a section of code performing some operation that is required at more than one point in the program. Often a
complicated I/O operation for a volume of data, a mathematical evaluation which is too complex for a user-defined function, or any number of other processes may best be performed in a subroutine.

Subroutines are generally placed physically at the end of a program, usually before DATA statements, if any, and always before the END statement. Two statements are used exclusively in BASIC to handle subroutines; these are the GOSUB and RETURN statements.

A program begins execution and continues until it encounters a GOSUB statement of the form:

## (line number) GOSUB x

where x represents the first line number of the subroutine. Control then transfers to that line. For example:

50 GOSUR 20の

When program execution reaches line 50 , control transfers to line 200; the subroutine is processed until execution encounters a RETURN statement of the form:

## (line number) RETURN

which causes control to return to the statement following the GOSUB statement. Before transferring to the subroutine, BASIC internally records the next statement to be processed after the GOSUB statement; thus the RETURN statement is a signal to transfer control to this statement. In this way, no matter how many different subroutines are called, or how many times they are used, BASIC always knows where to go next.

The following program demonstrates a simple subroutine:

```
1 REM - THIS PROGRAM ILLUSTRATES GOSUB AND RETURN
10 DEF FNA(X)=ABS(INT(X))
20 INPUT A,B,C
3\emptyset GOSUB 10\emptyset
40 LET A=FNA (A)
50 LET B=FNA (B)
60 LET C=FNA(C)
7 0 ~ P R I N T
8\emptyset GOSUB 10\emptyset
90 STOP
1\emptyset\emptyset REM - THIS SUBROUTINE PRINTS OUT THE SOLUTIONS
110 REM - OF THE EQUATION: A(X+2) + B(X) + C = \emptyset
120 PRINT "THE EQUATION IS "A"*X'2 + "B"*X + "C
13\emptyset LET D=B*B-4*A*C
14\emptyset IF D<>者 THEN 17\emptyset
150 PRINT "ONLY. ONE SOLUTION... X ="-B/(2*A)
160 RETURN
170 IF D<\emptyset THEN 20\emptyset.
180 PRINT "TWO SOLUTIONS... X =";
185 PRINT (-B+SQR(D))/(2*A)"AND X =''(-B-SQR(D))/(2*A)
190 RETURN
2\emptyset\emptyset PRINT "IMAGINARY SOLUTIONS... X = ('';
205 PRINT - B/(2*A)','SQR(-D)/(2*A)'') AND ('';
207 PRINT - B/(2*A)'",'-SQR(-D)/(2*A)"')"
210 RETURN
900 END
```

RUN
?1,.5,-. 5
THE EQUATION IS 1 *Xi2 + . 5 *X + -. 5
TWO SOLUTIONS... $X=.5$ AÑD $X=-1$
THE EQUATION IS $1 * X+2+\theta * X+1$
IMAG INARY SOLUTIONS... $X=(\varnothing, 1)$ AND. $(\varnothing,-1)$
READY.

Line 100 begins the subroutine. There are several places in which control may return to the main program, depending upon a certain. condition being satisfied. The subroutine is executed from line 30 and again from line 80 . When control returns to line 90 , the program encounters the STOP statement and execution is terminated.

It is important to remember that subroutines should generally be kept distinct from the main program. The last statement in the main program should be a STOP or GOTO statement, and subroutines are normally placed following this statement.

More than one subroutine may be used in a single program, in which case these can be placed one after another at the end of the program (in line number sequence). A useful practice is to assign distinctive line numbers to subroutines. For example, if the main program is numbered with line numbers up to 199,200 and 300 could be used as the first numbers of two subroutines.

## Nesting Subroutines

Nesting of subroutines occurs when one subroutine calls another subroutine. If a RETURN statement is encountered during execution of a subroutine, control returns to the statement following the GOSUB which called it. From this point, it is possible to transfer to the beginning or any part of a subroutine, even back to the calling subroutine. Multiple entry points and RETURN statements make subroutines more versatile.

The maximum level of GOSUB nesting is about thirty-three (33) levels, which should prove more than adequate for all normal uses. Exceeding this limit will result in the message:

GOSUB ERROR AT LINE XXXX
where XXXX represents the line number where the error occurred. An example of GOSUB nesting follows (execution has been stopped by typing a CTRL/C, as the program would otherwise continue in an infinite loop; see Stopping a Run.)

```
10 REM FACTORIAL PROGRAM USING GOSUB TO
15 REM RECURSIVELY GOMPUTE THE FACTORS
4 0 ~ I N P U T ~ N ~
50 IF N>2\emptyset THEN 120
60 X=1
70 K=1
80 GOSUB 20\emptyset
90 PRINT 'FACTORIAL'N'" ='X
110 GO TO 40
120 PRINT 'MUST BE 2\emptyset OR LESS''
130 GO TO 40
200 X=X*K
210 K=K+1
220 IF K<=N THEN GOSUB 20.0
230 RETURN
240 END
```

```
RUN
?2
FACTORIAL 2 = 2
?4
FACTORIAL 4 = 24
?5
FACTORIAL 5 = 120
?
STOP.
READY.
```

## Functions

BASIC performs several mathematical calculations for the programmer, eliminating the need for tables of trig functions, square roots, and logarithms. These functions have a three letter call name, followed by an argument, $x$, which can be a number, variable, expression, or another function. Table 1 lists the functions available in 8 K BASIC. Most are self-explanatory; those that are not and are provided in greater detail are marked with asterisks.

