## PREFACE

This manual is intended as a detailed reference source for programming the Honeywell 300 Electronic Data Processing System. It contains a functional description of the system components and a detailed explanation of the instruction repertoire. No previous knowledge of the Honeywell 300 is assumed.

## SECTION I

THE CENTRAL PROCESSOR

The Model 301 central processor is the computing and control center of the Honeywell 300 system. Functionally, it is composed of high-speed magnetic core main memory and control memory, an arithmetic unit, a control unit, and a direct input/output channel.

A major design feature of the central processor is the use of integrated system modules. Each module contains all of the circuitry required for a specific function. For example, one module contains all of the card control circuitry, another contains the arithmetic unit, and so on. This modularity greatly enhances the expandibility of the system. In most cases, expansion involves little more than plugging in additional modules. The reliability of the modular components has been enhanced through the use of high-temperature lithium ferrite cores and silicon semiconductors.

## CONTROL PANEL

An operator's control panel is included in the basic system. This panel contains displays for the important arithmetic and control unit registers together with six sense switches for manually controlling the path of the program. Controls are also provided for starting and stopping a program and for interrogating main memory and control memory.

## MAIN MEMORY

The main memory contains 4, 096 locations, each capable of storing one 24-bit word and one automatically generated and checked parity bit. Additional memory is available in modules of 4,096 words up to a system total of 32,768 words. Thereafter, additional memory is available in modules of 8,192 words up to a system total of 65,536 words.

One memory cycle (that is, the time required to retrieve a word from a memory location and restore the cores to their original states) is 1.75 mic roseconds. The memory has an operating range of $0^{\circ}$ to $125^{\circ}$ Fahrenheit. The contents of memory are protected when power is turned on or off.

## CONTROL MEMORY

The control memory contains sixteen 24-bit words of storage, comprising six index registers, eight general-purpose registers, the accumulator (A register), and the auxiliary arithmetic register (B register). It is driven as a linear-select memory with a split 500 -nanosecond cycle (250-nanosecond read and 250-nanosecond write). The contents of control memory are protected when power is turned on or off.

Summary of H-300 Central Processor Characteristics

| INFORMATION UNIT | 24-bit word. |
| :---: | :---: |
| MEMORY CAPACITY | 4,096 words ( 16,384 characters), expandable to 65,536 words (262, 144 characters). |
| CONTROL MEMORY | 16 words. |
| ACCESS TIME | Main memory: 875 nanoseconds. Control memory: 250 nanoseconds. |
| CYCLE TIME | Main memory: l. 75 microseconds. Control memory: 500 nanoseconds. |
| PROCESSOR SPEED | Fixed-point add to accumulator: 3.5 microseconds. 285,000 fixed-point binary add instructions per second without memory interlace; up to 380,000 with interlace. Gibson mix: 180,000 instructions per second without interlace; 236,000 with interlace. |
| INTERNAL OPERATIONS | Fixed-point, twos-complement binary arithmetic; logic; control; and input/output. Optional multiply, divide, floating-point, and character instructions. |
| INSTRUCTION FORMAT | Single-address, variable format. A typical instruction includes an op code, a variant character, and an address field. |
| ADDRESSING | Direct main memory within a 32,768 -word bank, indexed main memory, indirect main memory, and indirect indexed main memory. Optional facility to address individual characters. |
| CHECKING | One parity bit automatically generated and checked in each main memory word. |
| HARDWARE BYPASS | Use of an optional instruction which is not installed in the machine causes a subsequence to a fixed memory location. The program may there identify the instruction and execute it by means of a subroutine. |
| DIRECT INPUT/OUTPUT CHANNEL | One 24-bit, non-buffered input bus and one 24-bit non-buffered output bus, with control lines and an interrupt line. Up to 64 peripheral devices may be directly addressed by this channel. A standard peripheral control is supplied which services the keyboard printer, the paper tape reader, and the paper tape punch. |
| EXTERNAL LINES | 15 external sensing lines and 15 external activating lines. |
| READ/WRITE CHANNELS | Up to three optional read/write channels. Data transfer over these channels can occur simultaneously with computing. |
| SENSE SWITCHES | Six. |
| INDEX REGISTERS | Six. |
| PRIORITY INTERRUPT | Six levels, expandable to 24 levels. |
| TEMPERATURE RANGE | The temperature range of the central processor (including memory) is $0^{\circ}$ to $125^{\circ}$ Fahrenheit. |
| POWER FAILURE PROTECTION | Sensing circuitry is provided which detects power failure and causes a subsequence. Sufficient energy is retained to store the status of the machine. Power cycling, on and off, is done in such a way as to protect the contents of main memory and control memory. |

## CONTROL UNIT

The control unit controls the flow of information within the central processor; it selects, interprets, and controls the execution of all instructions and governs address selection within the main memory. The control unit includes a sequence register, an operation code register, a shift counter, a clocking system, and subcommand generators.

ARITHMETIC UNIT
The arithmetic unit performs twos-complement arithmetic operations, as well as logical, shift, and comparison operations. The arithmetic registers that are accessible by program are located in the control memory. The arithmetic unit also includes an addend register, an augend register, and some auxiliary circuitry; these are not accessible by program.

## MEMORY INTERLACE

In systems containing more than 8,192 words of memory, an interlace option is available which permits simultaneous addressing of two or more 8, 192-word blocks. Using this option, if the program is stored in one block and data are stored in another, the central processor can automatically overlap operand processing for the current instruction with retrieval of the next instruction. Execution times for instructions may thereby be reduced by as much as one memory cycle.

In systems containing both the buffered input/output (i. e., one or more read/write channels) and the memory interlace features, if data transfer uses a memory block not used in computing, the transfer is overlapped with computing. That is, data may be transferred into or out of one block while the program is processing instructions in another block. To achieve both the instruction interlace and the input/output interlace, more than two blocks of memory are required. Then operand processing, instruction retrieval, and input/output can be overlapped in their respective blocks.

## SECTION II

## THE INPUT/OUTPUT SYSTEMS

The standard input/ output systems consist of two sets of external lines, a direct input/ output channel, a standard peripheral control, and a priority interrupt system.

## EXTERNAL LINES

There is a set of 15 activating lines from the central processor to external points and another set of 15 sensing lines from external points to the central processor. Two instructions address these lines. The STE (Set External Point) instruction delivers a pulse to the external activating line(s) specified by the low-order 15 bits of the instruction. The SKE (Skip if Signal Not Set) instruction examines the external sensing line(s) specified by the low-order 15 bits of the instruction. If any of the external sensing lines tested is not set, the next instruction is skipped. Any combination of external lines may be set or tested with the appropriate instruction.

## DIRECT INPUT/OUTPUT CHANNEL

The H-300 is equipped with a direct input/output channel consisting of a 24 -bit input bus, a 24-bit output bus, an interrupt line, and a set of control lines (see Figure 1). The control lines carry control pulses, data pulses, and responses from peripheral control units. Control pulses and data pulses are used to define the meaning of the information that is on the input or output bus. The addressed peripheral control interprets the pulses and control information and either issues a response or directs the actions of the attached peripheral devices.

## Standard Peripheral Control

A standard peripheral control which services a keyboard printer, a paper tape reader, and a paper tape punch is part of the central processor. The control is permanently attached to the direct input/output channel as illustrated in Figure l. Up to seven additional peripheral controls handing up to 60 additional devices may be attached to the direct input/output channel. Since the devices controlled by this unit read or write one character at a time, the control is designed to receive or transmit the largest of the characters, which is the eight-bit character from the eight-channel paper tape device. The devices that may be connected to the standard control are as follows:

Model 309 Paper Tape Reader ( 300 characters per second)
Model 310 Paper Tape Punch ( 120 characters per second)
Model 320 Keyboard Printer (10 characters per second)
As illustrated in Figure l, the keyboard printer is attached to separately addressable input and output lines.

