MODULE FUNCTION:
 This REQUIRE file contains all literal, macro, and data structure definitions used by new Bliss modules in the Debugger. Old Bliss modules do not use this file for historical reasons.

GENERAL DEBUGGER DEFINITIONS

The declarations in this section define symbols of general utility throughout the Debugger. This includes widely used literals and various utility macros.

DATA STRUCTURE DEFINITION AND ACCESS

Here we declare all the macros used to define and access BLISS data structures. These are the names L_, W_, B_, W0_, W1_, and so forth. The actual definitions are in a separate REQUIRE file, but they are required for the LIBRARY compilation of the present REQUIRE file.

LIBRARY 'LIBS:STRUCDEF.L32';

BLISS-32 LANGUAGE EXTENSIONS

Here we declare various minor extensions to the Bliss-32 language.

LITERAL

TRUE = 1, ! Define TRUE and FALSE
FALSE = 0;

MACRO

REPEAT = WHILE 1 DO%, ! Infinite Loop

! ZEROCOR zeroes an area of memory. The two parameters are ADDRESS and COUNT, which are the address of the area to be zeroed and the number of contiguous longwords to be zeroed, respectively.

ZEROCOR (ADDRESS, COUNT) =
CH\$FILL (0, (COUNT) * 4, CH\$PTR (ADDRESS))%,

ONEOF (X) [] =
(MASK (%REMAINING)) ^ (X) LSS 0%,

OR_OP (X) [] =
OR%,

MASK (X) [] =
1 ^ (31-X) OR_OP (%REMAINING) MASK (%REMAINING)%,

CH\$SEQUENCE (N) =

: 0242 0

VECTOR [CH\$ALLOCATION (N)]%,
CONSECUTIVE [X] = LITERAL X = %COUNT%;

ERROR REPORTING

The following macro is used for reporting internal DEBUG coding errors symbolically. The macro is used as follows:

```
$DBG_ERROR('MODNAME\ROUTNAME number');
```

This signals the internal DEBUG error message DBGS_INTERR which prints the text of the macro parameter. The convention is that this parameter should include the module name and the routine name of the signal location so that the point where the error was signalled can be easily determined by DEBUG developers. In addition, a number may be included in the signal text to make the text unique when there is more than one \$DBG_ERROR invocation in the same routine.

```
MACRO $DBG_ERROR (STRING) =
  SIGNAL (DBGS_INTERR, 1, UPLIT BYTE (%ASCIC STRING)
  %IF %LENGTH GTR 1
  %THEN
    %REMAINING)
  %ELSE
  )
  %FI %;
```

DEBUG OUTPUT MACROS

The following MACROS are used in several places in the debugger to do formatted ASCII output (\$FAO).

MACRO

\$FAO_STG_COUNT makes a counted byte string out of an ASCII string. This macro is useful to transform an FAO control string into the address of such a string, whose first byte contains the length of the string in bytes.

\$FAO_STG_COUNT (STRING) =
 OPLIT BYTE (%CHARCOUNT (STRING), %ASCII STRING)%.

\$FAO_TT_OUT constructs a call to FAO with a control string, and some arguments to the control string. This formatted string is then output to the output device.

\$FAO_TT_OUT (CTL_STRING) =
 DBGSFAO OUT (\$FAO_STG_COUNT (CTL_STRING)
 %IF %LENGTH GTR 1
 %THEN
 %REMAINING
 %FI
)%;

This section defines literals which are used throughout the Debugger but which do not belong with any specific data structures.

COMMAND EXECUTION TREES

This section contains the definitions for the nodes that are part of a command execution tree. A command execution tree is built when a debug command is parsed. The tree contains a verb node representing the command (e.g., EXAMINE, DEPOSIT, etc.) as the header node. Linked to the verb node are chains of adverb nodes and noun nodes. The noun node chain hangs off the OBJECT_PTR field and the adverb node chain hangs off the ADVERB_PTR field. The exact structure of the tree depends on the command.

COMMAND INPUT STREAM

The Command Input Stream (CIS) is a linked list that the debugger maintains to describe where it is currently taking input from.

The format of a Command Input Stream Descriptor is:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	Unused	SB_INPUT_TYPE	CISW_LENGTH
1	CISW_INPUT_PTR		
2	CISW_NEXT_LINK		
3	CISW_INIT_ADDR		
4	Unused	Flags	CISW_INIT_LENGTH
5	CISW_WHILE_CLAUSE		
6	CISL_FOR_UPPER_BOUND or CISL_REPEAT_COUNT		
7	CISW_FOR_LOOP_VAR		
8	CISL_FOR_LOOP_INCR		
9	CISL_SCREEN_OUTPUT		
10	CISL_SCREEN_SOURCE		
11	CISL_SCREEN_ERROR		
12	CISW_BUFLIST		
13	CISW_WHILE_LENGTH		

A pointer to a command input stream descriptor block is declared with:

CIS_PTR: REF CISLINK

Define the fields, the descriptor size, and the declaration macro.

FIELD CIS_FIELDS =

C O N T R O L F L A G S

Control flags are global DEBUG status flags used to control the overall flow of DEBUG execution. They represent the major state of DEBUG.

MACRO DBG\$CONTROL_FLAGS = BITVECTOR[];

LITERAL

DBG\$V_CONTROL_TDBG	= 0,	Set if this is a testable DEBUG
DBG\$V_CONTROL_SDBG	= 1,	Set if this is SUPERDEBUG
DBG\$V_CONTROL_KDBG	= 2,	Reserved for future development
DBG\$V_CONTROL_URUN	= 3,	Set if user program has been run to stop DEBUG allocating memory
DBG\$V_CONTROL_EXIT	= 4,	Set if DEBUG is about to EXIT
DBG\$V_CONTROL_FAIL	= 5,	Set by DEBUG internal errors
DBG\$V_CONTROL_DONE	= 6,	Set if user execution complete
DBG\$V_CONTROL_ALLOCATE	= 7,	Set if OK to allocate more memory (e.g., SET MODULE/ALLOCATE)
DBG\$V_CONTROL_USER	= 8,	Set if user program is running
DBG\$V_CONTROL_STOP	= 9,	Set by ^Y,DEBUG sequence to abort processing DEBUG command files
DBG\$V_CONTROL_TBIT	= 10,	Used by DBGEVENT and DBGSTART to control AST/TBIT interactions.
DBG\$V_CONTROL_SCREEN	= 11,	Set if screen displays must be updated because user program has run
DBG\$V_CONTROL_VERSION_4	= 12;	Set if VMS 3B or 4.0 is running

We also define a macro \$ABORT_ON_CONTROL_Y. The purpose of this macro is to allow premature termination of commands which can take a large amount of time to complete but to allow the individual command routines to make sure that they leave all DEBUGs internal data structures in a consistent state. Execution of this macro will have no effect if the Control-Y flag is clear, but will SIGNAL back to DEBUG command level if the flag is set

MACRO \$ABORT_ON_CONTROL_Y =

BEGIN

EXTERNAL DBG\$GV_CONTROL : BITVECTOR[];

IF .DBG\$GV_CONTROL[DBG\$V_CONTROL_STOP] THEN SIGNAL(DBG\$_ABORTED);

END;

DEFINE SYMBOL TABLE

The Define Symbol Table contains information about the symbols that are currently defined with the DEFINE command.

There is a doubly linked list for all globally-defined symbols. (I.e. symbols defined with DEFINE <symbol> == <definition>)
 The global variable DBG\$GL_GLOBAL_DEFINE_PTR points to this list.

For each command procedure that is active, there may also be a define list that is local to the procedure. The variable DBG\$GL_LOCAL_DEFINE_PTR points to a doubly-linked list of header blocks. Each header block points to a doubly-linked list of symbols.

Pictorially,

GLOBAL_DEFINE_PTR -> [entry] <-> [entry] <-> ...

LOCAL_DEFINE_PTR -> [header] <-> [header] <-> ...

The format of a header block is:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	DEFSA_NEXT_LINK
1	DEFSA_PREV_LINK
2	DEFSA_DEFINE_LIST

The format of an entry is:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	DEFSA_ENTRY_NEXT_LINK
1	DEFSA_ENTRY_PREV_LINK
2	DEFSA_NAME
3	DEFSA_VALUE
4	Unused
	DEFSB_KIND

Define the fields of a DEFINE entry.

FIELD DEFINE_ENTRY_FIELDS =

EVENT TABLE ENTRY FOR [BREAK:TRACE] [/RETURN] POINTS

This form of the Event Table Entry is used for ordinary and /RETURN breakpoints and tracepoints. It is thus used whenever the implementation of the eventpoint is to store a BPT instruction at the event location. This form is not used for threaded code (used only for COBOL-74), however.

EVENT TABLE ENTRY FOR /CALL, /BRANCH, /INSTRUCTION

This form of Event Table Entry is used for the SET BREAK and SET TRACE commands when the /CALL, /BRANCH, or /INSTRUCTION qualifier is present. It is thus used in all cases where instructions must be traced (T-bitted), one instruction at a time, and the event is activated when an instruction of a certain class is encountered.

EVENT DO LIST DESCRIPTOR

An Event DO List Descriptor is created for each event-point which has an associated DO-action. This descriptor points to the text of the DO-action itself and is thus what allows the DO-action to be accessed when the event-point is taken. This is the format of the Event DO List Descriptor:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	EVENT\$DO_LIST_FLINK
1	EVENT\$DO_LIST_BLINK
2	EVENT\$DO_LIST_COUNT
3	EVENT\$DO_LIST_POINT

A pointer to an Event DO List Descriptor is declared as follows:

DOPTR: REF EVENT\$DO_LIST_DESCRIPTOR

Define the fields of the Event DO List Descriptor. Also declare the descriptor size and define the declaration macro.

```

FIELD  EVENT$DO_LIST_DESCRIPTOR_FIELDS =
SET
EVENT$A_DO_LIST_DESCRIPTOR = [0,A], ! DO List Descriptor address

EVENT$L_DO_LIST_FLINK      = [0,L], ! DO queue forward
EVENT$L_DO_LIST_BLINK      = [1,L], ! and backward links

EVENT$L_DO_LIST_COUNT      = [2,L], ! DO reference count

EVENT$L_DO_LIST_POINT      = [3,L]  ! DO list pointer
TES;
```

```

LITERAL
EVENT$K_DO_LIST_DESCRIPTOR_SIZE = 4; ! Descriptor size (longwords)
```

```

MACRO
EVENT$DO_LIST_DESCRIPTOR =
BLOCK [EVENT$K_DO_LIST_DESCRIPTOR_SIZE]
FIELD (EVENT$DO_LIST_DESCRIPTOR_FIELDS) %;
```

An Event WHEN Descriptor is created each time a SET BREAK, SET TRACE, or SET WATCH statement has a WHEN clause. The Event WHEN Descriptor points to the location of the boolean WHEN-expression and allows this expression to be evaluated each time the X-point is reached. This is the format of the Event WHEN Descriptor:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1 0 9 8 7 6 5 4 3 2 1 0

0	EVENTSL_WHEN_FLINK
1	EVENTSL_WHEN_BLINK
2	EVENTSL_WHEN_COUNT
3	EVENTSL_WHEN_POINT

WHENPTR: REF EVENTSWHEN_DESCRIPTOR

Define the fields of the Event WHEN Descriptor, its size, and its declaration macro.