Table 1 8K BASIC Functions

| Function | Meaning |
| :--- | :---: |
| $\operatorname{SIN}(x)$ | Sine of $x(x$ is expressed in radians $)$ |
| $\operatorname{COS}(x)$ | Cosine of $x(x$ is expressed in radians) |
|  | 34 |

Table 1 8K BASIC Functions (Cont.)

| Function | Meaning |
| :---: | :---: |
| TAN(x) | Tangent of $x$ ( $x$ is expressed in radians) |
| ATN(x) | Arctangent of $x$ (result is expressed in radians) |
| EXP(x) | $e^{x}(\mathrm{e}=2.718282)$ |
| LOG(x) | Natural $\log$ of $x\left(\log _{e} x\right)$ |
| *SGN(x) | Sign of $x$-assign a value of +1 if $x$ is positive, 0 if $x$ is zero, or -1 if $x$ is negative |
| *INT ( x ) | Integer value of $x$ |
| $\operatorname{ABS}(\mathrm{x})$ | Absolute value of $\mathrm{x}(\|\mathbf{x}\|)$ |
| SQR (x) | Square root of $x(\sqrt{x})$ |
| *RND ( x ) | Random number |
| *TAB (x) | Print next character at space x |
| *GET(x) | Get a character from input device |
| *PUT(x) | Put a character on output device |
| *FNA(x) | User-defined function |
| * UUF(x) | User-coded function (machine language code) |

## SIGN FUNCTION—SGN(X)

The sign function returns the value +1 if $x$ is a positive value, 0 if x is zero, and -1 if x is negative. For example, $\operatorname{SGN}(3.42)=1$, $\operatorname{SGN}(-42)=-1$, and $\operatorname{SGN}(23-23)=0$. The following example in which X is assigned the sign of y illustrates the use of this function:

```
25 }\textrm{x}=\textrm{SQR}(\textrm{A}+2+2*BC)*\operatorname{SGN}(A
```

INTEGER FUNCTION-INT(X)
The integer function returns the value of the nearest integer not greater than x . For example, $\operatorname{INT}(34.67)=34$. By specifying

INT ( $x+.5$ ) the INT function can be used to round numbers to the nearest integer; thus, $\operatorname{INT}(34.67+.5)=35$. INT can also be used to round numbers to any given decimal place by specifying:

$$
\text { INT }\left(x^{*} 10 \uparrow \mathrm{D}+.5\right) / 10 \uparrow \mathrm{D}
$$

where D is the number of decimal places desired. The following program illustrates this function; execution has been stopped by typing a CTRL/C:

```
1| REM - INT FUNCTION EXAMPLE
2\emptyset PRINT 'NUMBER TO BE ROUNDED';
30 INPUT A
40 PRINT 'NO. OF DECIMAL PLACES'';
50 INPUT D
60 LET B=INT(A*10tD+.5)/10\uparrowD
7\emptyset PRINT "A ROUNDED = ''B
80 GO TO 20
90 END
```

```
RUN
NUMBER TO BE ROUNDED?55.65342
NO. OF DECIMAL PLACES?2
A ROUNDED = 55.65
NUMBER TO BE ROUNDED?78.375
NO. OF DECIMAL PLACES?-2
A ROUNDED = 1Ø\emptyset
NUMBER TO BE ROUNDED?67.89
NO. OF DECIMAL PLACES?-1
A ROUNDED = 7\emptyset
NUMBER TO BE ROUNDED?
STOP.
READY.
```

If the argument is a negative number, the value returned is the largest negative integer (rounded to the higher value) contained in the number. For example, INT $(-23)=-23$ but INT $(-14.39)=-15$.

## RANDOM NUMBER FUNCTION—RND(X)

The random number function produces a random number between 0 and 1. The numbers are not reproducible, a fact the programmer should keep in mind when debugging or checking his
program. The argument $x$ in the $\operatorname{RND}(\mathrm{x})$ function call can be any number, as that value is ignored. The following program illustrates the use of this function to generate a table of random numbers:

```
10 REM - RANDOM NUMBER EXAMPLE
25 PRINT "RANDOM NUMBERS'"
30 FOR I= 1 TO 30
4 0 ~ P R I N T ~ R N D ( 0 ) ,
5 0 ~ N E X T ~ I ~
60 END
```

RUN
RANDOM NUMBERS
.9547609 . 2890875 . 1416765 . 2482717 . 45417
$.05280478 \quad .3859534 \quad .8404774$. 8514056
$.9848808 \quad .2466345 \quad .61588 \quad .4755698$. 3104984
.5828625 . 7026891 . 9703719 . 2548929298
$.04672124 \quad .9868434 \quad .5005693 \quad .1218251 \quad .2258269$
-2585353 . 5187701 .7858024 .04588368 .2030807
READY.