Figure 1. The Direct Input/Output Channel

Three instructions are used in conjunction with the direct input/output channel. These are the Control and Skip instruction (SKC), the Peripheral Input instruction (PIN), and the Peripheral Output instruction (POT). The SKC instruction generates control pulses to inform the peripheral controls attached to the direct input/output channel that the bus contains control information. The PIN and POT instructions transfer data to and from the central processor, respectively.

## Operation of the Standard Peripheral Control

When any one of the devices attached to the standard peripheral control is ready to transmit or receive information, an interrupt signal is generated on the interrupt line servicing the direct input/output channel. The program may then scan the devices connected to the standard control to determine which one caused the interrupt. This is done by means of a series of SKC instructions which inter rogate each attached device in turn. When the device issuing the interrupt is determined, it can be serviced by a PIN or POT instruction as appropriate.

When an SKC instruction is executed, the specified control line is energized. All the peripheral controls attached to the bus examine the bits on the control line. These bits designate the address of the device to which the SKC instruction is directed as well as the question or command to be interpreted by the peripheral control.

Only the addressed device responds to the SKC instruction by connecting itself logically to the bus. If a response is requested by the SKC instruction, it is sent over the appropriate response line to the central processor; if a response is not received within a set time period (e.g., if a non-existent device is addressed or if the addressed device has been powered down), a negative response is assumed.

When a PIN or POT instruction is issued, a "ready" response is required. Since only one device may be connected logically to the bus at a time, there can be no ambiguity as to which device is to respond. If the response is positive, the instruction is executed and the next instruction is skipped. If the response is negative, the instruction is not executed but the next instruction is executed. In any case, the central processor does not stall while waiting for a peripheral device.

## Priority Interrupt

The H-300 has six levels of priority interrupt. These may be optionally expanded in groups of six levels to a maximum of 24 levels. One of the basic six interrupt lines is associated with the direct input/output channel.

The priority interrupt system features automatic generation of subsequence addresses for each external line according to a fixed priority, with the ability to block (disable) individual lines selectively. Priority of the interrupt lines is determined according to bit position in the interrupt register, with the high-order bit position having the highest priority.

## Blocking

Only the bit positions in the interrupt register for which there is a corresponding one-bit in the inter rupt mask register can cause a subsequence. The mask register may be loaded from memory by using the LIM (Load Interrupt Mask) instruction or its contents may be exchanged with memory using the XML (Exchange Interrupt Mask) instruction.

The inter rupt block is automatically set when a subsequence occurs. It remains set until cleared by the SRB (Set/Reset Interrupt Block) instruction. The block may also be set by the program using the $S R B$ instruction.

## Operation of the Interrupt System

If (1) an inter rupt signal exists when execution of an instruction has been completed, (2) one or more bits of the inter rupt register contain a one, (3) the corresponding bit(s) in the inter rupt mask register are one, and (4) the interrupt block is not set, a subsequence is automatically made to the address corresponding to the bit of highest priority and the interrupt block is set. The bit corresponding to the interrupt line which caused the subsequence is cleared to zero in the interrupt register. All other interrupts which are present when the block is set or which are generated after the block is set are remembered for later servicing when the inter upt block is cleared. Clearing of the interrupt block by means of the Set/Reset Interrupt Block instruction (SRB) is delayed long enough to permit one additional instruction to be executed before the block is cleared. Thus, uninter rupted execution of the instruction following the SRB instruction is guaranteed.

## BUFFERED INPUT/OUTPUT

Up to three optional read/write channels may be installed which permit simultaneous operation of up to three peripheral devices with either a direct input/output operation or computing. Buffered input/output makes it possible, for example, to print, read and write tape, and compute - all at the same time.

Simultaneity of operation is achieved through time sharing and is based on the fact that all input/output operations require access to the main memory for only a small part of the time that they are in progress. Therefore, when an input/output operation is in progress but is not using the main memory, another peripheral device or the central processor may gain access to the main memory. It is the function of the input/output traffic control to direct the time sharing of the main memory by the various peripheral devices and the central processor.

In order to understand how the traffic control does this, the programmer must have an understanding of how data is transferred between a peripheral device and the main memory. Figure 2 illustrates the basic elements which form the data path between a peripheral device and the main memory.

Figure 2. Buffered Input/Output Data Path

## Input/ Output Trunks

The H-300 System can be equipped with eight input/output lines (expandable to 16 ) which permanently connect the control units of the various peripheral devices to the peripheral interface. For example, a card reader and its control are permanently connected to the interface via an input trunk, while a printer and its associated control are attached via an output trunk. Each of these trunks is 6 bits wide and is therefore compatible with all standard Honeywell peripheral controls.

## Read/Write Channels

Notice that the data path shown in Figure 2 is incomplete: there is no connection across the peripheral interface. This final link in the data path, known as a "read/write channel," is inserted when an input/output instruction is executed. Up to three read/write channels, labeled RWCl, RWC2, and RWC3 are available as options.

When the programmer codes an input/output instruction, he specifies, among other things, the peripheral control that is to receive or transmit data and the read/write channel over which the data transfer is to take place. For example, an instruction might specify a card read operation in which the card reader control transmits data over RWC2. When this instruction is executed in the stored program, the data path will look like this.

As soon as the data transfer is completed, RWC2 is automatically removed from the interface. This means that the programmer can assign RWC2 to another peripheral control in another input/output instruction. This is an extremely important feature. There is no predefined relationship between the read/write channels and the peripheral devices. The programmer can assign read/write channels with complete freedom.

Each read/write channel consists of a current location counter, a starting location counter, two buffer registers, a current word counter, a starting word counter, and a character counter. Most of these registers are accessible to the program by means of the Alter Register instruction (ALR). When a peripheral transfer is to be performed, the address at which the transfer is to begin is stored in both location counters.

When a six-bit (character) trunk is being controlled, there is provision for automatic packing or unpacking of the characters to or from 24-bit words. The character counter is incremented by one as each successive character is transferred. Each time the character count passes four, the contents of the present location counter and the word counter are also incremented by one.

## Traffic Control

While a peripheral operation is in progress, it requires access to the main memory for only a fraction of the total time to complete the operation; most of the time is taken up by mechanical activities. Therefore, there is time available for another peripheral control to transfer data to or from the memory via another RWC. This second input/output operation can in turn share access to the main memory with a third operation which uses the remaining RWC. A typical data path configuration is shown below.

The rate at which each of the above devices transfers data over the programmer-assigned channel is dependent upon the mechanical characteristics of the particular device. For instance, the transfer rate for the printer is considerably faster than that for the card punch; therefore, the printer will require access to the main memory more frequently than the card punch. It is the function of the traffic control to monitor the requests for access to the main memory and to insure that all requests are honored within the prescribed time interval for each unit. Any device connected to a buffered I/ Otrunk is guaranteed an opportunity to transfer data once every 6 microseconds.

## SECTION III

## INFORMATION FORMAT

The Honeywell 300 uses a fixed-length, 24-bit word. Associated with each word is a parity bit, the value of which is not subject to program control. Subsequent discussion of the H-300 word, therefore, refers only to the 24 information bits, unless otherwise noted.

Each memory location and each arithmetic register is capable of storing one word. A machine word may represent an instruction or one or more units of data.

The H-300 is a twos-complement machine. That is, all negative numbers are stored in memory in their twos-complement form, and twos-complement arithmetic is used exclusively. Appendix A contains a discussion of twos-complement arithmetic.

## FIXED-POINT WORD

The fixed-point word contains a 24 -bit, twos-complement binary number in the range minus $8,388,608$ to plus $8,388,607$.

