MODULE FUNCTION

This REQUIRE file describes the structure of the Debug Symbol Table
generated by the VAX compilers and interpreted by the VAX Debugger.
It includes definitions for all field names and literals used in
building or interpreting the Debug Symbol Table (DST).

DISCLAIMER

This interface is not supported by Digital. While the Debug Symbol
Table interface is believed to be correctly described here, Digital
does not guarantee that all descriptions in this definition file are
correct and complete. Also, while this interface is expected to be
reasonably stable across releases, Digital cannot guarantee that it
will not change in future releases of VAX DEBUG, VAX VMS, the VAX
compilers, or other software. Upward-compatible additions to this
interface are more likely than incompatible changes, but individuals
and organizations who use this interface stand some risk that their
work will be partially or wholly invalidated by future releases of
VAX DEBUG or other Digital software. Digital reserves the right to
make future incompatible changes to the Debug Symbol Table interface.

PURPOSE OF THE DEBUG SYMBOL TABLE

The Debug Symbol Table (DST) is the symbol table that the VAX compilers produce to pass symbol table information to the VAX Debugger and to the VAX Traceback facility. The DST is a language-independent symbol table in the sense that all VAX compilers output symbol information in the same format, regardless of source language. This symbol information is emitted into the object modules produced by the compiler. It is then passed through the Linker into the executable image file that the linker generates. DEBUG or TRACEBACK can then retrieve the symbol information from the image file.

The purpose of the Debug Symbol Table is thus to permit the Traceback facility to give a symbolic stack dump on abnormal program termination and to permit DEBUG to support fully symbolic debugging. Other Digital software may also use the DST information for various purposes.

To support these purposes, the Debug Symbol Table represents all major aspects of program structure and data representation. It can represent modules, routines, lexical blocks, labels, and data symbols and it can represent all nesting relationships between such symbols. It can also describe line number and source line information. It can describe all data types supported by DEBUG, including complex types such as record structures and enumeration types. In addition, it can describe arbitrarily complex value and address computations.

The Debug Symbol Table is solely intended to support compiled languages, not interpreted languages. The DST representation assumes that source lines have been compiled into VAX instructions and that those instructions are actually executed, not interpreted. Such DEBUG facilities as breakpoints and single-stepping will not work if this assumption is violated. Similarly, it is assumed that data objects have addresses that can be accessed directly when these objects are examined or deposited into. DST information is thus generated by all compilers that VAX DEBUG supports, but not by the interpreters for languages such as APL or MUMPS.

This section describes the general structure of the Debug Symbol Table. It explains how the DST is generated by the various VAX compilers, how it is passed along to the executable image file by the linker, and how it is accessed in the image file by DEBUG or TRACEBACK. This section also describes in general terms how the DST is structured internally: how it is subdivided into modules, routines, lexical blocks, and individual symbols, how nesting relationships are represented, and how data symbols, including their values and data types, are represented. The exact formats of the various Debug Symbol Table records and other fine-grained detail are described later in this definition file, not here, but the coarse structure of the DST and how that structure is accessed are outlined in this section.

GENERATION OF THE DST

The Debug Symbol Table (DST) is generated by the compilers for all VAX languages supported by DEBUG. During compilation, the compiler outputs the DST for the module being compiled into the corresponding object file. When the linker is invoked, it does relocation and global-symbol resolution on the DST text and then outputs it into the executable image file. Beyond knowing what must be relocated, the linker has no special knowledge of the format or contents of the DST. Finally, the Debugger reads the DST information from the executable image file during a debugging session, or Traceback reads it when giving a traceback in response to an unhandled severe exception during image execution.

A compiler outputs DST information in the form of two kinds of object records, TBT records and DBT records. (See the linker manual for a full description of the VAX object language accepted by the linker.) All "traceback" information goes into the TBT records and all "symbol" information goes into the DBT records. When the user later links using the plain LINK command, only the DST information in the TBT records are copied to the executable image file. These records contain enough information for Traceback to give a call-stack traceback. If the user links with the LINK/DEBUG command, all information in both the TBT and the DBT records are copied to the executable image file. These records together give all DST information needed for full symbolic debugging. The user can also link with LINK/NOTRACEBACK, in which case no DST information at all is copied to the executable image file.

It is not possible to have the linker copy the DBT records without also copying the TBT records; the information in the TBT records is required for the information in the DBT records to make sense.

The "traceback" information in the TBT records includes all Module Begin and End DST records, all Routine Begin and End DST records, all Lexical Block Begin and End DST records, and all Line Number PC-Correlation DST records. It may also include Version Number DST records. All other DST records should be included in DBT records.

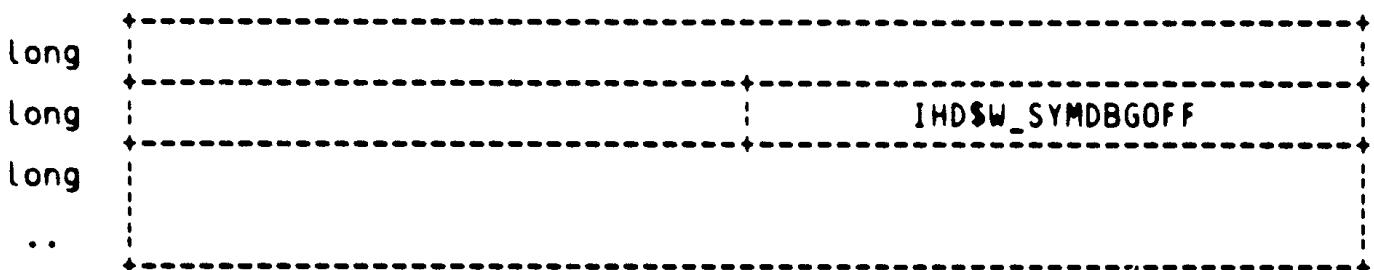

0281 0 Most VAX compilers have a /DEBUG qualifier which in its most general
0282 0 form has two subqualifiers: /DEBUG=([NO]TRACEBACK,[NO]SYMBOLS). The
0283 0 unadorned /DEBUG qualifier is equivalent to /DEBUG=(TRACEBACK,SYMBOLS);
0284 0 it causes all DST information to be output. /DEBUG=TRACEBACK causes
0285 0 only the traceback information (the TBT records) to be output by the
0286 0 compiler. /DEBUG=(NOTRACE,NOSYMBOL) causes no DST information to be
0287 0 output at all. Finally, /DEBUG=(NOTRACE,SYMBOLS) causes all DST infor-
0288 0 mation except Line Number PC-Correlation DST records to be output (this
0289 0 combination is largely pointless although it saves some DST space).
0290 0 Note that the module, routine, and lexical block information, which
0291 0 counts as traceback information, must be output if any symbol infor-
0292 0 mation is output since it defines the scopes within which other symbols
0293 0 are defined.
0294 0

0295 0 When the linker outputs the Debug Symbol Table to the executable image
0296 0 file, it may also output two more image sections: the Global Symbol
0297 0 Table (GST) and the Debug Module Table (DMT). These two tables are
0298 0 generated if the LINK/DEBUG command is used, not otherwise. The Global
0299 0 Symbol Table contains records for all global symbols known to the linker
0300 0 in the current user program. DEBUG uses the GST as a symbol table of
0301 0 last resort when DST information is not available, either because the
0302 0 module containing some global symbol was compiled without DST informa-
0303 0 tion being output or because the module is not set (with SET MODULE) in
0304 0 the current debugging session. The GST information is not as complete
0305 0 as the DST information for the same symbols because the GST has no type
0306 0 description (the linker does not need to know about data types).
0307 0

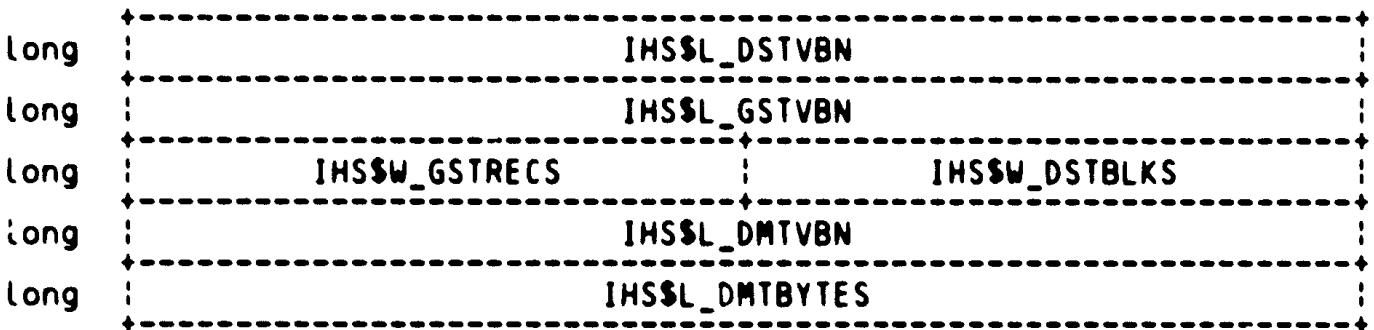

0308 0 The Debug Module Table (DMT) is an indexing structure for the DST. It
0309 0 contains one record for each module in the DST. This record contains
0310 0 a pointer to the start of the DST for the corresponding module, the size
0311 0 of the DST for that module, the number of PSECTs in that module, and the
0312 0 address ranges of all those PSECTs. The DMT allows DEBUG to initialize
0313 0 its Module Table and its Static Address Table without actually having to
0314 0 read through the entire DST; because the DMT is very small compared to
0315 0 the DST, it can be scanned much more efficiently.
0316 0
0317 0 The details of how the DST, the GST, and the DMT are accessed in the
0318 0 executable image file are explained in the next section.

0319 0 | LOCATION OF THE DST WITHIN THE IMAGE FILE

0320 0 |
0321 0 |
0322 0 | The Debug Symbol Table is accessed through pointer information found in
0323 0 | the executable image file header block. This header block contains a
0324 0 | pointer in a fixed location (IHD\$W_SYMDBGOFF) which points to a small
0325 0 | block later in the header which gives the size and location of the
0326 0 | Debug Symbol Table (DST), the Global Symbol Table (GST), and the Debug
0327 0 | Module Table (DMT). The first part of the executable image file header
0328 0 | looks as follows:

0343 0 | Here IHD\$W_SYMDBGOFF contains the byte offset relative to the start of
0344 0 | the header of an Image Header Symbol Table Descriptor. The Image Header
0345 0 | Symbol Table Descriptor (IHS) in turn has the following format:

0362 0 | Here IHSSW_DSTBLKS and IHSSL_DSTVBN give the size (in blocks) and loca-
0363 0 | tion (Virtual Block Number) of the Debug Symbol Table (DST) within the
0364 0 | executable image file. The fields IHSSW_GSTRECS and IHSSL_GSTVBN give
0365 0 | the size (in GST records) and start location (Virtual Block Number) of
0366 0 | the Global Symbol Table (GST). Finally, the fields IHSSL_DMTBYTES and
0367 0 | IHSSL_DMTVBN give the size (in bytes) and start location (Virtual Block
0368 0 | Number) of the Debug Module Table (DMT). The DMT is described below.
0369 0 | These field names are declared by macros in SYSSLIBRARY:LIB.L32. The
0370 0 | symbol IHD\$W_SYMDBGOFF is also defined in SYSSLIBRARY:LIB.L32.

0372 0 | Pointers to the Image Header and the Image Header Symbol Table Descrip-
0373 0 | tor are declared as follows:

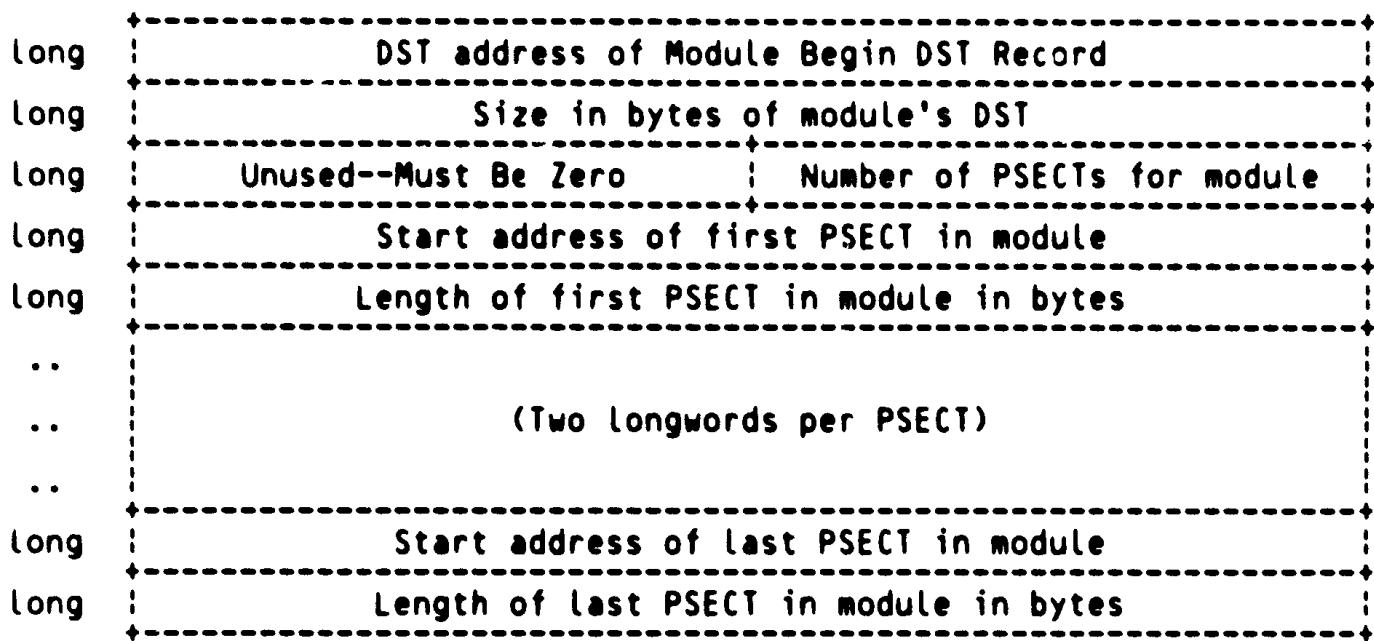

0374 0 | IHDPTR: REF BLOCK[,BYTE]
0375 0 |

0376 0

0377 0

0378 0 The Image File Header in an executable image file points to the Image
 0379 0 Header Symbol Table descriptor as described above. If bit 5 of field
 0380 0 IHSSL_LNKFLAGS in the image header is set, this is a "new" image, i.e.
 0381 0 one produced by the VMS V4.0 or later linker, and the IHSSL_DMTVBN and
 0382 0 IHSSL_DMTBYTES fields exist in the Image Header Symbol Table descriptor.
 0383 0 (If bit 5 is not set, this is an "old" image and those fields do not
 0384 0 exist.) If non-zero, IHSSL_DMTVBN gives the Virtual Block Number in
 0385 0 the image file of the Debug Module Table (the DMT). IHSSL_DMTBYTES
 0386 0 then gives the size of the DMT in bytes. The DMT is only Built if the
 0387 0 user did a LINK/DEBUG; if he did not, IHSSL_DMTVBN and IHSSL_DMTBYTES
 0388 0 are zero.

0389 0
 0390 0 The Debug Module Table contains one entry per module in the Debug
 0391 0 Symbol Table (the DST). This is the format of each such DMT entry:

0418 0 Longword 0 gives the address relative to the start of the DST of the
 0419 0 Module Begin DST Record for this module. Longword 1 gives the size
 0420 0 of the DST in bytes for the same module. Longword 2 gives the number
 0421 0 of PSECTs in the module (i.e., the number of statically allocated
 0422 0 program sections), and this is followed by that number of two-longword
 0423 0 pairs which give the start address and length (in bytes) of each such
 0424 0 PSECT. Since the number of PSECTs cannot exceed 65K, the upper two
 0425 0 bytes of longword 2 are available for future expansion.

0426 0
 0427 0 The DMT is used during DEBUG initialization to initialize DEBUG's Run-
 0428 0 Time Symbol Table (RST) and Program Static Address Table (Program SAT).
 0429 0 Using the DMT is much faster than the alternative procedure, namely,
 0430 0 reading through the entire DST to pick up the needed information. The
 0431 0 information in the DMT entry is enough to build a Module RST Entry for
 0432 0 each module in the DST and the PSECT information is used to build the

0433 0 |
0434 0 | Program SAT. The amount of RST symbol table space needed per module is
0435 0 | not computable from the DMT information, but is estimated by multiplying
0436 0 | the DST size of each module by an appropriate scale factor.
0437 0 |
0438 0 |
0439 0 |
0440 0 |
0441 0 |

OVERALL STRUCTURE OF THE DST

0442 0 |
0443 0 | The Debug Symbol Table consists of a contiguous sequence of DST records.
0444 0 | Each DST record contains a two-byte header which gives the length of the
0445 0 | record in bytes and the type of the record. The structure of the rest
0446 0 | of the record (if any) is determined by the record type. The length of
0447 0 | the DST in 512-byte blocks is given in the image file header; if the DST
0448 0 | does not fill the last block, that block is zero-padded to the end.
0449 0 |
0450 0 |
0451 0 |
0452 0 |
0453 0 |
0454 0 |
0455 0 |
0456 0 |
0457 0 |
0458 0 |
0459 0 |

0460 0 |
0461 0 | The largest structural unit within the DST is the module. Each module
0462 0 | represents the symbol table information of a separately compiled object
0463 0 | module. The DST for a module always begins with a Module Begin DST rec-
0464 0 | ord and ends with a Module End DST record. The Module Begin DST record
0465 0 | gives the name of the module and the source language in which it was
0466 0 | written. The Module End DST record simply marks the end of the module
0467 0 | and contains no other information. As noted above, if present, the
0468 0 | Debug Module Table (DMT) points to the Module Begin DST record of each
0469 0 | module represented in the DST. DEBUG uses the DMT (if present) to lo-
0470 0 | cate all modules in the DST.
0471 0 |
0472 0 |
0473 0 |

0474 0 |
0475 0 | The DST as a whole thus always begins with the Module Begin DST record
0476 0 | for the first module in the DST. It is followed by the symbol informa-
0477 0 | tion for that module. Then comes the Module End DST record for that
0478 0 | module. Immediately after that Module End DST record comes the Module
0479 0 | Begin DST record for the next module, and so on to the end of the whole
0480 0 | DST, where the Module End DST record for the last module is found. The
0481 0 | rest of that image file block is zero-filled to the next block boundary.
0482 0 | Note that there is no break between modules in the DST.
0483 0 |
0484 0 |
0485 0 |
0486 0 |
0487 0 |
0488 0 |
0489 0 |

NESTING WITHIN THE DST

0474 0 |
0475 0 | For most languages, the symbol table must represent a variety of nesting
0476 0 | relationships. Routines are nested within modules, data symbols are
0477 0 | declared within routines, and even routines are nested within routines.
0478 0 | Certain data constructs, in particular record structures, contain addi-
0479 0 | tional nesting relationships. In the Debug Symbol Table, such nesting
0480 0 | relationships are represented by Begin-End pairs of DST records. We
0481 0 | have already seen above that the largest subunit of the DST, namely the
0482 0 | module, is represented by a Module Begin DST record and a Module End DST
0483 0 | record bracketting the DST information for the module.
0484 0 |
0485 0 |
0486 0 |
0487 0 |
0488 0 |
0489 0 |

This principle extends to other nesting relationships. The DST information for a routine is thus represented by a Routine Begin DST record and a Routine End DST record enclosing the DST information for all symbols local to or nested within that routine. Similarly, lexical blocks (such as BEGIN-END blocks or their equivalents in various languages) are represented by Block Begin and Block End DST records enclosing the symbol

0490 0 DST records local to that lexical block. The nesting of routines and
 0491 0 blocks within one another to any depth (within reason) is represented by
 0492 0 the proper nesting of the corresponding Begin and End DST records.
 0493 0

0494 0 An example may help clarify this notion. The following example shows a
 0495 0 program in a fictitious language along the corresponding sequence of DST
 0496 0 records:
 0497 0

0498 0 Program Structure

```

0500 0 -----
0501 0
0502 0 MODULE M =
0503 0     BEGIN
0504 0     VAR SYM_M1: INTEGER;
0505 0     VAR SYM_M2: REAL;
0506 0
0507 0     ROUTINE R1 =
0508 0         BEGIN
0509 0         VAR SYM_R11: BOOLEAN;
0510 0         VAR SYM_R12: INTEGER;
0511 0         END;
0512 0
0513 0     ROUTINE R2 =
0514 0         BEGIN
0515 0         VAR SYM_R21: DOUBLE;
0516 0         VAR SYM_R22: INTEGER;
0517 0         ROUTINE R2A =
0518 0             BEGIN
0519 0             VAR SYM_R2A: BYTE;
0520 0                 BEGIN
0521 0                 VAR BLK_V1: WORD;
0522 0                 ROUTINE R2BLKR =
0523 0                     BEGIN
0524 0                         FOO:BEGIN
0525 0                             VAR FOO_V:REAL;
0526 0                         END;
0527 0
0528 0                         VAR R2BLK_V2:REAL;
0529 0                         END;
0530 0
0531 0                         VAR BLK_V2: DOUBLE;
0532 0                         END;
0533 0
0534 0             END;
0535 0
0536 0             VAR SYM_R23: REAL;
0537 0             END;
0538 0
0539 0         END;
0540 0
0541 0

```

0542 0 Here module (compilation unit) M contains two module-level data items,
 0543 0 SYM_M1 and SYM_M2, and two routines, R1 and R2. Routine R2 in turn con-
 0544 0 tains several local data symbols (SYM_R21, SYM_R22, and SYM_R23) and a
 0545 0 nested routine R2A. R2A in turn contains an anonymous BEGIN-END block,
 0546 0 that blocks contains two local data symbols BLK_V1 and BLK_V2 and a

0532 0     Block End (for no name)
0533 0
0534 0     Routine End (for R2A)
0535 0
0536 0     Data SYM_R23 (DTYPE_F)
0537 0     Routine End (for R2)
0538 0
0539 0     Module End
0540 0
0541 0

```

0547 0 local routine R2BLKR local routine R2BLKR contains a data symbol and a
 0548 0 labelled BEGIN-END block FOO, and block FOO contains one local symbol,
 0549 0 FOO_V. All this nesting is represented by Begin and End DST records in
 0550 0 the Debug Symbol Table as illustrated on the right.
 0551 0

0552 0 Additional nesting must be represented for data. A record (called a
 0553 0 structure in some languages) is a composite data object containing some
 0554 0 number of record components of various data types. A record component
 0555 0 may itself be a record. In addition, some languages allow records to
 0556 0 have "variants" (as in PASCAL), which imposes additional structure that
 0557 0 must be represented in the DST.
 0558 0

0559 0 A record type is represented by a Record Begin and Record End DST record
 0560 0 pair bracketting the DST records for the record components. This notion
 0561 0 is illustrated by this program segment and the corresponding DST:
 0562 0
 0563 0

0564 0 **Program Structure**
 0565 0 -----

```
0567 0 TYPE RECTYP =  

0568 0   RECORD OF  

0569 0     COMP1: INTEGER;  

0570 0     COMP2: REAL;  

0571 0     COMP3: DOUBLE;  

0572 0   END;
```

0564 0 **DST Record Sequence**
 0565 0 -----

```
0567 0 Record Begin (RECTYP)  

0568 0 Data COMP1 (DTYPE_L)  

0569 0 Data COMP2 (DTYPE_F)  

0570 0 Data COMP3 (DTYPE_D)  

0571 0 Record End (for RECTYP)
```

0575 0 Here RECTYP is a record type. Each object of this type is a record con-
 0576 0 taining three components, COMP1, COMP2, and COMP3. This structure is
 0577 0 represented in the DST by a Record Begin DST record followed by Data DST
 0578 0 records for the components followed by a Record End DST record. The
 0579 0 addresses specified in the component DST records are bit or byte offsets
 0580 0 from the start of the RECTYP record as a whole.
 0581 0

0582 0 In this example, the Record Begin DST record for RECTYP may in fact re-
 0583 0 present either a record type or a record object. A field in the Record
 0584 0 Begin DST record indicates which. However, let us assume that RECTYP
 0585 0 defines a record type. How do we then declare objects of that type?
 0586 0 The following example illustrates how:
 0587 0
 0588 0

0589 0 **Program Structure**
 0590 0 -----

```
0593 0 TYPE RECTYP =  

0594 0   RECORD OF  

0595 0     COMP1: INTEGER;  

0596 0     COMP2: REAL;  

0597 0     COMP3: DOUBLE;  

0598 0   END;
```

```
0600 0 VAR REC1: RECTYP;  

0601 0 VAR REC2: RECTYP;
```

0589 0 **DST Record Sequence**
 0590 0 -----

```
0593 0 Data REC1 (SepTypSpec)  

0594 0 Record Begin (RECTYP)  

0595 0 Data COMP1 (DTYPE_L)  

0596 0 Data COMP2 (DTYPE_F)  

0597 0 Data COMP3 (DTYPE_D)  

0598 0 Record End (for RECTYP)
```

```
0600 0 Data REC2 (SepTypSpec)  

0601 0 Type Spec DST record  

0602 0 (Indirect Type Spec)
```

0603 0

pointing to RECTYP)

0604 0

0612 0
0613 0
0614 0
0615 0
0616 0
0617 0

Here the same record type RECTYP is defined. Two objects of that type are also defined, REC1 and REC2. Both data objects are represented by Separate Type Specification DST records. Such a DST record must be immediately followed by a DST record that defines the symbol's data type. The REC1 Separate Type Specification DST record is immediately followed by the RECTYP Record Begin DST record; hence REC1 is of the RECTYP data type. The REC2 Separate Type Specification DST record is immediately followed by a Type Specification DST record. This record contains an Indirect Type Specification that points back to the Record Begin DST record for RECTYP. Hence REC2 is also of that record type.

0618 0

0631 0
0632 0
0633 0

Records may be nested in the sense that a record component may itself be an object of some record type. A record component of a record type is represented the same way as any other object of a record type, namely by a Separate Type Specification DST record. This record must be followed by a Record Begin DST record or by a Type Specification DST record that points to a Record Begin DST record. The record component can also be represented by a Record Begin DST record directly if this record is marked as defining an object rather than a type.

Record variants, as found in PASCAL, introduce additional structure. A detailed description of how variants are represented in the DST is found in the section on "Record Structure DST Records" later in this definition file. Here we will only give an example that illustrates the general scheme that is used:

Program Structure

```
-----  
TYPE RECTYP =  
  RECORD OF  
    COMP1: INTEGER;  
    CASE TAG: BOOLEAN OF  
      FALSE: (  
        COMP2: REAL;  
        COMP3: DOUBLE);  
      TRUE: (  
        COMP4: INTEGER);  
    END CASE;  
  END;  
  
VAR REC1: RECTYP;
```

DST Record Sequence

```
-----  
Data REC1 (SepTypSpec)  
Record Begin (RECTYP)  
  
Data COMP1 (DTYPE_L)  
Data TAG (BOOLEAN)  
Variant Set Begin  
  (tag variable = TAG)  
Variant Value for FALSE  
Data COMP2 (DTYPE_F)  
Data COMP3 (DTYPE_D)  
  
Variant Value for TRUE  
Data COMP4 (DTYPE_L)  
  