FIELD_EVENTS WHEN_DESCRIPTOR_FIELDS =

```

EVENTS WHEN_DESCRIPTOR = 0, ! WHEN Descriptor address
SET
EVENT$ WHEN_DESCRIPTOR = [0,A_], ! WHEN Descriptor address
EVENT$ WHEN_FLINK      = [0,L_], ! WHEN queue forward link
EVENT$ WHEN_BLINK      = [1,L_], ! WHEN queue backward link

 EVENTSB_PAGE_PROTECTION = [3,B2_] : Page old protection
 TES;

LITERAL

EVENTSK_PAGE_DESCRIPTOR_SIZE = 4; ! Descriptor size (longwords)

MACRO

EVENTSPAGE_DESCRIPTOR =
 BLOCK [EVENTSK_PAGE_DESCRIPTOR_SIZE]
 FIELD (EVENTSPAGE_DESCRIPTOR_FIELDS) %;

FREE MEMORY MANAGEMENT

The Free Memory Manager manages the Debugger's free memory pool. Its routines are thus called throughout the Debugger to allocate and de-allocate memory blocks used for RST entries, Static Address Table entries, and numerous other kinds of descriptors and records. The Free Memory Manager has two kinds of blocks in its memory pool: free blocks and allocated blocks. The formats of both kinds of blocks and the over-all structure of the memory pool is illustrated below.

FORMAT OF A FREE MEMORY BLOCK

The format of a free memory block is shown here:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1

1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Here SENT represents FMEMSB_SENTINEL, P is FMEMSV_PREVALLOC, and T is FMEMSV_THISALLOC as defined on the next page.

A free block has its length (in longwords) stored both at the beginning of the block (FMEMSV_LENGTH) and at the end (FMEMSL_PREVLEN). The minimum length of a free block is four longwords. Free blocks are chained together on a doubly linked free-list. This list has a list head which is never allocated--the list is thus never empty. The address of the free-list list head is always stored in the OWN variable DBG\$FREE_LIST.

FORMAT OF AN ALLOCATED MEMORY BLOCK

The format of an allocated block is as follows:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Here SENT represents FMEMSB_SENTINEL, P is FMEMSV_PREVALLOC, and T is FMEMSV_THISALLOC as defined below. In an allocated block, the address returned to the requestor is represented by FMEMSA_ALLOCBLK.

A pointer to a memory block (free or allocated) is declared as follows:

BLKPTR: REF FMEMSBLOCK

This declaration is used in the Free Memory Manager only.

Define the fields in the two kinds of memory blocks.

FIELD FMEM\$FLD_DEF =

```

SET
FMEMSV_LENGTH = [ 0, V_(0,22) ], ! The length of the block in longwords
FMEMSV_THISALLOC = [ 0, V_(22) ], ! Set to TRUE if this block is allocated
FMEMSV_PREVALLOC = [ 0, V_(23) ], ! Set to TRUE if the previous block is
                                   allocated (block at smaller addr)
FMEMSB_SENTINEL = [ 0, B3_ ], ! Sentinel value--always FMEM$K_SENTINEL
FMEMSL_FLINK = [ 1, L_ ], ! Forward link on free list
FMEMSL_BLINK = [ 2, L_ ], ! Backward link on free list
FMEMSL_PREVLEN = [ -1, L_ ], ! Length of this free block relative to
                                   the start of the next block
FMEMSA_ALLOCBLK = [ 1, A_ ], ! Address returned to caller requesting
                                   a new memory block
FMEMSA_HEADER = [ -1, A_ ], ! Address of block's header relative to
                                   the FMEMSA_ALLOCBLK location

```

TES;

```

: 1785 0
: 1786 0      ! Declare the sentinel value and the declaration macro.
: 1787 0      !
: 1788 0      LITERAL
: 1789 0          FMEMSK_SENTINEL = %X'B2':          ! Magic sentinel value--used for error

: 1791 0
: 1792 0      MACRO
: 1793 0          FMEM$BLOCK = BLOCK[,LONG] FIELD(FMEM$FLD_DEF) %;

```

OVERALL STRUCTURE OF MEMORY POOL

The memory pool consists of one or more memory pool areas. The first such area is initialized to have the format shown here:

3 3 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Here longword 0 contains a pointer to the next memory pool area (for this initial area the pointer is always zero) and longword 1 contains the size of this area in bytes. These two fields are present for internal error checking purposes only.

Longwords 2 - 5 contain the free-list list head. This is a free block which is always at the start of the doubly linked free list and which is never coalesced with any other free block--the code thus never has

to worry about a completely empty free list. The very last longword in the memory pool area is the header of an allocated block. It prevents any attempt to coalesce free blocks off the end of the area. The rest of the area (longword 6 to the next to last longword) is initially one big free block from which allocation can take place. Note how the P and T flags (FMEMSV_PREVALLOC and FMEMSV_THISALLOC) are set to prevent free block coalescing off either end of the memory pool area.

Additional memory pool areas may be acquired from LIB\$GET_VM during the Debugger's initialization phase. Each such area is initialized to have the same format as the first one except that the free-list list head is absent--only one is needed for the whole memory pool. The initial format of each additional memory pool area is illustrated here:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

TEMPORARY MEMORY BLOCKS

"Temporary" memory blocks are blocks which automatically are released at the end of the current command. Such blocks are allocated by a special allocation routine (DBG\$GET_TEMPMEM), but they do not have to be explicitly released to the memory pool. Instead one routine is called (DBG\$REL_TEMPMEM) which automatically releases all "temporary" blocks accumulated since the last such call. Temporary blocks have the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Longword 0 is the same as for any other memory pool block. Longword 1 contains a forward link to the next block on the temporary block list. Longword 2 is similar to longword 0, but the length there is two less and the sentinel value is a different sentinel value (FMEMSK_TEMPSENT).

Define the distinguishing sentinel value for "temporary" memory blocks.

LITERAL FMEMSK_TEMPSENT = XX'B4'; ! Sentinel value in longword 2

IMAGE FILE HEADER DEFINITIONS

The executable image file header block contains a pointer in a fixed location which points to a small block later in the header which gives the size and location of the Debug Symbol Table (DST) and the Global Symbol Table (GST). The first part of the executable image file header looks as follows:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Here IH\$W_SYMDBGOFF contains the byte offset relative to the start of the header of an Image Header Symbol Table descriptor.

IMAGE HEADER SYMBOL TABLE DESCRIPTOR

The Image Header Symbol Table Descriptor (IHS) pointed to by the IH\$W_SYMDBGOFF field in the header has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Here IH\$W_DSTBLKS and IH\$S_L_DSTVBN give the size (in blocks) and location (Virtual Block Number) of the Debug Symbol Table (DST) within the

IMAGE FILE DEBUG MODULE TABLE

The Image File Header in an executable image file points to the Image Header Symbol Table descriptor as described above. If bit 5 of field IHDSL_LNKFLAGS in the image header is set, this is a 'new' image, i.e. one produced by the VMS V4.0 or later linker, and the IHSSL_DMTVBN and IHSSL_DMTBYTES fields exist in the Image Header Symbol Table descriptor. (If bit 5 is not set, this is an 'old' image and those fields do not exist.) If non-zero, IHSSL_DMTVBN gives the Virtual Block Number in the image file of the Debug Module Table (the DMT). IHSSL_DMTBYTES then gives the size of the DMT in bytes. The DMT is only built if the user did a LINK/DEBUG; if he did not, IHSSL_DMTVBN and IHSSL_DMTBYTES are zero.

The Debug Module Table contains one entry per module in the Debug Symbol Table (the DST). This is the format of each such DMT entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	----- DST address of Module Begin DST Record -----
1	----- Size in bytes of module's DST -----
2	----- Number of PSECTs for this module -----
3	----- Start address of first PSECT in module -----
4	----- Length of first PSECT in module in bytes -----
..	-----
..	----- (Two longwords per PSECT) -----
..	-----
..	----- Start address of last PSECT in module -----
..	----- Length of last PSECT in module in bytes -----

Longword 0 gives the address relative to the start of the DST of the Module Begin DST Record for this module. Longword 1 gives the size of the DST in bytes for the same module. Longword 2 gives the number of PSECTs in the module (i.e., the number of statically allocated program sections), and this is followed by that number of two-longword pairs which give the start address and length (in bytes) of each such PSECT. Since the number of PSECTs cannot exceed 65K, the upper two bytes of longword 2 are available for future expansion.

The DMT is used during DEBUG initialization to initialize the RST and

```

: 2079 0

: 2082 0
: 2083 0
: 2084 0
: 2085 0
: 2086 0

```

```

the Program Static Address Table. Using the DMT is much faster than
the alternative procedure, namely reading through the entire DST to
pick up the needed information. The information in the DMT entry is
enough to build a Module RST Entry for each module in the DST and the
PSECT information is used to build the Program SAT. The amount of RST
symbol table space needed per module is not computable from the DMP in-
formation, but is estimated by multiplying the DST size of each module
by an appropriate scale factor.

```

LEAST RECENTLY USED MODULE TABLE

The Least Recently Used Module (LRUM) table keeps track of the Least Recently Used module in the RST. This information is used to select modules to be removed from the RST when the free memory pool is full and new space must be created by releasing old RST entries. The LRUM table is built and maintained by the DBG\$MOST RECENT MODULE routine in module RSTACCESS and is accessed by routine DBG\$GET MEMORY when memory space must be released by removing the Least Recently Used module. Routine DBG\$RST_INIT builds the initial LRUM list head.

The LRUM table consists of a doubly linked list of LRUM entries, with a permanent list head and one entry per module currently in the RST. The address of the list head is given by the global LRUMSLISTHEAD. The format of the individual LRUM entry is show here:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	----- LRUMSL_FLINK -----
1	----- LRUMSL_BLINK -----
2	----- LRUMSL_RSTPTR -----

A pointer to a Least Recently Used Module entry is declared as follows:

LRUMPTR: REF LRUM\$ENTRY

Define the fields in the Least Recently Used Module entry. Also define the entry size and the declaration macro.