## FLOATING-POINT WORD

A floating point number occupies two machine words, as shown below. The first word, and the high-order 15 bits of the second word, make up the mantissa. These 39 bits hold a twoscomplement binary number in the range $\pm 2.56 \times 10^{l l}$. The high-order bit of the first word represents the sign of the mantissa. The exponent occupies bits 16-24 of the second word and is a 9-bit, twos-complement binary number in the range minus 256 to plus 255.

## ALPHANUMERIC WORD

The alphanumeric word consists of four six-bit groups. Each group can represent one of 26 characters, 10 decimal digits, or 29 special characters such as punctuation marks, plus and minus signs, etc., or a blank. See Appendix B for a list of the H-300 character codes.

The optional character-handling instructions (Section VI) provide for the loading, testing, and storing of individual characters.

## THE INSTRUCTION WORD

Bits 1 through 6 of the instruction word represent the operation code. Up to 64 instructions may be specified by this field. Additional instructions are uniquely identified by parameters in the address field and in the variant character.

Bits 7 to 9 constitute the variant character. This octal character specifies whether the address of the word in which it appears is direct, indexed, or indirect as follows:

| Variant | Type of Addressing |
| :---: | :--- |
| 0 |  |
| 1 | Direct |
| 2 |  |
| 3 | Indexed by index register \#1 |
| 4 |  |
| 5 | Indexed by index register \#2 |
| 5 |  |
| 6 | Indexed by index register \#3 |
| 7 | Indexed by index register \#4 |
| 7 | Indirect by index register \#5 |

The types of addressing are described in Section IV.

The remaining bits of the instruction word are the address field, which provides for direct addressing of 32,768 words of memory.

In some instructions, the address field does not specify the address of an operand. Instead, this field contains one or more parameters specifying the number of words to be moved, the number of binary positions to be shifted, etc.

## THE INDIRECT ADDRESS WORD

In the indirect address word, the address variant occupies the high-order three bit positions. It has the same format and functions as in the instruction word.

The indirect address word contains no operation code. Bit positions 4 through 24 are a $21-$ bit address field which provides the capability of addressing memories larger than 32,768 words.

## SECTION IV

## ADDRESSING

## DIRECT ADDRESSING

When direct addressing is used, the variant character of the instruction word is zero. Direct addressing means that the address field contains the absolute main memory address of the operand. Accordingly, the address field is loaded directly into the address register, the operand so addressed is retrieved, and the instruction is executed.

## INDEXED ADDRESSING

When indexed addressing is used, the variant character of the instruction word has a value from one to six, specifying one of the six 21 -bit index registers. In this case the contents of the address field are augmented by the contents of the specified index register. The contents of the address field and the index register are not altered. The resulting sum is the absolute machine address of the operand; the operand so addressed is retrieved and the instruction is executed.

Figure 3. Types of Main Memory Addressing

## INDIRECT ADDRESSING

When indirect addressing is used, the variant character of the instruction word is seven. Indirect addressing means that the address field contains not the absolute main memory address of the operand but the address of a main memory location containing another address. The contents of the location specified by the address field of the instruction word are retrieved. The variant character of the word at that address has the normal meaning but is located at the highorder end of the word to allow a 21 -bit address field.

If the variant character of the indirectly addressed word is zero, bits 4 through 24 of the word are interpreted as the absolute address of the operand. This address is loaded directly into the address register, the operand so addressed is retrieved, and the instruction is executed.

If the variant character of the indirectly addressed word is seven, the addressing is multilevel indirect. The procedure for indirect addressing is repeated until a word is addressed whose variant character is not octal seven. This feature is represented by the loop in the flow chart in Figure 3.

## INDIRECT INDEXED ADDRESSING

If the variant character of the indirectly addressed word has a value from one to six, the addressing is indirect indexed. That is, the 21 -bit contents of the address field of the addressed word are augmented by the contents of the index register specified by the variant character. The instruction is then executed, using the operand addressed by the resulting sum.

## EXPANDED MEMORY ADDRESSING

For systems with more than 32,768 words of memory, there is additional logic which includes a bank register, additional bits in the sequence register, and three additional instructions. The memory is handled in banks of 32,768 words. The additional bits in the sequence register and those of the bank register are used to specify which bank is being addressed. The instructions are divided into two sets: those whose address field normally references data (e.g., ADD, LDA) and those whose address field normally references the sequence register (e.g., JMP, JAZ). Instructions that reference the sequence register retrieve the bank indicator from the sequence register; those that reference data take their bank indicator from the bank register.

The bank indicator in the sequence register is changed by normal incrementing or by execution of a Jump instruction with indirect or indexed addressing. The bank register is changed by means of the optional instructions Load Bank Register (LBR) and Equalize Bank Register (EBR). The Store Bank Register (SBR) instruction is used to store the status of the bank register in memory.

Effective addresses for instruction execution are derived from the appropriate bank indicating register. The instructions themselves are taken from the bank specified by the bank indicator bits of the sequence register. If direct addressing is used, the bank indicator is taken from the appropriate bank indicating register. If indirect addressing is used, the bank indicator is taken from the indirectly addressed word. If indexed addressing is specified, the effective address is computed from the sum of the contents of the index register, the low-order 15 bits of the instruction word, and the appropriate bank indicator.

# SECTION V <br> STANDARD INSTRUCTIONS 

## GENERAL SPECIFICATIONS

The following considerations apply to both the standard and the optional instructions (see Section VI).

Execution Timing
The execution time represents the time required to retrieve the instruction, execute it, and store the result. The following rules apply to the timing of instructions and should be used in conjunction with the timing formulas in the text. If only one timing formula is given for an instruction, the execution time is the same with and without interlace.

1. For conditional jump or skip instructions, the shorter time applies when the jump or skip is not made.
2. Indexed addressing requires, at most, an additional one-half cycle.
3. Indirect addressing requires one extra cycle per iteration.

Execution times are given in main memory cycles, where one cycle equals 1.75 microseconds.

Indicators
OVERFLOW INDICATOR. This indicator denotes the occurrence of twos-complement overflow of the accumulator. Overflow occurs when the precision of the fixed-point word is exceeded. This indicator is cleared (reset) upon being tested by an SKN instruction.

CARRY INDICATOR. The carry indicator stores the true binary carry from the high-order position of the 24 -bit accumulator. This indicator is not cleared by being tested; instead, it always indicates whether the result of the last operation that involved the accumulator produced a carry.

## No-Address Instructions (NAD)

There is a group of instructions all of which have the same operation code (NAD). Instead of specifying the addressing mode, the variant character is used to differentiate these instructions. The variant characters and the corresponding mnemonic operation codes are as follows:

| Octal <br> Variant | Mnemonic Operation <br> Code |
| :---: | :---: |

| 7 | SRB |

The PAS, EBR, and LBR instructions are differentiated by means of bits in the address field of the instruction word.

## Registers

The contents of control memory registers in the central processor remain unchanged during the execution of an instruction unless otherwise specified.

## Symbology

The following symbology is used to describe H-300 instructions:

1. $\mathrm{A}=$ the accumulator.
2. $B=$ the auxiliary arithmetic (B) register.
3. $S R=$ the sequence register.
4. () $=$ the contents of the location(s) indicated within the parentheses. For example, (SR) means "the contents of the sequence register."
5. Lower-case letters represent information that must be supplied by the programmer.
6. Upper-case letters and all digits and special characters except ellipsis (dots indicating progression) are coded literally in the position indicated. For example, digits appearing in the diagram of an instruction word must be coded literally in the positions shown for proper execution of the instruction. Thus, bits 7 through ll of the Pass instruction (page 22) must be zero.

CONTROL INSTRUCTIONS

BAR - Branch and Return

(SR) replace ( $x$ ). Then the address $x+1$ replaces (SR) and the instruction at that address is executed.