Variant Set End  
Record End (for RECTYP)
```

Nesting is also used to describe enumeration types as found in PASCAL and some other languages. An enumeration type is described by an Enumeration Type Begin DST record followed by Enumeration Type Element DST

0661 0 records for all the enumeration literals of the type followed by an
0662 0 Enumeration Type End DST record. Any actual object of the enumeration
0663 0 type must be described by a Separate Type Specification DST record.
0664 0 This example illustrates what the DST for an enumeration type looks
0665 0 like:
0666 0
0667 0

0668 0 **Program Structure**
0669 0 -----
0670 0

0671 0 TYPE COLOR = (
0672 0 RED
0673 0 GREEN,
0674 0 BLUE
0675 0);
0676 0
0677 0

0678 0 VAR HUE: COLOR;
0679 0 VAR PAINT: COLOR;

0695 0
0696 0
0697 0
0698 0
0699 0

0700 0 A more detailed description is found in the section entitled "Enumeration Type DST Records" later in this definition file.
0701 0
0702 0

0703 0 For some DST record types, DEBUG ignores all nesting relationships below
0704 0 the module level. Line Number PC-Correlation DST records, for example,
0705 0 may be scattered throughout the DST for a module. DEBUG treats all such
0706 0 DST records as defining the line number information for the module as a
0707 0 whole, regardless of how they may be scattered within or outside the
0708 0 routines and blocks of the module. Similarly, Source File Correlation
0709 0 DST records may be scattered throughout the DST for a module. Records
0710 0 such as these can be generated wherever the compiler finds it most con-
0711 0 venient to generate them.
0712 0
0713 0

0714 0 **DATA REPRESENTATION IN THE DST**
0715 0
0716 0

0717 0 Data Symbols are described in the DST by a variety of representations.
0718 0 Fundamentally, all such representations give three pieces of information
0719 0 about each data symbol: its name, its address or value, and its data
0720 0 type. DEBUG needs additional information about a data symbol, in parti-
0721 0 cular its scope of declaration, but that information is implicit in the
0722 0 nesting structure of the DST as described above.
0723 0
0724 0

0725 0 The name is given by a Counted ASCII string in the data symbol's DST
0726 0 record. The value or address can be given by a five-byte encoding con-
0727 0 taining one byte of control information and a longword address, offset,
0728 0 or value. However, if this five-byte encoding is not adequate to de-
0729 0 scribe the address or value, escapes to a more complex value specifica-
0730 0 tion later in the DST record are available. The data type may be repre-
0731 0 sented by a one-byte type code, but if that is not adequate there are
0732 0 several escapes to a more complex type description elsewhere in the DST.

The standard five-byte value specification can specify any 32-bit or smaller literal value, any static byte address, any register address, and any address that can be formed by one indexing operation off a register or one indirection or both. If a VAX Standard Descriptor exists for the symbol in user memory, the five-byte encoding can describe the descriptor address by any of the above means; the actual data address is then retrieved from the descriptor.

The standard five-byte value specification is adequate for the bulk of all data symbols. However, there are cases when it is inadequate. It cannot describe literal values longer than 32 bits, it cannot describe very complex address computations, and it cannot describe bit addresses unless an appropriate descriptor is available in user memory. For these cases, the first byte of the five-byte encoding must have one of several special escape values. The remaining longword then contains (in most cases) a pointer to a more complex value specification later in the same DST record. That more complex value specification may consist of a VAX Standard Descriptor or a "VS-Follows" Value Specification. A VS-Follows Value Specification can, in the most complex case, contain a routine to be executed by DEBUG to compute the desired value or address. This routine may even call compiler-generated thunks when the complexity of the address computation so requires.

The details of these more complex value specifications are given in the section entitled "DST Value Specifications" later in this definition file. The point being made here is simply that the DST provides a simple and compact value specification mechanism that is adequate for all simple cases, but it also provides several escapes to arbitrarily complex DST Value Specifications. These complex value specifications are capable of describing all known address and value computations required by the languages supported by DEBUG.

Data type specifications are done in a similar way. For all simple, atomic data types, a single type byte describes the data type of a data symbol. However, there are several escape mechanisms for more complex data types. One mechanism is to take the type information from a VAX Standard Descriptor found either in user memory or in the DST. Another is to use a Separate Type Specification DST record for the data symbol. The data type is then described by a second DST record which immediately follows the Separate Type Specification DST record. This second record must be a Record Begin DST record (describing a record type), an Enumeration Type Begin DST record (describing an enumeration type), or a Type Specification DST record. A Type Specification DST record can describe any data type supported by DEBUG. It contains a DST Type Specification for the data type in question. This Type Specification may be an Indirect Type Specification, pointing to a DST record elsewhere in the DST that defines the data type. Alternatively, it may describe the desired data type directly and may be as complex as the data type requires.

DST Type Specifications are described in a separation section elsewhere in this definition file. The point being made here is simply that the simple one-byte type specification is available for simple data types, but several escapes to arbitrarily complex DST type specifications are available when the simple type specification is inadequate.

0776 0

FIELD ACCESS MACROS

0777 0
0778 0 The following macros are used in defining BLISS field names for all data
0779 0 structures in the Debug Symbol Table. These macros supply the position,
0780 0 size, and sign-extension values when used in FIELD declarations for
0781 0 BLOCK and BLOCKVECTOR data structures. They are used instead of their
0782 0 numeric equivalents because they are clearer and less error-prone. The
0783 0 various generic forms (as specified by the letters in the names) are as
0784 0 follows:

A	Materialized address
L	Longword
W	Zero-extended word
B	Zero-extended byte
V	Zero-extended bit field
SW	Sign-extended word
SB	Sign-extended byte
SV	Sign-extended bit field

0794 0
0795 0 The "A" form should be used whenever the field being defined is such
0796 0 that only the address of the field may be materialized in a structure
0797 0 reference; that is, fetch and store operations on the field are not
0798 0 valid. An example of such a field is an ASCII string.

0799 0
0800 0 Each of the "V" and "SV" forms take one or two parameters. The first
0801 0 parameter is the bit position within the longword or byte and the
0802 0 second is the field size in bits. The second parameter is optional;
0803 0 if omitted, it defaults to 1. Thus V_(5) means bit 5 while V_(5,3)
0804 0 means the 3-bit field starting at bit 5 and ending at bit 7. Bit
0805 0 positions are counted from the low-order (least significant) end of the
0806 0 longword, starting at zero.

0807 0
0808 0 This following field access macros are used in DSTRECRDS.REQ. Their
0809 0 actual definitions are found in STRUCDEF.REQ, but are shown here for
0810 0 the convenience of the reader.

0866 0
0867 0
0868 0
0869 0 All supported values of the DST record type field (DST\$B_TYPE) are
0870 0 listed here. If the value is in the range of DSC\$K_DTYPE_LOWEST to
0871 0 DSC\$K_DTYPE_HIGHEST, it is a VAX Standard Type Code and gives the
0872 0 data type of the object being defined. In this case, the record is
0873 0 a Standard Data DST Record or one of its variants. Otherwise, the
0874 0 type value must be in the range DST\$K_LOWEST to DST\$K_HIGHEST or it
0875 0 may be DST\$K_BLI. In these cases, the type code denotes the type of
0876 0 the DST record and the format of the record is determined by type
0877 0 value. All other type codes are unsupported by DEBUG. The type codes
0878 0 between DSC\$K_DTYPE_HIGHEST and DST\$K_LOWEST are reserved for future
0879 0 use by Digital. The type codes in the range 192 - 255 are potentially
0880 0 reserved for use by customers, although DEBUG does not support any
0881 0 such type codes. DEBUG ignores all records with unsupported type
0882 0 codes.

VAX STANDARD TYPE CODES

As mentioned above, VAX Standard Type Codes can be used as DST record type codes for data symbols. The type code then gives the data type of the symbol in addition to indicating that the DST record has the Standard Data DST record format or a variant thereof.

All VAX Standard Type Codes are listed here for convenience. They are commented out since they are actually declared in STARLET.REQ.

1063	0	DST\$K_HIGHEST	= 191:	Highest numbered DST record in this range--used for range checking
1064	0			
1065	0			

! NOTE TO DEVELOPERS:

New DST Records should not be added at this end of the DST record number range. VAX Standard Type Codes 192 - 255 are reserved to users. Hence DEBUG does not use type codes in that range, even though DEBUG does not support user-defined type codes. New DST record numbers should be allocated by decrementing DST\$K_LOWEST and using that number for the new DST record.

MODULE DST RECORDS

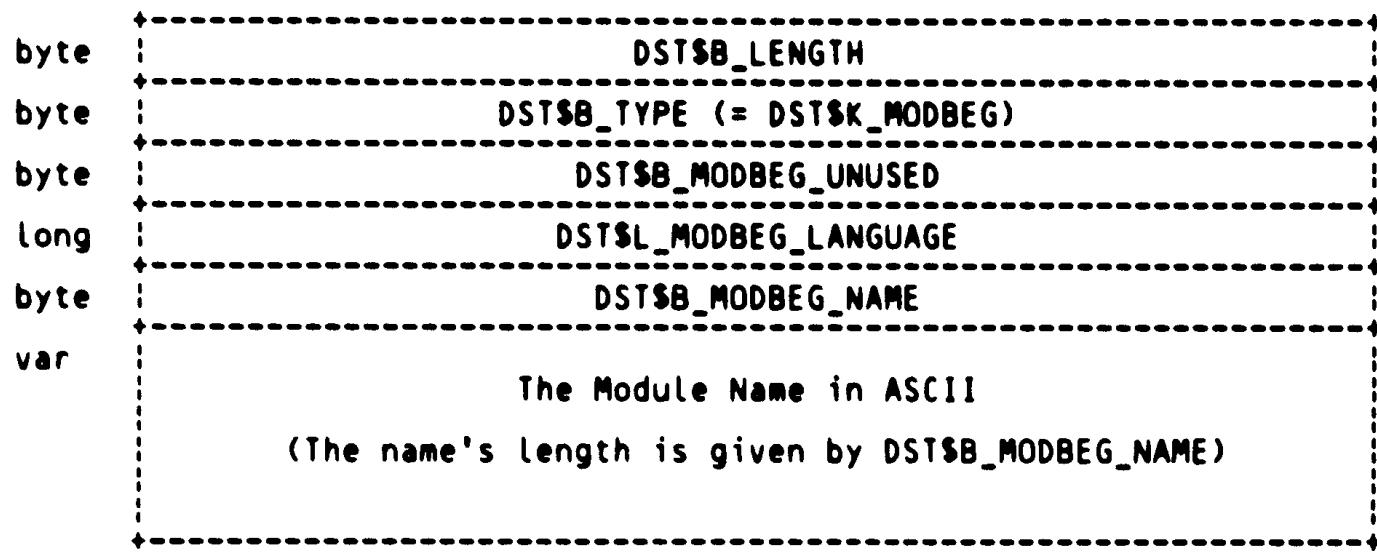

The Debug Symbol Table for each separately compiled module must be enclosed within a Module-Begin/Module-End pair of DST records. The Module Begin DST record must thus be the very first DST record for any separately compiled module (i.e., any object file) and the Module End DST record must be the very last DST record for the module. Only one Module-Begin/Module-End pair is allowed in what the linker sees as a single object module. (If multiple Module-Begin/Module-End pairs are included in one object module, DEBUG will only see the first such pair and ignore the rest because the linker will only tell DEBUG about the location of the first Module Begin record.)

The Module-Begin/Module-End pair defines a symbolic scope which contains all symbols defined by DST records within that pair. The module has the name given in the Module Begin DST record. The language of the object module is also encoded in the Module Begin record.

1092 0 THE MODULE BEGIN DST RECORD

1093 0
 1094 0
 1095 0 The Module Begin DST Record marks the beginning of the DST for a module.
 1096 0 This DST record also gives the name of the module and the source lan-
 1097 0 guage in which the module was written. The Module Begin DST Record
 1098 0 must be the first DST record of every compilation unit ('module')
 1099 0 and it must be matched by a Module End DST Record that ends the DST for
 1100 0 that module. Only one Module Begin DST Record is allowed to appear in
 1101 0 the DST for a separately compiled object module.

1102 0
 1103 0 This is the format of the Module Begin DST Record:
 1104 0
 1105 0

1180 0 DBG$K_MAX_LANGUAGE = DST$K_MAX_LANGUAGE; ! Largest language code
1181 0
1182 0

```

1183 0 ! Language UNKNOWN requires some special explanation. DEBUG supports "unknown"
1184 0 languages with a standard set of DEBUG functionality. This standard set in-
1185 0 cludes all language-independent functionality plus "vanilla-flavored" language
1186 0 expressions. Identifiers are assumed to allow A - Z, 0 - 9, \$ and _ . Symbol
1187 0 references may include subscripting (using round () or square [] parentheses)
1188 0 and record component selection (using dot-notation as in A.B().) Most simple
1189 0 operators are allowed in language expressions.

1190 0 While not officially supported, language UNKNOWN is intended as an escape for
1191 0 compilers which do not yet have true DEBUG support. By specifying language
1192 0 code DST\$K UNKNOWN in the DST\$L_MODBEG LANGUAGE field, such languages can
1193 0 take advantage of whatever support DEBUG provides for unknown languages. If
1194 0 and when true DEBUG support is provided, a new language code for the new
1195 0 language can be allocated by incrementing DST\$K_MAX_LANGUAGE by one and as-
1196 0 signing that language code to the new language.
1197 0
1198 0

1199 0 DEBUG treats any out-of-range language code in the Module Begin DST record as
1200 0 being equivalent to language UNKNOWN. Use of the DST\$K UNKNOWN language code
1201 0 or any out-of-range language code is intended for internal use by Digital
1202 0 only. DEBUG's unknown-language support is not officially supported and is
1203 0 subject to possibly incompatible changes in future releases of DEBUG.
1204 0
1205 0

! Internally, DEBUG treats the language code as a byte value. Hence any lan-

ROUTINE DST RECORDS

A routine is represented in the Debug Symbol Table by a pair of DST records, namely a Routine Begin DST record which is matched with a later Routine End DST record. All DST records between the Routine Begin and the Routine End DST records represent the symbols that are declared in that routine or in nested routines or blocks. Nested routines are represented in the DST by nested Routine-Begin/Routine-End pairs. Lexical blocks (BEGIN-END blocks or the like, depending on the language) may also be nested freely outside or inside routines, provided all blocks and routines are properly nested.

Consider the following example of nested blocks and routines. If routine R1 contains a nested routine R2 and a lexical block B1 and if block B1 contains routine R3 and Block B2, the DST would have the following sequence of DST records:

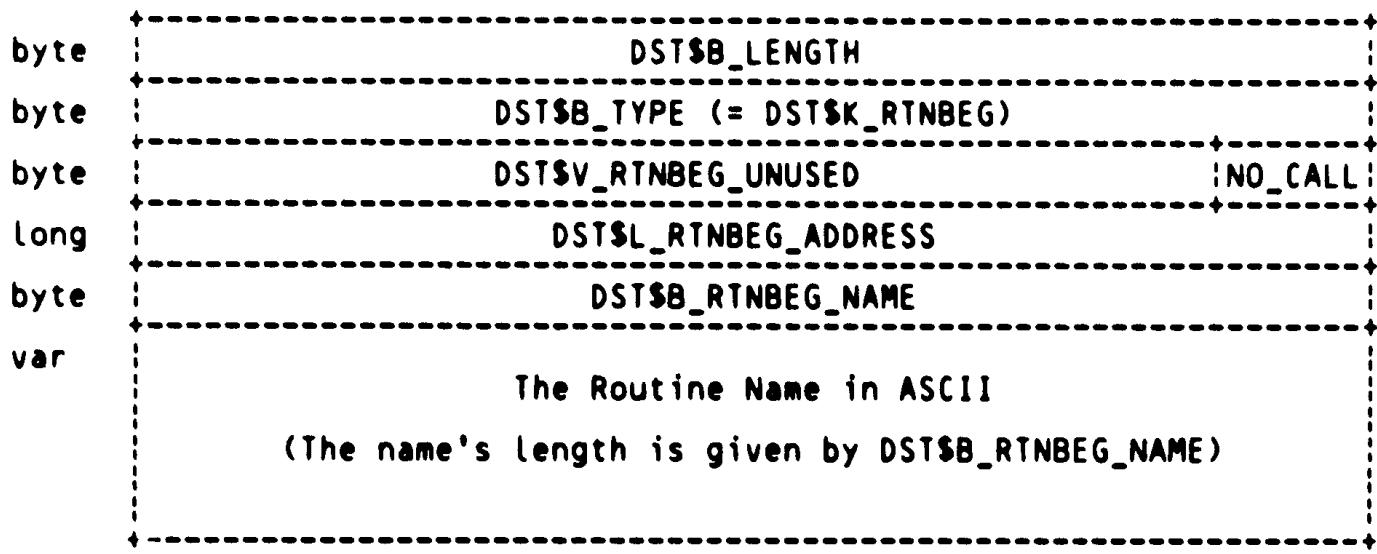

```
Module Begin for whole module
...module-level data DST records...
Routine Begin for R1
...local data DST records for R1...
Routine Begin for R2
...local data DST records for R2...
Routine End for R2
Block Begin for B1
...local data DST records for B1...
Routine Begin for R3
...local data DST records for R3...
Routine End for R3
Block Begin for B2
...local data DST records for B2...
Block End for B2
Block End for B1
Routine End for R1
Module End for whole module
```

In addition to defining a symbol scope, the Routine-Begin/Routine-End pair defines the name and address range of the corresponding routine. The name and start address is found in the Routine Begin DST record and the byte length of the routine is found in the Routine End DST record. It is assumed that the start address is also the entry point to the routine. The Routine Begin record also indicates whether the routine uses a CALLS/CALLG linkage or a JSB/BSB linkage.

1274 0 THE ROUTINE BEGIN DST RECORD

1277 0
 1278 0 The Routine Begin DST record marks the beginning of a routine and the
 1279 0 associated scope. This record contains the routine's name and start
 1280 0 address and indicates whether the routine is a CALLS/CALLG routine
 1281 0 or a JSB/BSB routine. It must be matched by a Routine End DST record
 1282 0 later in the DST, except if the language of the current module is
 1283 0 MACRO. (Since MACRO routines have entry points but no well defined
 1284 0 end points, the Routine End record can and must be omitted for this
 1285 0 language. This exception applies to no other language.)

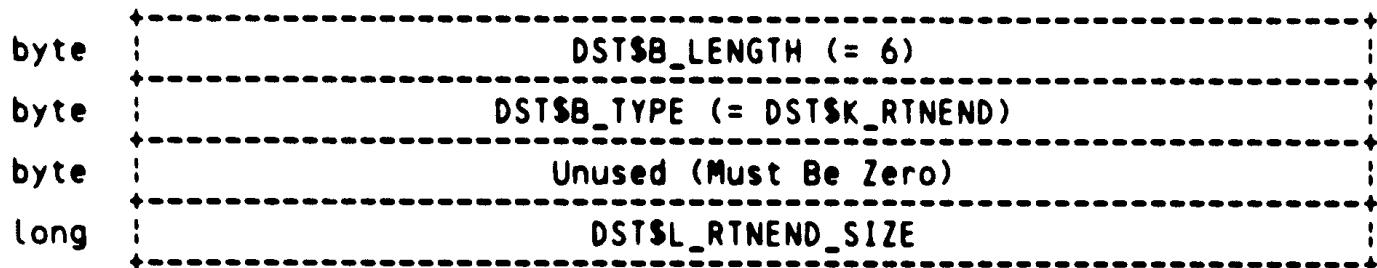

1286 0 This is the format of the Routine Begin DST record:

1311 0 FIELD DST\$RTNBEG_FIELDS =
 1312 0 SET
 1313 0 DST\$V_RTNBEG_UNUSED = [2, V_(0, 7)], ! Unused--Must Be Zero
 1314 0 DST\$V_RTNBEG_NO_CALL = [2, V_(7, 1)], ! This bit is set if this rou-
 1315 0 tine is invoked with a
 1316 0 JSB or BSB rather a CALLS
 1317 0 or CALLG instruction
 1318 0 DST\$L_RTNBEG_ADDRESS = [3, L_], ! The routine's start address
 1319 0 and entry point address
 1320 0 DST\$B_RTNBEG_NAME = [7, B_] ! The count byte of the rou-
 1321 0 tine's Counted ASCII name
 1322 0
 1323 0 TES:
 1324 0
 1325 0 LITEPAL DST\$K_RTNBEG_SIZE = 8: ! Byte size of the fixed part of the
 1326 0 Routine Begin DST record
 1327 0

1328 0 THE ROUTINE END DST RECORD

1329 0
1330 0
1331 0 The Routine End DST Record marks the end of a routine's scope in the
1332 0 DST. It also contains the byte length of the routine's code. (Note
1333 0 that Routine End DST records must be omitted for language MACRO but
1334 0 are mandatory for all other languages.) This is the format of the
1335 0 Routine End DST record:

1338 0
1339 0 Define the fields of the Routine End DST record.

1340 0
1341 0 FIELD DST\$RTNEND_FIELDS =
1342 0 SET
1343 0 DST\$L_RTNEND_SIZE = [3, L_] ! The length of the routine in bytes

1356 0

LEXICAL BLOCK DST RECORDS

1357 0

1358 0

1359 0

1360 0

A "Lexical Block" is any programming language construct other than a routine that defines a scope within which symbols can be declared. What distinguishes a "block" from a "routine", from DEBUG's point of view, is that a block is always entered by jumping to it or simply falling into it while a routine is always entered by a call instruction of some sort. A routine has a entry point that can be called; a block does not. Hence BEGIN-END blocks in BLISS and PL/I are blocks and so are Paragraphs and Sections in COBOL. Subroutines, functions, and procedures, on the other hand, are "routines".

1361 0

1362 0

1363 0

1364 0

1365 0

1366 0

1367 0

1368 0

1369 0

Blocks and routines do have one thing in common, however. Both define syntactic units within which other symbols can be defined. The purpose of representing blocks in the DST is to define the scopes they enclose and to give the address ranges of the corresponding bodies of code.

1370 0

1371 0

1372 0

1373 0

1374 0

1375 0

A lexical block is represented in the Debug Symbol Table by a pair of DST records, namely a Block Begin DST record which is matched with a later Block End DST record. All DST records between the Block Begin and the Block End DST record represent the symbols that are declared in that lexical block or in nested routines or blocks. Nested blocks are represented in the DST by properly nested Block-Begin/Block-End pairs. Routines and blocks may freely be nested within one another, using the appropriate proper nesting of the corresponding Begin and End DST records.

1376 0

1391 0

1392 0

1393 0 ! THE BLOCK BEGIN DST RECORD

The Block Begin DST Record marks the beginning of a lexical block and the associated scope. This record contains the block's name and start address. It must be matched by a Block End DST record later in the DST. This is the format of the Block Begin DST record:

```
-----+-----+
byte      DST$B_LENGTH
-----+-----+
byte      DST$B_TYPE (= DST$K_BLKBEG)
-----+-----+
byte      DST$B_BLKBEG_UNUSED
-----+-----+
long      DST$L_BLKBEG_ADDRESS
-----+-----+
byte      DST$B_BLKBEG_NAME
-----+-----+
var       The Block's Name in ASCII
          (The name's length is given by DST$B_BLKBEG_NAME)
```

Define the fields of the Block Begin DST record.

1432 0 | THE BLOCK END DST RECORD

1433 0 |
1434 0 |
1435 0 | The Block End DST Record marks the end of a lexical block's scope in
1436 0 | the DSi. It also contains the byte length of the block's code. This
1437 0 | is the format of the Block End DST record:

```
1438 0 |-----+  
1439 0 | byte | DST$B_LENGTH (= 6)  
1440 0 |-----+  
1441 0 | byte | DST$B_TYPE (= DST$K_BLKEND)  
1442 0 |-----+  
1443 0 | byte | Unused (Must Be Zero)  
1444 0 |-----+  
1445 0 | long | DST$L_BLKEND_SIZE  
1446 0 |-----+
```