It is possible to generate random numbers over any range by using the following formula:

$$
(\mathrm{B}-\mathrm{A}) * \mathrm{RND}(0)+\mathrm{A}
$$

This produces a random number ( n ) in the range $\mathrm{A}<\mathrm{n}<\mathrm{B}$.
In order to obtain random integer digits in the range $0<=n<9$, line 40 in the previous example is changed to read:

```
4の PRINT INT(9*RND(0)),
```

When the program is run again, the results will look as follows:

| RANDOM NUMBERS |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| 8 | 8 | 3 | 0 | 0 |
| 3 | 0 | 1 | 0 | 4 |
| 8 | 3 | 1 | 4 | 6 |
| 2 | 2 | 0 | 6 | 5 |
| 7 | 6 | 7 | 7 | 6 |
| 2 | 0 | 2 | 8 | 6 |
| READY. |  |  |  |  |

Notice that the range has changed to $0<=\mathrm{n}<9$. This is because the INT function returns the value of the nearest integer not greater than n .
TAB FUNCTION
The TAB function allows the user to position the printing of characters anywhere on the Teletype (or line printer) line. Print
positions can be thought of as being numbered from 1 to 72 across the Teletype from left to right. (For printing devices with long lines, the number of positions may be as large as 255 , but it is unlikely that more than 160 spaces will be required for most printers.) The form of this function is:

## TAB (n)

where the argument n represents the position (from 1 to the total number of spaces available) in which the next character will be typed.

Each time the TAB function is used, positions are counted from the beginning of the line, not from the current position of the printing head. For example, $\mathrm{TAB}(3)$ causes the character to be printed at position 3 ; the following statement:

```
10 PRINT ''X ='';TAB(3);'/'';3.14159
```

will print the slash on top of the equal sign, as shown below:
$x \neq 3.14159$
READY.

The following is an example of the sort of graph that can be drawn with BASIC using the TAB function:

```
3\emptyset FOR X=\emptyset TO 15 STEP . 5
4\emptyset PRINT TAB(30+15*S IN (X)*EXP (-.1*X));'**'
50 NEXT X
60 END
```

RUN

READY•

## PUT AND GET FUNCTIONS

8K BASIC provides two additional functions, PUT and GET, to increase input/output flexibility. Using these statements, the programmer can "PUT" an ASCII character on the current output device, or "GET" a character from the current input device. GET is of the form:

GET (x)
where the argument x is a dummy variable which may be any value. GET (x) will be assigned the decimal value of the ASCII code of the next character input on the current input device.

For example, if the following statement appears in a program:

19 LET L=GET $(X)$
and the next character input is an $M$, the variable $L$ will be assigned the value $77_{(10)}$.

PUT is of the form:

## PUT (x)

where the argument $x$ represents the decimal value of the ASCII code of the character to be output. For example, the statement:

```
15 L=PUT(GET(V))
```

will wait for a character to be read from the current input device and then print it on the current output device. A statement such as:

```
3\emptyset PRINT PUT(Q)
```

will print the character typed as well as the decimal value of the ASCII code for that character. To get 10 characters from a paper tape and print them on the line printer, a suitable program is:

```
100 LPT
110 PTR
12\emptyset FOR A=1 TO 10
130 LET B=PUT(GET(0))
140 NEXT A
150 END
```

The GET(0) will contain the most recently obtained character which is then "PUT" to the line printer. The user should be careful to position the tape on the first character to be input. Otherwise
blank tape may be entered, resulting in spaces being printed as output.

The PUT statement can also be used to format output. For example, to print a trig table on the line printer with a heading and 50 data lines per page, the line feed character $\left(12_{(110)}\right)$ can be "PUT" to the printer as follows:

```
1Ø0 LPT
110 GOSUB 1000
120 GOSUB 500
125 REM - SET UP TRIG TABLE
130 FOR J=0 TO 360 STEP . 5
140 LET L=L+1
150 LET B=J/180*3.14
160 PRINT J,SIN(B),COS(B),TAN(B),ATN(B)
165 REM - PRINT 50 ENTRIES IN TABLE
17\emptyset IF L=5\emptyset THEN GOSUB 50\emptyset
180 NEXT J
190 GOSUB 1000
200 GOSUB 1000
210 STOP
500 REM PRINT HEADER
505 GOSUB 1000
510 PRINT
520 PRINT
530 PRINT "'ANGLE","SINE'","COSINE","'TANGENT'',"ARCTANGENT"
540 PRINT
550 RETURN
1000 REM PRINT FORM FEEDS TO ADUANCE PAPER
1005 X=PUT(12)
1010 L=0
1020 RETURN
1030 END
```

The beginning of the line printer output from this program follows. The first page of the table continues through an angle of 24.5 degrees: then the header and the next 50 entries are printed on the next page, and so on until the values have been output for all angles through 360 degrees (in steps of .5).

| ANGLE | SINE | cosine | tangent | ARCTANGENT |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 0 | 1 | 0 | $\theta$ |

| 24.5 | .414496 | .9100512 | .4554645 | .4038923 |

The GET statement cannot be used to get binary characters.