```

FIELD LRUM$FLD_DEF =
  SET
    LRUMSL_FLINK   = [ 0, L_ ],      ! The LRUM chain forward link
    LRUMSL_BLINK   = [ 1, L_ ],      ! The LRUM chain backward link

L E X I C A L S C A N N E R C H A R A C T E R T A B L E

The Lexical Scanner (routine DBG\$LEXICAL_SCANNER) operates on a Character Table which gives lexical information about each ASCII character. This information consists of bits and small integer values which characterize the character from the Lexical Scanner's point of view--they indicate whether a given character can be part of an identifier, a numeric constant, an operator, or whatever. The Character Table is thus a vector of 256 elements, indexed by the ASCII character code, where each element contains the information defined here.

A Lexical Scanner Character Table is declared as follows:

CHARTBL: CHRTBL\$TABLE

Define the fields of the Character Table element. Also define the declaration macro.

FIELD CHRTBL\$FLD_DEF =

SET

CHRTBL\$V_IDENT_START	= [0, V_(0)],	Identifier start character
CHRTBL\$V_IDENT_MIDDLE	= [0, V_(1)],	Identifier middle character
CHRTBL\$V_IDENT_END	= [0, V_(2)],	Identifier end character
CHRTBL\$V_NUMBER_START	= [0, V_(3)],	Number start character
CHRTBL\$V_NUMBER_CLASS	= [0, V_(4,4)],	Numeric constant character class
CHRTBL\$V_ALPHABETIC	= [0, V_(8)],	Alphabetic character (A-Z)
CHRTBL\$V_DIGIT	= [0, V_(9)],	Numeric digit (0-9)
CHRTBL\$V_STRING_QUOTE	= [0, V_(10)],	String quote character
CHRTBL\$V_OPCHAR	= [0, V_(11)],	Operator character
CHRTBL\$V_OPCHAR_PREFIX	= [0, V_(12)],	Operator prefix character
CHRTBL\$V_OPCHAR infix	= [0, V_(13)],	Operator infix character
CHRTBL\$V_OPCHAR_POSTFIX	= [0, V_(14)],	Operator postfix character
CHRTBL\$V_ADDRESS_OP	= [0, V_(15)],	Address Expression operator
CHRTBL\$V_SPECIAL_SYMBOL	= [0, V_(16)],	Special DEBUG symbol (. \ ^)
CHRTBL\$V_SPACE	= [0, V_(17)],	Space or Tab character
CHRTBL\$V_TERMINATOR	= [0, V_(18)],	May start Terminator Token
CHRTBL\$V_SPECIAL_CASE	= [0, V_(19)],	Special case in lex scanner
CHRTBL\$L_WHOLE_ENTRY	= [0, L_]	The whole entry for a char.

TES;

2216 0      ! values as are allowed in the NUMST$B_CHAR_CLASS field and their names all
2217 0      ! have the form NUMST$K_CLASS_xxx.

```

L E X I C A L T O K E N E N T R Y

A Lexical Token Entry is returned by the Lexical Scanner every time it is called. Operator Token Entries are found in predefined tables specific to each language supported by DEBUG while Operand Token Entries are built as needed by the Lexical Scanner (DBG\$LEXICAL_SCANNER). The format of a Lexical Token Entry depends on the kind of Token Entry it is, but all Lexical Token Entries have this general format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

A pointer to a Lexical Token Entry is defined as follows:

TOKENPTR: REF TOKEN\$ENTRY

Define the fields of the Lexical Token Entry.

FIELD TOKEN\$FLD_DEF =

SET		
TOKEN\$B_KIND	= [0, B0_]	Token kind
TOKEN\$B_FLAGS	= [0, B1_]	Token Entry flag bits
TOKEN\$V_PRIMARY	= [0, V1_(0)]	Token is Primary Symbol operator (used in Operator entries only)
TOKEN\$V_LEXICAL	= [0, V1_(1)]	Token is a lexical operator (used in Operator entries only)
TOKEN\$V_SGNEXT	= [0, V1_(2)]	Sign extension S in X<P,S,E> operation (used in Operator Lexical Token for the bit-select operation)
TOKEN\$V_BALANCED_PARENS	= [0, V1_(0)]	Token is Terminator Token only if parentheses are balanced (used in Terminator entries only)
TOKEN\$V_MUST_BE_SINGLE	= [0, V1_(1)]	Token is Terminator Token only if this character is not followed by it- self (: is term but not ::) (used in Terminator entries only)
TOKEN\$V_ARGUMENT_LIST		Argument list follows this Ada tick operator.
TOKEN\$W_CODE	= [0, W1_]	Operand or operator code for token
TOKEN\$B_BIF	= [1, B0_]	Built-in Function Code

```

OPERAND LEXICAL TOKEN ENTRY

Operands are identifiers, numeric constants, string or character constants, or special constructs such as %LINE nnn which generate identifiers. The Lexical Token Entry for an operand has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	TOKEN\$W_CODE	TOKEN\$B_FLAGS	TOKEN\$B_KIND
1	Unused		TOKEN\$B_BIF
2	TOKEN\$A_NAME		TOKEN\$B_LENGTH
..	(Operand name in Counted ASCII)		
..	(Includes TOKEN\$B_LENGTH and TOKEN\$A_NAME fields)		
..			

The TOKEN\$B_KIND field of an Operand Lexical Token Entry always has the value TOKEN\$K_OPERAND.

Define the valid values of the TOKEN\$W_CODE field for operands. This field says what kind of operand this Token Entry represents.

LITERAL

TOKEN\$K_MIN_OPERAND	= 1.	!-- Minimum value for TOKEN\$W_CODE
TOKEN\$K_IDENTIFIER	= 1.	Identifier
TOKEN\$K_STRING	= 2.	Character String Constant
TOKEN\$K_CHARACTER	= 3.	Single Character Constant
TOKEN\$K_INTEGER	= 4.	Integer Constant
TOKEN\$K_HEX_INTEGER	= 5.	Hexadecimal Integer Constant
TOKEN\$K_FLOATING	= 6.	Floating Point Constant
TOKEN\$K_EXP_E_FLOAT	= 7.	Floating Constant with E Exponent
TOKEN\$K_EXP_D_FLOAT	= 8.	Floating Constant with D Exponent
TOKEN\$K_EXP_Q_FLOAT	= 9.	Floating Constant with Q Exponent
TOKEN\$K_BIN_INTEGER	= 10.	Binary Constant
TOKEN\$K_OCT_INTEGER	= 11.	Octal Constant
TOKEN\$K_COMPLEMENT	= 12.	1's Complement
TOKEN\$K_BIT_STRING	= 13.	Bit String Constant (as in PL/I)
TOKEN\$K_PACK_DECIMAL	= 14.	Packed Decimal Constant
TOKEN\$K_EXP_G_FLOAT	= 15.	Floating Constant with G Exponent
TOKEN\$K_BUILTIN_FUNCTION	= 16.	Built-in Function
TOKEN\$K_MAX_OPERAND	= 16.	--- Maximum value for TOKEN\$W_CODE

OPERATOR LEXICAL TOKEN ENTRY

The Lexical Token Entry for an operator contains additional information not needed for operands, namely the left and right precedences of the operator. This is the format of an Operator Lexical Token Entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	TOKEN\$W_CODE	TOKEN\$B_FLAGS	TOKEN\$B_KIND
1	TOKEN\$W_SUBCODE	TOKEN\$B_L_PREC	TOKEN\$B_R_PREC
2	TOKEN\$W_BIT_LENGTH	TOKEN\$W_BIT_OFFSET	
3	TOKEN\$A_OPNAME	TOKEN\$B_OPLEN	
..	(Operator name string in Counted ASCII)		
..	(Includes TOKEN\$B_OPLEN and TOKEN\$A_OPNAME fields)		
..			

The TOKEN\$B_KIND field of an Operator Lexical Token Entry always has one of the three values TOKEN\$K_PREFIX_OP, TOKEN\$K infix_OP, or TOKEN\$K postfix_OP.

Define some size literals used for allocating memory.

```

LITERAL
  TOKEN$K_FIXED_SIZE_BYTE = 13,      ! Fixed size (not including
                                        ! the name) of an operator
                                        ! token. Actual size in
                                        ! bytes is this value plus
                                        ! the OPLEN field.
  TOKEN$K_FIXED_SIZE_LONG = 4;       ! Fixed size (not including
                                        ! the name) of an operator
                                        ! token. Actual size in
                                        ! longwords is this value
                                        ! plus OPLEN / 4.
  
```

Define the valid values of the TOKEN\$W_CODE field for operators. This field indicates which operation is to be performed. Not all languages allow all operators, but all operators allowed in at least one language are listed in this table. Note that the same operator may be represented differently in different languages--thus "=" and ".EQ." are both considered to be the same comparison operator.

! Define the possible values for the TOKENSK_SUBCODE field.
This field is used to store additional information about the operator.
At present the one use of this field is for the ADA attribute operators.
For these, the TOKENSW_CODE field contains "TOKENSK_ADA_TICK" and the
subcode field identifies which tick operator is present ("FIRST",
"LAST", etc.
The reason for doing it this way is because there may be a large number
of tick operators, all of which are treated the same for purposes of
operator precedence parsing. Tables thus are smaller if there is only
one code for "tick" and a subcode for each tick operator.

TERMINATOR LEXICAL TOKEN ENTRY

Terminators are lexical tokens which mark the end of an expression. For example, in subscript expressions, "''" and "''" mark the ends of the expressions as in 'ARR(K+2, I+3-4)'. Similarly, in the command SET BREAK X+4 DO(...), the keyword 'DO' marks the end of the expression as long as it does not appear within parentheses. Terminator Lexical Token Entries define tokens which act as expression terminators in specified contexts. The Terminator Lexical Token Entry has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	TOKEN\$W_CODE	TOKEN\$B_FLAGS	TOKEN\$B_KIND
1	unused		
2	TOKEN\$A_NAME	TOKEN\$B_LENGTH	
..	(Terminator name in Counted ASCII)		
..	(Includes TOKEN\$B_LENGTH and TOKEN\$A_NAME fields)		
..			

The TOKENSB_KIND field of a Terminator Lexical Token Entry always has the value zero (0).

The TOKENSB_FLAGS field can contain the flag TOKENSV_BALANCED_PARENS which, if set, indicates that this token acts as a terminator only if parentheses are balanced when it is encountered. For example, "''" terminates a subscript expression only the subscript expression's parentheses are balanced so far. Similarly, DO terminates the address expression in SET BREAK expr DO ... only if it is not enclosed in parentheses; otherwise there would be no way to include the identifier 'DO' (as allowed in many languages) in the address expression.

Define the valid values of the TOKENSW_CODE field for terminators. This field says what kind of terminator this Token Entry represents.

