MODULE FUNCTION: This REQUIRE file contains all macros used in defining and accessing data structures (BLISS BLOCKs) in the VAX Debugger. These symbolic names should always be used in BLISS Field-References.

DATA STRUCTURE DEFINITION AND ACCESS

The following macros must be used in defining field names for all data structures in the Debugger. These macros supply the position, size, and sign-extension values when used in FIELD declarations for BLOCK and BLOCKVECTOR data structures. The various generic forms (as specified by the letters in the names) are as follows:

- A Materialized address
- L Longword
- W Zero-extended word
- B Zero-extended byte
- V Zero-extended bit field
- SW Sign-extended word
- SB Sign-extended byte
- SV Sign-extended bit field

The "A" form should be used whenever the field being defined is such that only the address of the field may be materialized in a structure reference; that is, fetch and store operations on the field are not valid. An example of such a field is an ASCII string.

Each of the "V" and "SV" forms take one or two parameters. The first parameter is the bit position within the longword (or byte) and the second is the field size in bits. The second parameter is optional; if omitted, it defaults to 1. Thus V\_(5) means bit 5 while V\_(5,3) means the 3-bit field starting at bit 5 and ending at bit 7. Bit positions are counted from the low-order (least significant) end of the longword, starting at zero.

The following data structure picture shows the locations of the various fields that can be specified. Note how the bit positions are numbered along the top of the illustration.