## FNA FUNCTION

In some programs it may be necessary to execute the same mathematical formula in several different places. 8K BASIC allows the programmer to define his own function in the BASIC language and then call this function in the same manner as the square root or a trig function is called. Only one such userdefined function may be included per program. The function is defined once at the beginning of the program before its first use, and consists of a DEF statement in combination with a threeletter function name, the first two letters of which must be FN. The format of the defining statement is as follows:

$$
\text { (line number) DEF FNA }(x)=\text { formula }(x)
$$

A may be any letter. The argument (x) has no significance; it is strictly a dummy variable, but must be the same on each side of the equal sign. The function itself can be defined in terms of numbers, several variables, other functions, or mathematical expressions. For example:

```
1\emptyset DEF FNA(X)=Xt2+3*X+4
```

The function:
$10 \operatorname{DEF} \operatorname{FNA}(S)=S \uparrow 2$
will cause the later statement:
$2 \emptyset$ LET R=FNA (4) + 1
to be evaluated as $\mathrm{R}=17$.
The user-defined function can be a function of only one variable.

## USER-DEFINED FUNCTION-UUF

A special user-coded function is available for the programmer who wishes to define an additional 8 K BASIC function permanently or one which cannot be defined with one BASIC expression, as an FNA function must be. The UUF function routine is coded in PDP-8 assembly language, assembled with one of the available assemblers, and loaded as an overlay to 8 K BASIC. While 8 K BASIC is running, the special function can be used in a fashion analogous to the regular 8 K BASIC functions. The usercoded function, if present, is referenced in the BASIC program as:

## UUF(n)

where n can be any BASIC expression.
The programmer who defines the UUF function should be familiar with the information on assembly language programming which is in Introduction to Programming 1972 chapters 1-5, and the material on the Floating Point Package, chapter 8. He should also be familiar with the information on the assembler he intends to use by reading the appropriate manual.

## Coding Formats

8K BASIC uses a floating point package which has been modified to allow 27-bit, sign-magnitude mantissa floating point. In sign-magnitude convention the sign bit, rather than the mantissa, expresses the sign of the entire number. This format is described more fully below. All coding must be compatible with this format. The floating point instructions are discussed later in this manual.

Upon entrance to the UUF subroutine the value of the argument is in the FAC (floating accumulator). The value which is calculated for the function must be in the FAC in normalized form on exit.

When floating point statements are to be included in the program, the start of a series of floating point instructions must be indicated by the instruction:

## FENTER

immediately before the first floating point instructions. Each series of floating point instructions is terminated by the instruction:

## FEXIT

immediately after the last floating point statement. There can be as many sections of floating point code as necessary in the program, but each must be delimited in this manner.

## Floating-Point Format

The floating-point format used by 8 K BASIC allocates three storage words to each number as follows:

The FAC occupies five locations on page 0 :

| Location Name | Location Number | Contents |
| :---: | :---: | :---: |
| ACS | 0024 | Sign |
| ACE | 0025 | Exponent ( $200{ }_{8}$ biased) |
| AC1 | 0020 | High-order word |
| AC2 | 0017 | Mid-order word |
| AC3 | 0016 | Low-order word |

The constant $200_{8}$ is added to the exponent to make its range 0 to 377.

All of BASIC's mathematical operations are in floating point format. Therefore, if any temporary storage locations are to be used, they will require three words, for example:

## Addressing

The floating point package uses only relative addressing. Therefore all statements that require an address specification must include one of the operators FWD or BKWD plus a reference to the current location. Such a reference is generally of the form:

```
    instruction+FWD+LTEMP-.
Or
    sogectidda -nsf...d.
    instruction+BKWD+.-LTEMP
```

where LTEMP is the first of the three locations containing the number to be used. The operator FWD is used when the address of the location to be referenced is numerically greater than the address of the instruction; BKWD is used when the address of the location to be referenced is numerically less than the address of the instruction. The floating point interpreter uses the number of locations between the instruction and the data to locate the data. The location referenced must be within $200_{8}$ locations of the instruction.

The following two examples cause the contents of LTEMP to be added to the contents of the FAC, and the result left in the FAC:

```
00200 4210
FAD+FWD+LTEMP-.
•
002100000 LTEMP 0
002110000 0
00212 0000
or
\begin{tabular}{ll}
002000000 LTEMP & 0 \\
002010000 & 0 \\
002020000 & 0 \\
\(\cdot\) & \\
0. & \\
0.104610 & \(F A D+B K N D+.-L T E M P\)
\end{tabular}
```

## Floating-Point Instruction Set

The legal instructions in the modified Floating-Point Package used by 8 K BASIC are explained in Table 2 :