!***

MOVED DST ENTRY DEFINITIONS

To support DST continuation records, every continued DST record is merged with its continuation records into one record and is moved to DEBUG permanent memory. A list of moved DST records is kept to allow access to these moved records. Each entry on that list has the following structure:

```

3 3 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

0	-----MDES_LFLINK-----
1	-----MDES_ORIGINAL_DSTPTR-----
2	-----MDES_REAL_DSTPTR-----
3	-----MDES_REAL_LENGTH-----
4	-----MDES_NEXT_DSTPTR-----

As the RST for a module is built, continuation records are merged and the new "moved" DST pointer is placed in the RST entry. Thus, moved DSTs are transparent for those routines that access the RST.

Those routines that obtain DST pointers from the DST itself are:

- o Routines that deal with SEPTYP records
- o Routines that access indirect type specs
- o Routines that access novel length type specs
- o Routines that access the next DST record

These routines must access those pointers through routines that search the structure to make sure that the DST hasn't been moved. The routines currently provided are:

- o DBG\$RST_DST_PTR - Return the "real" DST pointer
- o DBG\$RST_NEXT_DST - Return the "next" DST pointer

The structure is a singly linked list with its head being DBG\$GL_MOVED_DST_LIST_HEAD.

Define the fields of the Moved DST Record Entry. Also define the entry length and the declaration macro.

```

FIELD MDESFIELDS =
SET
MDES_LFLINK      = [ 0, L_ ],    ! Forward link
MDES_ORIGINAL_DSTPTR = [ 1, L_ ], ! The Original DST pointer

```

```

2728 0      MDES_L_REAL_DSTPTR      = [ 2, L_ ],      ! The new, moved, real DST pointer
2729 0      MDES_L_REAL_LENGTH      = [ 3, L_ ],      ! The moved DST's length
2730 0      MDES_L_NEXT_DSTPTR      = [ 4, L_ ],      ! The next DST pointer
2731 0      TES;
2732 0
2733 0      LITERAL
2734 0      MDES_K_LENGTH = 5;          ! Length of an entry in longwords
2735 0
2736 0      MACRO
2737 0      MDES_RECORD = BLOCK[.LONG] FIELD(MDES_FIELDS) %;
2738 0
2739 0
2740 0      ! NOTE: MDES_L_NEXT_DSTPTR is a simple address calculation to the next DST record
2741 0      ! with all the continuation records consumed. At the time the calculation is
2742 0      ! made it is not known if the record will be relocated. Thus any access to it
2743 0      ! must also check it for being relocated by calling DBG$RST_DST_PTR.

```

NUMBER SCANNER STATE TABLE

The Lexical Number Scanner in routine DBG\$LEXICAL_SCANNER operates off a Finite-State Machine state table which defines the allowed formats of numeric constants in the current language. There is thus one Number State Table for each language supported by DEBUG (although some languages can share state tables). Each state in the state table is represented by a list of two or more State Table Transition Entries, each of which specifies a state transition to be taken if the current input character is of a class specified in the Transition Entry. The format of a Number Scanner State Table Entry is as follows:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0 First State Table Transition Entry
 1 Additional State Table Transition Entries
 .. State Table Transition Entry for NUMST\$K_CLASS_OTHER

The individual State Table Transition Entry has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0 NUMST\$W_NEXT_STATE : NUMST\$B_ACTION : \$B_CHAR_CLASS :

The whole Number Scanner State Table for a language simply consists of a sequence of concatenated State Table Entries, one entry per state in the Finite-State Machine. The whole State Table is thus a vector of State Table Transition Entries. Element zero of the state table is the beginning of the state table's Start State, and each transition's NUMST\$W_NEXT_STATE pointer is a state table index which points to the beginning of the next state's State Table Entry.

A pointer to a Number Scanner State Table is declared as follows:

STATE_TABLE: REF NUMST\$TABLE

This declares STATE_TABLE to be a block vector which is referenced as .STATE_TABLE[STATE_INDEX, field-name] where STATE_INDEX is the vector index which points to a specific Number Scanner State Table

Transition Entry.

Define the fields in the Number Scanner State Table Transition Entry.
 Also define the declaration macro.

```
FIELD NUMST$FLD_DEF =
  SET
  NUMST$B_CHAR_CLASS = [ 0, B0_ ], Character class that activates
                                this state transition
  NUMST$B_ACTION      = [ 0, B1_ ], CASE index for semantic action to be
                                taken during state transition
  NUMST$W_NEXT_STATE = [ 0, W1_ ], Index of next state after transition
  TES;
```

```
MACRO
  NUMST$TABLE = BLOCKVECTOR[1, LONG] FIELD(NUMST$FLD_DEF) %;
```

Define the allowed values of the character class field NUMST\$B_CHAR_CLASS.
 These are the different classes of characters which are significant when
 scanning numeric constants.

```
LITERAL
  NUMST$K_MIN_CLASS      = 0, --- Minimum character class code
  NUMST$K_CLASS_OTHER    = 0, All other characters
  NUMST$K_CLASS_DIGIT     = 1, The decimal digits, '0' - '9'

values are stored in the ORTSW_ROUT field of the Operator Routine
 Table entry for a given operator operating on a given pair of
 types. The literal is used as a case index in the DBG\$PERFORM_OPERATOR
 routine in order to actually do operations.

Note - the order of the case indices in DBGPERMOP must correspond
 exactly to the ordering of the literals here. One must be very careful
 in changing this list.

This situation is of course a maintenance problem and we should eventually
 figure out a better way to get these literals shared.

In the meantime, the list below must be kept dense and must correspond
 exactly to the case labels in DBGPERMOP.

TYPE GRAPH

The type conversions that are done for a given operator in a given language are specified by a set of directed acyclic graphs. For example, part of the graph that specifies the implicit type conversions to be done for FORTRAN addition might look like:

```

L -> F -> D -> H
      \      \
      FC -> DC

```

Each graph is represented by listing its edges. Each edge is just a pair of Type IDs.

Below we define the data structure used to declare the edges of these graphs.

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

```

+-----+
| HIGHER_TYPE | LOWER_TYPE |
+-----+

```

Define the fields in an entry in an edge of a Type Graph.

```

FIELD TYPE_GRAPH$FLD_DEF =
SET
TYPE_GRAPH$B_LOWER_TYPE = [0,B0_],
TYPE_GRAPH$B_HIGHER_TYPE = [0,B1_],
TYPE_GRAPH$W_BOTH_TYPES = [0,W0_]
TES;

```

! Define the macro which is used to declare an entry in a Type Graph

```

MACRO
TYPE_GRAPH$ENTRY = BLOCK [1,WORD] FIELD (TYPE_GRAPH$FLD_DEF) %;

```

TYPE CONVERSION INFORMATION TABLE

The Type Conversion Information Table is a vector of longwords used by a language which gives pointers to tables which contain the information necessary to select the type conversions and then the routine invocations which does the type conversion.

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	↑-----↑	CVTINFO\$MPTBL	↑-----↑
1	↑-----↑	CVTINFO\$CVTBL	↑-----↑
2	↑-----↑	flags	↑-----↑

A pointer to an Type Conversion Information Table is declared as follows:

CVTINFO_TABLE: REF CVTINFO\$TABLE

Define the fields of the Type Conversion Information Table entry. Also define the declaration macro.

```

FIELD CVTINFO$FLD_DEF =
  SET
    CVTINFO$MPTBL = [ 0, L_ ], ! Address of Type Map Table
    CVTINFO$CVTBL = [ 1, L_ ], ! Address of Type Conversion Table
    CVTINFO$V_ROUND = [ 2, V_(0) ], ! Flag to indicate conversion result
                                     ! is rounded
  TES;

```

```

MACRO
  CVTINFO$TABLE = BLOCK[3, LONG] FIELD (CVTINFO$FLD_DEF) %;

```

TYPE CONVERT ENTRY

A Type Convert Entry contains a type conversion routine index which identifies the routine to be invoked, from data type, and to data type.

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

+-----+
| TYPE_CVT$W_ROUT      | HIGHER_TYPE | LOWER_TYPE |
+-----+

```

A pointer to an Type Map Entry is declared as follows:

CVTPTR : REF TYPE_CVT\$ENTRY

Define the fields of the Type Map Table entry. Also define an entry declaration macro.

FIELD

```

TYPE_CVT$FLD_DEF =
SET
TYPE_CVT$B_LOWER_TYPE = [0, B0_],
TYPE_CVT$B_HIGHER_TYPE = [0, B1_],

CVT$K_MAX_ROUT      = 2;

```

!***-

PATHNAME DESCRIPTORS

The pathname descriptor is used internally in the Debugger to represent a pathname, including data qualification. Thus 'MOD\ROUT\X' is a pathname in this sense, and so is 'MOD\ROUT\A.B.C'. The format of a pathname descriptor is shown here:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

The Pathname Descriptor contains two counts fields which give the total number of names in the pathname (five for M\R\A.B.C) and the total number of names before the first dot (three for M\R\A.B.C). It also contains an invocation number (which is zero if none was explicitly specified) and an index into PTH\$A_PATHVECTOR which indicates which pathname component was qualified by the invocation number (1 for A 2\X and 4 for M\R1\R2\R3 5\X). This index is zero if no invocation number was given. The rest of the descriptor consists of longwords containing pointers to the individual names in the pathname, each represented by a Counted ASCII String.

A pointer to a Pathname Descriptor is declared as follows:

PATHPTR: REF PTH\$PATHNAME

Define the Pathname Descriptor fields.

FIELD PTH\$FLD_DEF =

SET
 PTH\$B_TOTCNT = [0, 80_], ! Total number of names in pathname
 ! including all data qualification

```

Language reserves Predeclared Identifier as names of functions, procedures, types, values, etc. Predeclared Identifier Entry is used by DEBUG to describe one of these predeclared identifiers. An identifier is looked up in this table, if an entry is found, a value descriptor is created for this entry. For example, TRUE, FALSE in PASCAL, .TRUE., .FALSE., in FORTRAN. The Predeclared Identifier Entry has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	unused	PRIDSB_FCODE	PRIDSB_DTYPE	PRIDSB_KIND
1	PRIDSL_VALUE			
2		PRIDSA_NAME	PRIDSB_LENGTH	
..	(Predeclared Identifier name in Counted ASCII)			
..	(Includes PRIDSB_LENGTH and PRIDSA_NAME fields)			
..				

The PRIDSB_KIND field defines the kind of Predefined Identifier. The PRIDSB_KIND field of an Predefined Identifier Constant Entry always has the value of PRIDSK_CONSTANT. It has the following format.

A pointer to a Predefined Identifier Value Entry is defined as follows:

PRIDPTR: REF PRIDSENTRY

Define the fields of the Predefined Identifier Entry.