1447 0 | Define the fields of the Block End DST record.

```
1448 0 | FIELD DST$BLKEND_FIELDS =  
1449 0 |   SET

DATA SYMBOL DST RECORDS

Data symbols are represented in the Debug Symbol Table by data DST records which come in several varieties. All such DST records give three pieces of information about each symbol: the data type of the symbol, the value or address of the symbol, and the name of the symbol.

The Standard Data DST record is the simplest form of data DST symbol record and is used for most ordinary atomic data objects. It represents the data type by a one-byte VAX Standard Type Code. It represents the value or address of the symbol by a simple five-byte encoding capable of specifying 32-bit literal values, absolute addresses, register locations, and addresses computed as offsets from a register, possibly including indirection. It is also possible to specify that the computed address is the address of a VAX Standard Descriptor for the data symbol. Finally, the name is represented as a Counted ASCII character string.

There are several reasons why a Standard Data DST record may not be adequate to represent a data symbol. First, the symbol's data type may be too complicated to represent by a one-byte type code. In this case, one of several available escape mechanisms must be used so that expanded type information can be included in the symbol's DST information. Second, if the symbol is a literal (a named constant), its value may be too large to fit in one longword. In this case, an expanded value specification must be used. And third, if the symbol is a variable, its address may be specified by a more complicated computation than can be represented in the Standard Data DST record. In this case, an escape to a more complicated value specification must be used.

Expanded type specifications come in three main forms: Descriptor Format DST records, Separate Type Specification DST records, and various specialized DST records that handle various special kinds of data types such as record structures, enumeration types, and BLISS structures.

Descriptor Format DST records are used when the data object must be described by a VAX Standard Descriptor and has a static address. A packed decimal data object, for example, must be described by a descriptor that specifies the object's length and scale factor. If a descriptor exists in user memory at run-time, the Standard Data DST record can be used, but otherwise it is necessary to include the descriptor directly in the DST within a Descriptor Format DST record. These DST records are used for all static arrays and other data objects that can be described by VAX Standard Descriptors.

For data types that can be described by neither one-byte type codes nor VAX Standard Descriptors, a Separate Type Specification DST record must be used. In this case the DST record's type field indicates that the type specification is found in a separate DST record which immediately follows the present DST record. The DST record that follows must be a Type Specification, Record Begin, or Enumeration Type Begin DST record. These records can describe all data types supported by

1515 0 | DEBUG in full detail.

1516 0 |
1517 0 | As mentioned above, the third data type "escape" mechanism is to use
1518 0 | one of a number of specialized DST records that describe data symbols
1519 0 | of special kinds. BLISS structures and fields, for example, are de-
1520 0 | scribed by special DST records, as are enumeration type elements.
1521 0 | These DST records will not be further described in this section; they
1522 0 | are described elsewhere in this definition file.
1523 0 |

1524 0 | Expanded "Value Specifications" must be used for data symbols whose
1525 0 | values or addresses are too long or too complicated to be described
1526 0 | by the Standard Data DST record. A D-Floating constant, for example,
1527 0 | has too large a value (8 bytes) to fit in a Standard Data DST record.
1528 0 | A "based variable" in PL/I may require a complicated computation or
1529 0 | even a call on a compiler-generated thunk to compute the variable's
1530 0 | address. For these and other cases, a Trailing Value Specification
1531 0 | DST record must be used. Such a record includes a Value Specifica-
1532 0 | tion which may be arbitrarily complex.
1533 0 |

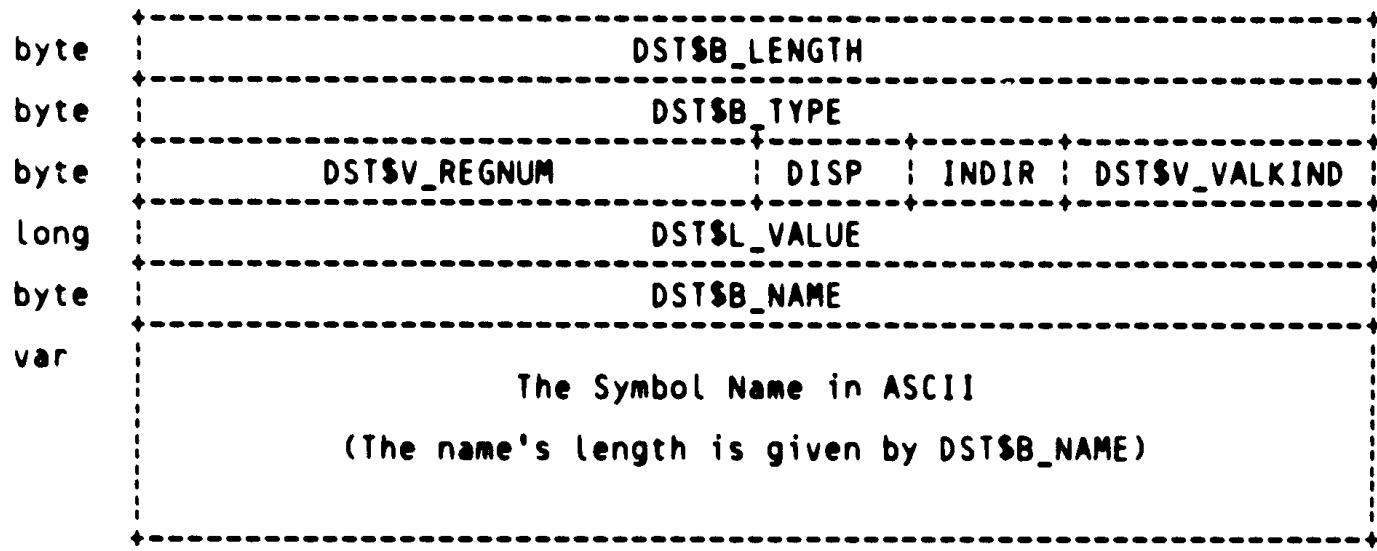

1534 0 | Trailing Value Specification DST records are sometimes used to speci-
1535 0 | fy both type and address information. An array with dynamic array
1536 0 | bounds, for instance, must be described in the DST if no descriptor
1537 0 | exists in user memory at run-time. A Trailing Value Specification
1538 0 | can be used to compute the entire descriptor for such an array at
1539 0 | DEBUG-time. The descriptor then gives both the array address and
1540 0 | type information such as the element type and the array bounds.
|

1541 0 ! THE STANDARD DATA DST RECORD

1544 0
 1545 0 The Standard Data DST record is used to describe most simple scalar
 1546 0 data objects such as integers, floating-point numbers, and complex
 1547 0 numbers. The data type is represented by the one-byte VAX Standard
 1548 0 Type Code in the DST\$B_TYPE field. The value DST\$K_BOOL is also
 1549 0 accepted; it denotes that the data symbol is a Boolean variable or
 1550 0 value which is TRUE if the low-order bit is set and FALSE otherwise.

1551 0
 1552 0 The value specification in the Standard Data DST record indicates
 1553 0 the symbol's value or address or how to compute the symbol's address.
 1554 0 The details are found below.

1555 0 This is the format of the Standard Data DST record:

1579 0 Define the fields of the Standard Data DST record. These fields are also
 1580 0 used in many other DST records of similar formats.

1582 0 FIELD DST\$STD_FIELDS =
 1583 0 SET
 1584 0 DST\$B_VFLAGS = [2, B_], Value-flags (access information)
 1585 0 DST\$V_VALKIND = [2, V_(0,2)], How to interpret the specified value
 1586 0 DST\$V_INDIRECT = [2, V_(2)], Set if address of address is produced
 1587 0 by indicated computation (do an
 1588 0 indirect to compute address)
 1589 0 DST\$V_DISP = [2, V_(3)], Set if content of DST\$L_VALUE is used
 1590 0 as a displacement off a register
 1591 0 specified in DST\$V_REGNUM
 1592 0 DST\$V_REGNUM = [2, V_(4,4)], Number of register used in displace-
 1593 0 ment mode addressing
 1594 0 DST\$L_VALUE = [3, L_], Value, address, or bit offset
 1595 0 DST\$B_NAME = [7, B_], Count byte of the symbol name field,
 1596 0 a counted ASCII string
 1597 0
 TES:

1598 0
 1599 0
 1600 0 Define all special values that may appear in the DST\$B_VFLAGS field. If one
 1601 0 of these values appears in that field, the DST\$L_VALUE field has some special
 1602 0 meaning indicated by the special value. In such cases, the DST\$B_VFLAGS sub-
 1603 0 fields have no meaning. Not all of these special values may appear in a
 1604 0 Standard Data DST record (see the comments below), but they are all listed
 1605 0 here for completeness. Note that these values (with one exception) all have
 1606 0 the top four bits set--hence they cannot be normal VFLAGS values since the
 1607 0 REGNUM field cannot contain 15 (indicating the PC) in a normal VFLAGS value.
 1608 0

1609 0 LITERAL

DST\$K_VFLAGS_NOVAL	= 128.	A flag which indicates that no value is specified, i.e. the object being described is a type. This value may only appear in a Record Begin DST record.
DST\$K_VFLAGS_UNALLOC	= 249.	This value is DST\$B_VFLAGS signals a data item that was never allocated (and hence has no address). For example, PASCAL does not allocate variables that are not referenced.
DST\$K_VFLAGS_DSC	= 250.	This value in DST\$B_VFLAGS signals a Descriptor Format DST record
DST\$K_VFLAGS_TVS	= 251.	This value in DST\$B_VFLAGS signals a Trailing Value Spec DST record
DST\$K_VS_FOLLOWS	= 253.	Value Specification Follows (allowed only in a Trailing Value Spec)
DST\$K_VFLAGS_BITOFFS	= 255:	A flag indicating that DST\$L_VALUE contains a bit offset (used only for record components)

1631 0
 1632 0 Provided the DBG\$B_VFLAGS field does not have one of the above special values,
 1633 0 the DBG\$V_VALKIND field indicates what kind of value or address is computed
 1634 0 by the value computation. The possible values of this field are defined here.
 1635 0

1636 0 LITERAL

DST\$K_VALKIND_LITERAL	= 0,	DST\$L_VALUE contains a literal value
DST\$K_VALKIND_ADDR	= 1,	Computation produces the address of the data object
DST\$K_VALKIND_DESC	= 2,	Computation produces the address of a VAX Standard Descriptor for the data object
DST\$K_VALKIND_REG	= 3:	Value is contained in the register whose number is in DST\$L_VALUE

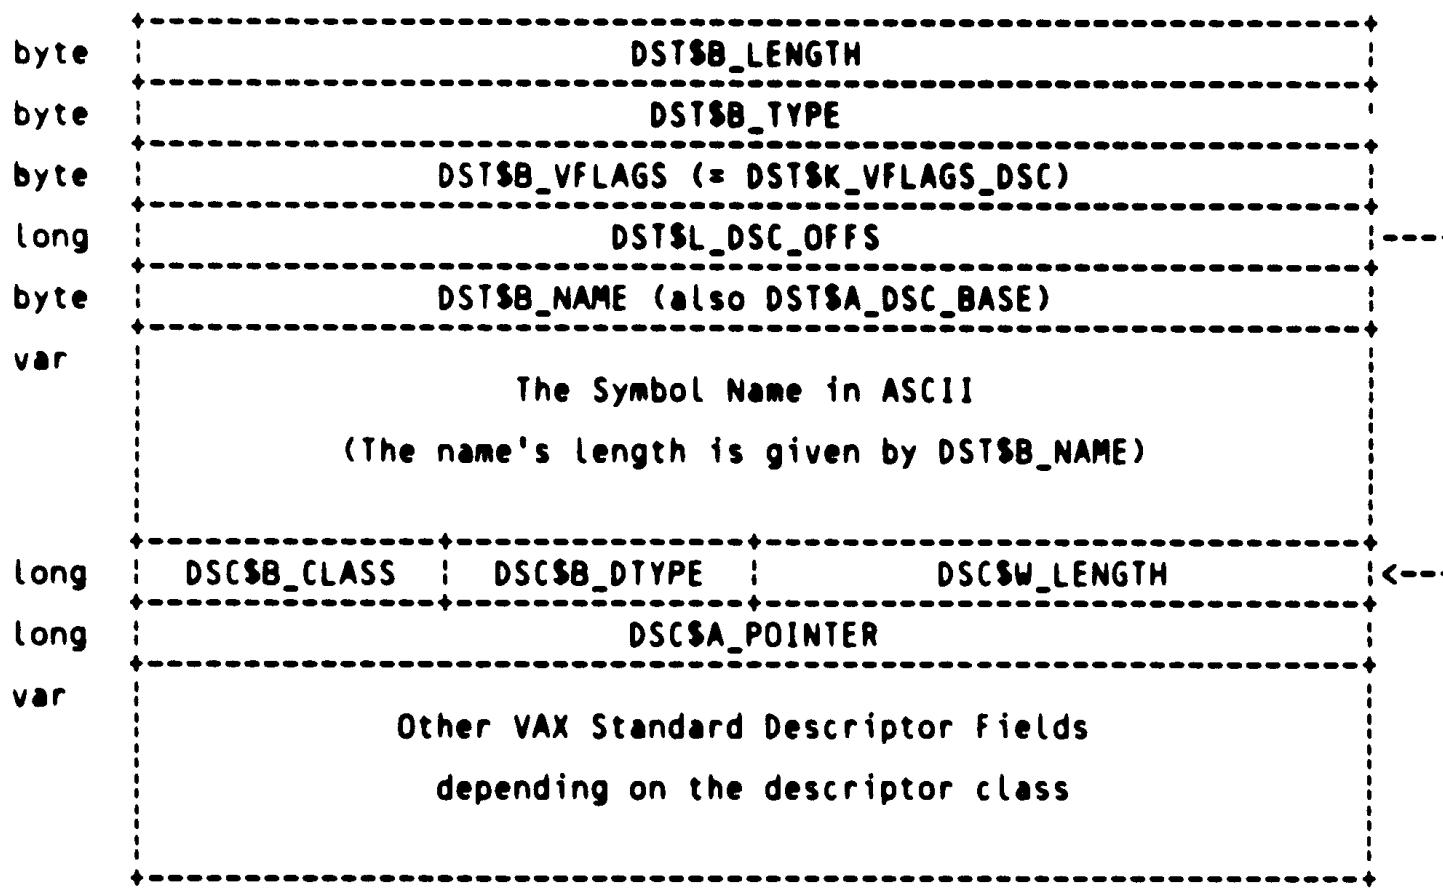

1646 0
 1647 0 If the DST\$K_VFLAGS field does not contain one of the special values listed
 1648 0 above, then the computation that produces the value or address of the data
 1649 0 object proceeds as follows:
 1650 0

1. If the VALKIND field contains DST\$K_VALKIND_LITERAL, the symbol is a
constant whose value is given by the DST\$L_VALUE field. Such constants
can be up to 32 bits long.

- 1655 0 | 2. If the VALKIND field contains DST\$K_VALKIND_REG, the symbol is a variable bound to a register. The register number of that register is given by the DST\$L_VALUE field.
- 1656 0 | 3. Otherwise, the symbol is a variable with a non-register address. To compute that address, the DST\$L_VALUE field is picked up.
- 1657 0 | 4. If the DST\$V_DISP bit is set, the contents of the register whose register number is given by the DST\$V_REGNUM field is added to the value picked up from the DST\$L_VALUE field.
- 1658 0 | 5. If the DST\$V_INDIRECT bit is set, the address computed so far is treated as the address of a pointer that points to the actual data object. In other words, an indirection is done.
- 1659 0 | 6. If the value of the VALKIND field is DST\$K_VALKIND_ADDR, the address computed so far is treated as the address of the data object.
- 1660 0 | 7. If the value of the VALKIND field is DST\$K_VALKIND_DESC, the address computed so far is treated as the address of a VAX Standard Descriptor for the data object. The actual address of the object, along with its other attributes such as type and size, must therefore be retrieved from that descriptor.
- 1661 0 |
1662 0 | As this description indicates, moderately complicated address computations can be specified in the Standard Data DST record. For example, the address of the second formal parameter to a routine, passed by reference, can be described by making DST\$V_REGNUM = 12 (for register AP), DST\$L_VALUE = 8 (to indicate an offset of 8 bytes from AP to get at the second longword in the argument vector), DST\$V_DISP = 1 (to indicate that DST\$L_VALUE is to be treated as a displacement off AP), and DST\$V_INDIRECT = 1 (to indicate an indirection since the argument is passed by reference). DST\$V_VALKIND = DST\$K_VALKIND_ADDR in this case. If the parameter were passed by descriptor, however, DST\$V_VALKIND should be DST\$K_VALKIND_DESC, with all other fields having the same values as in the passed-by-reference case.
- 1663 0 |

1690 0 THE DESCRIPTOR FORMAT DST RECORD

1693 0
1694 0 The Descriptor Format DST record is used when a VAX Standard
1695 0 Descriptor must be included in the DST for a static symbol. It
1696 0 includes the descriptor directly in the DST record right after
1697 0 the name field. This record is essentially identical to the
1698 0 Standard Data DST record except that the DST\$B_VFLAGS field has
1699 0 the special value DST\$K_VFLAGS_DSC and the DST\$L_VALUE field is
1700 0 a relative byte offset to the VAX descriptor later in the record.
1701 0 This is the format:

1735 0 Define the fields of the Descriptor Format DST record.

1737 0 FIELD DST\$DSC_FIELDS =
1738 0 SET
1739 0 DST\$L_DSC_OFFSET = [3, L_], ! Offset in bytes to descriptor
1740 0 from DST\$A_DSC_BASE
1741 0 DST\$A_DSC_BASE = [7, A_] ! Descriptor starts at this loc-
1742 0 ation + DST\$L_DSC_OFFSET
1743 0 TES:

1746 0 ! Note that the address of the descriptor is computed as follows:

1749 0 | THE TRAILING VALUE SPECIFICATION DST RECORD

1750 0 |
1751 0 |
1752 0 | The Trailing Value Specification DST record is used when an expanded
1753 0 | value specification is needed to compute a data symbol's value or
1754 0 | address. It includes a Value Specification directly in the DST rec-
1755 0 | ord right after the name field. This record is essentially identical
1756 0 | to the Standard Data DST record except that the DSTSB_VFLAGS field has
1757 0 | the special value DSTSK_VFLAGS_TVS and the DSTSL_VALUE field is a
1758 0 | relative byte offset to the Value Specification later in the record.
1759 0 | This is the format:

1788 0 | Define the fields of the Trailing Value Specification DST record.

1789 0 |
1790 0 | FIELD DST\$TVS_FIELDS =
1791 0 | SET
1792 0 | DSTSL_TVS_OFFSET = [3, L_], ! Offset in bytes to trailing Value Spec
1793 0 | from DSTSA_TVS_BASE
1794 0 | DSTSA_TVS_BASE = [7, A_] ! Trailing Value Spec starts at this
1795 0 | location + .DST\$L_TVS_OFFSET
1796 0 | TES:

1797 0 |
1798 0 | Note that the address of the trailing Value Specification is computed as
1799 0 | follows:

1800 0 | DST_RECORD[DSTSA_TVS_BASE] + .DST_RECORD[DSTSL_TVS_OFFSET]

1801 0 |
1802 0 | Also note that Value Specifications are described in a separate section

THE SEPARATE TYPE SPECIFICATION DST RECORD

1808 0

1809 0

The Separate Type Specification DST record is used when the data type of the symbol being described is too complex to be described by a one-byte type code or a VAX Standard Descriptor. This DST record must be immediately followed by a Type Specification, Record Begin, or Enumeration Type Begin DST record which describes the data type of the data symbol. (Only continuation DST records may intervene.) The format of the Separate Type Specification DST record is essentially identical to that of the Standard Data DST record. It may contain a Trailing Value Specification if necessary to describe the symbol's value or address. This is the format of the record:

D S T V A L U E S P E C I F I C A T I O N S

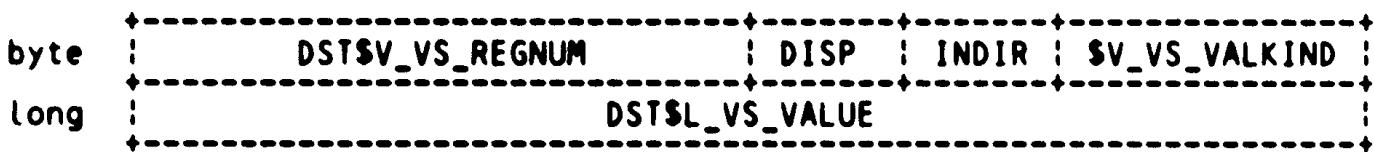

A DST Value Specification specifies the value or address of some symbol. Value Specification can occur in a number of places in the Debug Symbol Table. The simplest forms of Value Specifications occur in the Standard Data DST record. A somewhat more complicated form occurs in Descriptor Format DST records where a VAX Standard Descriptor is included in the DST record to give more complete address information (and type information). The Trailing Value Specification DST record has a simple five-byte Value Specification at the beginning of the record which points to a more complex Value Specification at the end of the record. That more complex Value Specification can be any kind of Value Specification, including the most general forms.

In addition, Value Specifications may occur in a number of Type Specifications. In these cases, they typically generate values (as opposed to addresses), such as subrange bounds for a subrange data type, or they generate full VAX Standard Descriptors in order to specify some sort of data type, such as a dynamic array.

All Value Specifications start with one byte, the DST\$B_VS_VFLAGS field. In Standard Data DST records, this field and the DST\$B_VFLAGS field are synonymous. If this field has one of the special values DST\$K_VFLAGS_xx described in the Standard Data DST Record section above, the format of the Value Specification depends on that value. Otherwise the VFLAGS field is interpreted as a set of subfields, namely DST\$V_VS_REGNUM, DST\$V_VS_DISP, DST\$V_VS_INDIRECT, and DST\$K_VS_VALKIND. This is also described in detail in the Standard Data DST Record section above.

S T A N D A R D V A L U E S P E C I F I C A T I O N S

As indicated above, if the DST\$B_VS_VFLAGS field does not have a special value, the Value Specification is a Standard Value Specification and has the following structure:

Define the fields of the various kinds of Value Specifications. Also define the declaration macro.

```
FIELD DST$VS_HDR_FIELDS =
  SET
  DST$B_VS_VFLAGS      = [ 0, B ], ! Value-flags (access info)
  DST$V_VS_VALKIND     = [ 0, V-(0,2) ], ! How to interpret the value
  DST$V_VS_INDIRECT    = [ 0, V-(2) ], ! Set to get indirection
```

```

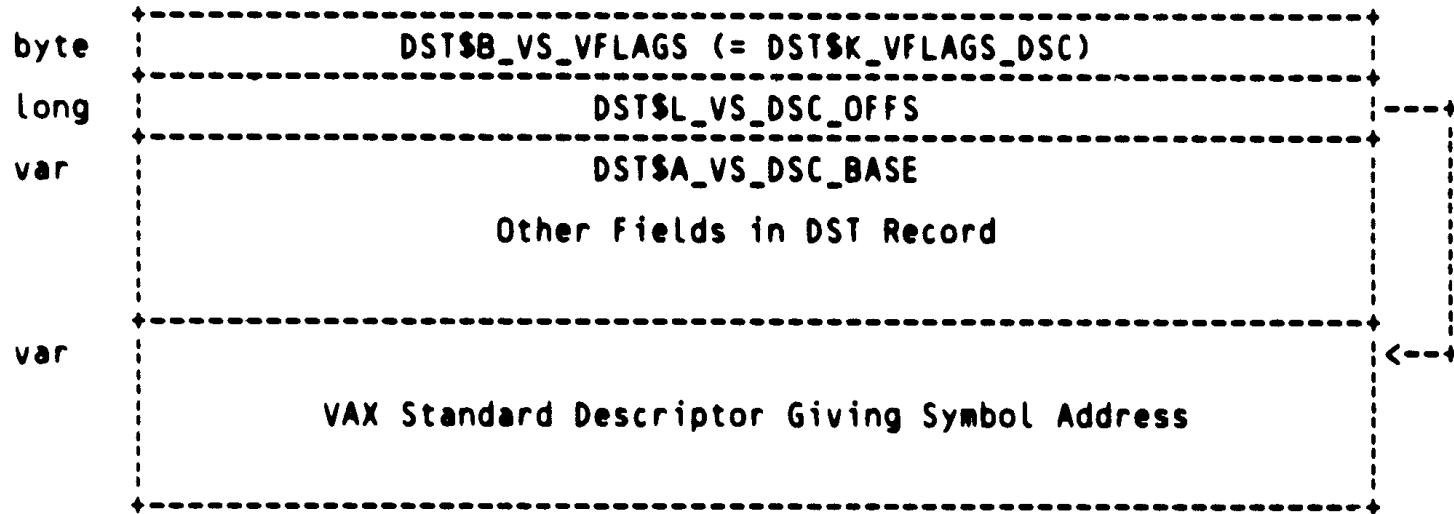

1904 0      DST$V_VS_DISP        = [ 0, V_(3) ],   ! Set for register displacement
1905 0      DST$V_VS_REGNUM     = [ 0, V_(4,4) ], ! Register number for indexing
1906 0      DST$L_VS_VALUE      = [ 1, L_ ];      Value, address, or bit offset
1907 0      DST$L_VS_DSC_OFFSET = [ 1, L_ ];      Offset in bytes to descriptor
1908 0      DST$A_VS_DSC_BASE    = [ 5, A_ ],       from DST$A VS DSC BASE
1909 0      DST$L_VS_TVS_OFFSET = [ 1, L_ ],       Descriptor starts at this loca-
1910 0      DST$A_VS_TVS_BASE    = [ 5, A_ ],       tion + DST$L_VS_DSC_OFFSET
1911 0      DST$W_VS_LENGTH      = [ 1, W_ ],       Offset in bytes to Value Spec
1912 0      DST$B_VS_ALLOC      = [ 3, B_ ],       from DST$A VS TVS BASE
1913 0      DST$A_VS_MATSPEC    = [ 4, A_ ]        Value Spec starts at this loca-
1914 0      DST$W_VS_LENGTH      = [ 1, W_ ],       tion + DST$A_VS_TVS_OFFSET
1915 0      DST$B_VS_ALLOC      = [ 3, B_ ],       Length of Value Spec in bytes
1916 0      DST$A_VS_MATSPEC    = [ 4, A_ ]        not counting the VFLAGS

1975 0 DESCRIPTOR VALUE SPECIFICATIONS
1976 0
1977 0

1978 0 If the DST\$B_VS_VFLAGS field has the special value DST\$K_VFLAGS_DSC,
1979 0 this is a Descriptor Value Specification. Such a Value Specification
1980 0 contains an offset relative to the end of the Value Specification that
1981 0 points to a VAX Standard Descriptor later in the same DST record. That
1982 0 descriptor then contains the actual address that the Value Specifica-
1983 0 tion seeks to specify. This is thus the format:

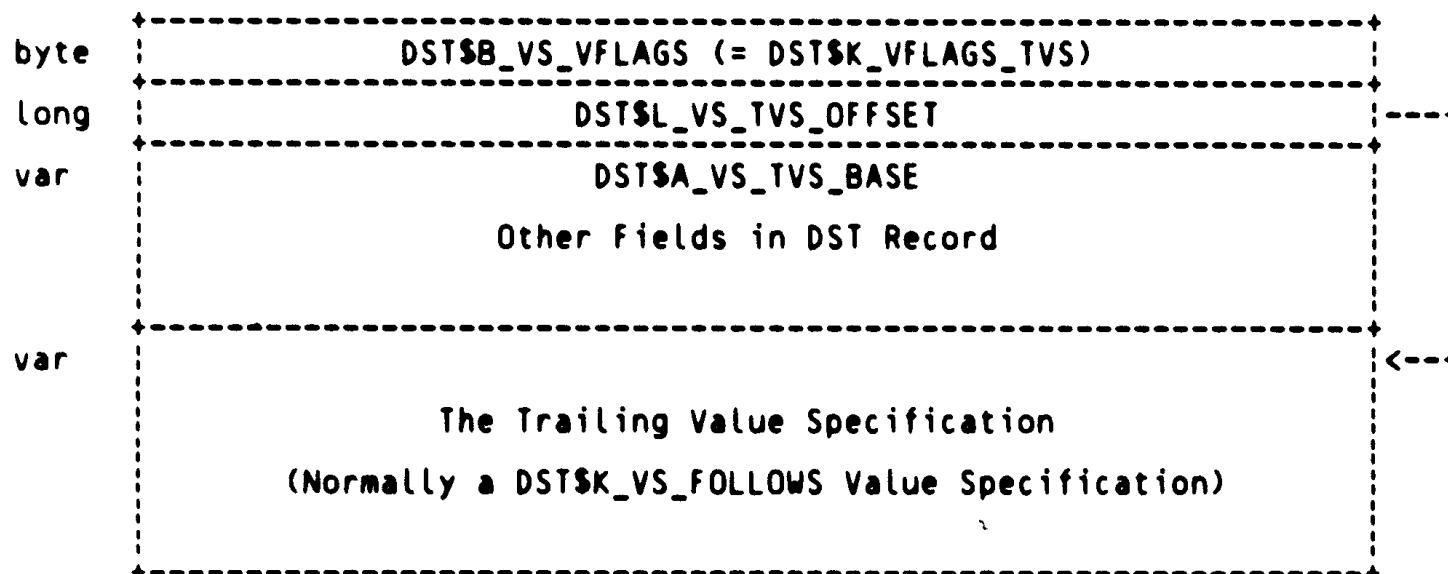

1984 0
1985 0
1986 0
1987 0
1988 0
1989 0
1990 0
1991 0
1992 0
1993 0
1994 0
1995 0
1996 0
1997 0
1998 0
1999 0
2000 0
2001 0
2002 0
2003 0
2004 0
2005 0
2006 0
2007 0
2008 0 The address of the VAX Standard Descriptor is computed as follows:
 $DSC_PTR = VS_PTR[DST\$A_VS_DSC_BASE] + .VS_PTR[DST\$L_VS_DSC_OFFS];$

2009 0 TRAILING VALUE SPEC VALUE SPECIFICATIONS
2010 0
2011 0

2012 0 If the DST\$B_VS_VFLAGS field has the special value DST\$K_VFLAGS_TVS,
2013 0 this is a Trailing Value Spec Value Specification. Such a Value
2014 0 Specification contains a pointer relative to DST\$A_VS_TVS_BASE that
2015 0 points to another Value Specification later in the same DST record.
2016 0 This second Value Specification is normally of the most general and
2017 0 powerful form of Value Specification, namely the VS-Follows Value Spec-
2018 0 ification. In effect, the Trailing Value Spec format is a five-byte
2019 0 Value Specification (small enough to fit in a Data DST Record) which
2020 0 points to a larger Value Specification elsewhere in the same DST record.
2021 0 This larger Value Specification can be arbitrarily large and complex
2022 0 in order to do whatever computation is necessary to obtain the desired
2023 0 value, address, or descriptor.
2024 0

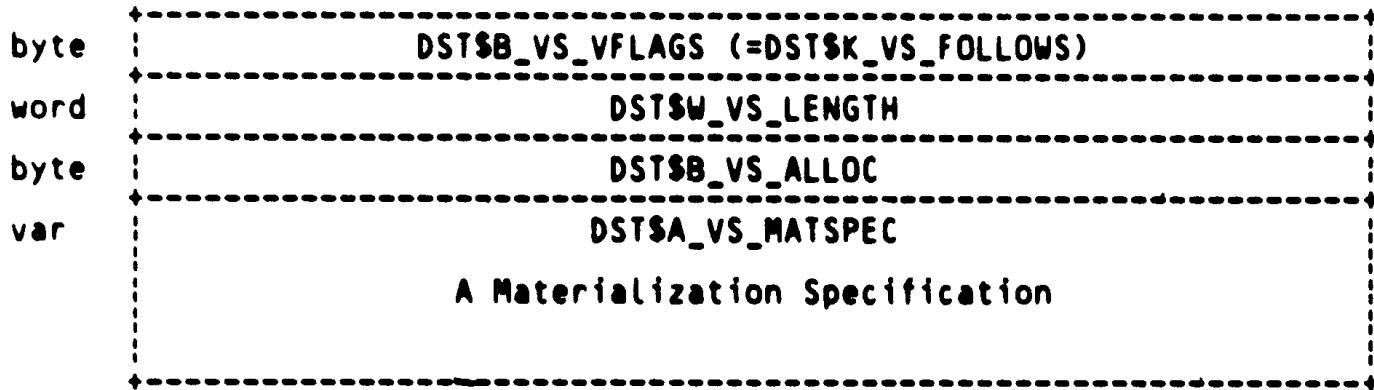

2025 0 This is the format of the Trailing Value Spec Value Specification:
2026 0
2027 0

2028 0
2029 0
2030 0
2031 0
2032 0
2033 0
2034 0
2035 0
2036 0
2037 0
2038 0
2039 0
2040 0
2041 0
2042 0
2043 0
2044 0
2045 0
2046 0
2047 0
2048 0
2049 0
2050 0
2051 0
2052 0 The address of the Trailing Value Specification is computed as follows:
 TVS_PTR = VS_PTR[DST\$A_VS_TVS_BASE] + .VS_PTR[DST\$L_VS_TVS_OFFSET];

2053 0 | VS-FOLLOWS VALUE SPECIFICATIONS

2056 0 | If the DSTSB_VS_VFLAGS field has the special value DST\$K_VS_FOLLOWS,
2057 0 | this is a VS-Follows Value Specification. This is the most general
2058 0 | and powerful form of Value Specification. The specification itself
2059 0 | can be arbitrarily long, but it can also do an arbitrarily complex
2060 0 | computation in order to compute the desired value, address, or de-
2061 0 | scriptor. This is the format of the VS-Follows Value Specification:

2079 0 | A VS-Follows Value Specification contains a Materialization Specifica-
2080 0 | tion which indicates how the value is materialized. This specifica-
2081 0 | tion indicates what kind of value is being produced, by what mechanism
2082 0 | it is produced, and in detail how it is produced. It also contains
2083 0 | some flag bits.

2086 0 | The kind of value being produced can be a 32-bit byte address, a 64-bit
2087 0 | bit address (a byte address followed by a 32-bit bit offset), a bit
2088 0 | offset (relative to the start of a record--used only for record compon-
2089 0 | ents), a literal value (a constant or "R-value"), a register address,
2090 0 | or an actual VAX Standard Descriptor. VAX Standard Descriptors are
2091 0 | mainly produced by Value Specification within Type Specifications where
2092 0 | a descriptor must be built to describe a data type such as an array
2093 0 | type with run-time subscript bounds.

2095 0 | Values can be produced by two mechanisms. One is a routine call on a
2096 0 | compiler-generated thunk. In this case, the compiler generates a rou-
2097 0 | tine in the object code which when called produces the desired value.
2098 0 | The address of the routine is specified in the Mechanism Specification.
2099 0 | The other mechanism is a DST Stack Machine routine. The DST Stack
2100 0 | Machine is a virtual machine which DEBUG emulates. To use it, the com-
2101 0 | piler generates code for this virtual machine which, when executed at
2102 0 | DEBUG-time, produces the desired value. The DST Stack Machine form of
2103 0 | Mechanism Specification constitutes the most general and powerful form
2104 0 | of value specification supported by DEBUG.

2105 0 | CALLS ON COMPILER-GENERATED THUNKS

2108 0 | The Routine Call Mechanism Specification specifies the address of a
2109 0 | compiler-generated routine (a thunk) which DEBUG can call to perform
2110 0 | the desired value computation. This form of Mechanism Specification
2111 0 | must be used for PL/I 'BASED' variables since the address of such a
2112 0 | variable can depend on the value returned by a user-defined function.
2113 0 | In this case, the Mechanism Specification consists of a single longword
2114 0 | giving the address of the compiler-generated thunk to call.