Table 2 Floating-Point Instructions

| Instruction | Value | Meaning |
| :---: | :---: | :---: |
| FST | 2000 | Store the contents of the floating accumulator (FAC). The contents of the FAC are not changed. |
| FLD | 3000 | Load FAC with contents of relative address. |
| FAD | 4000 | Add contents of relative address to FAC. |
| FSB | 5000 | Subtract contents of relative address from FAC. |
| FMP | 6000 | Multiply the contents of the FAC by the contents of the relative address. |
| FDV | 7000 | Divide FAC by contents of relative address. |
| FJMP | 1000 | Floating-point jump to relative address. |
| FENTER | 4435 | Start floating-point code. |
| FEXIT | 0000 | Exit floating-point code. Return to PDP-8 code. |
| FWD | 0200 | Access a relative location in the forward direction. |
| BKWD | 0600 | Access a relative location in the backward direction. |
| FSNE | 0040 | Skip if FAC $\neq 0$ |
| FSEQ | 0050 | Skip if FAC $=0$ |
| FSGE | 0100 | Skip if FAC $\geqslant 0$ |
| FSLT | 0110 | Skip if FAC $<0$ |
| FSGT | 0140 | Skip if FAC $>0$ |
| FSLE | 0150 | Skip if FAC $\leqslant 0$ |

The following list contains floating-point instructions for indirect relative addressing. The indirect addressing is similar to the I construction used in regular PDP-8 assembly language coding.

Floating-Point Instructions (Indirect Relative Addressing)

| Instruction | Value | Operation |
| :---: | :---: | :---: |
| FSTI | 2400 | Store |
| FLDI | 3400 | Load |
| FADI | 4400 | Add |
| FSBI | 5400 | Subtract |
| FMPI | 6400 | Multiply |
| FDVI | 7400 | Divide |
| FJMPI | 1400 | Jump |

## Writing the Program

UUF must be made a defined function for 8 K BASIC. This is done by inserting the starting address of the UUF subroutine in BASIC's table of subroutine addresses. The subroutine address must be placed in location 1156 of field 0 . If UUF is the first location of the subroutine, the following code is sufficient:
*1156

## UUF

The UUF subroutine may be placed in the area of core normally occupied by the RIM and BIN loaders, location 7600-7777 of field 0 . To do this, the loaders are placed in field 1. The loading instructions for UUF are contained in the section called Loading and Operating Procedures.

If mass storage devices are in use, they may destroy the data break locations on the last page of field 0. If TC08 DECtape is used, locations 7752 and 7753 must be reserved. If an RF08 or DF32 disk is used, locations 7750 and 7751 must be reserved.

There are three subroutines in 8 K BASIC which are available to maintain a floating-point format acceptable to the modified floating-point package in 8 K BASIC. These subroutines are described below. The listing of 8 K BASIC is available from the Software Distribution Center for the programmer who wishes to call other subroutines in the compiler.

BEGFIX If a value is to be returned to the FAC as a result of the UUF function, that value must be in normalized floating point format in the FAC on exit from the subroutine. If floating point arithmetic is used throughout the user function, then the value in the FAC is in normalized floating point format and need not be converted. If fixed point arithmetic (single word) is used anywhere in the function, then the subroutine BEGFIX must be called to initialize the FAC before the fixed point number is placed in the FAC and subsequently converted to floating point (see ANORM below). After BEGFIX is called, the 12-bit number is stored by a simple DCA AC3 instruction and then ANORM is called. BEGFIX is located at 3762 and is called with a JMS instruction; on return from BEGFIX the AC is clear.

ANORM If a fixed point value is placed in the FAC, ANORM may be called to normalize the FAC. After the fixed point value has been placed in AC3, ANORM may be called to supply the acceptable values for ACE, ACS, AC1, and AC2. ANORM is located at 4600; on return, the AC is clear.

FIX When the value in the FAC must be made into an integer, FIX may be called to perfom that job. The 12-bit value of the FAC is left in AC3 and that value plus 1 is left in the AC. FIX is located at 4744.

## Examples

The following examples illustrate the method of writing and calling a UUF routine.

Example 1:
This UUF routine is an example of a fixed point calculation. The value of $\operatorname{UUF}(\mathrm{X})$ is $3 \mathrm{X}+2$.
$\operatorname{IUUF}(x)=3 x+2$

The following BASIC program uses the above UUF to produce a table of squares and square roots:

READY.

READY.

## EDITING AND CONTROL COMMANDS

Errors made while typing at the console keyboard are easily corrected. BASIC provides special commands to facilitate the editing procedure.

## Erasing Characters and Lines

## SHIFT/O, RUBOUTS, NO RUBOUTS

There are two methods available for erasing a character or series of characters one at a time. Typing a SHIFT/O causes the deletion of the last character typed, and echoes as a back arrow $(\leftarrow)$ on the Teletype. One character is deleted each time the key is typed.

The RUBOUT key may also be used for deletion of characters one at a time providing the command:

RUBOUTS
has been typed on the keyboard before the editing is done. This command enables the RUBOUT key to be used. If the user has neglected to type this command, he may not use the RUBOUT key. A later command of:

```
NO RUBOUTS
```

disables the key for use. (This is desirable when programs created on other systems which use rubouts as null characters are to be read into core. See the section entitled PTP AND LPT under Listing and Punching a Program.) For example:

```
10 LER-T A=10*B
```

The user types a B instead of T and immediately notices the mistake. He may type SHIFT/O (or RUBOUT key, if enabled) once to delete the B , and as many times more as characters, including spaces, are to be deleted. After the correction is made, he may continue typing the line. The typed line enters the computer only when the RETURN key is pressed. Before that time any number of corrections can be made to the line.