FIELD PRID\$FLD_DEF =

```

SET
PRIDSB_KIND      = [ 0, B0 ],      ! Predefined Identifier Kind

PRIMARY AND VALUE DESCRIPTOR HEADER FOR COBOL AND PL/I

The Primary Descriptor and the Value Descriptor for COBOL and PL/I are descriptor blocks built by the language-specific routines for those two languages. As such their contents are unknown to the Debugger kernel (and are not described here), but they all must have the common header described here. A Primary Descriptor or Value Descriptor for COBOL or PL/I thus has this format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

A pointer to a descriptor header block is declared as follows:

DESCPTR: REF DBG\$DHEAD

Define the Value or Primary Descriptor Header Block fields and the declaration macro.

FIELD DBG\$DHEAD_FIELDS =

SET
DBG\$W_DHEAD_LENGTH = [0, W0_], ! Length of descriptor in bytes including this header
DBG\$B_DHEAD_TYPE = [0, B2_], ! The type of this descriptor
DBG\$B_DHEAD_LANG = [0, B3_], ! Language of the descriptor
DBG\$L_DHEAD_POINTER = [1, L_] ! Unused at present
TES;

LITERAL

DBG\$K_DHEAD_SIZE = 2; ! Size of descriptor header in longwords

: 3831 0 :     DBG$K_VALUE_DESC       ! This is a non-volatile Value Descriptor
: 3832 0 :     DBG$K_V_VALUE_DESC     ! This is a volatile Value Descriptor
: 3833 0 : **-
```

PRIMARY DESCRIPTOR DEFINITIONS

Primary Descriptors describe Primary Symbols parsed in DEBUG commands. A Primary Symbol may be a simple name, such as "ABC", or a more complex name including pathname qualification, data qualification, subscripting, and dereferencing, such as "MOD\ROUT\A.B[2,3]^C(4).D".

The Primary Descriptor described here is the Primary Descriptor built by the language-independent parser in module DBGPARSER.

A Primary Descriptor consists of a Root Node followed by a doubly linked list of Sub-Nodes which describe the individual components of the symbol described by the Primary Descriptor. Each Sub-Node thus describes an instance of data qualification, subscripting, dereferencing, or the like. The last Sub-Node describes the final object named by the Primary Symbol.

Consider the Primary Symbol "A\B\C.D[2]^E" for example. The Primary Descriptor Root Node would point to a Sub-Node for A\B\C which requires a Record Sub-Node. It points to another Sub-Node for component D of record A\B\C. This component is an array and requires an Array Sub-Node. The next node is the Sub-Node for the array element A\B\C.D[2]. This element is of a pointer type. The next Sub-Node is a node for the pointed-to object which happens to be a record and therefore calls for a Record Sub-Node. Finally, the last Sub-Node on the chain is for component E of that record. The type of Sub-Node required depends on the data type of E, but would be a Normal Sub-Node for all data types other than arrays and records.

PRIMARY DESCRIPTOR ROOT NODE

A Primary Descriptor consists of a Root Node followed by a doubly linked list of Sub-Nodes which describe the individual components of the symbol described by the Primary Descriptor. The format of the Primary Descriptor Root Node is as follows:

3 3 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	\$B_DHDR_LANG	\$B_DHDR_TYPE	DBG\$W_DHDR_LENGTH
1	\$B_DHDR_KIND	\$B_DHDR_FCODE	DBG\$W_DHDR_FLAGS
2	DBG\$L_DHDR_TYPEID		
3	DBG\$L_DHDR_SYMIDO		
4	DBG\$W_PRIM_LENGTH	DBG\$W_PRIM_OFFSET	
5	DBG\$L_PRIM_FLINK		
6	DBG\$L_PRIM_BLINK		
7	Unused		_SCOPE_STATE
8	DBG\$L_PRIM_SCOPE		

A pointer to a Primary Descriptor Root Node is declared as follows:

PRIMPTR: REF DBG\$PRIMARY

Define the fields of the language-independent Primary Descriptor Root Node.

FIELD DBG\$PRIM_FIELDS =

```

SET
DBG$W_PRIM_OFFSET      = [ 4, SW0 ], ! Offset within data item

PRIMARY DESCRIPTOR NORMAL SUB-NODE

Primary Descriptor Sub-Nodes are attached to the Primary Descriptor Root Node via a doubly linked list. The first Sub-Node represents the first data item in the Primary Symbol (for example, A/B in 'A/B.C[2].D') and subsequent nodes represent subsequent items (such as .C, .C[2], and .D). All Primary Descriptor Sub-Nodes include a 'common core' of information, with other fields added for certain specific sub-nodes. The 'Normal Sub-Node' described here is used for all 'normal' symbols, meaning all symbols for which no specific Primary Descriptor Sub-Node has been defined below. This Sub-Node has only the 'common core' fields and no type-specific fields:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	DBG\$PNODE_FLINK
1	DBG\$PNODE_BLINK
2	Unused ; SB_PNODE_FLAGS ; SB_PNODE_FCODE ; SB_PNODE_KIND
3	DBG\$PNODE_TYPEID
4	DBG\$PNODE_SYMID
5	DBG\$PNODE_RELOC

A pointer to a Primary Descriptor Sub-Node is declared as follows:

PNODEPTR: REF DBG\$PRIM_NODE

The following are the meanings of the fields in the Normal Sub-Node.

DBG\$B_PNODE_KIND -- May be any RST kind, although it usually is RST\$K_DATA or RST\$K_TYPCOMP.
DBG\$B_PNODE_FCODE -- Can be any FCODE other than those for which separate Primary Descriptor Sub-Nodes are described below.
DBG\$PNODE_TYPEID -- The Type ID for the object's type.
DBG\$PNODE_SYMID -- The SYMID for the object. This field may be zero, as it is for an array element or a pointed-to element.
DBG\$PNODE_RELOC -- A 'relocation constant' for the address. This is normally zero, but can contain a user address (in the case of anonymous references) or a byte offset (for strings)

PRIMARY PARSER STATE TABLE

The Primary Parser (DBG\$PRIMARY_PARSER) operates off a Finite-State Machine (FSM) state table which defines the allowed formats of Primary Symbols in the current language. A Primary Symbol consists of a symbol name which may include pathname qualification, data qualification, subscripting, dereferencing, and possibly other qualification depending on the language. In PASCAL, for example, M[R\A.B[2,3]^C[4].D is a valid Primary Symbol. The operators in a Primary Symbol may include '[', '^', ']', and so on. Exactly which operators are allowed and in which order they are allowed is language-dependent, and this is what is specified by the Primary Parser State Table. Each state in the state table is represented by zero or more Primary Parser State Table Transition Entries, each of which specifies a transition to be taken if the current operator is the one specified in the transition entry. The format of a Primary Parser State Table Entry is as follows:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

0	-----	First Primary Parser State Table Transition Entry	-----
1	-----	Additional State Table Transition Entries	-----
..	-----	Longword with value zero (0)	-----

The individual Primary Parser State Table Transition Entry has this format:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

0	-----	PRIMARY\$W_NEXTSTATE	;	\$B_ACTION	;	\$B_OPCODE	;
---	-------	----------------------	---	------------	---	------------	---

The whole Primary Parser State Table for a language simply consists of a sequence of concatenated State Table Entries, with one entry per state in the Finite-State Machine. The whole state table is thus a vector of transition entries and is indexed as such. Element zero of the state table is the beginning of the state table's Start State, and each transition's next state pointer (PRIMARY\$W_NEXT STATE) is a state table index which points to the beginning of the next state's state table entry.

A pointer to a Primary Parser State Table is declared as follows:

PRIMARY_TABLE: REF PRIMARY\$TABLE

This declares PRIMARY_TABLE to be a block vector which is referenced as .PRIMARY_TABLE[STATE_INDEX, field-name] where STATE_INDEX is the vector index pointing to the current Primary Parser State Table Transition Entry.

Define the fields in the Primary parser State Table Transition Entry. Also define the declaration macro.

FIELD PRIMARY\$FLD_DEF =

SET

PRIMARY\$B_OPCODE = [0, B0_], : Operator code which activates this state transition

PRIMARY\$B_ACTION = [0, B1_], : CASE index for semantic action to be taken during state transition

PRIMARY\$W_NEXTSTATE=[0 , W1_] : Index of next state after transition

TES;

MACRO

PRIMARY\$TABLE = BLOCKVECTOR[,1, LONG] FIELD(PRIMARY\$FLD_DEF) %;

Define the allowed values of the PRIMARY\$B_ACTION field. These values are CASE indices which select the semantic action routine to be executed for each state transition.

REGISTER DESCRIPTORS

A Register Descriptor is used to describe the absolute address of a register or of a byte address within a register. It thus contains a register number, a byte offset within that register (0, 1, 2, and 3 are the only possible values), and a scope number which indicates to which call frame in the call stack this register belongs. The descriptor also contains a "sentinel" value which is used for validity checking and for ensuring that a Register Descriptor always has a non-zero value.

Register Descriptors are built by routine DBG\$STA_ADDRESS_TO_REGDESCR and are later used for various purposes when registers are examined. They are also required by routine DBG\$STA_REGISTER_NAME which generates the register name for printing.

A Register Descriptor fits in a single longword. This is the format:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0
+-----+-----+-----+-----+
|          DBG$W_REGD_SCOPENUM          | $B_REGD_REGNUM | _SENTINEL |OFF|
+-----+-----+-----+-----+
```

A Register Descriptor is declared as follows:

```

REGDESCR: DBG$REGDESCR
```

Define the fields of the Register Descriptor. Also define the declaration macro.

```

FIELD DBG$REGD_FLD_DEF =
SET
DBG$V_REGD_OFFSET = [ 0, V_(0,2) ], ! Byte offset from start of register
DBG$V_REGD_SENTINEL = [ 0, V_(2,6) ], ! Sentinel value--must be %X'2D'
DBG$B_REGD_REGNUM = [ 0, BT_ ], ! The actual register number
DBG$W_REGD_SCOPENUM = [ 0, W1_ ], ! The register's scope number
TES;

MACRO
DBG$REGDESCR = BLOCK[1, LONG] FIELD(DBG$REGD_FLD_DEF) %;
```

This section contains all definitions related to the structure and contents of the Run-Time Symbol Table (RST) through which the Debugger accesses the Debug Symbol Table (DST) in the user's executable image. The RST itself is built and accessed entirely through the Symbol-Table Access Routines in modules RSTCNTRL and RSTACCESS.

The RST is the structure through which the DST is accessed, one module at a time. This means that for each "active" module in the user's program, there is an RST data structure which describes that module and all lexical entities and data items in it. This structure, which is scattered through the Debugger's free memory, contains one entry for each lexical entity and data item in the module's DST. Each RST entry contains a pointer to the corresponding DST entry so all the DST entry information can be accessed rapidly. In addition, the RST itself is hashed by symbol name so that a symbol's RST and DST entries can be located rapidly given the symbol name.