By storing (SR), this instruction provides the option of performing a subroutine beginning at $x+1$ and then returning to the main sequence by jumping indirectly to $x$.

Timing. 2 cycles.

EXC - Execute

The instruction at location $x$ is executed out of sequence. That is, (SR) are not altered. The address of the next instruction is (SR).

Timing. l cycle plus the time required to execute the addressed instruction.

HTJ - Halt Jump

(x) replace (SR). Then the central processor halts.

Timing. 1 cycle.

JAN - Jump on Accumulator Negative

The main memory address x replaces (SR) if the (A) are less than zero (i.e., if the highorder bit is one); else (SR) are incremented by one.

Timing. 1 or 2 cycles.

JAP - Jump on Accumulator Positive

The main memory address $x$ replaces (SR) if (A) are equal to or greater than zero; else (SR) are incremented by one.

Timing. 1 or 2 cycles.

JAZ - Jump on Accumulator Zero

The main memory address x replaces (SR) if (A) equal zero; else (SR) are incremented by one.

Timing. 1 or 2 cycles.

JMP - Jump

The address x replaces (SR) unconditionally.
Timing. 1 cycle.

PAS - Pass (NAD)

No operation. (SR) are incremented by 1.
Timing. 1 cycle.

SKM - Skip if Accumulator and Memory are Equal

If (A) equal ( x ), (SR) are incremented by two (thus the next instruction is skipped); else (SR) are incremented by one.

Timing. 2 or 3 cycles. With interlace: 1 or 2 cycles.

SKN - Skip if Signal is Not Set (NAD)

Each l-bit in the address field $x$ specifies an internal test point to be sensed. If any of the test points that are sensedis not set, (SR) are incremented by two (thus the next instruction is skipped); else (SR) are incremented by one. Any combination of test points maybe sensed with one SKN instruction. The internal test points are:

| Overflow | Sense Switch \#5 |
| :--- | :--- |
| Carry | Sense Switch \#6 |
| Sense Switch \#1 | Exponential Overflow |
| Sense Switch \#2 | Exponential Underflow |
| Sense Switch \#3 | Division Overcapacity |

Sense Switch \#4
Timing. 2 cycles.

SMZ - Skip if Memory is Zero

If ( x ) equal zero, (SR) are incremented by two (thus the next instruction is skipped); else
(SR) are incremented by one.
Timing. 2 or 3 cycles. With interlace: 1 or 2 cycles.

ADD - Add to Accumulator

(A) are added to (x). The sum replaces (A).

Indicators. Overflow, carry.

Tinaing. 2 cycles. With interlace: 1.5 cycles.

ADM - Add to Memory

(A) are added to (x). The sum replaces (x). (A) are not altered.

Indicators. None. The current contents of the overflow and carry indicators are not altered.

Timing. 3 cycles. With interlace: 2.5 cycles.

SUB - Subtract from Accumulator

(x) are subtracted from (A). The difference replaces (A).

Indicators. Overflow, carry.

Timing. 2 cycles. With interlace: 1.5 cycles.

TLY - Tally

(x) are incremented by one. The sum replaces (x).

Timing. 3 cycles. With interlace: 2.5 cycles.

## INDEXING INSTRUCTIONS

Indexing instructions are those that manipulate the contents of general purpose register 0 or the contents of one of the six index registers. The desired register is specified by the variant character of the instruction word as follows:

| Octal <br> Variant | Register |
| :--- | :--- |
|  |  |
| 1 | General Purpose Register 0 |
| 2 | Index Register \#1 |
| 3 | Index Register \#2 |
| 4 | Index Register \#3 |
| 5 | Index Register \#4 |
| 6 | Index Register \#5 |
| 7 | Index Register \#6 |
|  | Indirect Addressing |

Note that a variant character of zero does not specify direct addressing.

For indexing instructions, the effective address (i.e., $x$ in the specifications) is the contents of the address field of the first non-indirectly addressed word (namely, the first word whose variant character is not 7).

Indexing instructions can be divided into two classes depending on whether they use the effective address itself or the contents of the location specified by that address. They are designated as class I and class II indexing instructions, respectively. Class I instructions are DJX, JIX, and STX; these instructions use $x$ and not (x). Class II instructions are AUX, LDX, and SKX; these instructions use ( x ) and not x .

## Class I Indexing Instructions

DJX - Decrement and Jump on Index Not Zero

The contents of register $v$ are decremented by one. The result replaces the contents of that register. Then if the contents of that register are not zero, the address x replaces (SR); else (SR) are incremented by one.

Timing. 2 cycles.

JIX - Jump on Index Not Zero

The address x replaces (SR) if the contents of register vare not zero; else (SR) are incremented by one.

Timing. 1 or 2 cycles.

STX - Store Index Register

The contents of register veplace (x).

Timing. 2 cycles. With interlace: 1 cycle.

## Class II Indexing Instructions

AUX - Augment Index

( x ) are added to the contents of register v . The sum replaces the contents of thatregister.

Timing. 2 cycles. With interlace: 1 cycle.

LDX - Load Index Register

(x) replace the contents of register $v$.

Timing. 2 cycles. With interlace: 1 cycle.

SKX - Skip on Index High

If the contents of register $v$ are greater than ( x ), ( SR ) are incremented by two (thus the next instruction is skipped); else (SR) are incremented by one.

Timing: 2 or 3 cycles.

## INPUT/OUTPUT INSTRUCTIONS, DIRECT

PIN - Peripheral Input

If the device connected to the input bus is not ready, the next instruction in sequence is executed; else the 24 -bit word on the input bus replaces (x), and (SR) are incremented by two (thus the next instruction is skipped).

Timing. 3 cycles. With interlace: 2 cycles.

POT - Peripheral Output

If the device connected to the output bus is not ready, the next instruction in sequence is executed; else (x) are transferred to the output bus and (SR) are incremented by two (thus the next instruction is skipped).

Timing. 3 or 4 cycles. With interlace: 2 or 3 cycles.

SKC - Control and Skip (NAD)

This instruction interrogates and controls peripheral devices by way of peripheral controls attached to the direct input/output channel. If a positive response is received, (SR) are incremented by one; if a negative response or no response is received, (SR) are incremented by two (thus the next instruction is skipped).

The commands that may be directed to the keyboard printer, the paper tape reader, and the paper tape punch by way of the standard peripheral control unit are as follows:

Test the addressed device for an interrupt signal.
Test the addressed device for a stored error condition.
Test the addressed device for a busy condition.
Start the addressed device.
Stop the addressed device.
Timing. 2 cycles.

SKE - Skip if External Signal is Not Set (NAD)

Each l-bit in the address field $x$ specifies one of 15 external sensing lines to be tested.
If all of the lines that are tested are set (carry a logical l), (SR) are incremented by one; else $(S R)$ are incremented by two (thus the next instruction is skipped). The status of the sensing lines is not altered.

Timing. 1 or 2 cycles.

STE - Set External Point (NAD)

Each l bit in the address fieldxcauses a pulse to be sent over one of 15 external activating lines.
Timing. 1 cycle.

## INTERRUPT INSTRUCTIONS

LIM - Load Interrupt Mask

(x) replace the contents of the interrupt mask register.

Timing. 2 cycles. With interlace: 1 cycle.

SRB - Set/Reset Interrupt Block (NAD)

If parameter a (the low-order bit of the address field) is one, the interrupt block is set, blocking all peripheral interrupts. If parameter a is zero, the interrupt block is cleared, enabling all peripheral interrupts; in this case the next instruction in sequence will be under way before the status change occurs and is therefore not interrupted.

Timing. 1 cycle.

STI - Store Interrupt Register

The contents of the interrupt register replace ( x ) and are not altered.

Timing. 2 cycles. With interlace: 1 cycle.