2116 0 | This is the format of the whole Value Specification when the Routine
2117 0 | Call Mechanism Specification is used:

2120 0 | +-----
2121 0 | byte | DST\$B_VS_VFLAGS (=DST\$K_VS_FOLLOWS)
2122 0 | +-----
2123 0 | word | DST\$W_VS_LENGTH (= 8)
2124 0 | +-----
2125 0 | byte | DST\$B_VS_ALLOC (= DST\$K_VS_ALLOC_DYN)
2126 0 | +-----
2127 0 | byte | DST\$B_MS_KIND
2128 0 | +-----
2129 0 | byte | DST\$B_MS_MECH (= DST\$K_MS_MECH_RTNCALL)
2130 0 | +-----
2131 0 | byte | DST\$B_MS_FLAGBITS
2132 0 | +-----
2133 0 | long | DST\$L_MS_MECH_RTNADDR
2134 0 | +-----

2138 0 | The called routine is passed the address of a vector of register values
2139 0 | as its one argument. This vector contains all register value for the
2140 0 | scope (call frame) in which the symbol having this Value Specification
2141 0 | is declared. The vector contains the values of registers R0 - R11, AP,
2142 0 | FP, SP, PC, and PSL in that order. The routine is allowed to use all
2143 0 | such values in its computations, but is not allowed to change the con-
2144 0 | tents of the register vector. In addition, the routine is passed the
2145 0 | value of FP (the Frame Pointer) in register R1.

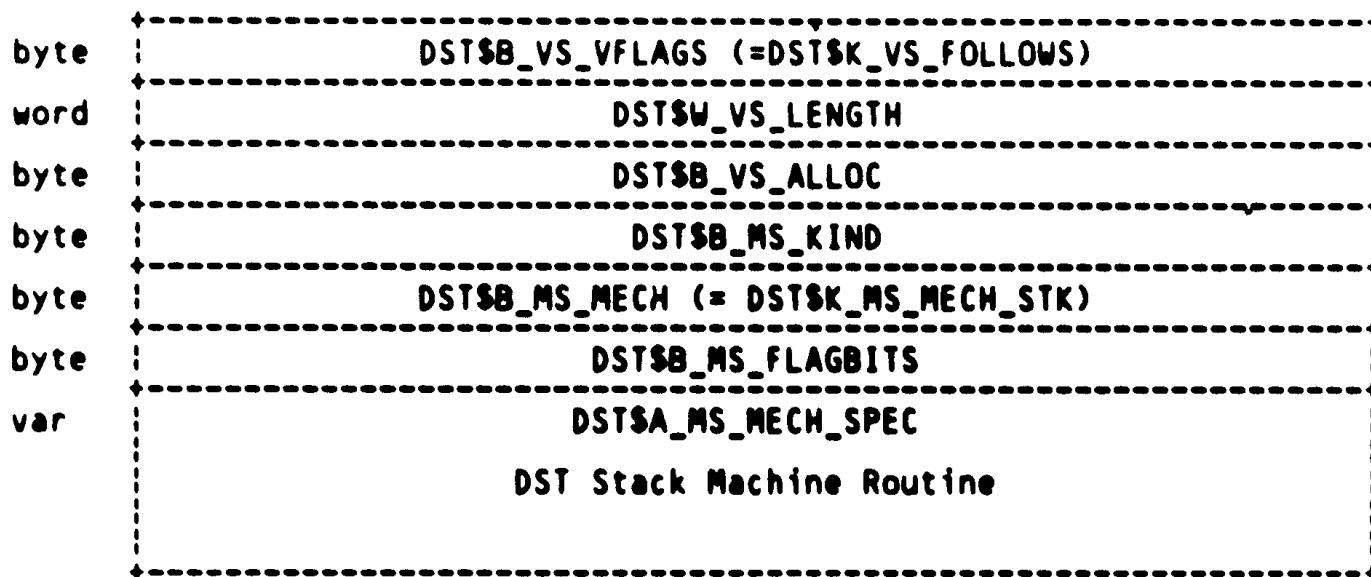

2147 0 | The value of the routine should be returned to DEBUG in register R0.

2149 0 | The DST\$V_MS_DUMARG bit should be set in the DST\$B_MS_FLAGBITS field if
2150 0 | the called routine expects to return a value longer than one longword.
2151 0 | If DST\$V_MS_DUMARG is set, the address of an octaword (four-longword)
2152 0 | buffer is passed as the first argument to the called routine with the
2153 0 | expectation that the routine's value will be returned to this buffer.
2154 0 | The address of the register vector is then the second argument.

2155 0 THE DST STACK MACHINE
2156 0
2157 0

2158 0 The DST Stack Machine is a virtual machine emulated by DEBUG. This
2159 0 machine can push and pop values on a stack and can perform a variety
2160 0 of arithmetic and logical operations. It can also call compiler-
2161 0 generated thunks. The DST Stack Machine is used when a value must be
2162 0 computed at DEBUG-time and the Standard Format Value Specification is
2163 0 not adequate and a compiler-generated thunk to do the whole computation
2164 0 seems undesirable. In such cases, the compiler can generate a Mechanism
2165 0 Specification which consists of code for the Stack Machine. At
2166 0 DEBUG-time, when the value in question is needed, DEBUG will interpret
2167 0 this code until the STOP instruction is encountered. The value that
2168 0 remains on the top of the Stack Machine stack is then taken to be the
2169 0 desired value.
2170 0

2171 0 The format of the whole Value Specification when a DST Stack Machine
2172 0 Mechanism Specification is used is as follows:
2173 0
2174 0

2197 0 Here the DST\$B_VS_ALLOC field should have the value DST\$K_VS_ALLOC_DYN
2198 0 if any kind of address is computed and DST\$K_VS_ALLOC_STAT if a literal
2199 0 value (a constant) is computed. The need for this field is not clear
2200 0 since DEBUG ignores it at present.
2201 0

2202 0 The stack upon which the DST Stack Machine operates consists of 256
2203 0 locations where each location is a longword. The stack grows toward
2204 0 smaller addresses and shrinks toward larger addresses; in this regard
2205 0 it is like the VAX call stack. A DST Stack Machine Routine consists
2206 0 of a sequence of Stack Machine instructions ending in a STOP instruc-
2207 0 tion (DST\$K_STK_STOP). When the machine stops, the top location or
2208 0 locations on the stack constitute the value of the routine. The length
2209 0 of the value is determined by the DST\$B_MS_KIND field.
2210 0
2211 0

The DST Stack Machine supports the instructions tabulated in the re-

2212 0 |
2213 0 | remainder of this section. Each instruction consists of a one-byte op-
2214 0 | code followed by zero or more operand bytes, depending on the op-code.
2215 0 | In this description, the "top" stack cell refers to the most recently
2216 0 | pushed cell still on the stack and the "second" cell refers to the next
2217 0 | most recently pushed cell still on the stack. Each cell contains a
2218 0 | longword value.
2219 0 |
2220 0 |
2221 0 Define the Push Register instructions. These instructions push the indicated
2222 0 register value on the Stack Machine stack. The register values are taken from
2223 0 the scope (call frame) of the symbol for which the value is being computed.
2224 0 |
2225 0 LITERAL
2226 0 |
2227 0 | DST\$K_STK_LOW = 0, | Lower bound for range checking
2228 0 | DST\$K_STK_PUSHR0 = 0, | Push the value of register R0
2229 0 | DST\$K_STK_PUSHR1 = 1, | Push the value of register R1
2230 0 | DST\$K_STK_PUSHR2 = 2, | Push the value of register R2
2231 0 | DST\$K_STK_PUSHR3 = 3, | Push the value of register R3
2232 0 | DST\$K_STK_PUSHR4 = 4, | Push the value of register R4
2233 0 | DST\$K_STK_PUSHR5 = 5, | Push the value of register R5

2241 0 | DST\$K_STK_PUSHRFP = 13, | Push the value of the FP
2242 0 | DST\$K_STK_PUSHRSP = 14, | Push the value of the SP
2243 0 | DST\$K_STK_PUSHRPC = 15; | Push the value of the PC
2244 0 |
2245 0 | Define the Push Immediate instructions. These instructions are used to push
2246 0 | constant values on the Stack Machine stack. The constant value to push comes
2247 0 | immediately after the instruction op-code. For the signed and unsigned in-
2248 0 | structions, the value to push is zero-extended or sign-extended to 32 bits
2249 0 | as appropriate. In the case of the Push Immediate Variable instruction, the
2250 0 | byte after the op-code gives the byte length of the constant value to push.
2251 0 | The constant value to push then follows immediately after that length byte.
2252 0 | The constant value is zero-extended to the nearest longword boundary on the
2253 0 | high-address end and the resulting block is pushed onto the stack.
2254 0 |
2255 0 LITERAL
2256 0 |
2257 0 | DST\$K_STK_PUSHIMB = 16, | Push Immediate Byte (signed)
2258 0 | DST\$K_STK_PUSHIMW = 17, | Push Immediate Word (signed)
2259 0 | DST\$K_STK_PUSHIML = 18, | Push Immediate Longword (signed)
2260 0 | DST\$K_STK_PUSHIM VAR = 24, | Push Immediate Variable
2261 0 | DST\$K_STK_PUSHIMBU = 25, | Push Immediate Byte Unsigned
2262 0 | DST\$K_STK_PUSHIMWU = 26; | Push Immediate Word Unsigned
2263 0 |
2264 0 | Define the Push Indirect instructions. For these instructions, the top stack
2265 0 | cell is popped and the one, two, or four bytes at the address given by the
2266 0 | popped cell are sign extended to 32 bits and pushed on the stack. For the
2267 0 | unsigned instructions, the value is instead zero-extended to 32 bits and
2268 0 | pushed on the stack.

2342 0 | DST\$K_STK_POP = 39; ! Pop Top Stack Cell
2343 0 |
2344 0 |

2345 0 | Define the Stop instruction. This instruction stops the DST Stack Machine and
2346 0 | is required at the end of every DST Stack Machine routine. Whatever value is
2347 0 | left at the top of the stack when the Stop instruction is executed is taken to
2348 0 | be the value of the Stack Machine routine. This value may be a longword (a
2349 0 | byte address, for example), two longwords (byte address and bit offset), any
2350 0 | size literal value (an H-floating literal, for instance), or a full VAX Stan-
2351 0 | dard Descriptor, depending on the value of the DST\$B_MS_KIND field.
2352 0 |
2353 0 | LITERAL

2354 0 | DST\$K_STK_STOP = 23; ! Stop the Stack Machine
2355 0 |
2356 0 |

2357 0 | Define the Routine Call instructions. These instructions call a compiler-
2358 0 | generated routine (a thunk) whose address is given by the top stack cell.
2359 0 | Before the call actually occurs, the top stack cell is popped. The value
2360 0 | that is returned by the thunk is then pushed onto the stack.
2361 0 |

2362 0 | The Routine Call instruction works as follows. The address of the thunk to
2363 0 | be called is taken from the top stack cell. The top cell is then popped.
2364 0 | The thunk, which is called with a CALL instruction, gets two arguments. The
2365 0 | first argument is the address of a vector of register values for the scope
2366 0 | (call frame) of the symbol to which this Value Specification belongs. This
2367 0 | vector contains the values of registers R0 - R11, AP, FP, SP, PC, and PSL in
2368 0 | that order; the called thunk is free to read any value it wants from this
2369 0 | vector but may not store into it. The second parameter is a pointer to the
2370 0 | top of the DST Stack Machine stack after the thunk address has been popped.
2371 0 | A Stack Machine routine can thus compute arguments to the thunk and push them
2372 0 | on the stack before pushing the thunk address and calling the thunk. In
2373 0 | addition, the value of FP in the symbol's scope is passed to the thunk in
2374 0 | register R1. The routine's value is expected to be returned in register R0.
2375 0 | This value is pushed onto the stack.
2376 0 |
2377 0 |

2378 0 | The Routine Call With Alternate Return instruction works this same way except
2379 0 | that the address of an octaword buffer (4 longwords) is passed to the thunk
2380 0 | as the first argument, with the register vector being the second argument and
2381 0 | the stack address being the third argument. In this case, the routine value
2382 0 | is expected to be returned to the octaword buffer, not in register R0. The
whole octaword buffer is then pushed onto the stack.

2389 0 ! Define the Push Record Address instructions. These instructions push the
2390 0 address of the outer-most or inner-most record structure for which the cur-
2391 0 rent symbol is a record component. They are used for constructing VAX Stan-
2392 0 dard Descriptors on the Stack Machine stack when some part of the descriptor
2393 0 depends on some other component of the same record. In PL/I, for instance,
2394 0 the subscript bounds of an array component of a record may depend on another
2395 0 component of that record. In such cases, the only way to get the address of
2396 0 that other component in the current record is to use one of the Push Record
2397 0 Address instructions. The Push Outer Record Address instruction pushes the
2398 0 address of the outer-most record of which the current symbol is a component
2399 0 while the Push Inner Record Address instruction pushes the address of the
2400 0 inner-most record of which the current symbol is a component.

2415 0 THE TYPE SPECIFICATION DST RECORD

2416 0
2417 0
2418 0
2419 0 The Type Specification DST record gives the most general data type
2420 0 description available in the Debug Symbol Table. It contains the
2421 0 name of the data type being described and a DST Type Specification
2422 0 that describes the type. The type name is used in languages where
2423 0 data types can be named, such as PASCAL. If no type name exists,
2424 0 the null name (the name of zero length) is specified in this record.
2425 0 DST Type Specifications are described in detail in the next section
2426 0 of this definition file.

2427 0
2428 0 Type Specification DST records either immediately follow Separate
2429 0 Type Specification DST records or are pointed to by Indirect Type
2430 0 Specifications or Novel Length Type Specifications elsewhere in
2431 0 the DST for the current module.

2432 0
2433 0 This is the format of the Type Specification DST record:

2461 0 Define the fields of the Type Specification DST record.

2462 0

2469 0 TES;

: 2470 0 | DST TYPE SPECIFICATIONS
2471 0 |
2472 0 |
2473 0 |

2474 0 | A DST Type Specification specifies the data type of some data symbol.
2475 0 | DST Type Specifications constitute the most general form of data type
2476 0 | description available in the Debug Symbol Table. They are found in
2477 0 | only one kind of DST record, namely the Type Specification DST record.
2478 0 | However, some Type Specifications contain nested Type Specifications,
2479 0 | which permits quite complex type descriptions. For example, the parent
2480 0 | type for a Subrange data type is given by a nested Type Specification
2481 0 | within the Subrange Type Specification.
2482 0 |
2483 0 | This is the general format of all DST Type Specifications:
2484 0 |
2485 0 |
2486 0 | word |-----+
2487 0 | | DST\$W_TS_LENGTH
2488 0 | byte |-----+
2489 0 | | DST\$B_TS_KIND
2490 0 | var |-----+
2491 0 | | Zero or More Other Fields Depending on DST\$B_TS_KIND
2492 0 | |-----+
2493 0 |
2494 0 |
2495 0 |
2496 0 |
2497 0 |
2498 0 |
2499 0 |
2500 0 | A data symbol whose data type must be described by a DST Type Specifi-
2501 0 | cation is described by a Separate Type Specification DST record. This
2502 0 | DST record is immediately followed by a Type Specification DST record
2503 0 | which contains the DST Type Specification for the symbol's data type.
2504 0 |
2505 0 | To conserve DST space when several symbols have the same data type, the
2506 0 | Type Specification that follows the Separate Type Specification DST
2507 0 | record may be an Indirect Type Specification. The Indirect Type Speci-
2508 0 | fication then contains a DST pointer to the actual Type Specification
2509 0 | DST record for the symbol's type. Only a single copy of this actual
2510 0 | Type Specification is then needed. Multiple symbols of the same Record
2511 0 | or Enumeration type must also use Separate Type Specification DST
2512 0 | records followed by Type Specification DST records containing Indirect
2513 0 | Type Specifications. In this case, the Indirect Type Specifications
2514 0 | point to the Record Begin or Enumeration Type Begin DST record for the
2515 0 | record or enumeration type being specified.
2516 0 |
2517 0 | In fact, the only Type Specification that can refer to a record or enum-
2518 0 | eration type is the Indirect Type Specification. (The Novel Length Type
2519 0 | Specification can too but is not normally used this way.) This Type
2520 0 | Specification is thus used within other type Specifications when record
2521 0 | or enumeration types must be specified. For example, when the element
2522 0 | type of an array is a record or enumeration type, it is specified by an
2523 0 | Indirect Type Specification within the Array Type Specification. Simi-
2524 0 | larly, if the target of a typed pointer is a record or enumeration type
2525 0 | object, the target type is specified by an Indirect Type Specification
2526 0 | within the Typed Pointer Type Specification.

```

2621 0 | ATOMIC TYPE SPECIFICATIONS
2622 0 |
2623 0 |
2624 0 |

2625 0 | The Atomic Type Specification is used to describe an atomic VAX standard
2626 0 | data type. This Type Specification consists of the standard Type Speci-
2627 0 | fication header followed by a single byte containing the VAX standard
2628 0 | data type code (one of the DSC\$K_DTYPE_x codes). The Atomic Type Speci-
2629 0 | fication has the following format:

2642 0 | DESCRIPTOR TYPE SPECIFICATIONS
2643 0 |
2644 0 |
2645 0 |

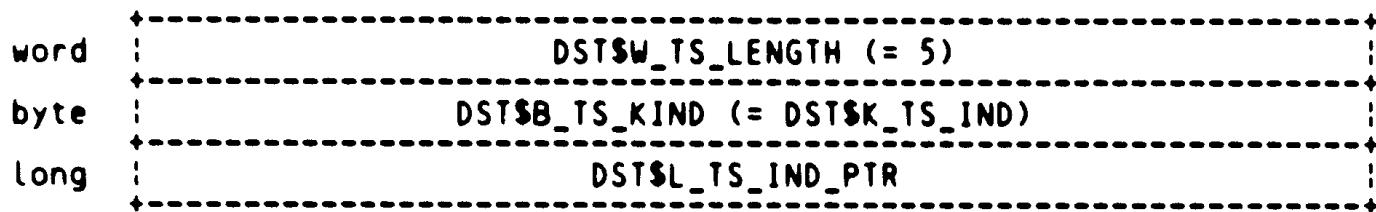

2646 0 | The Descriptor Type Specification is used for VAX Standard Data Types
2647 0 | that can be described by VAX Standard Descriptors but cannot be de-
2648 0 | scribed by an atomic type code. Packed decimal, which requires a
2649 0 | digit length and a scale factor, and ASCII text, which requires a
2650 0 | string length, are examples of such data types. The Descriptor Type
2651 0 | Specification contains a Value Specification which must produce a
2652 0 | VAX Standard Descriptor. This is the format:

2666 0
2667 0
2668 0

INDIRECT TYPE SPECIFICATIONS

The Indirect Type Specification is used when the actual Type Specification desired is found in another DST record. This Type Specification contains a DST pointer which points to that other DST record. The DST pointer contains the byte offset relative to the start of the whole DST of the DST record that gives the actual type information. The pointed-to DST record must be one of three kinds of DST records: a Type Specification DST record, a Record Begin DST record, or an Enumeration Type Begin DST record. The Indirect Type Specification is the only Type Specification that can refer to a record or enumeration type; those types are too complex (potentially) to be referred to any other way. This is the format of the Indirect Type Specification:

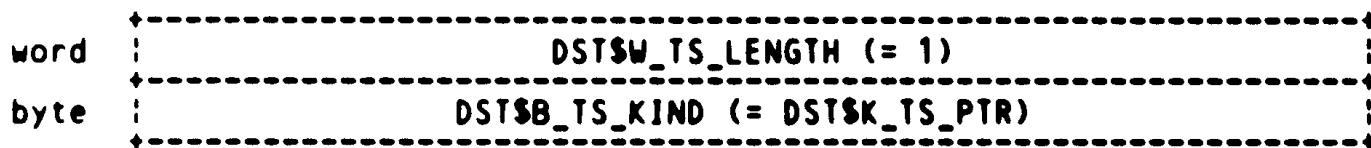

2690 0 ! TYPED POINTER TYPE SPECIFICATIONS

The Typed Pointer Type Specification describes a typed pointer data type, meaning a pointer to a specific other data type. Pointer-to-integer, as found in PASCAL and other languages, is an example of a typed pointer type. In this example, integer is the "parent type". This Type Specification contains an embedded Type Specification which specifies the parent type for the typed pointer type. This is the format of the Type Pointer Type Specification:

POINTER TYPE SPECIFICATIONS

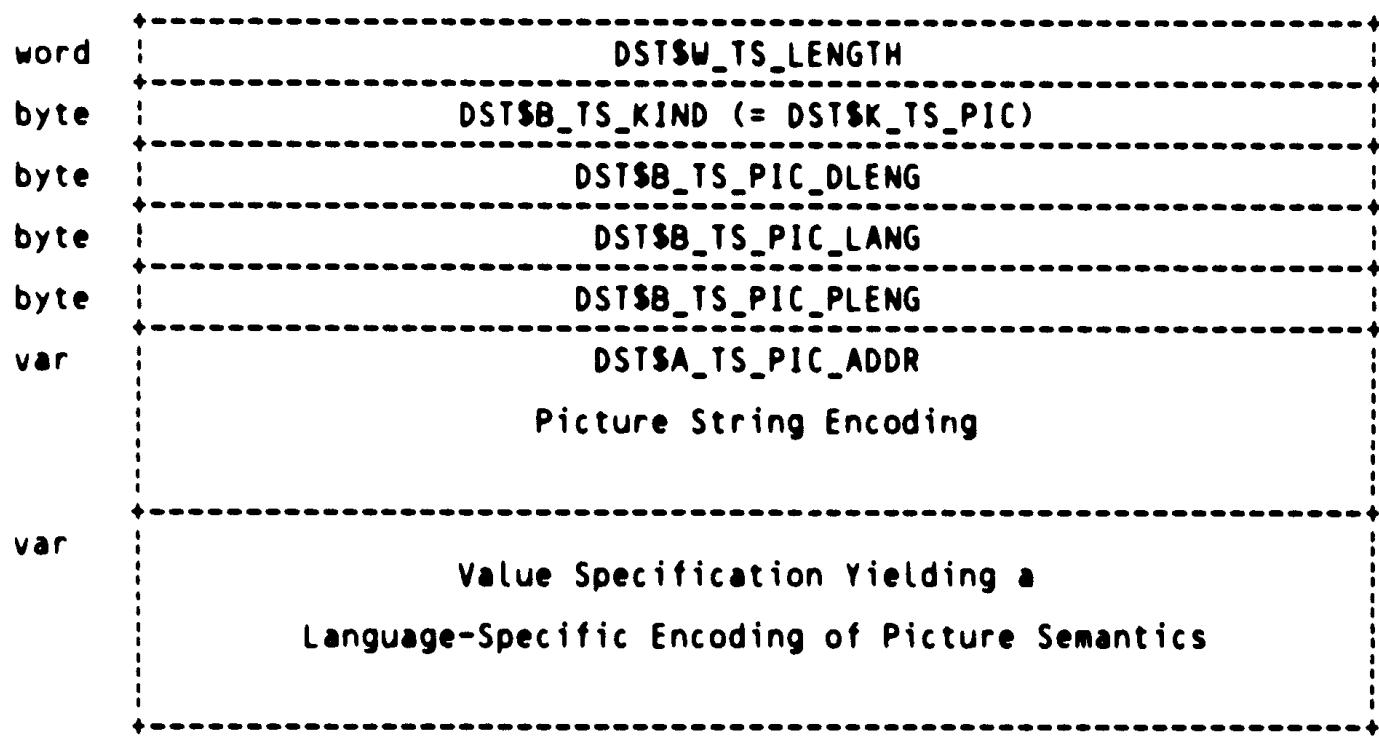

The Pointer Type Specification is used for pointer types which are not typed, meaning that the type of object that the pointer points to is not known at compile-time. PL/I pointers are examples of this kind of pointer type. Since there is no known parent type, none is specified in this Type Specification. The Pointer Type Specification thus has the simplest possible format:

2737 0 PICTURE TYPE SPECIFICATIONS

2738 0
2739 0
2740 0
2741 0 The Picture Type Specification is used for picture data types as found
2742 0 in COBOL and PL/I. Because the exact semantics of picture data types
2743 0 vary between languages, this Type Specification contains the language
2744 0 code associated with this specific picture type. It also contains the
2745 0 byte length of objects of the picture type, an encoding of the picture,
2746 0 and a language-specific picture encoding (usually the EDITPC pattern
2747 0 string). The actual data objects of the picture data type are assumed
2748 0 to be represented as ASCII character strings.
2749 0

2750 0 This is the format of the Picture Type Specification:

2750 0
2751 0
2752 0
2753 0
2754 0
2755 0
2756 0
2757 0
2758 0
2759 0
2760 0
2761 0
2762 0
2763 0
2764 0
2765 0
2766 0
2767 0
2768 0
2769 0
2770 0
2771 0
2772 0
2773 0
2774 0
2775 0
2776 0
2777 0
2778 0
2779 0
2780 0 The DSTSB_TS_PIC_DLENG field contains the length in bytes of each data
2781 0 object of this picture type. DEBUG assumes that picture objects are
2782 0 represented internally as ASCII character strings.
2783 0

2784 0 The language code in the DSTSB_TS_PIC_LANG field is the same as that
2785 0 used in the Module Begin DST record.

2786 0
2787 0 The DSTSB_TS_PIC_PLENG field gives the byte length of the picture
2788 0 encoding in the DSTSA_TS_PIC_ADDR field. The picture encoding in the
2789 0 DSTSA_TS_PIC_ADDR field consists of a sequence of words. The high-
2790 0 order byte of each word contains an unsigned repetition factor and
2791 0 the low-order byte contains the ASCII representation of the repeated
2792 0 picture character. Hence the picture \$999.99 is represented by this
2793 0 sequence of byte values: "S", 1, "9", 3, ".", 1, "9", 2. (The same

Page 63
(36)

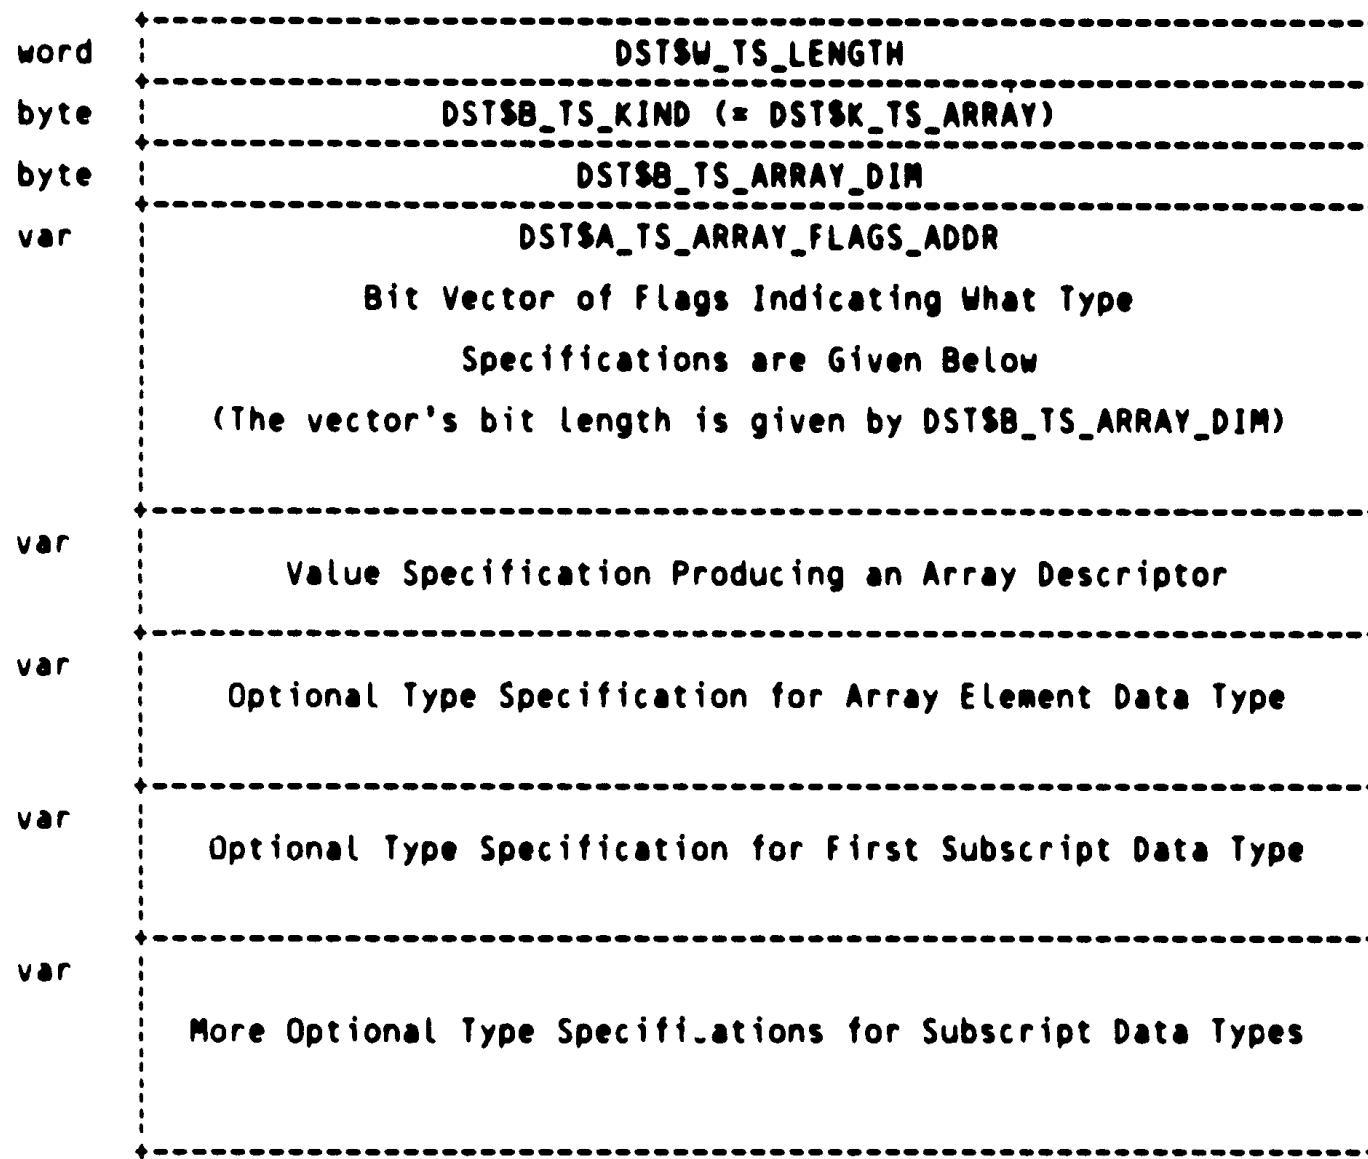

2794 0 picture can be written as "S(3)9.(2)9".)

2795 0
2796 0 The optional Value Specification at the end of the Picture Type Speci-
2797 0 fication yields the address of the EDITPC pattern string that performs
2798 0 the encoding associated with this picture type. DEBUG uses this pattern
2799 0 string with the EDITPC instruction when doing DEPOSITS into objects of
2800 0 this picture type. If the Value Specification is omitted, DEBUG can
2801 0 only deposit character strings into such objects since it does not know
2802 0 how to encode numeric values.

2803 0 : ARRAY TYPE SPECIFICATIONS

The Array Type Specification specifies an Array data type. This specification can be quite complex because it not only specifies the shape of each array of this type, but also specifies the corresponding element data type and all subscript data types. The element type and the types of the subscripts are given by additional Type Specifications nested within the Array Type Specification.

This is the format of the Array Type Specification:

Here the DST\$B_TS_ARRAY_DIM field gives the number of dimensions of this array type. Next, DST\$A_TS_ARRAY_FLAGS_ADDR gives the location of a

2860 0 | bit-vector which indicates what nested Type Specifications are found
2861 0 | later in this Array Type Specification. If bit 0 is set, a nested Type
2862 0 | Specification is included for the array element type (the cell type).
2863 0 | After that, if bit n is set, a nested Type Specification for the n-th
2864 0 | subscript type is included in this Array Type Specification. If a bit
2865 0 | in the bit-vector is zero (not set), the corresponding Type Specifica-
2866 0 | tion is omitted from the Array Type Specification. If the element type
2867 0 | specification is omitted, the element type is assumed to be given by the
2868 0 | array descriptor's DTTYPE field. If a subscript type specification is
2869 0 | omitted, the subscript type is assumed to be longword integer (DTTYPE_L).
2870 0 | (Subscript Type Specifications are mainly needed for enumeration type
2871 0 | subscripts as allowed in PASCAL.)

2872 0 |
2873 0 | The number of bits in the bit-vector is DST\$B_TS_ARRAY_DIM plus one more
2874 0 | for the element type. The whole DST\$A_TS_ARRAY_FLAGS_ADDR field is of
2875 0 | course rounded up to the nearest byte boundary.

2876 0 |
2877 0 | The array descriptor Value Specification that follows the bit-vector
2878 0 | field produces a VAX Standard Descriptor for the array. (The descriptor
2879 0 | class must be DSC\$K_CLASS_A, DSC\$K_CLASS_NCA, or DSC\$K_CLASS_UBA.) This
2880 0 | array descriptor gives the strides (or multipliers) and the lower and
2881 0 | upper bounds for all of the array dimensions. It also gives the element
2882 0 | data type, including its scale factor, digit count, or other type infor-
2883 0 | mation as appropriate. However, the descriptor's element type can be
2884 0 | overridden by an element Type Specification as noted above; in this case
2885 0 | the DSC\$B_DTTYPE field of the descriptor should be zero.

2886 0 |
2887 0 | The Array Type Specification is normally only used in two situations.
2888 0 | First, it is used if the array type does not have a compile-time-con-
2889 0 | stant descriptor (for example, if it has variable array bounds) and no
2890 0 | run-time descriptor exists in the user's address space. Second, it is
2891 0 | used if the array type cannot be described a VAX Standard Descriptor,
2892 0 | either because the element type cannot be described by a VAX Standard
2893 0 | Descriptor or because the subscript types are not integers. (Element
2894 0 | types such as records, enumeration types, and typed pointers cannot be
2895 0 | described by VAX Standard Descriptors.) If neither of these situations
2896 0 | pertains, there are simpler ways of describing array types in the DST
2897 0 | using Standard Data or Descriptor Format DST records.

2898 0 | SET TYPE SPECIFICATIONS
2899 0
2900 0
2901 0

2902 0 The Set Type Specification specifies a Set data type as in PASCAL. A
2903 0 Set type always has a parent data type. For the set-of-integers type,
2904 0 for example, integer is the parent type. The parent type must be either
2905 0 integer, some enumeration type, or a subrange of those types. DEBUG
2906 0 assumes that the Set type is represented internally as a bit-string
2907 0 where a given bit is set if and only if the corresponding integer or
2908 0 enumeration type element is a member of the set. The n-th bit of the
2909 0 bit-string (starting at bit 0) is assumed to correspond to the n-th
2910 0 element of the parent type. The length of the bit-string is part of
2911 0 the Set type and is specified in the Set Type Specification.
2912 0
2913 0 This is the format of the Set Type Specification:
2914 0
2915 0
2916 0
2917 0 word +-----+
2918 0 | DSTSW_TS_LENGTH |
2919 0 +-----+
2920 0 byte +-----+
2921 0 | DSTSB_TS_KIND (= DSTSK_TS_SET) |
2922 0 +-----+
2923 0 long +-----+
2924 0 | DSTSL_TS_SET_LEN |
2925 0 +-----+
2926 0 var +-----+
2927 0 | DSTSA_TS_SET_PAR_TSPEC_ADDR |
2928 0 +-----+
2929 0
2930 0
2931 0
2932 0 Here the DSTSL_TS_SET_LEN field gives the bit length of an object of
2933 0 the Set data type. DSTSA_TS_SET_PAR_TSPEC_ADDR marks the location of
2934 0 an embedded DST Type Specification for the parent type of the Set type.
2935 0 Typically this is an Atomic Type Specification for type integer, an
2936 0 Indirect Type Specification that points to an Enumeration Type Begin
2937 0 DST record, or a Subrange Type Specification.

SUBRANGE TYPE SPECIFICATIONS

The Subrange Type Specification describes a Subrange data type, meaning a subrange of some ordinal type such as integer or an enumeration type. This Type Specification specifies the parent type (the original ordinal type) and the lower and upper bounds of the subrange. It also gives the bit length of objects of the Subrange type. This is the format of the Subrange Type Specification:

```
word      DSTSW_TS_LENGTH
byte      DSTSB_TS_KIND (= DSTSK_TS_SUBRANGE)
long      DSTSL_TS_SUBR LENG
var       DSTSA_TS_SUBR_PAR_TSPEC_ADDR
          Type Specification Specifying the Subrange's Parent Type
var       Value Specification Giving the Lower Bound of the Subrange
var       Value Specification Giving the Upper Bound of the Subrange
```

Here the DSTSL_TS_SUBR LENG field gives the length in bits of objects of the Subrange data type. DSTSA_TS_SUBR_PAR_TSPEC_ADDR marks the location of a DST Type Specification for the parent type of the subrange. Typically this is an Atomic Type Specification for type integer or an Indirect Type Specification pointing to an Enumeration Type Begin DST record.

The two Value Specifications in this Type Specification specify the lower and upper bounds of the subrange. These bounds values must be values of the parent type.

2986 0 | FILE TYPE SPECIFICATIONS

2987 0 |
2988 0 |
2989 0 |
2990 0 | The File Type Specification specifies a file data type as found in
2991 0 | PASCAL or PL/I, for example. Since the interpretation of file types
2992 0 | varies from language to language, the language code for this file
2993 0 | type is included in the Type Specification. Optionally, a file record
2994 0 | Type Specification can be included specifying the type of a record in
2995 0 | this file type. A PASCAL file-of-Reals, for instance, would have Real
2996 0 | (F-Floating) as its file record type.
2997 0 |
2998 0 |
2999 0 | This is the format of the File Type Specification:
3000 0 |
3001 0 |-----+
3002 0 | word | DST\$W_TS_LENGTH
3003 0 |-----+
3004 0 | byte | DST\$B_TS_KIND (= DST\$K_TS_FILE)
3005 0 |-----+
3006 0 | byte | DST\$B_TS_FILE_LANG
3007 0 |-----+
3008 0 | var | DST\$A_TS_FILE_RCRD_TYP
3009 0 |-----+
3010 0 | Type Specification Giving the File Record Type
3011 0 |-----+
3012 0 |
3013 0 |
3014 0 |
3015 0 |
3016 0 |
3017 0 | Here the DST\$B_TS_FILE_LANG field contains the language code for this
3018 0 | file. The same language codes are used as in the Module Begin DST
3019 0 | record. DST\$A_TS_FILE_RCRD_TYP is the location of a DST Type Specifi-
3020 0 | cation for the record type, if applicable. This Type Specification is
3021 0 | optional; if omitted, file-of-characters is assumed.

3085 0

NOTE: THIS TYPE SPECIFICATION IS NOT SUPPORTED BY DEBUG V4.0.

The Offset Type Specification describes a PL/I "offset" type. PL/I offsets are offsets relative to the start of a PL/I "area" (see above), a dynamically allocated region of memory. The Offset Type Specification specifies the base address of the associated area and the byte offset value of this offset type. This is the format:

Here the DST\$A_TS_OFFSET_VALSPEC Value Specification produces the base address of the associated area and the second Value Specification gives the byte offset value into the area.

3086 0

NOVEL LENGTH TYPE SPECIFICATIONS

3087 0

3088 0

3089 0

3090 0

The Novel Length Type Specification is used to specify any data type that is identical to a parent data type except that the objects of this new type have a different length (a "novel" or atypical length). This Type Specification is used for the components of PACKED records in PASCAL, for example. A boolean component of a packed record consists of a single bit (the novel length) while all other booleans consist of a byte (the normal length). To describe the packed boolean type, a Novel Length Type Specification is used which specifies the novel length and points to the DST description of the parent type, namely the normal boolean type. DEBUG accessed objects of a Novel-Length type by expanding them to the normal length for that type.

3125 0 | SELF-RELATIVE LABEL TYPE SPECIFICATIONS

3129 0 |
3130 0 | The Self-Relative Label Type Specification specifies the type of a PL/I
3131 0 | "self-relative" label. Such a label is actually a label array, meaning
3132 0 | that it must be indexed by an integer value to yield a specific label
3133 0 | value. The internal representation consists of an array of longwords
3134 0 | where each array element contains a label value relative to the start of
3135 0 | the array. Making the element values relative to the start of the array
3136 0 | ensures that the label array is Position-Independent (PI).
3137 0 |
3138 0 | This is the format of the Self-Relative Label Type Specification:

3140 0 |-----+
3141 0 | word : DST\$W_TS_LENGTH (= 1)
3142 0 |-----+
3143 0 | byte : DST\$B_TS_KIND (= DST\$K_TS_SELF_REL_LABEL)
3144 0 |-----+

3145 0 |
3146 0 |
3147 0 |
3148 0 |
3149 0 | TASK TYPE SPECIFICATIONS
3150 0 |
3151 0 |
3152 0 |
3153 0 | NOTE: THIS TYPE SPECIFICATION IS NOT SUPPORTED BY DEBUG V4.0.
3154 0 |
3155 0 | The Task Type Specification specifies the data type of task objects
3156 0 | as found in ADA. Objects of the Task data type are assumed to have
3157 0 | longword values understood by the ADA multi-tasking kernel. Since
3158 0 | no additional information is associated with the Task data type, the
3159 0 | Task Type Specification has the minimal format:
3160 0 |
3161 0 |
3162 0 |-----+
3163 0 | word : DST\$W_TS_LENGTH (= 1)
3164 0 |-----+
3165 0 | byte : DST\$B_TS_KIND (= DST\$K_TS_TASK)
3166 0 |-----+

3167 0 |
3168 0 |
3169 0 |
3170 0 | END OF TYPE SPECIFICATION DESCRIPTION.

3171 0 | ENUMERATION TYPE DST RECORDS
3172 0 |
3173 0 |
3174 0 |

3175 0 Enumeration types, as found in PASCAL and C, are represented in the
3176 0 DST by three kinds of DST records. The Enumeration Type Begin DST
3177 0 record describes the type itself, giving the bit length of objects
3178 0 of that type and the name of the type (e.g., COLOR). This record
3179 0 is followed by some number of Enumeration Type Element DST records,
3180 0 one for each element, or literal, in the type (e.g., RED, BLUE, and
3181 0 GREEN). Each Enumeration Type Element DST record gives the name and
3182 0 numeric value of one literal of the enumeration type. The whole type
3183 0 description is then terminated by an Enumeration Type End DST record.

3184 0
3185 0 The Enumeration Type Begin and Enumeration Type End DST records thus
3186 0 bracket the list of elements of the type, much like other Begin-End
3187 0 pairs in the DST. The Enumeration Type Element DST records within
3188 0 those brackets do not have to be in numeric order of their values,
3189 0 although it is desirable if they are. For languages like ADA, where
3190 0 the numeric values of the elements need not go up sequentially with
3191 0 the logical element positions, the Enumeration Type DST Elements do
3192 0 have to be order of their logical positions, however. No other kinds
3193 0 of DST records (except Continuation DST records) may appear between
3194 0 the Enumeration Type Begin and the Enumeration Type End DST records.

3195 0 .
3196 0 THE ENUMERATION TYPE BEGIN DST RECORD
3197 0

3198 0 The Enumeration Type Begin DST record specifies the name of an
3199 0 enumeration type and the bit length of objects of that type.
3200 0 It also serves as the opening bracket for a list of Enumeration
3201 0 Type Element DST records, and must be matched by a closing
3202 0 Enumeration Type End DST record. This is record's format:
3203 0
3204 0

```
3205 0 +-----+  
3206 0 | byte | DST$B_LENGTH  
3207 0 +-----+  
3208 0 | byte | DST$B_TYPE (= DST$K_ENUMBEG)  
3209 0 +-----+  
3210 0 | byte | DST$B_ENUMBEG_LEN  
3211 0 +-----+  
3212 0 | byte | DST$B_ENUMRFG_NAME  
3213 0 +-----+  
3214 0 var  
3215 0 | The Name of the Enumeration Type in ASCII  
3216 0 | (The name's length is given by DST$B_ENUMBEG_NAME)  
3217 0 +-----+
```

3223 0 Define the fields of the Enumeration Type Begin DST record.

```
3224 0 FIELD DST$ENUMBEG_FIELDS =  
3225 0 SET  
3226 0 DST$B_ENUMBEG_LEN = [ 2, B_ ], | Bit length of data objects of  
3227 0 | this enumeration type  
3228 0 DST$B_ENUMBEG_NAME = [ 3, B_ ] | Count byte for the Counted  
3229 0 | ASCII Type Name  
3230 0 TES;
```

3233 0

THE ENUMERATION TYPE ELEMENT DST RECORD

3234 0

3235 0

The Enumeration Type Element DST record specifies the name and value of one element (one literal) of an enumeration type. It may only appear between an Enumeration Type Begin and an Enumeration Type End DST record. The underlying representation of enumeration types is assumed to be unsigned integer. The DST\$B_VFLAGS field in this record has its normal interpretation (see the Standard Data DST record for the details). Hence the DST\$V_VALKIND field will have the value DST\$K_VALKIND_LITERAL and the DST\$L_VALUE field will have the appropriate integer value in this case.

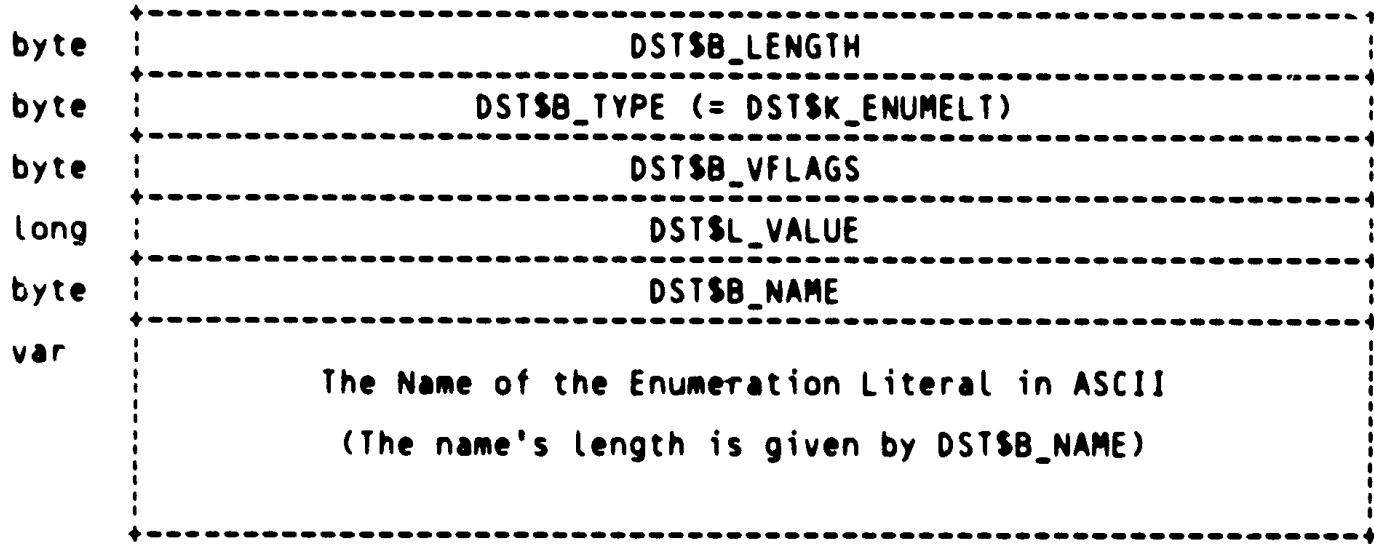

3245 0

This is the format of the Enumeration Type Element DST record:

3246 0

3247 0

3248 0

3249 0

3250 0

3251 0

THE ENUMERATION TYPE END DST RECORD

3270 0

3271 0

3272 0

3273 0

3274 0

The Enumeration Type End DST record terminates the description of an enumeration type. This is the record's format:

3275 0

3276 0

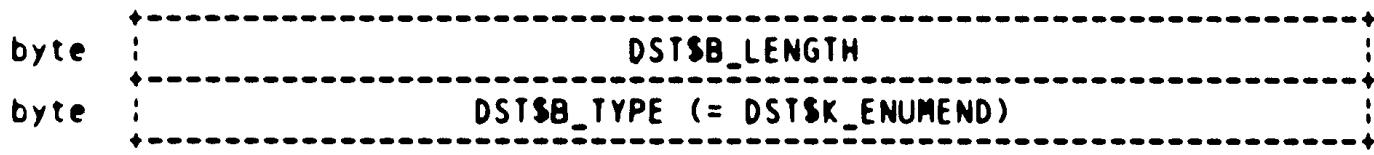

3277 0

3278 0

3279 0

3280 0

3281 0

3282 0 R E C O R D S T R U C T U R E D S T R E C O R D S
3283 0
3284 0
3285 0

3286 0 Record structures, or simply records, refer to the aggregates of non-
3287 0 homogeneous components found in many languages. In some languages,
3288 0 such constructs are called "records" (in PASCAL and COBOL, for example)
3289 0 and in others they are called "structures" (in PL/I, for example).
3290 0 Here we will call them "records". What all records have in common is
3291 0 that they consist of a set of named components, each corresponding to
3292 0 some field in the record structure. The components can in general be
3293 0 of any data types supported by the language.
3294 0

3295 0 In the Debug Symbol Table, a record is represented by a Record Begin
3296 0 DST record followed by some number of data object DST records, one for
3297 0 each record component, followed by a Record End DST record. Any data
3298 0 object DST record within a Record-Begin/Record-End pair is taken to
3299 0 denote a component of that enclosing record specification. Other DST
3300 0 records may also appear between the Record-Begin/Record-End pair, such
3301 0 as Type Specification and other DST records that specify the data types
3302 0 of the components. However, only data DST records denote record com-
3303 0 ponents.
3304 0

3305 0 Nested records are defined by record components which are themselves
3306 0 records. The type of a record component which is itself a record is
3307 0 defined by another Record-Begin/Record-End pair of DST records. This
3308 0 additional record definition may appear inside the original record
3309 0 definition, but does not have to do so--an Indirect Type Specification
3310 0 pointing to a record definition outside the original record definition
3311 0 is also legal. Conversely, a record definition inside another record
3312 0 definition does not define a nested record unless some component of
3313 0 the outer record actually references the inner record definition. In
3314 0 short, the DST can only describe one level of record components at a
3315 0 time, but any component can be of any arbitrary data type including
3316 0 another record type.
3317 0

3318 0 The Record Begin DST record is unusual in that it can define both a
3319 0 data type and a data object. If the DST\$B_VFLAGS field has the special
3320 0 value DST\$K_VFLAGS_NOVAL, then the Record Begin DST record defines an
3321 0 abstract data type. Any object of this data type must be represented
3322 0 by a Separate Type Specification DST record which immediately precedes
3323 0 either the Record Begin DST record or a Type Specification DST record
3324 0 that contains an Indirect Type Specification that points to the Record
3325 0 Begin DST record. In this case, the name in the Record Begin record is
3326 0 taken to be the name of the data type, not of any object of that type.
3327 0

3328 0 However, if the DST\$B_VFLAGS field does not contain DST\$K_VFLAGS_NOVAL,
3329 0 then the Record Begin DST record defines both a data type and a data
3330 0 object of that type. This form can be used for languages such as COBOL
3331 0 which do not have named data types. In this case, the DST\$B_VFLAGS and
3332 0 DST\$L_VALUE fields specify the address of the record object in the same
3333 0 way as in the Standard Data DST record. It is still legal to have
3334 0 Indirect Type Specifications pointing to this Record Begin DST record,
3335 0 using it strictly as a type definition.
3336 0

3337 0 Some languages, such as PASCAL, allow record variants. (In ADA, the
3338 0 same concept is called "discriminated" records.) An object of a record

3339 0 type with variants contains some set of components found in all objects
3340 0 of that type plus some set of components that vary from one record
3341 0 variant to the next. Which of the varying components are actually
3342 0 present in a given record may be determined by the value of a "tag
3343 0 variable" which is a fixed component of the record. Variants may also
3344 0 be nested so that variants have variants.
3345 0

3346 0 In the DST, record variants are described by Variant Set Begin DST
3347 0 records, Variant Value DST records, and Variant Set End DST records.
3348 0 The Variant Set Begin DST record marks the beginning of a set of record
3349 0 variants, where each variant consists of some set of record components.
3350 0 The Variant Set Begin DST record indicates which record component con-
3351 0 stitutes the tag variable that discriminates between the variants in
3352 0 the set. This tag variable must be a component of the same record and
3353 0 must precede the Variant Begin DST record in the DST. The Variant
3354 0 Begin DST record also gives the bit size of the variant, if known at
3355 0 compile-time.
3356 0

3357 0 The Variant Value DST record marks the beginning of a single record
3358 0 variant. It also specifies all tag variable values or value ranges
3359 0 that indicate the presence of this variant in a given record object.
3360 0 All record components (indicated by data DST records) after this Vari-
3361 0 ant Value DST record and before the next Variant Value or Variant Set
3362 0 End DST record are taken to be components in this variant.
3363 0

3364 0 The Variant Set End DST record marks the end of some set of variants
3365 0 within a record specification. It also terminates the last variant
3366 0 within the set.
3367 0

3368 0 A record type with variants is thus specified as follows. First a
3369 0 Record Begin DST record marks the beginning of the record specifica-
3370 0 tion. After that come data DST records that denote all fixed compo-
3371 0 nents of the record type. Then comes a Variant Set Begin DST record
3372 0 that marks the beginning of a set of variant definitions and identi-
3373 0 fies the tag variable (if any) for that variant set. Immediately
3374 0 thereafter comes the first Variant Value DST record. It marks the
3375 0 start of the first variant and identifies the values or value ranges
3376 0 of the tag variable that correspond to this specific variant.
3377 0

3378 0 After the first Variant Value DST record come the data DST records
3379 0 for the record components in this particular variant. Next comes the
3380 0 Variant Value DST record for the next variant, along with its component
3381 0 DST records, and so on for each variant in the variant set. After the
3382 0 last component DST record for the last variant in the set comes a
3383 0 Variant Set End DST record. It is followed by the DST records for any
3384 0 additional record components, possibly including additional variant
3385 0 set definitions. Then comes the the Record End DST record.
3386 0

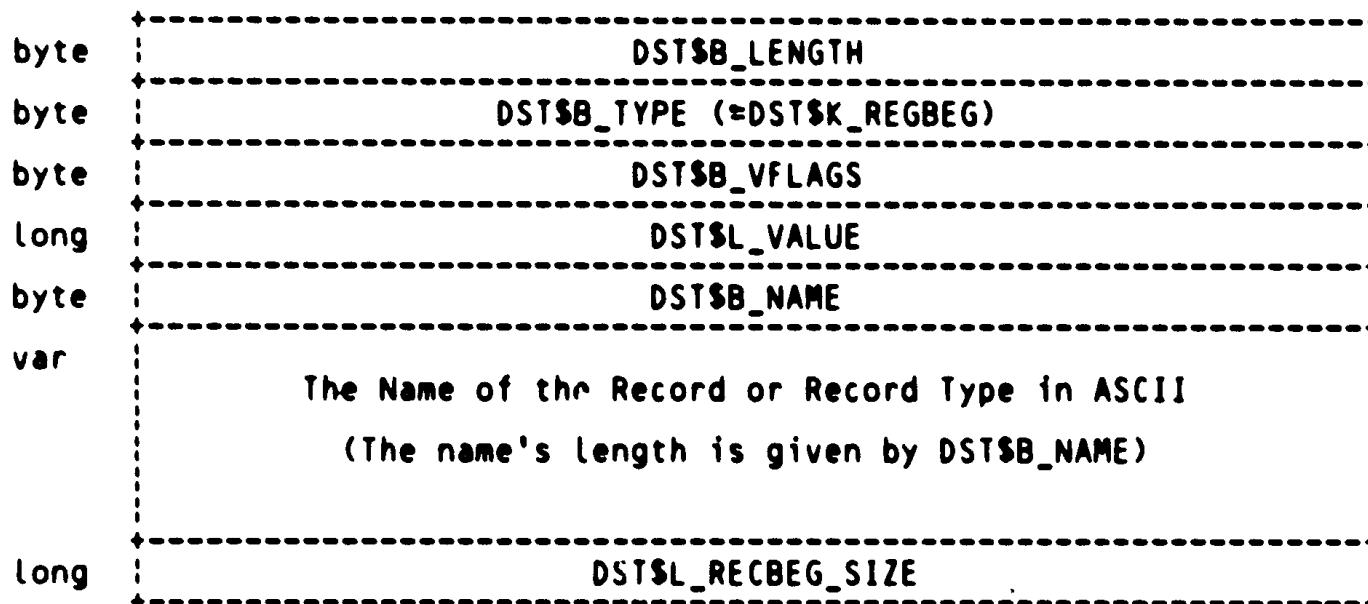

3387 0 Variant sets may be nested inside variant sets. Such nesting is indi-
3388 0 cated in the DST by the corresponding proper nesting of Variant Set
3389 0 Begin and Variant Set End DST records.

3390 0 THE RECORD BEGIN DST RECORD

3391 0
3392 0
3393 0 The Record Begin DST record marks the beginning of a record type
3394 0 definition in the DST. It must be followed by the DST records for
3395 0 the components of that record and by a matching Record End DST record.
3396 0 The Record Begin DST record has essentially the same format as the
3397 0 Standard Data DST record, but with two exceptions. First, an extra
3398 0 longword gives the bit length of the record type and second, the
3399 0 DBG\$B_VFLAGS field may have the special value BST\$K_VFLAGS_NOVAL to
3400 0 indicate that this is strictly a type definition, not also the defini-
3401 0 tion of a record object. If a normal value specification is used, a
3402 0 record object is being declared as well as a record type. In this
3403 0 case, a Trailing Value Specification may be included at the end of the
3404 0 DST record if necessary to describe the record's address.

3405 0
3406 0 The bit size of objects of this record type is also given in the DST
3407 0 record. This size should be included if the size is known at compile-
3408 0 time. If it is not known at compile-time, it should be specified as
3409 0 zero.

3410 0
3411 0 This is the format of the Record Begin DST record:

3437 0 Define the fields of the Record Begin DST record. Also declare the macro
3438 0 that defines the trailer part of the DST record.

3439 0
3440 0 FIELD DST\$RECBEG_TRAILER_FIELDS =
3441 0 SET
3442 0 DST\$L_RECBEGL_SIZE = [0 , L_] ! The bit size of data objects of this
3443 0 record type (or 0 if unknown)
3444 0 TES;

3445 0
3446 0 MACRO

3447 0 DST\$RECBEG_TRLR = BLOCK[,BYTE] FIELD(DST\$RECBEG_TRAILER_FIELDS) %;
3448 0
3449 0
3450 0
3451 0
3452 0
3453 0
3454 0
3455 0 THE RECORD END DST RECORD
3456 0
3457 0
3458 0
3459 0
3460 0
3461 0 byte |-----+-----+
3462 0 |-----| DST\$B_LENGTH (= 1)
3463 0 |-----+-----+
3464 0 byte |-----+-----+
 |-----| DST\$B_TYPE (= DST\$K_RECEND)
 |-----+-----+

3465 0 THE VARIANT SET BEGIN DST RECORD

3466 0
 3467 0
 3468 0 The Variant Set Begin DST record marks the beginning of the DST
 3469 0 description of a set of record variants. This DST record also
 3470 0 identifies the tag variable that discriminates between the variants
 3471 0 in the variant set. The tag variable is identified by a pointer
 3472 0 to the DST record for the tag variable. This DST pointer consists
 3473 0 of a byte address relative to the start of the DST. The size in
 3474 0 bits of this variant set, meaning the size of the largest variant
 3475 0 in the set, is also included. If this size is not known at compile-
 3476 0 time, it should be set to zero.

3477 0
 3478 0 This is the format of the Variant Set Begin DST record:

```

3481 0
3482 0     +-----+
3483 0     |       DST$B_LENGTH
3484 0     +-----+
3485 0     |       DST$B_TYPE (= DST$K_VARBEG)
3486 0     +-----+
3487 0     |       DST$B_VFLAGS
3488 0     +-----+
3489 0     |       DST$L_VALUE
3490 0     +-----+
3491 0     |       DST$B_NAME

3503 0     +-----+
3504 0     |       DST$L_VARBEG_TAG_PTR
3505 0     +-----+
3506 0
3507 0
3508 0 Define the fields of the Variant Set Begin DST record. Also define the
3509 0 declaration macro for the trailer part of the record.
3510 0

```

```

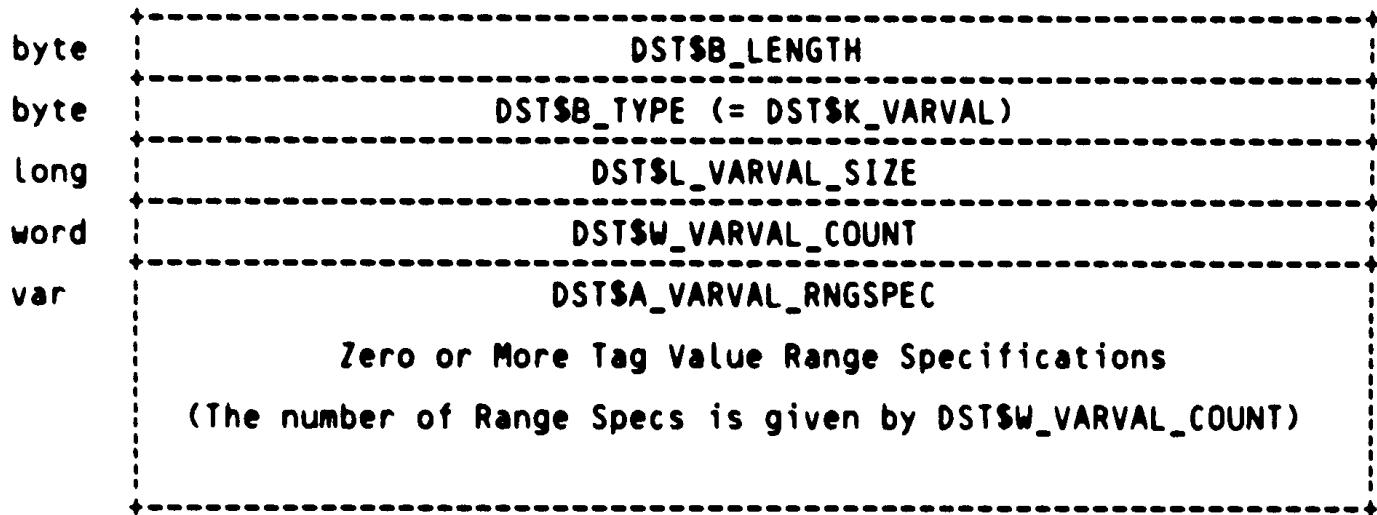

3511 0 FIELD DST$VARBEG_TRAILER_FIELDS =
3512 0     SET
3513 0     DST$L_VARBEG_SIZE      = [ 0, L_ ],   ! Size in bits of variant part
3514 0                               ! of record (or zero)
3515 0     DST$L_VARBEG_TAG_PTR  = [ 4, L_ ]   ! Pointer to TAG field DST
3516 0                               ! record relative to the
3517 0                               ! start of the DST
3518 0     TES;
3519 0
3520 0 MACRO
3521 0     DST$VARBEG_TRAILER = BLOCK[,BYTE] FIELD(DST$VARBEG_TRAILER_FIELDS) %;
```

3522 0 THE VARIANT VALUE DST RECORD
3523 0
3524 0

3525 0 The Variant Value DST record marks the beginning of a new record
3526 0 variant within a variant set. It also marks the end of the previous
3527 0 variant (if any). It is always found between a Variant Set Begin
3528 0 and a Variant Set End DST record. Since the Variant Set Begin DST
3529 0 record has already specified the tag variable, the Variant Value
3530 0 DST record only specifies the tag value or values that correspond
3531 0 to the present variant. It also specifies the size in bits of this
3532 0 variant if known at compile-time (otherwise zero is specified). The
3533 0 Variant Value DST record is followed by the data DST records (includ-
3534 0 ing nested variants if appropriate) which constitute the components
3535 0 of this specific variant.
3536 0

3537 0 A variant may have many tag values or tag value ranges. This DST
3538 0 record thus specifies a set of tag value ranges. The way these
3539 0 ranges are specified is described in detail on the following page.
3540 0

3541 0 This is the format of the Variant Value DST record:
3542 0
3543 0

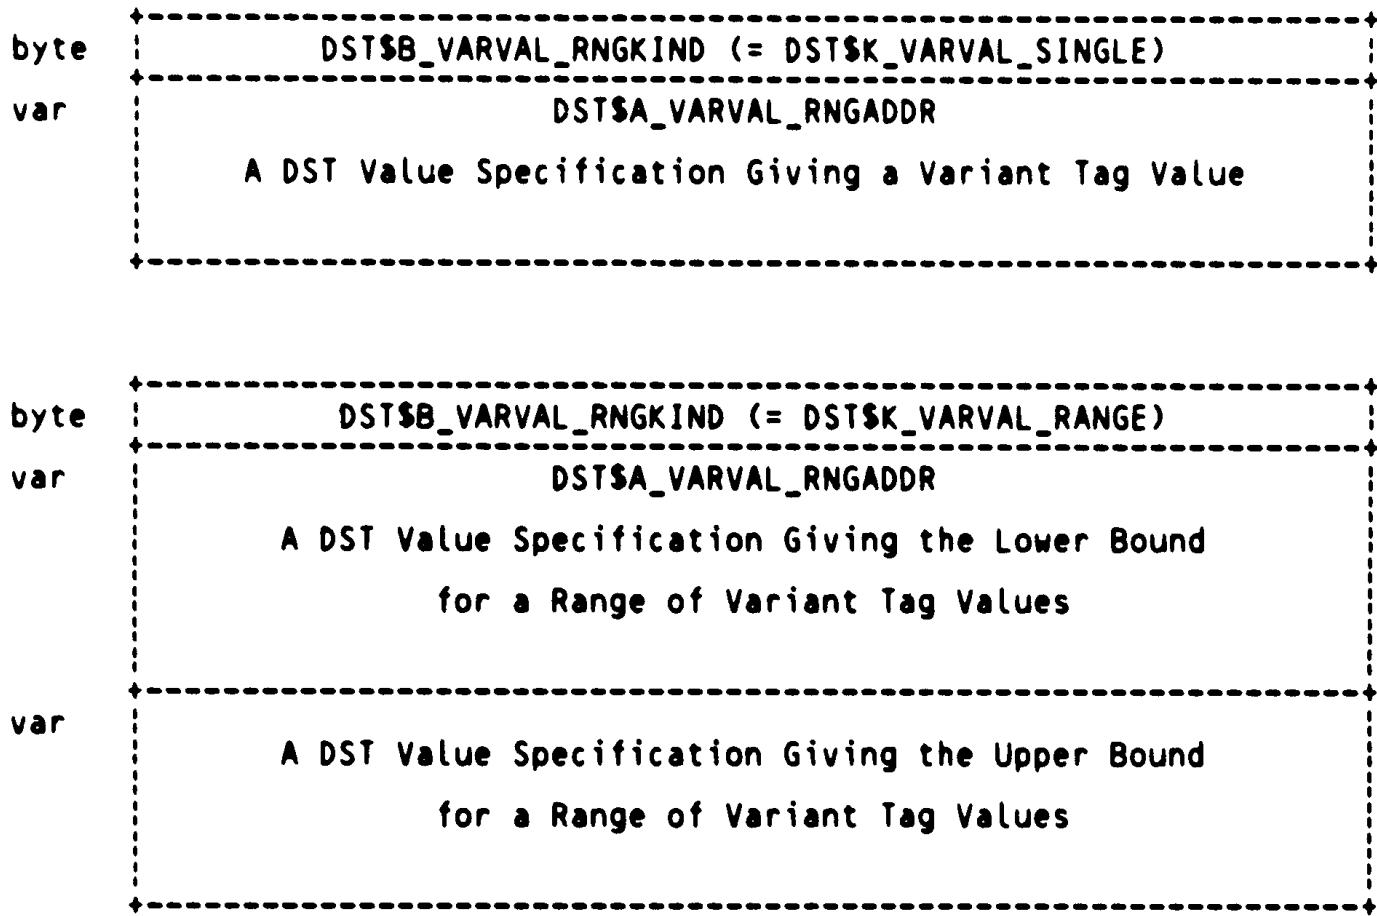

3564 0 Define the fields of the Variant Value DST record.
3565 0

FIELD DST\$VARVAL_FIELDS =
3567 0 SET
3568 0 DST\$L_VARVAL_SIZE = [2, L_], ! Bit size of this variant part
3569 0 DST\$W_VARVAL_COUNT = [6, W_], ! The number of tag value ranges
3570 0 which follow
3571 0 DSTSA_VARVAL_RNGSPEC = [8, A_] ! Location where the tag value
3572 0 range specs start
3573 0 TES:

3574 0 | TAG VALUE RANGE SPECIFICATIONS

3577 0 |
3578 0 | Each Tag Value Range Specification in a Variant Value DST record
3579 0 | consists of a byte specifying the kind of the range specification
3580 0 | followed by one or two Value Specifications. If one Value Speci-
3581 0 | fication is given, that gives the tag value--the range consists of
3582 0 | that one value. If two Value Specifications are given, they speci-
3583 0 | fy the lowest and highest values in the tag value range. The illu-
3584 0 | strations below show the two possible formats of Tag Value Range
3585 0 | Specifications:

3622 0 | FIELD DST\$VARVAL_RNG_FIELDS =
3623 0 | SET
3624 0 | DSTSB_VARVAL_RNGKIND = [0, B], ! Tag Value Range Spec kind
3625 0 | DSTSA_VARVAL_RNGADDR = [1, A] ! Location of first Value
3626 0 | Specification
3627 0 | TES:
3628 0 |
3629 0 |
3630 0 | ! Define the possible values of the DSTSB_VARVAL_RNGKIND field.

3663 0 |
3664 0 |
3665 0 |
3666 0 |

BLISS data objects are represented by several different kinds of DST records. Ordinary scalar objects, such as simple integers, are represented by the Standard Data DST record or its variants. However, the more specialized BLISS data types such as Vectors, Bitvectors, Blocks, and Blockvectors, are represented by a special DST record called the BLISS Special Cases DST record. Pointers to such objects (e.g., REF VECTOR) are also represented by this DST record. In addition, BLISS field names are represented by their own kind of DST record, the BLISS Field DST record. Both of these record kinds are described in this section.

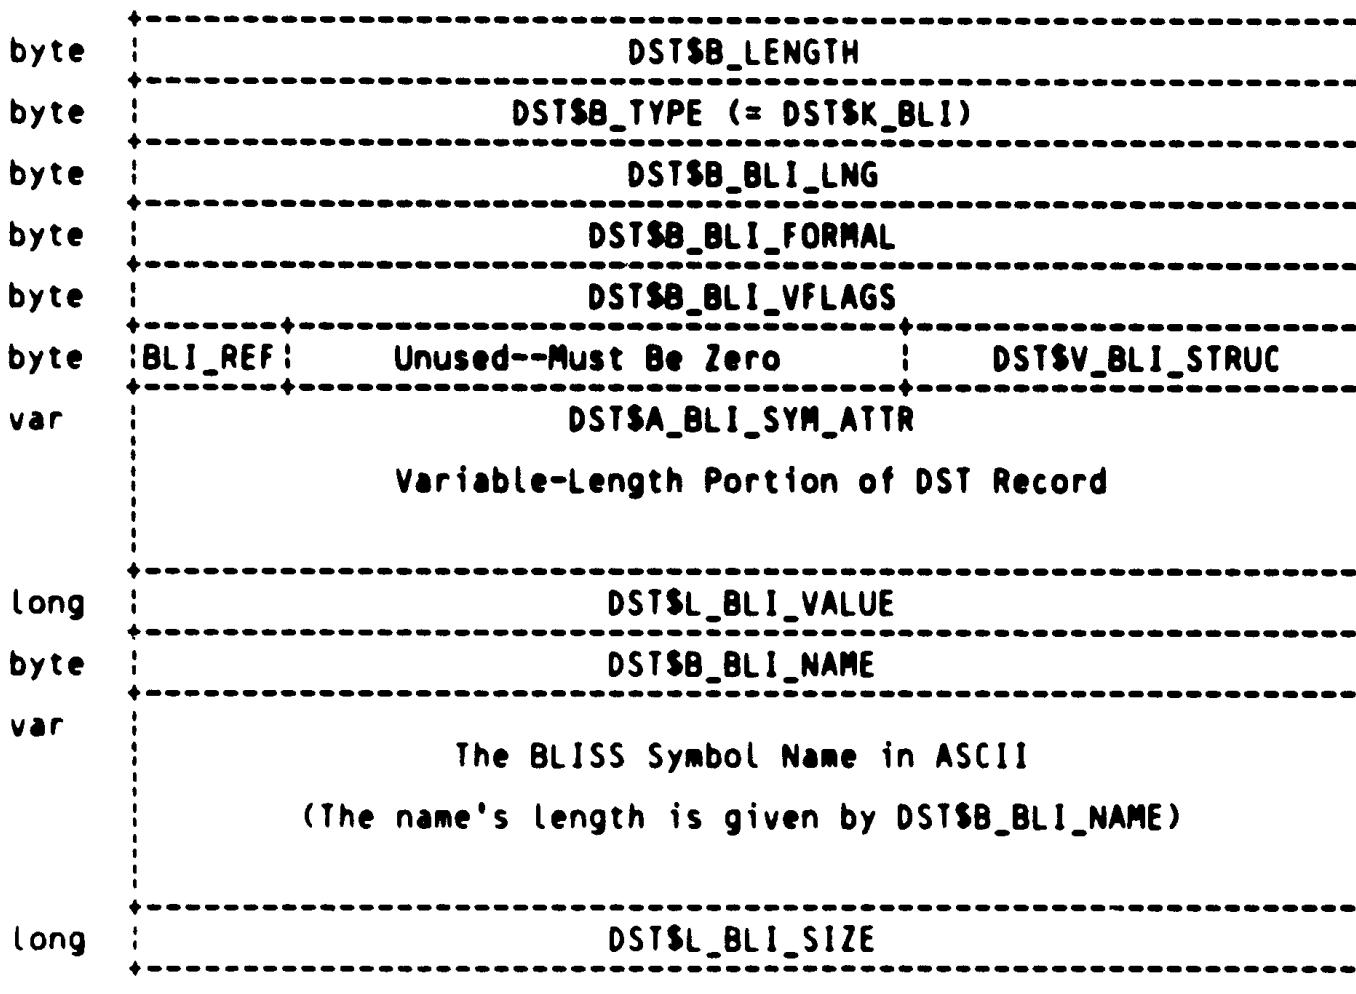

The BLISS Special Cases DST record and the BLISS Field DST record are supported for BLISS only. They should not be generated by compilers for any other language.

3667 0 THE BLISS SPECIAL CASES DST RECORD
 3668 0
 3669 0

3670 0 The BLISS Special Cases DST record is used to describe a number of
 3671 0 data objects whose data types are specific to the BLISS language only.
 3672 0 This includes such objects as BLISS Vectors, Bitvectors, Blocks, and
 3673 0 Blockvectors and pointers to these objects (REF VECTOR, REF BLOCK,
 3674 0 and so on). This DST record should not be generated for any language
 3675 0 other than BLISS.

3676 0
 3677 0 This DST records consists of four parts: The DST header fields, the
 3678 0 fields in the set DST\$BLI FIELD, a variable-length set of fields, and
 3679 0 the fields in the set DST\$BLI TRAIL FIELDS. The variable-length set
 3680 0 of fields can be empty, consist of the fields in DST\$BLI_VEC FIELDS,
 3681 0 the fields in DST\$BLI_BITVEC FIELDS, the fields in DST\$BLI_BLOCK FIELDS,
 3682 0 or the fields in DST\$BLI_BLKVEC_FIELDS. Which set of fields appears
 3683 0 in the variable-length part depends on the value of BLISV_BLI_STRUC,
 3684 0 which indicates which type of symbol is being defined.

3685 0
 3686 0 This is thus the format of the BLISS Special Cases DST record:
 3687 0
 3688 0

3724 0 | The variable-length portion of the DST record can have several forms
3725 0 | as discussed above. One possibility is that it is absent altogether.
3726 0 | This occurs if the DST\$V_BLI_STRUC field contains DST\$K_BLI_NOSTRUC.
3727 0 |
3728 0 | However, if DST\$V_BLI_STRUC has the value DST\$K_BLI_VEC, the variable-
3729 0 | length portion of the DST record has the following format:
3730 0 |
3731 0 |
3732 0 |-----+
3733 0 | Long : DST\$L_BLI_VEC_UNITS
3734 0 |-----+
3735 0 | byte : DST\$V_BLI_VEC_SIGN_EXT : DST\$V_BLI_VEC_UNIT_SIZE
3736 0 |-----+
3737 0 |
3738 0 |
3739 0 |
3740 0 | If DST\$V_BLI_STRUC has the value DST\$K_BLI_BITVEC, the variable-length
3741 0 | portion of the DST record has the following format:
3742 0 |
3743 0 |-----+
3744 0 | Long : DST\$L_BLI_BITVEC_SIZE
3745 0 |-----+
3746 0 |
3747 0 |
3748 0 |
3749 0 |
3750 0 | If DST\$V_BLI_STRUC has the value DST\$K_BLI_BLOCK, the variable-length
3751 0 | portion of the DST record has the following format:
3752 0 |
3753 0 |-----+
3754 0 | Long : DST\$L_BLI_BLOCK_UNITS
3755 0 |-----+
3756 0 | byte : Unused : DST\$V_BLI_BLOCK_UNIT_SIZE
3757 0 |-----+
3758 0 |
3759 0 |
3760 0 |
3761 0 |
3762 0 | If DST\$V_BLI_STRUC has the value DST\$K_BLI_BLKVEC, the variable-length
3763 0 | portion of the DST record has the following format:
3764 0 |
3765 0 |-----+
3766 0 | Long : DST\$L_BLI_BLKVEC_BLOCKS
3767 0 |-----+
3768 0 | Long : DST\$L_BLI_BLKVEC_UNITS
3769 0 |-----+
3770 0 | byte : DST\$B_BLI_BLKVEC_UNIT_SIZE
3771 0 |-----+
3772 0 |
3773 0 |
3774 0 |
3775 0 |
3776 0 | Define the fields in the header portion of the BLISS Special Cases DST
3777 0 | Record.
3778 0 |
3779 0 | FIELD DST\$BLI_FIELDS =
3780 0 | SET

```

3781 0 DST$B_BLI_LNG      = [ 2, B_ ], ; Length in bytes of the set of

3897 0 THE BLISS FIELD DST RECORD
3898 0
3899 0

3900 0 The BLISS Field DST record describes a BLISS field name. BLISS field
3901 0 names are declared in FIELD declarations in BLISS. Each BLISS field
3902 0 name is bound to an n-tuple of numbers. Usually the n-tuple is a four-
3903 0 tuple and the numbers represent a byte or longword offset, the bit
3904 0 offset within that byte or longword, the bit length of the field being
3905 0 described, and a sign-extension flag. DEBUG supports references to
3906 0 such fields in BLISS Blocks and Blockvectors. However, a BLISS field
3907 0 can be any n-tuple. If n is not 4, the field name can only be used in
3908 0 EXAMINE commands, but not in Block or Blockvector references.
3909 0

3910 0 The BLISS Field DST record should not be generated for any language
3911 0 other than BLISS. This is the format of the record:

L A B E L D S T R E C O R D S

Labels are represented by two different DST records. A label, in the sense used here, is a symbol bound to an instruction address. Labels do not include routine, lexical block, and entry point symbols, however. A label can be represented by either a Label DST record or a Label-or-Literal DST record. The Label-or-Literal DST record is intended only for language MACRO, it appears. (The history on the origin and intent of this record is unclear, however.) All other languages should use the Label DST record for labels.

THE LABEL DST RECORD

The Label DST record specifies the name and address of a label in the current module. A label in this sense is always bound to an instruction address, not a data address. This is the DST record normally used for labels in high-level languages. The DSTSL_VALUE field of this record contains the code address to which the label is bound.

This is the format of the Label DST record:

3998 0

4018 0

4019 0

THE LABEL-OR-LITERAL DST RECORD

The Label-or-Literal DST record specifies the name and address of a label (meaning a code location) or the name and value of an integer literal (a named constant). It is not entirely clear why this DST record exists since labels can be described by Label DST records and integer literals can be described with Standard Data DST records. Most likely this DST record was intended for language MACRO where there is little distinction between labels and literals; one is relocatable and the other is not, but that is about all. If DST\$V_VALKIND has the value DST\$K_VALKIND_ADDR, the symbol is a label and if it has the value DST\$K_VALKIND_LITERAL, the symbol is a literal. The address of the label or the value of the literal is found in the DST\$L_VALUE field. It is recommended that high-level languages avoid this DST record and use the Label DST record or the Standard Data DST record instead.

This is the format of the Label-or-Literal DST record:

THE ENTRY POINT DST RECORD

The Entry Point DST record describes an ENTRY name in the FORTRAN or PL/I sense. In other words, it describes a secondary entry point to the routine within which this DST record is nested. This record should never be generated for the main entry point to a routine since that entry point is already described by the Routine Begin DST record. An entry point described by the Entry Point DST record is always assumed to be called through the CALLS/CALLG instructions (not JSB/BSB). The DST\$L_VALUE field contains the address of the entry point.

This is the format of the Entry Point DST record:

4071 0 THE PSECT DST RECORD
4072 0
4073 0
4074 0

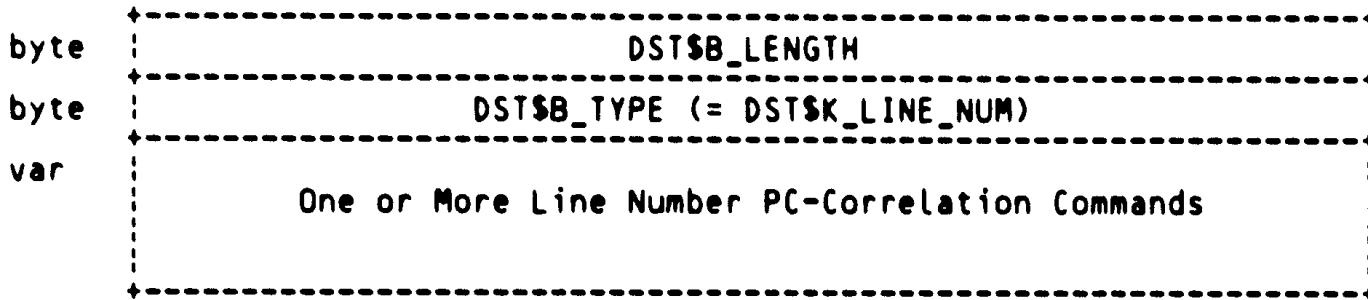

4075 0 The PSECT DST record specifies the name, address, and length of
4076 0 a PSECT where a PSECT is a Program Section in the linker sense.
4077 0 PSECT DST records are only used for language MACRO where it is
4078 0 possible to generate code or data at the beginning of a PSECT
4079 0 without having any other label on that code. DEBUG ignores PSECT
4080 0 DST records for all other languages since high-level languages
4081 0 have other code and data labels that are more appropriate.
4082 0
4083 0
4084 0

The Line Number PC-Correlation DST record specifies the correlation between listing line numbers, as assigned by the compiler, and PC addresses. It thus means whereby the compiler tells DEBUG where the generated object code for each source line starts and how long it is in bytes. This is the format of the Line Number PC-Correlation DST record:

4167 0 After the two-byte header, each Line Number PC-Correlation DST record
4168 0 contains a sequence of Line Number PC-Correlation commands. Each such
4169 0 command sets or manipulates one or more state variables used by DEBUG
4170 0 in the interpretation of these commands. The main state variables are
4171 0 the current line number and the current PC address, but there are sev-
4172 0 eral others as well. The exact semantics of the various commands are
4173 0 described in the sections that follow.

4174 0
4175 0 Line Number PC-Correlation DST records are associated with the module
4176 0 within which they appear. They must thus appear between the Module
4177 0 Begin and the Module End DST records for the current module. There are
4178 0 no further restrictions on where they may appear, however. In particu-
4179 0 lar, they need not be nested within the routines or lexical blocks that
4180 0 they describe. It is thus legal to generate all Line Number PC-Corre-
4181 0 lation DST records for a module after the last Routine End DST record,
4182 0 for instance. These records can also be interspersed between Routine
4183 0 and Block Begin and End records in any way convenient for the compiler
4184 0 implementer. However it is done, DEBUG treats them as belonging to the
4185 0 module as a whole.

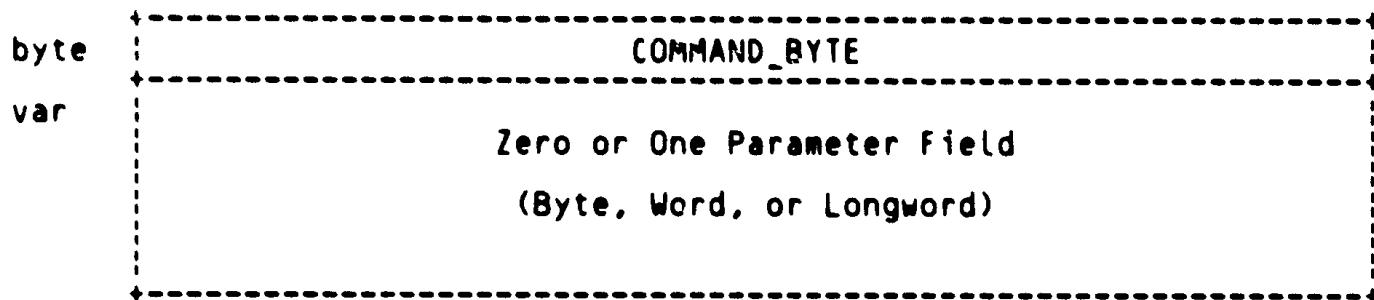

4186 0
4187 0 The Line Number PC-Correlation information may be spread over as many
4188 0 DST records as necessary. No Line Number PC-Correlation command may be
4189 0 broken across record boundaries, but otherwise the Line Number PC-Corre-
4190 0 lation DST records within a module are considered to constitute a single
4191 0 command stream. The Continuation DST record may not be used to continue
4192 0 Line Number PC-Correlation DST records.

4193 0 Define the fields of the Line Number PC-Correlation DST record.

```

4197 0
4198 0 ! FIELD DST$LINE_NUM_FIELDS =
4199 0     SET
4200 0     DST$A_LINE_NUM_DATA = [ 2, A_ ] ! Start address of PC-correlation data
4201 0     TES;

4253 0

```

The command byte contains a command code. If this command code is negative, this is a Delta-PC command. A Delta-PC command specifies by how many bytes to increment the PC to get to the start of the next line (see detailed description below). This byte count is encoded directly in the command byte: If the command code is negative, its negative is the PC increment. The Delta-PC command has no parameter field. If the command code is positive, it specifies some other command as described below. In this case, there may be a parameter field, depending on the command code.