RST ENTRY COMMON CORE

All entries in the Run-Time Symbol Table have the same information in their first parts. This RST entry "common core" is described here:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 9 8 7 6 5 4 3 2 1 0

0	RST\$L_HASH_FLINK		
1	RST\$L_HASH_BLINK		
2	RST\$L_SYMCHNPTR		
3	RST\$L_DSTPTR		
4	RST\$L_UPSCOPEPTR		
5	RST\$W_REFCOUNT	Flag bits	RST\$B_KIND

The hash chain forward and backward links link together all RST entries for symbols whose names have the same hash value. The hash chain is doubly linked so that RST entries can be removed from the hash chains when the whole RST for a module is removed to free up its space. Each hash chain has a permanent list head; RST entries in the RST Hash Table therefore never have zero hash links.

Some RST entries are not in the RST Hash Table, however. Such entries are "temporary" in the sense that they are created when needed and are thrown away when no longer referenced. Examples include many Data Type RST Entries and RST entries with invocation numbers. Such RST entries are put on the Temporary RST Entry List. This is a singly linked list which uses the RSTSL_HASH_FLINK field for the links; RSTSL_HASH_BLINK is left zero in this case.

ALL RST entries for a given module are linked together through the RSTSL SYMCHNPTR pointer in a singly linked list. The list starts at the Module RST Entry and is terminated by a zero forward link. This list is traversed when the Module's whole RST is released to make room for another module.

The `RST$L_DSTPTR` pointer gives the address of the symbol's DST entry. The `RST$L_UPSCOPEPTR` pointer generally points to the RST entry of the symbol's "containing" entity. This usually means the containing lexical entity, but for data record components it means the containing record.

The RST\$B_KIND field identifies what kind of symbol and what kind of RST entry this is. The possible values are listed at the end of this section. The RST\$W_REFCOUNT field contains a reference count which specifies how many references (pointers) to this RST entry have been passed

to the rest of the Debugger. When this count is non-zero, this RST entry cannot be released to free storage. The reference count is thus used to prevent a "dangling pointer" problem.

A pointer to a Run-Time Symbol Table Entry is declared as follows:

RSTPTR: REF RST\$ENTRY

This declaration macro collects together all the individual FIELD sets declared below for the various kinds of RST entries.

MACRO

RST\$ENTRY = BLOCK[,LONG] FIELD(RST\$FLD_CORE,RST\$FLD_MOD,RST\$FLD_LEX,RST\$FLD_DATA) %;

These are the RST entry common core field definitions.

FIELD RST\$FLD_CORE =

SET		
RST\$L_HASH_FLINK = [0, L_],		Symbol name hash chain forward link
RST\$L_HASH_BLINK = [1, L_],		Symbol name hash chain backward link
RST\$L_SYMCNPTR = [2, L_],		Pointer to the next RST entry belong-
		to the same module as this one
RST\$L_DSTPTR = [3, L_],		Pointer to this symbol's DST entry
RST\$L_UPSCOPEPTR = [4, L_],		Pointer to the RST entry one level up
		in scope from this one
RST\$B_KIND = [5, B0],		The kind of RST entry this is
RST\$V_GLOBAL = [5, V1_(0)],		Flag set if this is a global symbol
RST\$V_NONZLENGTH = [5, V1_(1)],		Flag set to TRUE if this symbol has a
		non-zero length
RST\$V_INVOCNUM = [5, V1_(2)],		Flag set if symbol has invocation num.
RST\$V_SET_TYPEPTR = [5, V1_(3)],		Flag set to indicate that the Data RST
		Entry RST\$L_TYPEPTR field should
		be set during RST build.
RST\$V_MARKBIT = [5, V1_(4)],		Mark bit available for temporary use
		(such as stopping recursion)
RST\$V_COBOLGBL = [5, V1_(5)],		Flag bit set to indicate this symbol
		has the COBOL "global" attribute
RST\$V_REGISTER = [5, V1_(6)],		Flag set if SYMID represents a register
RST\$W_REFCOUNT = [5, W1_],		Reference count for storage management
TES;		

The following are the possible values for the RST\$B_KIND field. This field specifies what kind of RST entry this is; it thus indicates both what kind of symbol the RST entry represents and what the format of the RST entry is after the "common core" part.

RST ENTRY FOR A MODULE

A module is represented by a Module RST Entry at all times, whether the rest of the module is in the RST or not. This Module Entry then points to a linked list of RST entries for the remaining symbols in the module via the RST\$L_SYMCHNPTR pointer; the end of this list is indicated by a zero pointer. The RST\$L_UPSCOPEPTR pointer is not used as an up-scope pointer in a Module Entry--there is nothing up-scope from a module. Instead RST\$L_NXTMODPTR, which occupies the same location in the RST entry as RST\$L_UPSCOPEPTR, is used to link all Module RST Entries in the whole program into a singly linked list. This list is scanned during RST initialization and when processing the SHOW MODULES command.

13	Unused	SB_IMGFILCHAN	

The RST\$L_MODPCTBL field points to a table of pointers to the PC-Correlation Table DST records for this module (used for PC to line number correlation and vice versa). The first cell of this table (namely MOD_PC_TBL[0]) gives the number of PC-Correlation Table DST records in the module's DST, and the remaining cells (i.e., MOD_PC_TBL[1] through MOD_PC_TBL[MOD_PC_TBL[0]]) contain pointers to those DST records. Each cell is one longword. If there are no PC-Correlation Table DST records

for a given module, the RST\$\$_MODPCTBL field is zero.

PC-Correlation Table DST records need not have any special order or nesting with respect to the DST records for routines and lexical blocks and are therefore viewed as belonging to the module as a whole. The PC-Correlation Tables for a module are scanned by searching them in the order of their pointers in the RST\$\$_MODPCTBL table. The addresses given by the PC Correlation Table DST records are relative to the value of the RST\$\$_PCTBL_BASE field, which contains the address of the lowest address routine in the module.

The RST\$\$_MODSRCTBL field points to a table of pointers to the Source Line Correlation DST Records for this module. The first cell of this table (i.e., MODSRCTBL[0]) contains the number of Source Line Correlation DST Records in this module's DST and the remaining cells (i.e., MODSRCTBL[1] through MODSRCTBL[MODSRCTBL[0]]) contain pointers to those DST records. Each cell in the table is a longword. If there are no such DST records at all, the RST\$\$_MODSRCTBL field is zero.

The memory blocks pointed to by RST\$\$_MODPCTBL and RST\$\$_MODSRCTBL both have the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0
 1
 ..
 ..
 ..

When registers are examined using a numbered scope which does not correspond to any routine in the RST, a dummy Module RST Entry is created to represent that scope. In such an RST entry, the RST\$\$_MODNUMSCP bit is set to distinguish it from other Module RST Entries. In addition, the scope number (the number of call frames from the top of the call stack) of the desired scope is stored in the RST\$\$_MODSCPNUM field. This field overlays the RST\$\$_MODRSTSI2 field, which is not needed in this case. The name of such a "module" is just the scope number in decimal ASCII. These special Module RST Entries are built by the GET_REGISTER_SYMID routine and are recognized by the DBG\$\$_STA_SETCONTEXT routine. Both in RSTACCESS.

This set of field declarations includes all fields outside the RST common core used in the Module RST Entry.

The RST entry for a routine has the format shown here. Each Routine RST Entry has an up-scope pointer (RST\$UPSCOPEPTR) which points to the RST entry for the containing lexical entity. That can be a module, a lexical block, or another routine. The start and end addresses of the routine's code are also given in the RST entry. There is also a Static Address Table (SAT) pointer which points to the SAT entry for this routine, and there is a Static Link pointer which points to the routine's Static Link DST record (or is zero). The routine breakpoint address is also kept in the RST Entry--this address may be set from a Prolog DST Record. The Routine RST Entry is always built when the RST for a module is built.

RST ENTRY FOR A LEXICAL BLOCK

The RST entry for a lexical block has the same format as that for a routine. Again the up-scope pointer points to the RST entry of the containing lexical entity, and the start and end addresses of the block's code are given. The Lexical Block RST Entry is always built when the RST for the whole module is built.

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1

RST ENTRY FOR AN ENTRY POINT

The RST entry for an entry point (i.e., an alternate point through which a routine can be called) is shown here. The up-scope pointer points to the RST entry of the containing lexical entity. An entry point has no independent extent and therefore its RST entry has only a start address. The Entry Point RST Entry is always built when the whole module's RST is built.

3 3 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1

3	-----RST\$L_DSTPTR-----
4	-----RST\$L_UPSCOPEPTR-----
5	-----RST\$W_REFCOUNT : Flag bits : RST\$B_KIND-----
6	-----RST\$L_STARTADDR-----

RST ENTRY FOR A LINE NUMBER

The RST entry for a line number has the format shown here. The up-scope pointer points to the RST entry of the containing lexical entity (always a routine or a block). Both the start and the end address are given. Line Number RST Entries are not built when the whole module's RST is built, however; there are too many lines in a program to make this practical. Instead each Line Number RST Entry is built when the corresponding line number is referenced through the Symbol Table Access routines. A dummy Label DST Record for the Line Number is built in the same memory block as the Line Number RST Entry. The RST entry points to this DST record and the DST record's name field contains the line number as a counted ASCII string (e.g. "%LINE 25.2").

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1

4	-----RST\$L_UPSCOPEPTR-----
5	-----RST\$W_REFCOUNT-----Flag bits-----RST\$B_KIND-----
6	-----RST\$L_STARTADDR-----
7	-----RST\$L_ENDADDR-----

RST ENTRY FOR A DATA SYMBOL

The RST entry for a data symbol has the format shown here. The up-scope pointer points to the RST entry for the containing lexical entity (i.e., module, routine, or lexical block) or, if this is a data component, to the RST entry for the containing data object. The Data Symbol RST Entry also has a Type Pointer (RST\$L_TYPEPTR). For simple data types (those defined by one-byte type codes or standard descriptors) this pointer is zero, but for more complex data types (records, variants, and enumeration types) this pointer points to the RST entry for that data type. If the type pointer is zero, the type can be found directly in the data symbol's DST entry.

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

RST ENTRY FOR A DATA TYPE COMPONENT

The RST entry for a data type component has the format shown here. A "component" in this sense is a record component, one of a set of variants, or one of the enumeration literals of an enumeration type. The interpretation of a data type component is thus dependent on the "type kind" of the containing data type.

The up-scope pointer always points to the RST entry for the data type to which this is a component. Data Type Component RST Entries are always built when the RST for the whole module is built.

Like the Data Item RST Entry, the this RST entry also has a type pointer which specifies the data type of the component. This is zero for simple types or a pointer to a Data Type RST Entry for a more complex data type (such as records).