When the RETURN key is typed, the line is input as:
$2 \varnothing$ DEF $\operatorname{FNA}(X, Y)=X \uparrow 2+3 * Y$
Notice that spaces, as well as printing characters, may be erased.
The user may erase an entire line (provided the RETURN key has not been typed) by typing the ALTMODE key (ESCAPE key on some keyboards). BASIC echos back:

DELETED
at the end of the line to indicate that the line has been removed. The user continues as though it were a new line. If the RETURN key has already been typed, the user may still correct the line by simply typing the line number and retyping the line correctly. He may delete the line by typing the RETURN key immediately after the line number, thus removing both the line number and line from his program.

If the line number of a line not needing correction is accidentally typed, the SHIFT/O or RUBOUT key may be used to delete the number( $s$ ); the user may then type in the correct numbers. Assume the line:

10 IF A>5 GO TO 230
is correct. The programmer intends to insert a line 15 , but instead types:

10 LET

He notices the mistake and makes the correction as follows:
10 LET…… 5 LET $\mathrm{X}=\mathrm{X}-3$

Line 10 remains unchanged, and line 15 is entered.
Following an attempt to run a program, error messages may be
output on the Teletype indicating illegal characters or formats, or other user errors in the program. Most errors can be corrected by typing the line number(s) and the correction(s) and then rerunning the program. As many changes or corrections as desired may be made before runs.

## Listing and Punching a Program

LIST
An indirect program or data can be listed on the active output device by typing the command:

## LIST

followed by the RETURN key. The entire program (or data) will be listed.

A part of a program may be listed by typing LIST followed by a line number. This causes that line and all following lines in the program to be listed. For example:

LIST $10 \emptyset$
will list line 100 and all remaining lines in the program.

## PTP AND LPT

The LIST command may be issued in conjunction with the LPT or PTP commands as follows:

```
PTP LPT
LIST LIST
```

This will list the current program on the high-speed paper tape punch or line printer respectively. Control is reset to the Teletype after the listing is completed.

Occasionally, when 8 K BASIC is reading in a program from the low-speed reader, it may drop a character since the Teletype buffer cannot accept input at a prolonged fast rate. To eliminate this possibility, use LIST as follows when punching out paper tapes:

## PTP

LIST*

This inserts null characters after carriage returns and is recommended when punching any tapes that will later be read in from the low-speed paper tape reader. ( 8 K BASIC does not use rubouts as null characters.)

## Reading a Program <br> PTR

The PTR command can be issued to read in a paper tape from the high-speed reader. This mode is particularly useful for reading in a user-coded "load and go" BASIC program. The tape should be positioned in the reader before the command is issued; if not, or if the reader runs out of tape, BASIC prints:

TTY
on the Teletype to indicate that there is no more input from the high-speed reader, and that it is waiting for input from the Teletype.

The user may cause tapes to be read in from the low-speed reader by simply placing the tape over the sprocket wheel and setting the reader to START.

## Running a Program

RUN
After a BASIC program has been typed and is in core, it is ready to be run. This is accomplished by simply typing the command:
followed by the RETURN key. The program will begin execution. If errors are encountered, appropriate error messages will be typed on the keyboard; otherwise, the program will run to completion, printing whatever output was requested. When the END statement is reached, BASIC stops execution and prints:

READY.

## PTP AND LPT

Either the high-speed paper tape punch or LP08 line printer, if available, can be used in conjunction with the RUN command. After the command is issued, all output during program execution is diverted from the Teletype to the specified device. The command sequence is:

| PTP | LPT |
| :--- | :--- |
| RUN | RUN |

This procedure eliminates the need to insert the PTP (or LPT) statement within the program. Output returns to the Teletype after execution.

## Stopping a Run

CTRL/C
To stop a program during execution or to return to BASIC at any time, type a CTRL/C (accomplished by typing the CTRL key and the C simultaneously). This causes the current operation to be aborted immediately, and the message:

STOP.
READY.
to be printed indicating that an 8K BASIC command can now be issued.

CTRL/O
The command CTRL/O (caused by typing the CTRL and O keys down simultaneously) is used to stop output temporarily. The program will continue to execute but output will not be printed on any output device unless an error occurs or unless BASIC is waiting for a command or for data from an input statement. In the latter case, the Teletype is the expected input device. This feature is particularly useful for programs that print lengthy introductions and then request a user-specified parameter. Typing CTRL/O after the program is started will cause BASIC to bypass printing the introduction and wait until the parameter is specified, thereby saving the time required to print the message. A second CTRL/O will resume output.

## NOTE

For most programs that do not wait for input from the Teletype, processing of the program after an initial CTRL/O will be completed before a second CTRL/O can be typed. Thus, it is very possible for no output to be printed rather than the anticipated partial output.

## Erasing a Program in Core SCR

The command:
SCRATCH
or
SCR
is provided to allow the programmer to clear his storage area, deleting any commands, or a program which may have been previously entered, and leaving a clean area in which to work. If the storage area is not cleared before entering a new program, lines from previous programs may be executed along with the new program, causing errors or misinformation. The SCRATCH command eliminates all old statements and numbers and should be used before any tapes are read into core, or new programs created.