Define the command codes allowed in Line Number PC-Correlation commands. If the command code is zero or negative, the command is a one-byte Delta-PC command. Here we define the command-code range for the Delta-PC command.

```

LITERAL
    DST$K_DELTA_PC_LOW      = -128, ! The lower bound on Delta-PC commands
    DST$K_DELTA_PC_HIGH     = 0;   ! The upper bound on Delta-PC commands

```

! Define the PC-correlation command codes other than the Delta-PC command.
 These command codes are always positive.

```

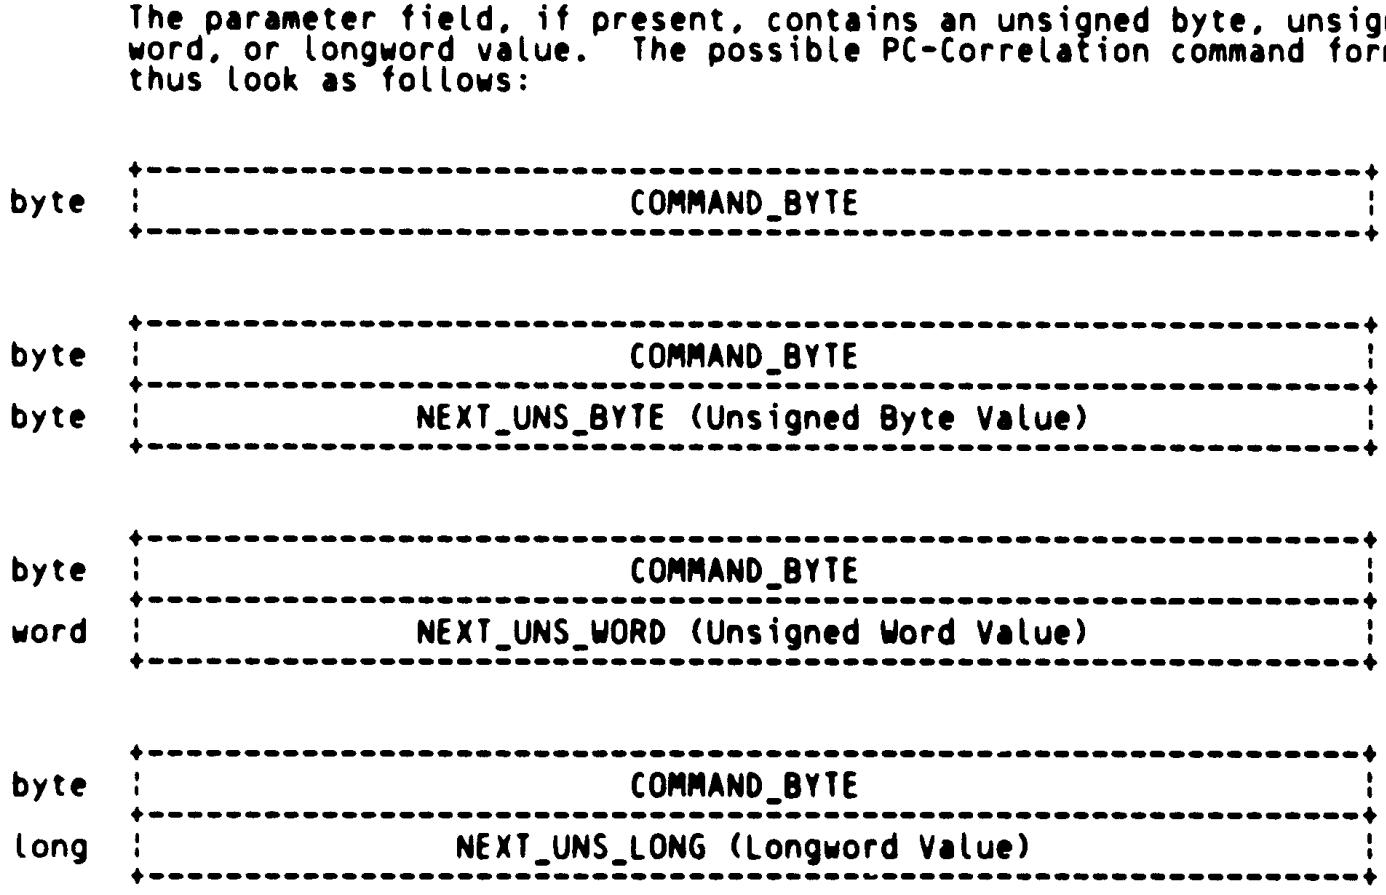

LITERAL
    DST$K_DELTA_PC_W       = 1,   ! Delta-PC Word command
    DST$K_DELTA_PC_L       = 17,  ! Delta-PC Longword command

```

```

4254 0 DST$K_INCR_LINUM      = 2,   | Increment Line Number Byte command
4255 0 DST$K_INCR_LINUM_W     = 3,   | Increment Line Number Word command
4256 0 DST$K_INCR_LINUM_L     = 18,  | Increment Line Number Longword command
4257 0 DST$K_SET_LINUM_INCR  = 4,   | Set Line Number Increment Byte command
4258 0 DST$K_SET_LINUM_INCR_W = 5,   | Set Line Number Increment Word command
4259 0 DST$K_RESET_LINUM_INCR= 6,   | Reset Line Number Increment command
4260 0 DST$K_BEG_STMT_MODE   = 7,   | Begin Statement Mode command
4261 0 DST$K_END_STMT_MODE   = 8,   | End Statement Mode command
4262 0 DST$K_SET_STMTNUM     = 13,  | Set Statement Number Byte command
4263 0 DST$K_SET_LINUM_B      = 19,  | Set Line Number Byte command
4264 0 DST$K_SET_LINUM        = 9,   | Set Line Number Word command
4265 0 DST$K_SET_LINUM_L      = 20,  | Set Line Number Longword command
4266 0 DST$K_SET_PC          = 10,  | Set Relative PC Byte command
4267 0 DST$K_SET_PC_W         = 11,  | Set Relative PC Word command
4268 0 DST$K_SET_PC_L         = 12,  | Set Relative PC Longword command
4269 0 DST$K_SET_ABS_PC       = 16,  | Set Absolute PC Longword command
4270 0 DST$K_TERM             = 14,  | Terminate Line Byte command
4271 0 DST$K_TERM_W           = 15,  | Terminate Line Word command
4272 0 DST$K_TERM_L           = 21,  | Terminate Line Longword command
4273 0
4274 0 DST$K_PCCOR_LOW        = -128, | Smallest value allowed in the first
4275 0                               byte of a PC-correlation command
4276 0 DST$K_PCCOR_HIGH        = 21;  | Largest value allowed in the first
4277 0                               byte of a PC-correlation command
4278 0
4279 0
4280 0 The parameter field, if present, contains an unsigned byte, unsigned
4281 0 word, or longword value. The possible PC-Correlation command formats
4282 0 thus look as follows:
4283 0
4284 0
4285 0
4286 0
4287 0

4367 0

CURRENT_LINE -- The current line number.
CURRENT_STMT -- The current statement number.
CURRENT_INCR -- The current line number increment.
CURRENT_STMT_MODE -- The statement mode flag; set to TRUE when statement mode is set, set to FALSE otherwise;
START_PC -- The start address of the lowest-address routine in the current module;
CURRENT_PC -- The current PC value (code address).
CURRENT_MARK -- The line-open/line-closed flag; set to LINE_OPEN when line numbers are being defined and set to LINE_CLOSED when a routine has been terminated and new lines are not being defined.

The initial values of these state variables when the PC-Correlation commands for a given module are interpreted are as follows:

CURRENT_LINE = 0;
CURRENT_STMT = 1;
CURRENT_INCR = 1;
CURRENT_STMT_MODE = FALSE;
START_PC = Start address of the lowest-address routine in the current module;
CURRENT_PC = START_PC;
CURRENT_MARK = LINE_CLOSED;

The sections below describe the format and semantics of each of the individual PC-Correlation commands.

THE DELTA-PC COMMAND

This command defines a correlation between a line number and a PC value. The current line number is incremented by the current increment value (normally 1) and the current PC value is incremented by the negative of the command byte. The resulting line number then has the resulting PC value. In other words, both the line number and the PC value are incremented before the correlation is established. The PC increment value (the negative of the command code) thus specifies how many bytes to go forward to get to the start of the line being defined. These are the formal semantics of the command:

IF CURRENT_STMT_MODE
THEN
 CURRENT_STMT = CURRENT_STMT + 1

```

```

```
    ELSE
        CURRENT_LINE = CURRENT_LINE + CURRENT_INCR;
        CURRENT_PC = CURRENT_PC - PC_COMMAND[COMMAND_BYT];
        CURRENT_MARK = LINE_OPEN;
```

The value of CURRENT_PC now contains the start address of the listing line specified by the values of CURRENT_LINE and CURRENT_STMT. Note that line-open mode is now set.

THE DST\$K_DELTA_PC_W COMMAND

This command is like the normal Delta-PC command except that the PC increment value is given in an unsigned word following the command code. These are the semantics:

```
    IF CURRENT_STMT_MODE
    THEN
        CURRENT_STMT = CURRENT_STMT + 1
    ELSE
        CURRENT_LINE = CURRENT_LINE + CURRENT_INCR;
        CURRENT_MARK = LINE_OPEN;
        CURRENT_PC = CURRENT_PC + PC_COMMAND[NEXT_UNS_WORD];
```

The value of CURRENT_PC now contains the start address of the listing line specified by the values of CURRENT_LINE and CURRENT_STMT. Note that line-open mode is now set.

THE DST\$K_DELTA_PC_L COMMAND

This command is like the normal Delta-PC command except that the PC increment value is given in an unsigned longword following the command code. These are the semantics:

```
    IF CURRENT_STMT_MODE
    THEN
        CURRENT_STMT = CURRENT_STMT + 1
    ELSE
        CURRENT_LINE = CURRENT_LINE + CURRENT_INCR;
        CURRENT_MARK = LINE_OPEN;
        CURRENT_PC = CURRENT_PC + PC_COMMAND[NEXT_UNS_LONG];
```

The value of CURRENT_PC now contains the start address of the listing line specified by the values of CURRENT_LINE and CURRENT_STMT. Note

4425 0 : that line-open mode is now set.

THE DSTSK_INCR_LINUM COMMAND

This command increments the current line number by the value given in the unsigned byte following the command code. If statement mode is set, the current statement is reset to 1 as well. These are the formal semantics of the command:

CURRENT_LINE = CURRENT_LINE + PC_COMMAND[NEXT_UNSL_BYTE];
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;

THE DSTSK_INCR_LINUM_W COMMAND

This command increments the current line number by the value given in the unsigned word following the command code. If statement mode is set, the current statement is reset to 1 as well. These are the formal semantics of the command:

```
CURRENT_LINE = CURRENT_LINE + PC_COMMAND[NEXT_UNS_WORD];  
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;
```

THE DSTSK_INCR_LINUM_L COMMAND

This command increments the current line number by the value given in the unsigned longword following the command code. If statement mode is set, the current statement is reset to 1 as well. These are the formal semantics of the command:

```
CURRENT_LINE = CURRENT_LINE + PC_COMMAND[NEXT_UNS_LONG];  
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;
```

THE DSTSK_SET_LINUM_INCR COMMAND

This command set the current line number increment value to the value specified in the unsigned byte following the command code. If statement mode is set, the current statement number is set to 1. These are the formal semantics of the command:

CURRENT_INCR = PC_COMMAND[NEXT_UNS_BYTE];
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;

THE DST\$K_SET_LINUM_INCR_W COMMAND

This command set the current line number increment value to the value specified in the unsigned word following the command code. If statement mode is set, the current statement number is set to 1. These are the formal semantics of the command:

```
CURRENT_INCR = PC COMMAND[NEXT UNS WORD];
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;
```

THE DST\$K_RESET_LINUM_INCR COMMAND

This command resets the current line number increment value to 1. If statement mode is set, the current statement number is set to 1 as well. These are the semantics:

```
CURRENT_INCR = 1;
IF CURRENT_STMT_MODE THEN CURRENT_STMT = 1;
```

THE DST\$K_BEG_STMT_MODE COMMAND

This command sets statement mode, meaning that subsequent Delta-PC commands will increment the current statement number within the current line and not the current line itself. This command is only allowed in the line-open state. Statement mode can optionally be used by languages that have multiple statements per line. This command also set the current statement number to 1. These are the semantics:

```
IF CURRENT_MARK NEQ LINE_OPEN THEN SIGNAL(Invalid DST Record);
CURRENT_STMT_MODE = TRUE;
CURRENT_STMT = 1;
```

THE DST\$K_END_STMT_MODE COMMAND

This command clears statement mode so that that subsequent Delta-PC commands will again increment the current line number, not the statement number. The command also set the current statement number to 1. These are the semantics:

```
CURRENT_STMT_MODE = FALSE;
```

4539 0 CURRENT_STMT = 1;

4540 0 THE DST\$K_SET_LINUM_B COMMAND

4541 0
4542 0 This command sets the current line number to the value specified in the
4543 0 unsigned byte that follows the command code. These are the semantics:

4544 0
4545 0 CURRENT_LINE = PC_COMMAND[NEXT_UNS_BYTE];

4546 0
4547 0 THE DST\$K_SET_LINUM COMMAND

4548 0
4549 0 This command sets the current line number to the value specified in the
4550 0 unsigned word that follows the command code. These are the semantics:

4551 0
4552 0 CURRENT_LINE = PC_COMMAND[NEXT_UNS_WORD];

4553 0
4554 0 THE DST\$K_SET_LINUM_L COMMAND

4555 0
4556 0 This command sets the current line number to the value specified in the
4557 0 longword that follows the command code. These are the semantics:

4558 0
4559 0 CURRENT_LINE = PC_COMMAND[NEXT_UNS_LONG];

4560 0
4561 0 THE DST\$K_SET_STMTNUM COMMAND

4562 0
4563 0 This command sets the current statement number to the value specified
4564 0 in the unsigned word that follows the command code. The command should
4565 0 only be used when statement mode is set. These are the semantics:

4566 0
4567 0 CURRENT_STMT = PC_COMMAND[NEXT_UNS_WORD];

4568 0
4569 0 THE DST\$K_SET_PC COMMAND

4570 0
4571 0 This command sets the current PC value to be the value specified in the
4572 0 unsigned byte following the command code added to the start address of
4573 0 the lowest-address routine in the current module. This command is only
4574 0 allowed in the line-closed state. These are the formal semantics:

4575 0
4576 0
4577 0
4578 0
4579 0
4580 0
4581 0

4592 0
4593 0
4594 0
4595 0

4596 0
4597 0 IF CURRENT_MARK NEQ LINE_CLOSED THEN SIGNAL(Invalid DST Record);
4598 0 CURRENT_PC = START_PC + PC_COMMAND[NEXT_UNS_BYTE];
4599 0
4600 0
4601 0
4602 0 THE DSTSK_SET_PC_W COMMAND
4603 0
4604 0

This command sets the current PC value to be the value specified in the unsigned word following the command code added to the start address of the lowest-address routine in the current module. This command is only allowed in the line-closed state. These are the formal semantics:

4611 0
4612 0 IF CURRENT_MARK NEQ LINE_CLOSED THEN SIGNAL(Invalid DST Record);
4613 0 CURRENT_PC = START_PC + PC_COMMAND[NEXT_UNS_WORD];
4614 0
4615 0
4616 0 THE DSTSK_SET_PC_L COMMAND
4617 0
4618 0

This command sets the current PC value to be the value specified in the longword following the command code added to the start address of the lowest-address routine in the current module. This command is only allowed in the line-closed state. These are the formal semantics:

4625 0
4626 0 IF CURRENT_MARK NEQ LINE_CLOSED THEN SIGNAL(Invalid DST Record);
4627 0 CURRENT_PC = START_PC + PC_COMMAND[NEXT_UNS_LONG];
4628 0
4629 0
4630 0 THE DSTSK_SET_ABS_PC COMMAND
4631 0
4632 0

This command sets the current PC value to be the absolute address specified in the longword following the command code. This command is only allowed in the line-closed state. These are the formal semantics:

4638 0
4639 0 IF CURRENT_MARK NEQ LINE_CLOSED THEN SIGNAL(Invalid DST Record);
4640 0 CURRENT_PC = PC_COMMAND[NEXT_UNS_LONG];
4641 0
4642 0
4643 0 THE DSTSK_TERM COMMAND
4644 0
4645 0

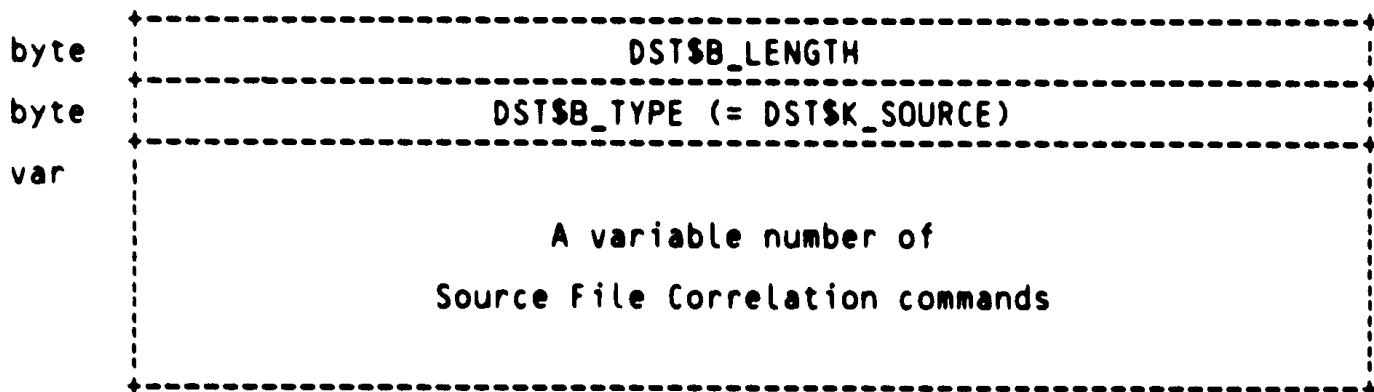

This command terminates the PC-Correlation command sequence for the current routine or other program unit and specifies the number of bytes in the last line specified by a Delta-PC command. Since the Delta-PC command specifies how many bytes precede the line being defined, the Terminate command is needed to say how many bytes are in that line (i.e., how many bytes will increment the PC to the first byte past the current program unit). The number of bytes in the last line is speci-

4653 0 | fied by the unsigned byte following the command code. This command also
4654 0 | sets the line-closed state. These are the semantics of the command:
4655 0 |
4656 0 |
4657 0 | CURRENT_PC = CURRENT_PC + PC_COMMAND[NEXT_UNS_BYTE];
4658 0 | CURRENT_MARK = LINE_CLOSED;
4659 0 |
4660 0 |
4661 0 |
4662 0 | THE DST\$K_TERM_W COMMAND
4663 0 |
4664 0 |
4665 0 | This command terminates the PC-Correlation command sequence for the cur-
4666 0 | rent routine or other program unit and specifies the number of bytes in
4667 0 | the last line of that program unit. It is a variant of the DST\$K_TERM
4668 0 | command described above. The number of bytes in the last line is speci-
4669 0 | fied by the unsigned word following the command code. This command also
4670 0 | sets the line-closed state. These are the semantics of the command:
4671 0 |
4672 0 |
4673 0 | CURRENT_PC = CURRENT_PC + PC_COMMAND[NEXT_UNS_WORD];
4674 0 | CURRENT_MARK = LINE_CLOSED;
4675 0 |
4676 0 |
4677 0 |
4678 0 | THE DST\$K_TERM_L COMMAND
4679 0 |
4680 0 |
4681 0 | This command terminates the PC-Correlation command sequence for the cur-
4682 0 | rent routine or other program unit and specifies the number of bytes in
4683 0 | the last line of that program unit. It is a variant of the DST\$K_TERM
4684 0 | command described above. The number of bytes in the last line is speci-
4685 0 | fied by the longword following the command code. This command also sets
4686 0 | the line-closed state. These are the semantics of the command:
4687 0 |
4688 0 |
4689 0 | CURRENT_PC = CURRENT_PC + PC_COMMAND[NEXT_UNS_LONG];
4690 0 | CURRENT_MARK = LINE_CLOSED;
4691 0 |
4692 0 |
4693 0 |
4694 0 | END OF LINE NUMBER PC-CORRELATION DST RECORD DESCRIPTION.

4695 0 | SOURCE FILE CORRELATION
4696 0 | DST RECORDS
4697 0 |

The Source File Correlation DST record is used to specify the correlation between listing line numbers on the one hand and source files and source file record numbers on the other. These records enable DEBUG to display source lines during the debugging session.

The Source File Correlation DST record has the following format:

After the length and DST type bytes, the record consists of a sequence of Source File Correlation commands. These commands specify what source files contributed source lines to this module and how the module's listing line numbers are lined up with the source files and record numbers within those source files. The available commands are described individually below.

If the Source File Correlation commands needed to fully describe the current module will not fit in a single Source Line Correlation DST record, they can be spread over any number of such DST records. These records will be processed sequentially, in the order that they appear, until there are no more such records for the current module.

The purpose of the Source File Correlation commands is to allow DEBUG to construct a table of correlations between line numbers and source records. A "line number" in this context means the listing line number. This is the line number which is printed in the program listing and is output to the PC-Correlation DST records by the compiler. (PC-Correlation DST records correlate listing line numbers with Program Counter values.) A corresponding source line is identified by two things: a source file and a record number within that source file.

The semantics of the Source File Correlation commands can be understood in terms of manipulating three state variables and issuing one command. The three state variables are:

LINE_NUM -- The current listing line number.
SRC_FILE -- The File ID of the current source file,

4808 0

i.e. a small integer uniquely defining
the source file.
SRC_REC -- The record number (in the RMS sense) in
the current source file of the current
source line.

LINE_NUM is assumed to have an initial value of 1 while SRC_FILE and
SRC_REC are initially undefined. The one command is:

DEFINE(LINE_NUM, SRC_FILE, SRC_REC)

This command declares that line number LINE_NUM is associated with the
source line at record number SRC_REC in the file specified by SRC_FILE.

Given this, the compiler must output a sequence of Source File Correla-
tion commands which cause LINE_NUM, SRC_FILE, and SRC_REC to be set up
appropriately and which cause the proper DEFINE operations to be issued
to allow DEBUG to generate the correct line number to source record
correlation table. (DEBUG may not actually generate the full table,
but it must be able to generate any part of such a table it needs.)
The semantics of each Source File Correlation command is described
below in terms of these state variables and commands.

Line numbers must be DEFINEd in sequential order, from lowest line
number to highest line number, in the Source File Correlation commands
for one module. The source records these line numbers correlate with
may be in any order, of course.

It should be clear from what follows that the source for one module may
come from many source files. This can be caused by plus-lists on the
compiler command (e.g., \$FORTRAN/DEBUG A+B+C) and by INCLUDE statements
in the source. Also, source lines may come from modules within source
libraries as well as from independent source files.

Form feeds in source files, or more precisely source file records which
contain nothing but a single form feed (CNTL-L) character, are counted
as individual sources lines in some languages but are ignored (not as-
signed line numbers) in other languages. DEBUG will handle either con-
vention, but DEBUG's default behavior is that form feed records are
ignored in sources files. They are not displayed and they do not count
toward the source file record number of subsequent source records. To
make DEBUG count such records, the DST\$K_SRC_FORMFEED command must be
used.

Define the location of the first command in the DST record.

FIELD DST\$SOURCE_FIELDS =
SET
DST\$A_SRC_FIRST_CMD = [2, A_] ! Location of first command in record
TES;

Define the command codes for all the Source File Correlation commands.

4874 0 | DECLARE SOURCE FILE (DST\$K_SRCDECLFILE)

4877 0 | This command declares a source file which contributes source lines to
4878 0 | the current module. It declares the name of the file, its creation
4879 0 | date and time, and various other attributes. The command also assigns
4880 0 | a one-word "file ID" to this source file. This is the format of the
4881 0 | Declare Source File command:

```
4884 0 | +-----+  
4885 0 | byte | DBG$B_SRC_COMMAND (= DST$K_SRCDECLFILE)  
4886 0 | +-----+  
4887 0 | byte | DST$B_SRC_DF_LENGTH  
4888 0 | +-----+  
4889 0 | byte | DST$B_SRC_DF_FLAGS  
4890 0 | +-----+  
4891 0 | word | DST$W_SRC_DF_FILEID  
4892 0 | +-----+  
4893 0 | quad | DST$Q_SRC_DF_RMS_CDT  
4894 0 | +-----+  
4895 0 | long | DST$L_SRC_DF_RMS_EBK  
4896 0 | +-----+  
4897 0 | word | DST$W_SRC_DF_RMS_FFB  
4898 0 | +-----+  
4899 0 | byte | DST$B_SRC_DF_RMS_RFO  
4900 0 | +-----+  
4901 0 | var | DST$B_SRC_DF_FILENAME  
4902 0 | +-----+  
4903 0 | var | DST$B_SRC_DF_LIBMODNAME  
4904 0 | +-----+
```

4907 0 | The fields in this command are the following:

4909 0 | DST\$B_SRC_DF_LENGTH - The length of this command, i.e. the number of
4910 0 | bytes remaining in the command after this field.

4912 0 | DST\$B_SRC_DF_FLAGS - Bit flags. This field is reserved for future use.
4913 0 | At present this field Must Be Zero.

4915 0 | DST\$W_SRC_DF_FILEID - The one-word "file ID" of this source file. This
4916 0 | file ID, which can later be used in the Set File command, is
4917 0 | simply a unique number which the compiler assigns to each source
4918 0 | file which contributes source lines to the current module. Each
4919 0 | source file thus has a number (the File ID) and is identified by
4920 0 | that number in the Set File (DST\$K_SRC_SETFILE) command.

4922 0 | DST\$Q_SRC_DF_RMS_CDT - The creation date and time of this source file.
4923 0 | This quadword quantity should be retrieved with a \$XABDAT
4924 0 | extended attribute block from RMS via the \$OPEN or \$DISPLAY
4925 0 | system service. The creation date and time should be taken
4926 0 | from the XAB\$Q_CDT field of the XAB.

4928 0 | If the source file is a module in a source library, this field
4929 0 | should contain the module's Insertion Date and Time in the lib-
4930 0 | rary. This value should be retrieved with the LBR\$SET_MODULE

4931 0 | Librarian call. The library file's creation date is not used.
4932 0 |

4933 0 | DST\$L_SRC_DF_RMS_EBK - The End-of-File block number for this source
4934 0 | file. This longword quantity should be retrieved with a
4935 0 | SXABFHc extended attribute block from RMS via the \$OPEN or
4936 0 | \$DISPLAY system service. The End-of-File block number should
4937 0 | be taken from the XAB\$L_EBK field of the XAB.
4938 0 |
4939 0 | This field should be zero for modules in source libraries.
4940 0 |
4941 0 | DST\$W_SRC_DF_RMS_FFB - The first free byte of the End-of-File block
4942 0 | for this source file. This word quantity should be retrieved
4943 0 | with a SXABFHc extended attribute block from RMS via the \$OPEN
4944 0 | or \$DISPLAY system service. The first free byte value should
4945 0 | be taken from the XAB\$W_FFB field of the XAB.
4946 0 |
4947 0 | This field should be zero for modules in source libraries.
4948 0 |
4949 0 | DST\$B_SRC_DF_RMS_RFO - The file organization and record format of this
4950 0 | source file. This byte value should be retrieved with a
4951 0 | SXABFHc extended attribute block from RMS via the \$OPEN or
4952 0 | \$DISPLAY system service. The file organization and record
4953 0 | format should be taken from the XAB\$B_RFO field of the XAB.
4954 0 |
4955 0 | This field should be zero for modules in source libraries.
4956 0 |
4957 0 | DST\$B_SRC_DF_FILENAME - The full filename of the source file. This is
4958 0 | the fully specified filename, complete with device name and
4959 0 | version number, in which all wild cards and logical names have
4960 0 | been resolved. This string should be retrieved with a \$NAM
4961 0 | block from RMS via the \$OPEN or \$SEARCH system service. The
4962 0 | desired string is the "Resultant String" specified by the
4963 0 | NAM\$L_RSA, NAM\$B_RSS, and NAM\$B_RSL fields of the \$NAM block.
4964 0 | Here the file name is represented as a Counted ASCII string (a
4965 0 | one-byte character count followed by the name string).
4966 0 |
4967 0 | DST\$B_SRC_DF_LIBMODNAME - The source library module name (if applicable)
4968 0 | or the null string. If the source file is actually a module in
4969 0 | a source library, the DST\$B_SRC_DF_FILENAME field gives the
4970 0 | filename of the source library and the DST\$B_SRC_DF_LIBMODNAME
4971 0 | field gives the name of the source module within that library.
4972 0 | If the source file does not come from a source library, this
4973 0 | field (DST\$B_SRC_DF_LIBMODNAME) contains the null (zero-length)
4974 0 | string. This field is represented as a Counted ASCII string.

4975 0 | SET SOURCE FILE (DST\$K_SRC_SETFILE)

4976 0 |
4977 0 | This command sets the current source file to the file denoted by the
4978 0 | one-word file ID given in the command. The set file is then the file
4979 0 | from which further source lines are taken when the corresponding list-
4980 0 | ing lines are defined. This is the format of the command:

4981 0 |
4982 0 |
4983 0 |
4984 0 |
4985 0 | byte +-----+
4986 0 | | DBG\$B_SRC_COMMAND (= DST\$K_SRC_SETFILE)
4987 0 | +-----+
4988 0 | word +-----+
4989 0 | | DST\$W_SRC_UNSWORD: The File ID of the desired source file
4990 0 | +-----+

4991 0 | The semantics of this command is:

4992 0 |
4993 0 | SRC_FILE := file ID from command
4994 0 | SRC_REC := set to current source record for this
4995 0 | source file

4996 0 |
4997 0 |
4998 0 |
4999 0 | SET SOURCE RECORD NUMBER LONG (DST\$K_SRC_SETREC_L)

5000 0 |
5001 0 | This command sets the current source file record number to the longword
5002 0 | value specified in the command. Its format is:

5003 0 |
5004 0 |
5005 0 |
5006 0 |
5007 0 | byte +-----+
5008 0 | | DBG\$B_SRC_COMMAND (= DST\$K_SRC_SETREC_L)
5009 0 | +-----+
5010 0 | long +-----+
5011 0 | | DST\$L_SRC_UNSLONG: The desired new source record number
5012 0 | +-----+

5013 0 | The semantics of this command is:

5014 0 |
5015 0 | SRC_REC := longword value from command

5016 0 | SET SOURCE RECORD NUMBER WORD (DST\$K_SRC_SETREC_W)

5017 0 |
5018 0 | This command set the current source file record number to the word
5019 0 | value specified in the command. It is thus a more compact form of
5020 0 | the DST\$K_SRC_SETREC_L command. Its format is:
5021 0 |
5022 0 |
5023 0 |

5024 0 |-----+
5025 0 | byte | DBG\$B_SRC_COMMAND (= DST\$K_SRC_SETREC_W)
5026 0 |-----+
5027 0 | word | DST\$W_SRC_UNSWORD: The desired new source record number
5028 0 |-----+
5029 0 |
5030 0 |
5031 0 | The semantics of this command is:
5032 0 |
5033 0 | SRC_REC := word value from command
5034 0 |
5035 0 |
5036 0 |
5037 0 | SET LINE NUMBER LONG (DST\$K_SRC_SETLNUM_L)
5038 0 |
5039 0 |
5040 0 | This command set the current listing line number to a longword value
5041 0 | specified in the command. Its format is:
5042 0 |
5043 0 |
5044 0 |-----+
5045 0 | byte | DBG\$B_SRC_COMMAND (= DST\$K_SRC_SETLNUM_L)
5046 0 |-----+
5047 0 | long | DST\$L_SRC_UNSLONG: The desired listing line number

5072 0
5073 0
5074 0 INCREMENT LINE NUMBER BYTE (DST\$K_SRC_INCRNUM_B)
5075 0
5076 0
5077 0 This command increments the current listing line number by a one-byte
5078 0 value specified in the command. Its format is:
5079 0
5080 0
5081 0 byte +-----+
5082 0 | DBG\$B_SRC_COMMAND (= DST\$K_SRC_INCRNUM_B) |
5083 0 +-----+
5084 0 byte +-----+
5085 0 | DST\$B_SRC_UNSBYTE: The desired listing line number increment |
5086 0 +-----+
5087 0
5088 0 The semantics of this command is:
5089 0
5090 0 LINE_NUM := LINE_NUM + byte value in command

5091 0 | COUNT FORM-FEEDS AS SOURCE RECORDS (DST\$K_SRC_FORMFEED)
5092 0 |
5093 0 |
5094 0 | This command specifies that DEBUG should count source records which
5095 0 | consists of nothing but a Form-Feed character (CRTL-L) as being
5096 0 | distinct, numbered source records. In some languages, such records
5097 0 | are not considered to be source lines; instead they are regarded as
5098 0 | control information. The compiler then does not assign line numbers
5099 0 | to them and DEBUG ignores them completely--they are not displayed
5100 0 | as part of the source and they do not contribute to the source record
5101 0 | numbering of source files. However, if the DST\$K_SRC_FORMFEED command
5102 0 | is specified in the Source File Correlation DST Record for a module,
5103 0 | then such records count as normal records; they can be displayed and
5104 0 | they are assigned source file record numbers.
5105 0 |
5106 0 | If used, this command must appear before any commands that actually
5107 0 | define source lines. Making it the first command in the first
5108 0 | Source File Correlation Record for the module is a good choice.
5109 0 |
5110 0 |
5111 0 |-----+-----+
5112 0 | | DBG\$B_SRC_COMMAND (= DST\$K_SRC_FORMFEED)|
5113 0 |-----+-----+
5114 0 |
5115 0 |
5116 0 | The semantics of th s command is to set a mode flag which says to
5117 0 | count Form-Feed records as normal records. The default behavior
5118 0 | is to ignore Form-Feed records.

5119 0 | DEFINE N LINES WORD (DST\$K_SRC_DEFINES_W)

5120 0 |
5121 0 | This command defines the source file and source record numbers for
5122 0 | a specified number of listing line numbers. The specified number is
5123 0 | given by a one-word count in the command. The command format is:
5124 0 |
5125 0 |
5126 0 |
5127 0 |
5128 0 |-----+
5129 0 | byte | DBG\$B_SRC_COMMAND (= DST\$K_SRC_DEFINES_W)
5130 0 |-----+
5131 0 | word | DST\$W_SRC_UNSWORD: The number of lines to define
5132 0 |-----+

5133 0 |
5134 0 | The semantics of this command is:
5135 0 |
5136 0 | DO the number of times specified in the command:
5137 0 |-----+
5138 0 | BEGIN
5139 0 | DEFINE(LINE_NUM, SRC_FILE, SRC_REC);
5140 0 | LINE_NUM := LINE_NUM + 1;
5141 0 | SRC_REC := SRC_REC + 1;
5142 0 | END;

5143 0 |
5144 0 |
5145 0 | DEFINE N LINES BYTE (DST\$K_SRC_DEFINES_B)

5146 0 |
5147 0 | This command defines the source file and source record number for
5148 0 | a specified number of listing line numbers. The specified number is
5149 0 | given by a one-byte count in the command. This is thus a more compact
5150 0 | form of the DST\$K_SRC_DEFINES_W command. Its format is:
5151 0 |
5152 0 |
5153 0 |
5154 0 |-----+
5155 0 | byte | DBG\$B_SRC_COMMAND (= DST\$K_SRC_DEFINES_B)
5156 0 |-----+
5157 0 | byte | DST\$B_SRC_UNSBYTE: The number of lines to define
5158 0 |-----+

5159 0 |
5160 0 |
5161 0 | The semantics of this command is:
5162 0 |
5163 0 |
5164 0 | DO the number of times specified in the command:
5165 0 |-----+
5166 0 | BEGIN
5167 0 | DEFINE(LINE_NUM, SRC_FILE, SRC_REC);
5168 0 | LINE_NUM := LINE_NUM + 1;
5169 0 | SRC_REC := SRC_REC + 1;
5170 0 | END;

5171 0 |
5172 0 |
5173 0 | END OF SOURCE FILE CORRELATION DST RECORD DESCRIPTION.

5211 0 | TES:

NOTE: THIS DST RECORD IS NOT SUPPORTED BY DEBUG V4.0.

The Definition Line Number DST record specifies the listing line number at which a data symbol or other object is defined or declared. The intent is to make use of this information in future DEBUG commands so that a user can see the declaration source line for a specified symbol. The Definition Line Number DST record must immediately follow the data DST record of the data object whose line of definition is being specified.

This is the format of the Definition Line Number DST record:

```
-----+
byte | DSTSB_LENGTH (= 6)
-----+
byte | DSTSB_TYPE = (DST$K_DEF_LNUM)
-----+
byte | Unused (Must Be Zero)
-----+
long | DST$L_DEF_LNUM_LINE
-----+
```

Define the fields of the Definition Line Number DST record. The unused byte in the DST record is reserved for future use.

```
FIELD DST$DEF_LNUM_FIELDS =
SET
DST$L_DEF_LNUM_LINE = [ 3, L_ ] ! The definition line number
TES:
```

5212 0

THE STATIC LINK DST RECORD

5213 0

5214 0

5215 0

5216 0

The Static Link DST record specifies the "Static Link" for a routine. The Static Link is a pointer to the VAX call frame for the proper up-scope invocation of the outer routine within which the present invocation of the present routine is nested. The Static Link is thus used when DEBUG does up-level addressing in response to user commands. A Static Link DST Record is always associated with the inner-most routine within whose Routine-Begin and Routine-End records it is nested. The Static Link DST Record is optional--it need not be used by languages or for routines which do not keep track of static links in their run-time environments. In fact, the Static Link DST record only makes a difference for recursive routines that pass routines as parameters, a fairly obscure situation.

THE PROLOG DST RECORD

5258 0

5259 0

5260 0

5261 0

The Prolog DST record tells DEBUG where to put routine breakpoints. It is used for routines that have prolog code that must be executed before data objects can be freely examined or otherwise accessed from DEBUG. Such prolog code typically sets up stack locations and descriptors for formal parameters or other data objects. By putting routine breakpoints on the first instruction after the prolog code, as specified in the Prolog DST record, DEBUG ensures that all local storage and formal parameters are accessible to the user.

5290 0

5291 0

5292 0

Prolog DST records are optional. If omitted for some routine, DEBUG simply uses the routine start address for routine breakpoints or tracepoints requested by the user. If specified, the Prolog DST record is counted as belonging with the nearest Routine Begin or Entry Point DST record before it, not counting nested routines. Placing the Prolog DST record immediately after the Routine Begin or Entry Point DST record with which it is associated is good practice.

This is the format of the Prolog DST record:

Define the fields of the Prolog DST record.

```
FIELD DST$PROLOG_FIELDS =
  SET
  DST$L_PROLOG_BKPT_ADDR = [ 2, L_ ]    ! The routine breakpoint address
  TES;
```

The Version Number DST record gives the version number of the compiler that compiled the current module. The Version Number DST Record must be nested within the Module Begin and Module End DST Records for the module in question. DEBUG ignores this record except in special cases when it is necessary to distinguish between old and new versions of the compiler that generated a given object module.

This is the format of the Version Number DST record:

Define the fields of the Version Number DST record.

FIELD DST\$VERSION_FIELDS =
 SET
 DST\$B_VERSION_MAJOR = [2, B_], ! The major version number
 DST\$B_VERSION_MINOR = [3, B_], ! The minor version number
 TES;

5330 0 | THE COBOL GLOBAL ATTRIBUTE
5331 0 | DST RECORD

5336 0 |
5337 0 | The COBOL Global Attribute DST record indicates that the symbol whose
5338 0 | DST record immediately follows has the COBOL "global" attribute. This
5339 0 | attribute specifies that the symbol is visible in nested COBOL scopes
5340 0 | (routines) within the scope (routine) in which the symbol is declared.
5341 0 | Without this attribute, a symbol is only visible in its scope of decla-
5342 0 | ration but not within any nested scopes. In this regard, COBOL differs
5343 0 | from most other languages. DEBUG thus needs to know this attribute in
5344 0 | order to implement the COBOL scope rules correctly.

5345 0 |
5346 0 | The COBOL Global Attribute DST record is only generated by the COBOL
5347 0 | compiler. If it precedes the DST record for some symbol, that symbol
5348 0 | is deemed to have the COBOL global attribute; if it omitted, the sym-
5349 0 | bol is deemed not to have the global attribute. DEBUG ignores this
5350 0 | attribute for all other languages.

5351 0 | This is the format of the COBOL Global Attribute DST record:

5359 0 THE OVERLOADED SYMBOL DST RECORD
5360 0
5361 0
5362 0

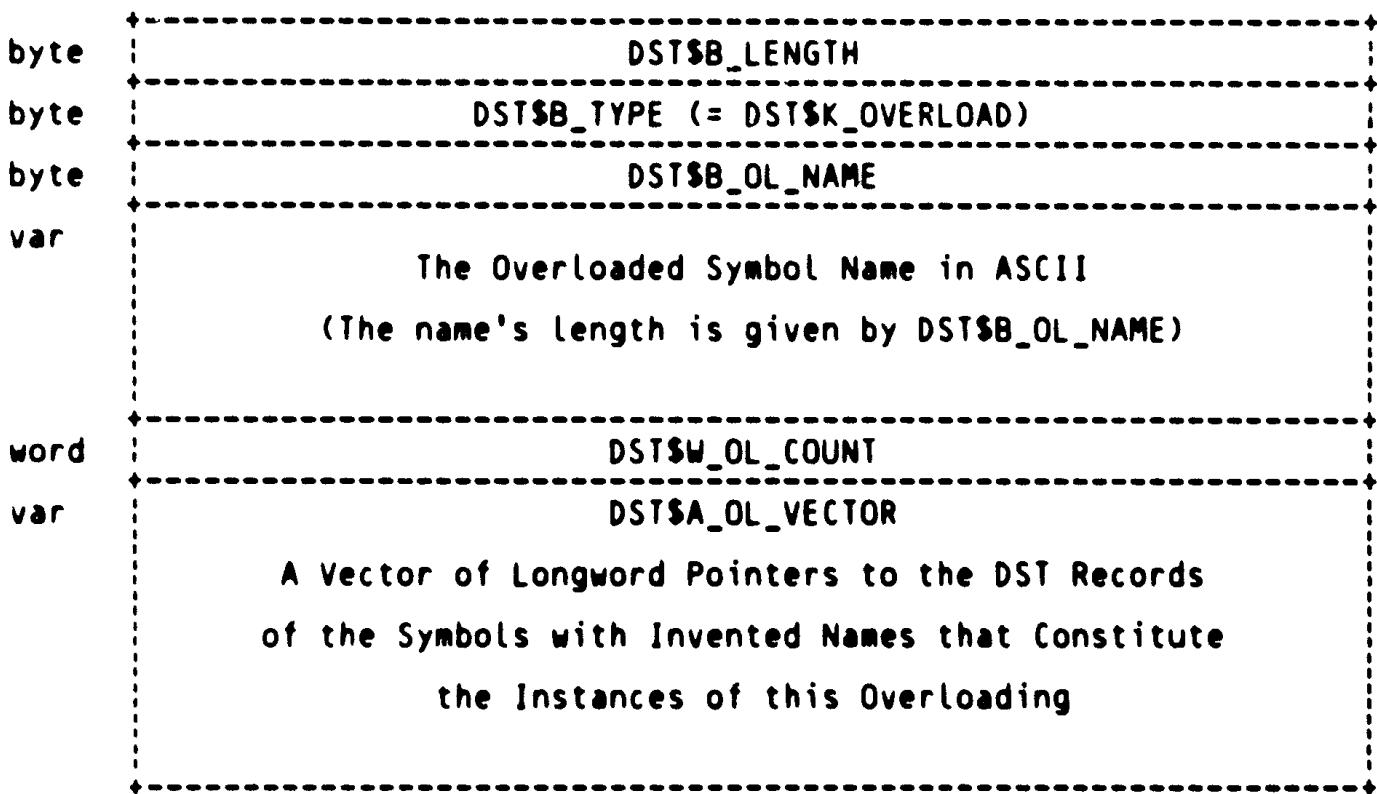

5363 0 NOTE: THIS DST RECORD IS NOT SUPPORTED BY DEBUG V4.0.
5364 0

5365 0 The Overloaded Symbol DST record is used to indicate that a given
5366 0 symbol name is overloaded. The record indicates which other symbols
5367 0 in the DST are possible resolutions to the overloading. It is used
5368 0 by the ADA compiler.
5369 0

5370 0 In ADA, it is possible to have more than one routine of the same name
5371 0 in the same scope. If the routine name is R, DEBUG disambiguates the
5372 0 individual instances of the overloaded routine name with the invented
5373 0 names R_1, R_2, R_3, and so on. DEBUG requires the ADA compiler to
5374 0 generate normal DST records for these routines, using the invented
5375 0 names. DEBUG also requires the ADA compiler to generate the Overloaded
5376 0 Symbol DST record with the original overloaded name "R" in order to
5377 0 inform DEBUG of the overloading.
5378 0

5379 0 After the length and type fields, this record contains a Counted ASCII
5380 0 string with the name of the overloaded symbol. Following the Counted
5381 0 ASCII string, there is a word field containing a count of the number
5382 0 of overloaded instances of the name in this scope. Next there is a
5383 0 vector of pointers, one for each instance, pointing to the DST records
5384 0 for the instances of the overloaded symbol. These DST pointers consist
5385 0 of byte offsets relative to the start of the whole DST.
5386 0

5387 0 This is the format of the Overloaded Symbol DST record:
5388 0
5389 0

```
5416 0
5417 0

5430 0 Define the fields of the Overloaded Symbol DST record trailer portion. Also
5431 0 define the corresponding declaration macro.
5432 0
5433 0 FIELD DST$OVERLOAD_TRLR_FIELDS =
5434 0     SET
5435 0     DST$W_OL_COUNT = [ 0, W_ ],      | Number of instances in this scope
5436 0     DST$A_OL_VECTOR = [ 2, A_ ]       | Vector of DST pointers to instances
5437 0                                         of overloaded symbol
5438 0     TES;
5439 0
5440 0 MACRO
5441 0     DST$OVERLOAD_TRLR = BLOCK[,BYTE] FIELD(DST$OVERLOAD_TRLR_FIELDS) %;
5442 0
5443 0
5444 0 This is a short BLISS example of how the trailer fields are accessed:
5445 0
5446 0
5447 0 LOCAL
5448 0     DSTPTR: REF DST$RECORD,          | Pointer to DST record
5449 0     OVERLOAD_COUNT,                 | The number of overloading
5450 0     OVERLOAD_TRAILER:              | Pointer to DST record trailer
5451 0     REF DST$OVERLOAD_TRLR,         | Vector of DST-record pointers to the
5452 0     OVERLOAD_VECTOR:               | instances of this overloading
5453 0     REF VECTOR[,LONG];
5454 0
5455 0
5456 0 ! Here we assume that DSTPTR points to the Overloaded Symbol DST record.
5457 0
5458 0     OVERLOAD_TRAILER = DSTPTR[DST$A_OL_TRAILER] + .DSTPTR[DST$B_OL_NAME];
5459 0     OVERLOAD_COUNT = .OVERLOAD_TRAILER[DST$B_OL_COUNT];
5460 0     OVERLOAD_VECTOR = OVERLOAD_TRAILER[DST$A_OL_VECTOR];
```

5461 0 | C O N T I N U A T I O N D S T R E C O R D S
5462 0 |
5463 0 |
5464 0 |
5465 0 |
5466 0 | When the text of a Debug Symbol Table record is longer than 255 bytes,
5467 0 | it is no longer possible to hold that text in a single DST record since
5468 0 | the DST\$B_LENGTH field cannot hold a value larger than 255. In this
5469 0 | case it is necessary to generate the original DST record followed by
5470 0 | as many Continuation DST records as necessary to hold the full text.
5471 0 | The original DST record then holds at least 100 and at most 255 bytes of
5472 0 | text. Each Continuation DST record consists of the standard two-byte
5473 0 | header followed by the continued text of the original DST record.
5474 0 |
5475 0 | This is the format of the Continuation DST record:
5476 0 |
5477 0 |
5478 0 | byte +-----+
5479 0 | | DST\$B_LENGTH
5480 0 | +-----+
5481 0 | byte +-----+
5482 0 | | DST\$B_TYPE (= DST\$K_CONTIN)
5483 0 | +-----+
5484 0 | var |
5485 0 | | The Continued Text of the Previous DST Record
5486 0 | +-----+
5487 0 |
5488 0 |
5489 0 |
5490 0 |
5491 0 |
5492 0 |
5493 0 | DEBUG reconstitutes a continued DST record by concatenating the text
5494 0 | of the first DST record with the text portions of its Continuation DST
5495 0 | records. In effect, the first two bytes of each Continuation DST record
5496 0 | are stripped out. Any further interpretation of the DST text is then
5497 0 | done on the concatenated copy.
5498 0 |
5499 0 | Certain kinds of DST records are not allowed to be continued with Con-
5500 0 | tinuation DST records. These records are Module Begin, Routine Begin,
5501 0 | Block Begin, Label, Label-or-Literal, Entry Point, PSET, Line Number
5502 0 | PC-Correlation, and Source File Correlation DST records. In addition,
5503 0 | DST records with fixed sizes, such as Module End and Routine End DST
5504 0 | records, are not allowed to be continued. Line Number PC-Correlation
5505 0 | and Source File Correlation DST records cannot be continued with Con-
5506 0 | tinuation DST records, but one can have multiple such records in one
5507 0 | module; they can thus be continued, but through a different mechanism.
5508 0 | The records that really need to be continued, such as Standard Data
5509 0 | DST records and their variants (Descriptor Format and Trailing Value
5510 0 | Specification Format records), Separate Type Specification DST records,
5511 0 | and Type Specification DST records, can all be continued using the
5512 0 | Continuation DST record mechanism.
5513 0 |
5514 0 | Define the fields of the Continuation DST record.
5515 0 |
5516 0 | FIELD DST\$CONTIN_FIELDS =
5517 0 |

O B S O L E T E D S T R E C O R D S

There are several obsolete DST records. These are records that were at one time generated by compilers, but are no longer used by any current version of any Digital compiler. Some of these records were not properly thought out and were abandoned when it was realized that their intended uses could not be implemented. Others were at one time used and useful, but were generated by now-obsolete compilers. Such records are not generated by current compiler versions, and the capabilities they provided are now provided more general mechanisms in other DST records.

None of the obsolete DST records should be generated by any future compilers, and their use will not necessarily be supported by DEBUG.

THE GLOBAL-IS-NEXT DST RECORD

The Global-is-Next DST record is now obsolete. It consisted of just the DST\$B_LENGTH byte and the DST\$B_TYPE byte. DST\$K_GLOBNXT was the type code. The purpose of this record was never properly thought out and no support for it was ever implemented. It should not be generated by any future compilers or compiler versions.

THE EXTERNAL-IS-NEXT DST RECORD

The External-is-Next DST record is now obsolete. It consisted of just the DST\$B_LENGTH byte and the DST\$B_TYPE byte. DST\$K_EXTRNXT was the type code. The purpose of this record was never properly thought out and no support for it was ever implemented. It should not be generated by any future compilers or compiler versions.

THE THREADED-CODE PC-CORRELATION DST RECORD

This DST record is identical in format to the Line Number PC-Correlation DST record except that the record type code is DST\$K LINE_NUM_REL_R11. It was used by an obsolete COBOL compiler according to Legend-(the memories are a bit hazy by now). The idea was that the threaded code generated by this compiler consisted of a vector of longwords where each longword contained the address of a run-time support routine to call. Register R11 pointed to the beginning of this vector. The code generated for a source line thus consisted of some number of longwords with addresses to call (or perhaps jump to-the exact details are lost in the mists of time). The line number PC-correlation information passed to DEBUG consisted of line numbers correlated with byte-offsets relative to R11 (i.e., to the start of the threaded code). Breakpoints were placed on a specified line by looking up the corresponding offset

5578 0 relative to R11 and then storing an address within DEBUG into that
5579 0 location. When the location was reached, DEBUG was entered. DEBUG
5580 0 could then convert the "PC", i.e. the threaded-code location, back to
5581 0 a line number to announce the breakpoint. It is not clear how, or even
5582 0 whether, tracing, stepping, and watchpoints were implemented.
5583 0

5584 0 The Threaded-Code PC-Correlation DST record is no longer supported by
5585 0 DEBUG and should not be generated by any current or future compilers.
5586 0
5587 0
5588 0

THE COBOL HACK DST RECORD

5592 0 The COBOL Hack DST record was at one time used to support formal argu-
5593 0 ments to COBOL procedures. It has now been superceded by the more
5594 0 general Value Specification mechanism, and is thus obsolete. It is
5595 0 no longer generated by the COBOL compiler, and it should not be gene-
5596 0 rated by any current or future compilers. Future versions of DEBUG
5597 0 may not support it.
5598 0

5599 0 The fields of this record consist of the fields of the Standard Data
5600 0 DST record followed by a type field that specifies the data type and
5601 0 then a sequence of commands for the DEBUG stack machine. (See the sec-
5602 0 tion on Value Specifications for details on the DEBUG stack machine.)
5603 0 The result of interpreting the stack machine routine is the address of
5604 0 the object described by this record. The DST\$B_VFLAGS and DST\$L_VALUE
5605 0 fields are zero unless the object has a descriptor. In this latter
5606 0 case they specify the location of the descriptor. The result of the
5607 0 stack machine routine is placed in the DS\$A_POINTER field of the
5608 0 descriptor before it is used. In addition, If it is an array descrip-
5609 0 tor, the DSC\$A_A0 field is added to the result of the stack machine
5610 0 routine and the result is placed in the DSC\$A_A0 field before the
5611 0 descriptor is used.
5612 0

5613 0 The type field following the name field contains the VAX Standard Type
5614 0 Code of the object being described here. If the object also has a
5615 0 descriptor, its DSC\$B_DTYPE field must agree with this code.
5616 0

5617 0 The stack machine commands used in this context are those described
5618 0 in the section entitled "The DEBUG Stack Machine" in the chapter on
5619 0 DST Value Specifications.
5620 0
5621 0 This is the format of the COBOL Hack DST record:

```
5622 0
5623 0

5646 0
5647 0
5648 0
5649 0
5650 0
5651 0
5652 0 Define the fields of the Cobol Hack DST record. Also define the declaration
5653 0 macro for the trailer fields.
5654 0
5655 0 FIELD DST$COB_HACK_FIELDS =
5656 0   SET
5657 0   DSTSA_COBHACK_TRLR    = [ 8, A_ ]      ! Location of trailer fields
5658 0   TES;
5659 0
5660 0 FIELD DST$CH_TRLR_FIELDS =
5661 0   SET
5662 0   DSTSB_CH_TYPE        = [ 0, B_ ],      ! VAX standard data type
5663 0   DSTSA_CH_STKRTN_ADDR = [ 1, A_ ],      ! Start of stack routine code
5664 0   TES;
5665 0
5666 0 MACRO
5667 0   DST$CH_TRLR = BLOCK[,BYTE] FIELD(DST$CH_TRLR_FIELDS) %;
```

5668 0

VALUE SPECIFICATION DST RECORDS

5669 0

5670 0

The Value Specification DST record contains nothing but a DST Value Specification. However, there appears to be no use for this record since all DST Value Specifications that are actually used appear in other DST records. This record was probably designed with some use in mind, but was then abandoned when better ways of addressing the original need were devised. DEBUG ignores this DST record, and it is believed that no compilers actually generate it. This DST record should not be generated by any future compilers.

5671 0

This is the format of the Value Specification DST record:

5672 0

5673 0

5674 0

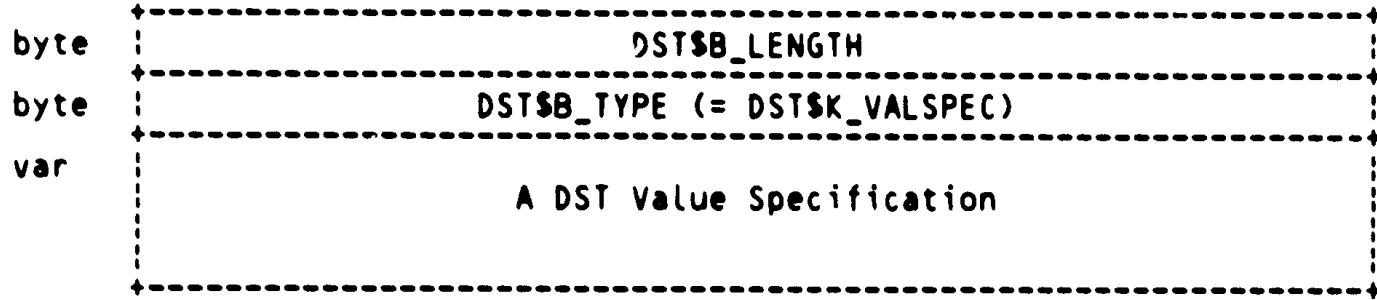

5675 0

5676 0

5677 0

5678 0

5679 0

5680 0

5681 0

5682 0

5683 0

5684 0

5685 0

5686 0

5687 0

5688 0

5689 0

5690 0

5691 0

5692 0

5693 0

5694 0

5695 0

5696 0

5697 0 Define the fields of the Value Specification DST record.

5698 0

```
FIELD DST$VALSPEC_FIELDS =
    SET
        DST$A_VS_VALSPEC_ADDR = [ 2, A_ ]      ! The start location of the
                                                ! Value Specification
    TES;
```

5699 0

5701 0

5702 0

5703 0

5704 0 DST RECORD DECLARATION MACRO
5705 0
5706 0
5707 0

5708 0 This macro allows BLISS symbols which are declared DST\$RECORD or
5709 0 REF DST\$RECORD to be qualified by all the field names present in
5710 0 the various DST record formats. It is anticipated that users will
5711 0 declare separate symbols for field sets which describe trailing
5712 0 fields in DST records; a pointer to the PSECT DST record trailer,
5713 0 for example, would be declared to be a REF DST\$PSECT TRAILER.
5714 0 Separate macros are supplied above for all such trailer fields.
5715 0
5716 0

5717 0 Define the declaration macro for all DST records.
5718 0

5719 0 MACRO

M 5720 0 DST\$RECORD = BLOCK [256,BYTE] FIELD(
M 5721 0 DST\$HEADER_FIELDS,