RST ENTRY FOR A DATA TYPE

The RST entry for a data type has the format shown here. Not all data types have RST entries--those described by one-byte type codes or standard descriptors do not. Data Type RST Entries are used for all record, variant, and enumeration type data types, however. The up-scope pointer always points to the RST entry for the lexical entity (module, routine, or lexical block) in which the data type was declared. A data type need not have a name, however--it can be anonymous as it is in a PL/I or COBOL record declaration. Data Type RST Entries for records, variants, and enumeration types are built when the RST as a whole is built. All other Data Type RST Entries are built only when needed.

RST ENTRY FOR A RECORD VARIANT SET

The RST entry for a record variant set has the format shown here. A record variant set is the set of variants of some data record which are distinguished by the same tag variable. This RST entry does not appear free-standing--it is always built inside the memory block allocated for the containing record's Data Type RST Entry. Its hash links, symbol chain pointer, and up-scope pointers are thus not used. Its DST pointer points to the variant set's Variant-Set Begin DST record. The entry has extra fields which point to the tag variable's RST entry and give the list of individual record variants within the set.

RST ENTRY FOR AN INVOCATION NUMBER

The RST entry for an invocation number has the format shown here. This RST entry always follows the RST entry to which the invocation number belongs on the module's Symbol Chain. If a Data Item RST Entry, for example, has an associated invocation number, then its RST\$V_INVOCNUM bit is set and its RST\$L_SYMCHNPTR field points to an Invocation Number RST Entry. The Invocation Number RST Entry then specifies the desired invocation number (which is assumed to apply to the innermost routine in the scope of the symbol's declaration). The RST\$L_UPSCOPEPTR field in the Invocation Number RST Entry points to the original RST entry of the object (usually data item) without an invocation number. The format of the Invocation Number RST Entry is as follows:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	RST\$L_HASH_FLINK
1	RST\$L_HASH_BLINK
2	RST\$L_SYMCHNPTR
3	RST\$L_DSTPTR
4	RST\$L_UPSCOPEPTR
5	RST\$W_REFCOUNT : Flag bits : RST\$B_KIND
6	RST\$L_INVOCNUM

RST ENTRY FOR AN OVERLOADED SYMBOL

The RST entry for an Overloaded Symbol has the format shown below.
 An Overloaded Symbol RST Entry is created for each Overloaded Symbol
 DST record (DST\$K_OVERLOAD). The RST entry is hashed normally so that
 DBG\$STA_GETSYMBOL can find it.

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
 1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

2	-----RST\$L_SYMCHNPTR-----
3	-----RST\$L_DSTPTR-----
4	-----RST\$L_UPSCOPEPTR-----
5	-----RST\$W_REFCOUNT : Flag bits : RST\$B_KIND-----

SCOPE LIST DEFINITIONS

The scope list maintains the list of scopes declared with the SET SCOPE command. It is a singly linked list pointed to by the global variable SCOPE\$LIST in module RSTCNTRL. Each scope entry on the list has this format:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

0	-----SCOPE\$L_FLINK-----
1	-----SCOPE\$L_STATE-----
2	-----SCOPE\$L_RSTPTR-----
3	-----SCOPE\$L_MODPTR-----

A pointer to a scope list entry is declared as follows:

```
SCOPEPTR: REF SCOPE$ENTRY
```

Declare the scope entry fields and the definition macro.

```

FIELD SCOPE$FLD_DEF =
SET
SCOPE$L_FLINK   = [ 0, L_ ],      ! Scope list forward link or zero
SCOPE$L_STATE  = [ 1, L_ ],      ! The scope "state" or kind
SCOPE$L_RSTPTR = [ 2, L_ ],      ! Pointer to scope's own RST entry
SCOPE$L_MODPTR = [ 3, L_ ],      ! Pointer to scope's Module RST Entry
TES;

```

```

LITERAL
SCOPE$K_ENTSIZE = 4;              ! Size of scope entry in longwords

```

```

MACRO
SCOPE$ENTRY = BLOCK[SCOPE$K_ENTSIZE] FIELD(SCOPE$FLD_DEF) %;

```

! These are the possible values of the SCOPE\$L_STATE field. Each of these values indicates what kind of scope is to be searched to match a given pathname.

```

LITERAL

SCOPE$K_GLOBAL   = 3,              ! Global Symbol Table
SCOPE$K_SETMODS  = 4,              ! All SET modules

```

THE SCREEN DISPLAY ENTRY

The Screen Display Entry contains all information needed to represent and output a screen display on the terminal screen. All Display Entries are linked together by forward and backward links. Each Display Entry contains all information about where the corresponding display is placed on the screen, what attributes it has, and what the contents (the text) of the display is. The text is represented by pointers to the Screen Display Line Entries for the text lines that make up the display.

: 5631 0      DBG$K_SCROLL_RIGHT     = 4;      ! Scroll the display to the right
```

THE SCREEN DISPLAY LINE ENTRY

The Screen Display Line Entry holds the text and other attributes of a line within a screen display. This entry contains forward and backward links which link this Line Entry to the Line Entries for the previous line and the next line of the same display. The Line Entry also contains the line's rendition attributes (such as reverse video, blinking, etc.) which are to be passed to the Screen Management Package. Finally it contains the actual text of the line, including the length of that text, and the length of the text buffer.

Screen Display Line Entries come in two variants, the Normal and the Source Display Line Entry. Source Display Line Entries are used for source displays as the name implies, and Normal Display Line Entries are used for all other kinds of displays. Normal Display Line Entries can optionally include rendition information on a per-character basis.

NORMAL DISPLAY LINE ENTRY

The Normal Display Line Entry is used for all screen displays except Source screen displays. This is the format of the Normal Screen Display Line Entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

0      DBG$L_DLINE_FLINK
1      DBG$L_DLINE_BLINK
2      Unused      : $B_DLINE_LENGTH:      Flags      : $B_DLINE_REND
3      DBG$A_DLINE_TEXT
..
..      The Counted ASCII text of the display line
..

```

NORMAL DISPLAY LINE ENTRY WITH RENDITION VECTOR

The Normal Display Line Entry may include a "rendition vector" if the screen rendition is not the same for the entire line. In this case, the DBG\$V_DLINE_RENDFLG is set in the Display Line Entry's flag field and a "rendition vector" is present at the end of the Display Line Entry, immediately following the Counted ASCII text of the display line. The rendition vector contains one byte of rendition codes for each character in the Counted ASCII text of the line. The rendition vector has the same length as the Counted ASCII text.

3 3 2 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

SOURCE DISPLAY LINE ENTRY

The Source Display Line Entry is used for source displays only, and contains extra line number information which is not needed for other kinds of displays. The DBG\$V_DLINE_SOURCEFLG bit is always set in a Source Display Line Entry. This is the format of the Source Display Line Entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

Each Display Line Entry is part of a doubly linked list of such entries associated with some display. The fields DBG\$L_DISP_START_LINE_PTR and DBG\$L_DISP_END_LINE_PTR in the display's Screen Display Entry constitute the list head for this list of Display Line Entries.

The Display Line Entries associated with a display are reused as new text is added to the display contents. For this reason, each entry contains not only the length of the current text line but the length of the entry's text buffer as well. The text buffer will be longer than the current text line if it contained a longer text line earlier.

A pointer to the Screen Display Line Entry is declared as follows:

DLINK_PTR: REF DBG\$DLINE_ENTRY

Define the fields of the Screen Display Line Entry.

FIELD DBG\$DLINE_FLD =

THE SCREEN PASTEBOARD ENTRY

The screen pasteboard, on which all displays to be output on the terminal are pasted to determine what occludes what, is represented by a blockvector. The vector is indexed by line number and has one entry (block) for each line on the screen. The length of the vector is actually 21 (not 24) so that the last three lines on the screen are always reserved for user program output and DEBUG input prompting. For each line, the vector contains one Pasteboard Entry of the following format:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

SOURCE DIRECTORY SEARCH LIST

The Source Directory Search List is a list structure which keeps track of all source directory names specified by the user via SET SOURCE and SET SOURCE/MODULE=xxx commands. This structure is thus searched when a source file must be opened so that the file is opened in the proper directory.

The structure of this list is as follows. Variable DBF\$SRC DIR LIST in module DBG\$SOURCE points to a singly linked list of Source Directory Search List Header Blocks. Each Header Block contains a Module RST Entry pointer (which may be zero) and points to a singly linked list of Source Directory Search List Entries. Each such entry contains a directory name as a Counted ASCII string.

The list is searched by first searching all the Header Blocks for the Module RST Entry pointer for the current module, i.e. the module from which source lines are to be displayed. If the desired module is not found, the Header Block with the zero Module RST Entry pointer is used instead. The found Header Block then points to the linked list of directory names to use when searching for the desired source file. If there is no Header Block with either the desired module pointer or the zero module pointer, no Source Directory Search List Entries are used--the file name from the Declare Source File DST command is used as is.

The command SET SOURCE/MODULE=modname dir1,...,dirN is represented by a Header Block with a pointer to the Module RST Entry for module 'modname' and a pointer to a linked list of Entries. There is one Entry for each of dir1, ..., dirN. The command SET SOURCE dir1,...,dirN is represented by a Header Block with a zero Module RST Entry pointer and of course a pointer to a linked list of Entries for dir1, ..., dirN.

```

SOURCE DIRECTORY SEARCH LIST ENTRY

There is one Source Directory Search List Entry for each directory name specified on a SET SOURCE command. The "directory name" may in fact contain a full file name, including extension and version number, but in most cases it is used only to override the directory name as given in the Declare Source File DST command. This is the format of a Source Directory Search List Entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

A pointer to a Source Directory Search List Entry is declared like this:

SDSL_ENT_PTR: REF SDSL\$ENTRY

Declare the fields of the Source Directory Search List Entry. Also declare the declaration macro.

FIELD SDSL\$FLD_ENTRY =

SET
SDSL\$ENT_FLINK = [0, L], ! Forward link to next SDSL Entry

14	Unused SFCBSW_CUR_RFA4
15	SFCBSL_LBRINDEX

The Source File Control Blocks (SFCBs) keep track of all currently open source files. This includes modules within source libraries as well as normal RMS files. Each such block contains all information needed to read source records from the corresponding file. These blocks form a circular doubly linked list, where variable DBG\$SRC_SFCB_PTR in module DBG\$SOURCE points to the first block on the list. The blocks are always maintained in order so that the Most Recently Used SFCB is first on the list and the Least Recently Used block is last. This ordering allows DEBUG to close the Least Recently Used source file when a file must be closed in order to open a new file.

```

DEBUG always keeps a fixed number of Source File Control Blocks on the list. This number is given by variable DBG\$SRC_MAX_FILES in module DBGSOURCE. It can be changed by the user with the SET MAX_SOURCE_FILES command. This number limits the number of source files which are open at the same time. Such a limit is required to prevent DEBUG from using up too many of the limited number of channels the user can have open at any one time. Thus, when all SFCBs are in use and a new source file must be opened, the Least Recently Used file is closed and its SFCB is reused for the new file.