## LOADING AND OPERATING PROCEDURES

## BASIC Compiler

The following procedure may be used to load in the 8 K BASIC binary tape.

1. Toggle the RIM Loader into field 0 and, using the appropriate reader, read the Binary Loader into field 0. (Refer to Appendix A for details.) 8K BASIC will not use locations 7600 to 7777, thereby preserving the Binary Loader if it is present.
2. Place the 8 K BASIC binary tape in the appropriate reader; set switches $6-8=0$, and $9-11=0$; press EXTD ADDRess LOAD.
3. Set the Switch Register $=7777$ and press ADDRess LOAD.
4. If using high-speed reader, set the Switch Register = 3777 and press CLEAR and CONTinue; otherwise, simply press CLEAR and CONTinue.
5. After the tape has read in, set the Switch Register $=1000$.
6. Press ADDRess LOAD, and CLEAR and CONTinue. BASIC responds by typing READY.
7. BASIC programs on paper tapes may be read in using the PTR command explained earlier, or created on-line.

## User-Defined Function

The following procedure may be used to load in a user-defined function.

1. Load the Binary Loader into field 1.
2. Load BASIC into field 0 .
3. Load the user-function (binary paper tape overlay) into field 0 with BIN leaLes.
4. Set Switch Register $=1000$; press ADDRess LOAD and START.

Note that the Binary Loader is destroyed. To reload BASIC, steps 1 through 6 must be repeated.

## 8K BASIC ERROR MESSAGES

The computer checks all commands before executing them. If for some reason it cannot execute the command, it indicates this by typing one of the error messages. The number of the line in which the error was found is also typed out. The form is:

ERROR MESSAGE AT LINE XXXX
Table 3 lists the errors 8 K BASIC checks for and reports before execution:

Table 3 8K BASIC Error Messages

| Message | Meaning |
| :--- | :--- |
| ARGUMENT ERROR | A function has been given an illegal argument; <br> for example: |
|  | SQR(-1) |
| DATA ERROR | There are no more items in the data list. <br> FOR ERROR |
| FOR loops are nested too deeply. |  |

| FUNCTION ERROR | The user has attempted to call a function which <br> has not been defined. |
| :--- | :--- |
| GOSUB ERROR | Subroutines are nested too deeply. <br> LINE NO ERROR |
| A GOTO, GOSUB, or IF references a non- |  |
| existent line. |  |
| FOR and NEXT statements are not properly |  |
| paired. |  |
| RETURN statement issued when not under |  |
| control of a GOSUB. |  |

The following programming errors are not reported by 8 K BASIC, but instead are used in the computation as specified. They are included here for the programmer's reference.

1. Attempting to use a number in a computation which is too large for BASIC to handle will produce a result which is meaningless.
2. Attempting to use a number in a computation which is too small for BASIC to handle will result in the value zero being used instead.
3. Attempting to divide by zero will produce a result which is meaningless.

## BASIC SYMBOL TABLE

Table 4 lists 8 K BASIC's symbols and their values. This information is useful when writing user-coded (machine language) functions.

Table 4 8K BASIC Symbol Table

## STATEMENT AND COMMAND SUMMARIES

Summaries of the editing and program control commands available in 8 K BASIC are presented below.

## Edit and Control Commands

| Command | Abbreviation | Action |
| :---: | :---: | :---: |
| CTRL/C |  | Stops a running program, and returns to the editing phase of BASIC. |
| CTRL/O |  | Stops output of a running BASIC program. Remains in this state until BASIC requests INPUT, an error occurs, or until another CTRL/O is typed. |
| LIST | LIS | Lists the entire program in core. |
|  | LIS n | Lists line $n$ through end of program. |
| NO RUBOUTS |  | Disables the RUBOUT key. |
| RUBOUTS |  | Enables the RUBOUT key. |
| RUN | RUN | Compiles and runs the program currently in core. |
| SCRATCH | SCR | Erases the current program from core. |

## BASIC Statements

| Statement | Example of Form |
| :---: | :---: |
| DATA | DATA n1, n2, . . . nn |
| DEF | $\begin{aligned} & \text { DEF FNB }(x)= \\ & \text { f(x) } \\ & \operatorname{DEF} \text { FNB }(x, y) \\ & =f(x, y) \end{aligned}$ |

$\left.\begin{array}{lll}\text { Statement } & \begin{array}{l}\text { Example of Form } \\ \text { DIM }\end{array} & \begin{array}{l}\text { DIM v(s) } \\ \text { Enables the user to create a table }\end{array} \\ \text { or array with the specified number } \\ \text { of elements where vis the variable } \\ \text { name and } s \\ \text { script value. Any number of ar- } \\ \text { rays can be dimensioned in a }\end{array}\right\}$

| Statement | Example of Form | Explanation |
| :---: | :---: | :---: |
| PRINT | $\begin{aligned} & \text { PRINT a1, a2, } \\ & \ldots . \text { an } \end{aligned}$ | Prints the values of the specified arguments, which may be variables, text or format control characters (, or ;). |
| PTP | PTP | Assigns high-speed paper tape punch as output device. |
| PTR | PTR | Assigns high-speed paper tape reader as input device. |
| READ | $\begin{aligned} & \text { READ v1, v2, } \\ & \ldots . \mathrm{v}^{2} \end{aligned}$ | Variables v1 through vn are assigned the value of the corresponding numbers in the DATA string. |
| REM | REM | When typed as the first three letters of a line, allows typing of remarks within the program. |
| RESTORE | RESTORE | Sets pointer back to the beginning of the string of DATA values. |
| RETURN | RETURN | Must be at the end of each subroutine to enable control to be transferred to the statement following the last GOSUB. |
| STOP | STOP | Terminates execution at that point at which the statement is reached in the program. |
| TTY IN | TTY IN | Assigns a console terminal as input device. |
| TTY OUT | TTY OUT | Assigns a console treminal as output device. |