XML - Exchange Interrupt Mask

The contents of the interrupt mask register are exchanged with (x).

Timing. 3 cycles. With interlace: 2 cycles.

## LOGIC INSTRUCTIONS

EXT - Extract (Logical AND)

(A) logical-AND (x) replace (A). That is, if corresponding bits in (A) and (x) are both one, a one replaces the bit in (A); else a zero replaces the bit in (A). (x) are unchanged. Hence the following truth table:

| $(\mathrm{A})$ | AND (x) | GIVING |
| :---: | :---: | :---: |
| 0 | 0 | $(A)$ |
| 0 | 1 | 0 |
| 1 | 0 | 0 |
| 1 | 1 | 0 |

Timing. 2 cycles. With interlace: 1 cycle.

HAD - Half Add (Exclusive OR)

(A) exclusive-OR (x) replace (A). That is, if corresponding bits in (A) and (x) are not identical, a one replaces the bit in (A); else a zero replaces the bit in (A). Hence the following truth table:

| $(\mathrm{A})$ | OR | (x) | GIVING |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 |  |
| 0 | 1 | 1 |  |
| 1 | 0 | 1 |  |
| 1 | 1 | 0 |  |

Timing. 2 cycles. With interlace: 1 cycle.

SMP - Superimpose (Inclusive OR)

(A) inclusive-OR (x) replace (A). That is, if corresponding bits in either (A) or (x), or both, are one, a one replaces the bit in (A); else a zero replaces the bit in (A). Hence the following truth table:

| $(A)$ | OR | (x) | GIVING |
| :---: | :---: | :---: | :---: |
| 0 | 0 |  | $(A)$ |
| 0 | 1 | 0 |  |
| 1 | 0 | 1 |  |
| 1 | 1 | 1 |  |

Timing. 2 cycles. With interlace: 1 cycle.

SST - Substitute

For corresponding bit positions in (A), (B), and (x), if the bit in (B) is one, the bit in (A) replaces the bit in $(x)$; else the bit in ( $x$ ) is protected. Thus, (B) are a mask. Hence the following truth table:

| $(A)$ | $(B)$ | $(x)$ GIVING $(x)$ |  |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 1 |
| 0 | 1 | 0 | 0 |
| 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 0 |
| 1 | 0 | 1 | 1 |
| 1 | 1 | 0 | 1 |
| 1 | 1 | 1 | 1 |

Timing. 3 cycles. With interlace: 2 cycles.

## SHIF T INSTRUCTION

```
SFT - Shift (NAD)
```

(A), or, if double precision is specified, (A, B) are shifted n places to the left or right in the rotate or arithmetic mode. In a left arithmetic shift, zero replaces each of the emptied positions. In a right arithmetic shift, the high-order bit of (A) is duplicated in each of the emptied positions.

| PARAMETER | INTERPRETATION |
| :---: | :---: |
| d | Direction Indicator |
|  | Left shift if d is 0 . |
|  | Right shift is d is 1. |
| m | Mode Indicator |
|  | Rotate if $m$ is 0 . Bits moved off the end of the word(s) are transferred end-around to the other end of the word(s). |
|  | Arithmetic if $m$ is 1 . Bits moved off the end of the word(s) are lost. |
| p | Precision Indicator |
|  | Single precision if $p$ is 0 . Only (A) are operated upon. <br> Double precision if $p$ is l. ( $A, B$ ) are operated upon. |
| n | Number of binary places to be shifted. |

Timing. $1+\frac{3 n}{7}$.

## WORD TRANSMISSION INSTRUCTIONS

ALR - Alter Register (NAD)

The contents of the control memory register specified by the source address s, under control of parameter $a_{s}$, replace the contents of the register specified by the destination address d. For an exchange, in addition to the above, the contents of the control memory register
specified by the destination address $d$, under control of parameter $a_{d}$, replace the content of the register specified by the source address $s$. If $d=s$, the contents of the register so specified are altered as specified by $a_{s}$. The control memory registers are addressed as follows:

| Register | Octal Address |
| :--- | :---: |
| General-Purpose Register 0 | 00 |
| Index Register 1 | 01 |
| Index Register 2 | 02 |
| Index Register 3 | 03 |
| Index Register 4 | 04 |
| Index Register 5 | 05 |
| Index Register 6 | 06 |
| A Register (Accumulator) | 07 |
| General-Purpose Register 1 | 10 |
| General-Purpose Register 2 | 11 |
| General-Purpose Register 3 | 12 |
| General-Purpose Register 4 | 13 |
| General-Purpose Register 5 | 14 |
| General-Purpose Register 6 | 15 |
| General-Purpose Register 7 | 16 |
| B Register (Auxiliary Arithmetic Register) | 17 |

Timing. 1.5 cycles.

DLD - Double-Precision Load

| OP CODE | $v$ | x |
| :---: | :---: | :---: |
|  | 7 | 0 |

(x) replace (A); (x+l) replace ( $\mathrm{B}^{\prime}$ ).

Timing. 3 cycles. With interlace: 2 cycles.

DST-Double-Precision Store

(A) replace (x); (B) replace (x+1).

Timing. 3 cycles. With interlace: 2 cycles.

LDA - Load Accumulator

(x) replace (A).

Timing. 2 cycles. With interlace: 1 cycle.

LDB - Load B Register

(x) replace (B).

Timing. 2 cycles. With interlace: l cycle.

MTR - Multiple Transfer

Starting with ( x ), w words ( $0 \leq \mathrm{w} \leq 63$ ) are transferred to consecutive main memory locations starting with address a. The addresses $x$ and a have independent variant characters. This is a two-word instruction.

Timing. $2.5+2 \mathrm{w}$ cycles. With interlace: $3.5+\mathrm{w}$ cycles.

STA - Store Accumulator

(A) replace (x).

Timing. 2 cycles. With interlace: l cycle.

STB - Store B Register

(B) replace (x).

Timing. 2 cycles. With interlace: 1 cycle.

STZ - Store Zeros in Memory

24 zeros replace (x).

Timing. 2 cycles. With interlace: 1 cycle.

## SECTION VI

## OPTIONAL INSTRUCTIONS

Four categories of optional instructions are available with the $\mathrm{H}-300$. The character instructions permit manipulation of individual characters within words while protecting the rest of the addressed word. The multiply/divide instructions, either by themselves or together with the floating-point instructions, increase the power of the system in scientific applications. The expanded memory instructions are included in all systems having more than 32,768 words of memory.

All systems include the hardware bypass feature: use of an optional instruction which is not installed in the machine causes a subsequence to a fixed memory location. The program there may identify the instruction and execute it by means of a subroutine.

## CHARACTER INSTRUCTIONS

The character instructions interpret the $\mathrm{H}-300$ main memory word as four alphanumeric (six-bit) characters. The low-order two bits, shown below as bits $n$, specify which of the four characters is to be used, counting from left to right in the addressed word.

The high-order bit of the variant character, shown below as bit $v$, specifies one of two available addressing modes. If the bit is zero, it specifies direct addressing; else it specifies indirect addressing.

CSK - Characters Skip if Equal

(SR) are incremented by two if character $n$ in (A) equals character $n$ in ( x ) (thus the next instruction is skipped); else (SR) are incremented by one.

Timing. 2 or 3 cycles. With interlace: 1 or 2 cycles.

LCH - Load Character

Character $n$ of (x) replaces character $n$ of (A). The other characters of (A) are unchanged.
Timing. 2 cycles. With interlace: 1 cycle.

SCH - Store Character

Character $n$ of (A) replaces character $n$ of ( x ). The other characters of ( x ) are unchanged.
Timing. 2 cycles. With interlace: l cycle.
EXPANDED MEMORY INSTRUCTIONS
EBR - Equalize Bank Register (NAD)

The contents of the bank indicator in the sequence register replace the contents of the bank register. Thus the contents of the sequence register bank indicator and the bank register are equalized.