A pointer to a Source File Control Block is declared as follows:

SFCB_PTR: REF SFCB\$BLOCK

Declare the fields of the Source File Control Block. Also declare the declaration macro.

FIELD SFCB\$FLD_DEF =

SOURCE FILE ID TABLE

The Source File ID Table is used during the decoding of the Source Line Correlation DST Record to keep track of the File IDs used to reference the current module's source files. The Source File ID Table consists of a singly linked list of Source File ID Table Entries, where each entry gives a File ID, a pointer to the corresponding Declare Source File command, (This command gives all needed information about the identity and nature of the source file.), and the current source record number. This table is used locally in routine DBG\$SRC_TYPE_LNUM SOURCE in module DBG\$SOURCE. This is the format of each Source File ID Table Entry:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	-----	SFIT\$L_FLINK	-----
1	-----	SFIT\$L_FILE_ID	-----
2	-----	SFIT\$L_DSTPTR	-----
3	-----	SFIT\$L_CURRECNUM	-----

A pointer to a Source File ID Table Entry is declared as follows:

SFIT_PTR: REF SFIT\$ENTRY

Declare the fields of the Source File ID Table Entry. Also declare the declaration macro.

FIELD SFIT\$FLD_DEF =

SET

SFIT\$L_FLINK = [0, L_], ! Forward link to next SFIT entry
SFIT\$L_FILE_ID = [1, L_], ! File ID value for this source file
SFIT\$L_DSTPTR = [2, L_], ! Pointer to DST Declare Source File
! command for this source file
SFIT\$L_CURRECNUM = [3, L_] ! Current source record number for
! this source file

TES;

LITERAL

SFIT\$K_SIZE = 4; ! Size of SFIT entry in longwords

MACRO SFIT\$ENTRY = BLOCK[SFIT\$K_SIZE] FIELD(SFIT\$FLD_DEF) %;

SOURCE FILE RECORD FILE ADDRESS TABLE

This is the format of each Record File Address Table entry:

```

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

The Record File Address Table correlates record numbers in a source file with RFA's for that file. It is used during the TYPE command and other commands that cause source lines to be displayed, to help locate the desired record more efficiently.

There is one RFA table for each open file. The table is allocated during DBG\$SRC_INIT and a pointer to the table is placed in the Source File Control Block. The table consists of a fixed number of entries (RFATBL_SIZE_ENTRIES, defined in DBG\$SOURCE).

For every N records in the file, there is one RFA entry. That is, the first entry is the RFA for record 1, the next for record (1+N), the next for record (1+2N), and so on. The spacing N can be adjusted dynamically and is kept in the Source File Control Block.

A pointer to an RFA table is declared as follows:

```
RFATBL_PTR : REF RFATBL$BLOCKVECTOR(RFATBL_SIZE_ENTRIES)
```

Declare the fields of an RFA table entry. Also declare the declaration macro.

```
FIELD RFATBL$FLD_DEF =
```

```
SET
```

```
RFATBL$RFA0 = [ 0 , L_ ] , ! Block number part of RFA
```

```

```

```
MACRO
```

```
RFATBL$BLOCKVECTOR(N) =  
BLOCKVECTOR [N, RFATBL$K_SIZE, BYTE] FIELD(RFATBL$FLD_DEF) %;
```

STATIC ADDRESS TABLE DEFINITIONS

The Static Address Table (SAT) consists of a two-level structure. There is a Program Static Address Table which specifies what static addresses (code addresses and static data addresses) belong to what modules. This table consists of a linked list of SAT entries where each entry specifies an address range and a pointer to the corresponding Module RST Entry. The list is ordered by start address so that low start addresses come before higher start addresses. It should be noted that a given address may be covered by more than one SAT entry because different modules can have global PSECTs in common--Fortran COMMON blocks cause this situation to arise. Given an address, the Program Static Address Table can thus be searched to find the module that contains the address.

On a second level, there is a Module Static Address Table for each module that is SET. This SAT is a linked list of exactly the same structure as the Program SAT except that the RST pointer in the SAT entry points to the RST entry of the symbol, not the module, containing the address range. This list is also ordered by start address and again more than one symbol may contain the same address (due to Fortran EQUIVALENCEing for example). If two entries have the same start address, the entry with the larger end address is placed first in the Module SAT; this is crucial to the correct behavior of the DBG\$STA_SETCONTEXT routine where routine addresses are compared to PC values from the VAX call stack. The Module RST Entry contains a pointer (RST\$SAT_PTR) which points to the first SAT entry on the module's SAT chain.

Note (R. Title)- for a future release of DEBUG, I intend to turn the SAT chains into binary trees, instead of linked lists. The reason for this is that for large programs, the SAT chains can grow quite long (e.g., 1000 entries), and it becomes quite expensive to search this list linearly.

The tree search algorithm will work something like this: If the desired address is greater than the address in the SAT\$END field of the current node, follow the "right son" pointer. If it is less than the address in the SAT\$START field of the current node, then follow the "left son" pointer. If it is in the range, then we have found the desired SAT entry and we are done.

During the transition to this new data structure, the same four fields are being kept in the SAT entry in the same place (so that the old code still works). The "right son" field is overlaid with the FLINK field, so that the tree search algorithm will work on the old linked lists (a linear list is just an extremely unbalanced tree, with no left branches). The "left son" field will occupy the fifth longword.

The individual Static Address Table entry has this format:

```

3 3 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

```

LITERAL

SAT\$K_ENTSIZE = 5; ! Size of one SAT entry in longwords

MACRO

SAT\$ENTRY = BLOCK[SAT\$K_ENTSIZE] FIELD(SAT\$FLD_DEF) %;

VALUE DESCRIPTOR DEFINITIONS

Value Descriptors describe language values generated during the processing of language expressions in DEBUG commands like EVAL and DEPOSIT. The language-independent version of the Value Descriptor consists of the Value and Primary Descriptor header fields followed by a 3-longword VAX Standard Descriptor followed by the actual value described by the Value Descriptor. It thus has the following format:

3 3 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1
1 0 9 8 7 6 5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

0	SB_DHDR_LANG	SB_DHDR_TYPE	DBG\$W_DHDR_LENGTH
1	SB_DHDR_KIND	SB_DHDR_FCODE	DBG\$W_DHDR_FLAGS
2	DBG\$L_DHDR_TYPEID		
3	DBG\$L_DHDR_SYMID0		
4	SB_VALUE_SIGN_CODE (constant)	SB_VALUE_TOKENCODE (constant)	
5	SB_VALUE_CLASS	SB_VALUE_DTYPE	DBG\$W_VALUE_LENGTH
6	DBG\$L_VALUE_POINTER		
7	Third longword of VAX descriptor--usage depends on class.		
8	DBG\$A_VALUE_ADDRESS		
..	If DBG\$B_DHDR_TYPE contains DBG\$K_VALUE_DESC, then the actual value will be stored here.		
..	A byte or word integer value is stored extended to longword integer using sign- or zero-extension, as appropriate.		
..			

A pointer to a Value Descriptor is declared as follows:

VALPTR: REF DBG\$VALDESC

Define the fields of the language-independent Value Descriptor. Also define the declaration macro.

```
FIELD DBG$VALUE_FIELDS =
SET
DBG$W_VALUE_TOKENCODE=[ 4, WO_ ],      ! Value of TOKEN$W_CODE for constants
```

```

6417 0      DBG$W_VALUE_SIGN_CODE=[ 4, W1_ ],      Sign code (Value of Unary -/+
6418 0      DBG$A_VALUE_VMSDESC = [ 5, A_ ],      TOKEN$W_CODE) for constants

Array Bounds Descriptor

An array bounds Descriptor is used to pass around all needed
information about an array and its associated dimensions.
Like VALU_DESCRIPTORs, they are simply 2-longword blocks,
but this might change.

!-----longword-----!
!-----!
! address of array      !
!-----!
! length of array      !
!-----!

Such Descriptors must be accessed via the following
field names.
--

FIELD
    ARRAY_BNDS_SET =
    SET
        ARRAY_ADDRESS = [ 0,0,32,0 ],      ! Beginning address of array.
        ARRAY_LENGTH  = [ 4,0,32,0 ]      ! Size, in bytes, of array.
    TES;

+

++

Now we bring in the GST definitions directly from STARLET.REQ.

The format of one of these concatenated GSD records is a single leading byte containing the value 1, indicating that the record is indeed a GSD record.

Each entry in the record has a fixed number of overhead bytes followed by a symbol name that is a variable number of bytes. The entries we are interested in processing are the global symbol definitions and entry point symbol and mask definitions. The other defined type, PSECT definition, is noted only because it must be successfully passed over. The format of each of these types is illustrated below:

Global symbol definition:

0	! GSD type 1 !	
1	! data type !	ignored for now
2	! flag	bit 1 set means that this is a definition. ignore bit 0.
3	! bytes !	
4	! psect index !	ignored.
5	! value	4 bytes
9	! symbol name	
		stock counted character string.

The entry point symbol and mask definition entry is identical to the global symbol definition illustrated above, with the addition of a two byte field for the procedure's register save mask. This two byte field is located after the symbol value field (which is an entry point address).

0	! GSD type 2 !	
1	! data type !	ignored for now
2	! flag	not relevant for entry point def.
3	! bytes !	
4	! psect index !	ignored
5	! value	4 bytes

```

! The name string itself. An undotted
reference is the address of the name,
a dotted one is the 1st character.

! The entry name is a counted string.
A dotted reference to this field
picks up the count, an undotted
one addresses the counted string.
The name string itself. An undotted
reference is the address of the name,
a dotted one is the 1st character.
Maximum number of formal arguments.
Remaining byte count of argument
descriptor.

! Minimum number of bytes in psect def
! Minimum number of bytes in a global entry
! Minimum number of bytes in entry
! point symbol and mask definition
! Minimum size of formal argument descriptor
! Size of min. and max. overhead in GST
! Type of GST record
! Record Type is GST

Dummy descriptors

Whenever a type DSC\$K_DTYPE_CAD item is being accessed by descriptor we must build a dummy one in free storage and put the current address in it. The address of this dummy descriptor is then used by the rest of the debugger in referencing the item. To be able to free up all this space, the items are kept on a linked list. At the end of command processing this list is walked down and all the space is returned to the free storage manager.

Each entry on the linked list is a 3 longword vector

pointer to next item on the linked list

pointer to the dummy descriptor

size in bytes of the dummy descriptor

The global variable DBG\$GL_DLISHEAD if nonzero points to the first item on the list.

LITERAL

DLIS_ENTRY = 3 ;	! Size in longwords of entry on list
DLIS_LINK = 0 ;	! Pointer to next item on list
DLIS_POINTER = 1 ;	! Pointer to dummy descriptor
DLIS_DESCSIZE = 2 ;	! Size in bytes of descriptor