During input to the editor or when executing an INPUT command, the following messages may be printed in response to the input:

Message

## LINE TOO LONG

DELETED
$\leftarrow$

TTY

Explanation
The line just typed exceeded the available core buffer and must be retyped.

The line has been deleted in response to an ALTMODE character and must be retyped.
Back arrow is printed any time a RUBOUT or SHIFT/O is used. The previous character is deleted.

BASIC prints TTY to indicate that there is no more input from the high-speed reader and that it is waiting for input from the Teletype.

# appendix a loading procedures 

## Initializing the system

Before using the computer system, it is good practice to initialize all units. To initialize the system, ensure that all switches and controls are as specified below.

1. Main power cord is properly plugged in.
2. Teletype is turned OFF.
3. Low-speed punch is OFF.
4. Low-speed reader is set to FREE.
5. Computer POWER key is ON.
6. PANEL LOCK is unlocked.
7. Console switches are set to 0 .
8. SING STEP is not set.
9. High-speed punch is OFF.
10. DECtape REMOTE lamps OFF.

The system is now initialized and ready for your use.

## Loaders

READ-IN MODE (RIM) LOADER
When a computer in the PDP-8 series is first received, it is nothing more than a piece of hardware; its core memory is completely demagnetized. The computer "knows" absolutely nothing, not even how to receive input. However, the programmer can manually load data directly into core using the console switches.

The RIM Loader is the very first program loaded into the computer, and it is loaded by the programmer using the console
switches. The RIM Loader instructs the computer to receive and store, in core, data punched on paper tape in RIM coded format (RIM Loader is used to load the BIN Loader described below.)

There are two RIM loader programs: one is used when the input is to be from the low-speed paper tape reader, and the other is used when input is to be from the high-speed paper tape reader. The locations and corresponding instructions for both loaders are listed in Table A-1.

The procedure for loading (toggling) the RIM Loader into core is illustrated in Figure A-1.

Table A-1. RIM Loader Programs

|  | Instruction |  |
| :---: | :---: | :---: |
| Location | Low-Speed Reader | High-Speed Reader |
| 7756 | 6032 | 6014 |
| 7757 | 6031 | 6011 |
| 7760 | 5357 | 5357 |
| 7761 | 6036 | 6016 |
| 7762 | 7106 | 7106 |
| 7763 | 7006 | 7006 |
| 7764 | 7510 | 7510 |
| 7765 | 5357 | 5374 |
| 7766 | 7006 | 7006 |
| 7767 | 6031 | 6011 |
| 7770 | 5367 | 5367 |
| 7771 | 6034 | 6016 |
| 7772 | 7420 | 7420 |
| 7773 | 3776 | 3776 |
| 7774 | 3376 | 3376 |
| 7775 | 5356 | 5357 |
| 7776 | 0000 | 0000 |

After RIM has been loaded, it is good programming practice to verify that all instructions were stored properly. This can be done by performing the steps illustrated in Figure A-2, which also shows how to correct an incorrectly stored instruction.

When loaded, the RIM Loader occupies absolute locations 7756 through 7776.

Figure A-1. Loading the RIM Loader

Figure A-2. Checking the RIM Loader

## BINARY (BIN) LOADER-

The BIN Loader is a short utility program which, when in core, instructs the computer to read binary-coded data punched on paper tape and store it in core memory. BIN is used primarily to load the programs furnished in the software package (excluding the loaders and certain subroutines) and the programmer's binary tapes.

BIN is furnished to the programmer on punched paper tape in RIM-coded format. Therefore, RIM must be in core before BIN can be loaded. Figure A-3 illustrates the steps necessary to properly load BIN. And when loading, the input device (low- or highspeed reader) must be that which was selected when loading RIM.

Figure A-3 Loading the BIN Loader
A-5

When stored in core, BIN resides on the last page of core, occupying absolute locations 7625 through 7752 and 7777.

BIN was purposely placed on the last page of core so that it would always be available for use-the programs in DEC's software package do not use the last page of core (excluding the Disk Monitor). The programmer must be aware that if he writes a program which uses the last page of core, BIN will be wiped out when that program runs on the computer. When this happens, the programmer must load RIM and then BIN before he can load another binary tape.

Binary tapes to be loaded should be started on the leader-trailer code (Code 200), otherwise zeros may be loaded into core, destroying previous instructions.

Figure A-4 lilustrates the procedure for loading binary tapes into core.

F:gure A-4. Loading A Binary Tape Using BIN