Timing. 1 cycle.

LBR - Load Bank Register

The contents of the bank-bit field of the instruction word replace the contents of the bank register.

Timing. 1 cycle.

SBR - Store Bank Register

The contents of the bank register replace the low-order portion of (x). The rest of ( x ) is protected. The format of ( $x$ ) is compatible with the Load Bank Register (LBR) instruction.

Timing. 2 cycles.

## MULTIPLY/DIVIDE INSTRUCTIONS

DIV - Divide

(A, B) are treated as a 48-bit dividend and divided by (x). The quotient replaces (A). The remainder replaces (B).

Indicators. Division overcapacity.

Timing. 12 cycles.

MPY - Multiply

(A) are multiplied by (x). The product replaces (A, B) taken as a 48 -bit register.

Timing. 4 cycles.

## FLOATING-POINT INSTRUCTIONS

This set of instructions provides a complete floating-point repertoire for the H-300. The multiply/divide instructions are a prerequisite to the floating-point instructions.

The variable $N$ in the timing formulas in this section represents the number of shifts required to justify the operands and/or to normalize the result.

FAD - Floating Add

(A, B) are treated as one 48-bit register, as are ( $\mathrm{x}, \mathrm{x}+1$ ). The two operands are justified and then added together. The normalized sum replaces (A, B). An operand can be normalized by adding it to a floating-point zero.

Indicators. Exponential overflow and underflow.

Timing. $4+\frac{N}{7}$ cycles.

FDV - Floating Divide

( $\mathrm{A}, \mathrm{B}$ ) are treated as one 48 -bit register, as are ( $\mathrm{x}, \mathrm{x}+\mathrm{l}) . \quad(\mathrm{x}, \mathrm{x}+1)$ are divided into (A, B). The quotient replaces (A, B). The operands are not justified and the quotient is not normalized. The remainder can be retrieved by means of the Floating Unload instruction (see page 43).

Indicators. Exponential overflow and underflow.

Timing. 26 cycles.

FMP - Floating Multiply

[^0]( $\mathrm{x}, \mathrm{x}+1$ ). The normalized high-order product replaces (A, B). The low-order product can be retrieved by means of the Floating Unload instruction (see below).

Indicators. Exponential overflow and underflow.

Timing. $\quad 9+\frac{N}{7}$ cycles.

FSB - Floating Subtract

| OP CODE |  | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

( $\mathrm{A}, \mathrm{B}$ ) are treated as one 48-bit register, as are ( $\mathrm{x}, \mathrm{x}+\mathrm{l}$ ). The two operands are justified and ( $\mathrm{x}, \mathrm{x}+1$ ) are subtracted from (A, B). The normalized difference replaces (A, B).

Indicators. Exponential overflow and underflow.

Timing. $\quad 4+\frac{N}{7}$ cycles.

FUL - Floating Unload

The floating-point low-order product or remainder replaces (A, B).

Timing. 4 cycles.

INPUT/OUTPUT INSTRUCTIONS, BUFFERED
The following instructions are used in conjunction with the optional read/write channels and the associated input/output traffic control described on page 8.

PCB - Peripheral Control and Branch (General Description)

(x) replace (SR) if the test(s) specified by the control characters is met; else the next sequential instruction is executed. Through the use of control characters, the PCB instruction can initiate operations such as error-card rejection on the card reader and tape rewind on magnetic tape units. Or it can test peripheral indicators such as error indicators, control unit busy indicators, and read/write channel busy indicators.

Timing. $3+4 w$ cycles.

\begin{tabular}{|c|c|}
\hline PARAMETER \& INTERPRETATION <br>
\hline \multirow[t]{3}{*}{w

$c_{1}$} \& | Second Word |

| * Optional instructions |  |  |  |  |  |  |  |  |

PDT - Peripheral Data Transfer (General Description)

The PDT instruction transfers data to or from main memory starting with location x . Data transfer terminates when an external end-of-record signal occurs or when words have been transferred, whichever occurs first. Each of the n words transferred will contain four characters, even if some zero characters are supplied to fill out the last word. The next instruction in sequence is in the first word after the control characters.

Timing. $3+4 \mathrm{w}$ cycles.

\begin{tabular}{|c|c|}

| :---: | :--- |
| $c_{2}$ | Peripheral control designation. This character designates the logical ad- <br> dress of the peripheral control (and associated device) to be used in the <br> data transfer. This address is established individually at each installation <br> and depends on the I/O trunk to which the peripheral control is permanently <br> attached. In general, a peripheral controlis designated by the number of <br> the input/output trunk to which it is permanently attached. |
| Any peripheral control capable of both reading and writing (e.g., the mag - <br> netic tape control) must be assigned two addresses: one for reading and <br> one for writing. In such cases, the high-order bit of control character two <br> must be one for input and zero for output, and the low-order three bits of <br> the two addresses must be identical. |  |
| Additional parameters. See Table II for a summary of these options. The <br> x'sin the table represent information that must be supplied by the pro- <br> grammer; the digits should be coded literally. |  |
| When associated with a magnetic tape operation, this character specifies <br> direction of tape motion, odd or even parity, tape unit, and presence or <br> absence of data transfer. |  |

Table II. Summary of PDT Instruction I/ O Control Characters

* Odd parity is assumed. If even parity is required, character should be 7.
**Odd parity is assumed. If even parity is required, character should be 3 .
*** Odd parity and short gap length are assumed.

## SECTION VII <br> BUFFERED INPUT/OUTPUT OPERATIONS

This section describes the programming of those input/output devices most commonly used with the buffered input/output system, viz., the card readers, card punches, magnetic tape units, and high-speed printers. Other devices available with the Honeywell 300 include paper tape readers and punches, random access disc and drum files, communication controls, magnetic ink character recognition device controls, and a keyboard printer.

## CARD READ OPERATIONS, MODEL 223

The Model 223 Card Reader and Control is an end-feed device capable of reading cards at the rate of 800 per minute (one card every 75 milliseconds). The cards are standard 12 -row, 80 -column (or 51 -column) cards punched in Hollerith code (See Appendix B). Cards are read a column at a time starting with column 1, all 12 rows in a column being read simultaneously. The card code is decoded in the card reader control and an 80 -character ( 20 -word) card image is formed in the main memory image area specified by the programmer. The card image is stored in the standard Honeywell 6-bit character code with four columns per word. Columns 1-4 make up word one, etc.

Figure 4. Model 223 Card Read Operation

Card reading is performed concurrently with central processor activities. A single card read operation can be performed during a 75 -millisecond processing interval, as shown above. This time interval is determined by the mechanical operations which must be performed when a card is read. The interval begins when a card read signal activates the card reader control. Thirteen milliseconds later, initial mechanical card-feed operations are completed and information transfer begins. During the next 46 milliseconds, the card reader control delivers 20

[^1]words to main memory, one word for each four card columns. The total time during which central processor activity is suspended due to word transfer is somewhat less than 50 microseconds. Thus, after 59 milliseconds of the processing interval has elapsed, the entire card image is stored in the main memory. The remaining time is required for terminal card-feed operations which have no effect on central processor activity.

It is important to realize that during a card read operation, central processor activity is inter rupted for a total of less than 50 microseconds. In other words, over $99.9 \%$ of a 75 -millisecond processing interval which is shared by a card read operation is available to the central processor for execution of other instructions and control of additional input/output operations.

## Programming Considerations

l. The card reader control contains two indicators: a card read error indicator and a control unit busy indicator. If a card read error occurs, the error indicator is turned on when information transfer terminates. The busy indicator is on during the first 59 milliseconds of the card read operation.
The status of either indicator may be tested by a PCB instruction. However, the control unit busy indicator should be tested before the card read error indicator is tested to insure that information $\operatorname{tr}$ ansfer has terminated. The card read error indicator, in turn, should be tested before a subsequent card read instruction addresses the same control unit, since the error indicator is automatically reset when a new card read operation begins.
2. To maintain continuous card reading at the maximum rate of 800 cards per minute, a card read instruction must be issued before the preceding card read operation terminates. This is necessary to insure that the new card read operation will begin immediately following the preceding one.

On a conventional clutch-operated reader, failure to time the read instructions properly severely reduces reading speed. This clutchless reader initiates the read cycle whenever it is activated instead of waiting for fixed clutch points.
If a second read instruction is issued to the card reader during the first 59 milliseconds of the current card read operation, the central processor senses a control unit busy signal and stalls; that is, it performs no further activities until the end of the 59 -millisecond period. At that point, the control unit busy signal is removed and the central processor is free to execute the second read instruction. To avoid stalling the central processor and still maintain full reading speed, a card read instruction should be issued within the last 16 milliseconds of the preceding card read operation (or from a programming standpoint, after a PCB instruction finds the control unit busy indicator off).

## Use of the PCB Instruction

A Peripheral Control and Branch instruction that addresses a card reader control can initiate the following activities:

1. Test the status of the device for busy, error, or inoperable conditions.
2. Set the control unit to perform a specific control function (e.g., accept error cards, reject error cards, read Hollerith code).

If the condition tested for exists, the program branches to the location specified by the address field of the PCB instruction.

Timing. 7 cycles minimum.

Table III. Summary of Card Reader PCB Functions (Model 223)

| Control Character 3 (octal) | Function |
| :---: | :---: |
| $\begin{aligned} & 10 \\ & 41 \\ & 42 \end{aligned}$ | Test Functions <br> Branch if device busy. <br> Branch if cycle check error. <br> Branch if illegal punch is detected. |
| 27 <br> 26 <br> **25 <br> 21 <br> 22 <br> 23 <br> 24 | Control Functions <br> Branch if device inoperable. If operable, set control unit to read Hollerith code. <br> Branch if device inoperable. If operable, set control unit to read special code.* <br> Branch if device inoperable. If operable, set control unit for direct transcription reading. <br> Branch if device inoperable. If operable, set control unit to reject cards on which cycle check errors are detected. <br> Branch if device inoperable. If operable, set control unit to reject cards with illegal punches. <br> Branch if device inoperable. If operable, set control unit to generate busy signal if cycle check error is detected. Busy status must be manually cleared at the card reader. <br> Branch if device inoperable. If operable, set control unit to generate busy signal if illegal punch is detected. Busy status must be manually cleared at the card reader. |
| This code is shown in Appendix B. **Optional Control Functions. |  |

1. $A P C B$ instruction can test the status of a read/write channel. The first I/O control character ( Cl ) is used for this purpose. If the RWC specified by this character is busy, the program branches to the location specified in the address field of the $P C B$ instruction. If an RWC status test is not desired, Cl must contain zeros.
2. In any program, the first instruction directed to the card reader must be PCB instruction in which control character 3 contains a 27 . In effect, this instruction "initializes" card read operations.
3. Additional control characters can be written in sequence following control character 3 when more than one control function is to be performed by a single PCB instruction. If more than two control functions are performed by a single PCB instruction, the timing of the instruction increases.

Use of the PDT Instruction
This instruction initiates a card read operation and causes all information on the card to be read into the main memory image area whose initial location is specified in the address field of the instruction. Data transfer terminates when the entire card image has been transferred or when the specified number of words has been transferred. General specifications for the PDT instruction are on page 47.

Timing. 7 cycles for instruction execution.

## CARD PUNCHING OPERATIONS, MODEL 224

The Model 224 is an end-feed card punch. Cards are punched a column at a time starting with column 1. All 12 rows of a column are punched simultaneously. Each six-bit character in the punch image area specified by the programmer is encoded into the corresponding card code (see Appendix B) ${ }^{1}$ by the card punch control.

There are two models of punch available. The model $224-1$ punches from 50 to 262 cards per minute, while the model $224-2$ punches from 91 to 354 cards per minute. Card punching is performed concurrently with central processor activities. The length of the processing interval depends on the number of columns punched. There is a fixed clutch-engaging time at the start of the interval and a fixed card stacking and feed cycle at the end of the interval. Between these fixed intervals, the actual punching takes a fixed amount of time per column. These times and the resulting punching speed formulas are shown in Table V. Note that during a card punch operation, central processor activity is interrupted for less than 50 microseconds, so that over $99.9 \%$ of the processing interval which is shared by a card punch operation is available to the central processor for execution of other instructions and control of additional input/outputoperations.

There are also two models of card punch control available with the 224 punches: the model 208-1 and the model 208-2. Either punch is capable of operating with either control for normal punching operations. If either punch is to be used for punch-feed read operations, it must be connected to the model 208-2 control.

[^2]Table IV. Model 224 Card Punching Speeds

| Punch | Clutch Engage | Punching Time | Stacking and Feeding | Formula |
| :--- | :---: | :---: | :---: | :---: |
| $224-1$ | $6.25 \mu \mathrm{~s}$ | $12.5 \mu \mathrm{~s} /$ column | $210 \mu \mathrm{~s}$ | $\mathrm{CPM}=\frac{60,000}{216.3+12.5 \mathrm{n}}$ |
| $224-2$ | $3.13 \mu \mathrm{~s}$ | $6.25 \mu \mathrm{~s} /$ column | $160 \mu \mathrm{~s}$ | $\mathrm{CPM}=\frac{60,000}{163.2+6.25 \mathrm{n}}$ |

where $n$ is the number of columns punched.

## Programming Considerations

The following points must be considered when progran:ming card punch operations:

1. The card punch control contains two indicators: a control unit busy indicator and an echo-check indicator. The busy indicator is on during the punch operation. If an echo-check error occurred during the preceding punch operation, the echo-check indicator is turned on when information transfer in the current punch operation is completed.
2. The status of either indicator may be tested by a PCB instruction. However, the echo-check indicator should be tested after the control unit busy indicator is found to be off and before a subsequent card punch instruction addresses the same control unit.

## Use of the PCB Instruction

A PCB instruction directed to the card punch control can test the status of the device or can set the control unit to perform a specific control function. If the condition tested for exists, the program branches to the location specified in the address field of the $P C B$ instruction.

Timing. 7 cycles, minimum.

Table V. Summary of Card Punch Control Parameters

| Control Character 3 (octal) | Function |
| :---: | :---: |
| $\begin{array}{r} 10 \\ * * 41 \end{array}$ | Test Functions <br> Branch if device busy. <br> Branch if echo check error. |
| $\begin{array}{r} 27 \\ * * 25 \\ * * 21 \end{array}$ | Control Functions <br> Branch if device inoperable. If operable, set control unit to punch Hollerith code. <br> Branch if device inoperable. If operable, set control unit for direct transcription punching. <br> Branch if device inoperable. If operable, set control unit to reject cards on which echo-check errors are detected. |

Table V (cont). Summary of Card Punch Control Parameters

| Control Character 3 <br> (octal) | Function |
| :---: | :--- |
| $* * 23$ | Branch if device inoperable. If operable, set control unit to <br> generate busy signal if echo-check error is detected. Busy <br> status must be manually cleared at the card punch. |
| Branch if device inoperable. If operable, set control unit to |  |
| punch special code. |  |

## Notes

1. The first I/O control character (Cl) is used to test the status of a read/write channel. If an RWC status test is not desired, 61 must be zero.
2. In any program, the first instruction directed to the card punch must be a PCB instruction in which control character 3 is 27 . This instruction initializes card punch operations.
3. Additional control characters can be written in sequence following control character 3 when more than one control function is to be performed by a single $P C B$ instruction. If more than two control functions are performed by a single PCB instruction, the timing of the instruction increases.

## Use of the PDT Instruction

The content of the main memory area whose initial location is specified in the address of the PDT instruction is punched into an 80 -column card. The operation is terminated when a complete 80 -character image has been punched or when the specified number of words has been transferred.

Timing. 7 cycles, minimum.

## MAGNETIC TAPE OPERATIONS, SERIES 204B

The H-300 magnetic tape system consists of one or more tape controls, each capable of directing from one to eight tape drives. Each tape control is attached to both an input and an output line. This means that one of the tape drives attached to a tape control may be reading while another is writing simultaneously. In addition, any number of tape drives attached to a tape control may rewind simultaneously. As an optional feature, the tape controls can be modified to permit the interchange of tapes from other manufacturers with the $\mathrm{H}-300$ system.

Information is recorded on magnetic tape in groups of characters called records. Since the number of characters in a record is variable, depending on the amount of information
required, the duration of the processing interval shared by a magnetic tape operation is likewise variable. This is in contrast to the fixed-length processing intervals associated with card and print operations.

## Programming Considerations

Table VI summarizes the tape unit characteristics necessary to estimate the processing interval shared by a tape read/write operation, and the total time during which central processor activity is interrupted due to character transfers.

Table VI. Tape Unit Characteristics

| TAPE UNIT |  | 2048-1,2 | 204 B-3,4 | 204B-5 | 204B-6 |  | $8-7$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| TAPE SPEED |  | 36 //sec. | $80 \mathrm{\prime} / \mathrm{sec}$. | $120 \mathrm{I} / \mathrm{sec}$. | 150 / sec. |  | sec |
| RECORDING DENSITY |  | 200 or 556 CHAR./ / NCH |  |  |  | 556 or | char/inch |
|  | SHORT GAP | 0.45 " | $0.60^{\prime \prime}$ | $0.70^{\prime \prime}$ | $n / a$ |  |  |
|  |  | $0.75{ }^{\prime \prime}$ | $0.75{ }^{\prime \prime}$ | $0.75{ }^{\prime \prime}$ | 0.75 |  |  |
| $*$ <br> $*$ <br> * TIME TOCROSS <br> INTER-REC. GAP <br>  | SHORT GAP | 12.5 ms | 7.5 ms | 5.8 ms | n/o |  |  |
|  |  | 20.8 ms | 9.4 ms | 6.3 ms | 5.0 ms |  |  |
| REWIND SPEED |  | $108{ }^{\prime \prime} / \mathrm{sec}$ | $240 \mathrm{\prime} \mathrm{\prime} \mathrm{sec}$ | $360 \mathrm{\prime} / \mathrm{sec}$ | $360 \mathrm{~L} / \mathrm{sec}$ |  | sec |
| CHAR RATE BETWEEN CONTROL UNIT AND MEMORY |  | .437 $/$ / ch | . $437 \mu s / c h$ | 437 $/$ s/ch | $437 \mu s / c h$ | 437 $\mu$ /ch |  |
| CHAR. RATE BETWEEN TAPE AND CONTROL UNIT | $\begin{aligned} & 200 \\ & \text { CPI } \end{aligned}$ | $0.139 \mathrm{~ms} / \mathrm{ch}$ | $0.061 \mathrm{~ms} / \mathrm{ch}$ | $0.042 \mathrm{~ms} / \mathrm{ch}$ | $0.033 \mathrm{~ms} / \mathrm{ch}$ | $\begin{aligned} & 556 \\ & C P I \end{aligned}$ | $\begin{aligned} & 0.050 \\ & \mathrm{~ms} / \mathrm{ch} . \end{aligned}$ |
|  | $\begin{aligned} & 556 \\ & C P I \end{aligned}$ | $0.050 \mathrm{~ms} / \mathrm{ch}$. | $0.022 \mathrm{~ms} / \mathrm{ch}$ | $0.015 \mathrm{~ms} / \mathrm{ch}$ | $0.012 \mathrm{~ms} / \mathrm{ch}$ | $\begin{aligned} & 800 \\ & C P 1 \end{aligned}$ | $\begin{aligned} & 0.035 \\ & \mathrm{~ms} / \mathrm{ch} . \end{aligned}$ |
| * Cross - gap time represents time required to read past gap at full speed. |  |  |  |  |  |  |  |

In order to estimate the duration of the processing interval shared by a tape read/write operation, three factors must be considered: the character rate between the tape and the control unit, the time required to cross the inter-record gap, and the number of characters in the record. Once these parameters have been determined, the following formula can be used to estimate the processing interval.

As an example, consider the following parameters:
Tape Unit - 204B-5
Recording Density - 200 characters per inch
Number of Characters in Record - 400
Operation - Read
The read operation defined by these parameters would share a processing interval of 22.64 milliseconds:
22.64 milliseconds $=5.84 \mathrm{~ms}+(400$ char. X $.042 \mathrm{~ms} /$ char. $)$

Within a processing interval which is shared by a magnetic tape operation, the total time during which central processor activity is suspended due to character transfers is expressed by the following formula.

```
TOTAL CENTRAL PROCESSOR = 0.437 \mus/char. X NUMBER OF
INTERRUPT TIME CHARACTERS
(in milliseconds)
    IN RECORD
```

In the example above, for instance, the total time during which central processor activity is interrupted due to character transfers is 0.174 milliseconds. In other words, 22.46 milliseconds is available for the execution of other instructions and other data transfer operations.

## Tape Checking

Automatic error-detection techniques are incorporated in the $\mathrm{H}-200$ tape units and controls which verify the validity of information transferred to or from tape. The presenceor absence of an error condition during a read or write instruction can be tested by issuing a PCB instruction following the completion of the read or write instruction.

PARITY CHECKING: Data can be recorded on tape with either odd or even parity (as specified by the programmer). Parity checking is applied to each character transferred from the tape, and if the required bit count is not present, the error indicator is turned on.

LONGITUDINAL CHECK: A longitudinal check frame is automatically appended at the end of each record stored on tape. When a record is written on tape, the bits in each channel are counted and the bits in the check frame are set to insure an even bit count for each channel. When the same record is read from tape, the longitudinal bit count is repeated, and if each channel in the complete record (including the check frame) does not have an even bit count, the error indicator is turned on.

Note: the contents of the check frame are not transferred to the main memory.

READ AFTER WRITE: Parity and longitudinal checks are performed only when information is read from tape. The read after write feature permits the detection of errors at the time that information is written on tape. In effect, when a character is written on tape, it is automatically read to determine if the information has been recorded correctly. If any discrepancy occurs, the error indicator is turned on.

ECHO CHECK: The error indicator is turned on if the write head is not writing at least one "l" bit in each frame.

## Tape Control Options

Three optional features are available with the H-300 l/2-inch tape system. Two options provide compatibility with other character-oriented systems. The first allows the H-200 tape control to recognize the end-of-file on magnetic tapes written by other systems. This is accomplished by sensing a special character called a "tape mark" which marks the end of recorded information on such tapes. The second feature equips the tape control with a translator which converts the BCD (binary coded decimal) code of such tapes into Honeywell internal code, and vice versa. Another feature is the ability to read tapes in the reverse direction and transfer the data in the normal (forward) direction into memory.

## Inter-Record Gaps

The $204 \mathrm{~B}-1,-2,-3,-4$, and -5 magnetic tape units have the ability to read and write tape using either of two inter-record gap lengths. A "short" or a "long" gap is specified in the control field of a tape write instruction and is automatically sensed during a tape read operation. The short gap length is normally used, since more tape surface is made available for data and less cross-gap time is used. The long gap is used when processing non-Honeywell tapes, since tapes read or written by non-Honeywell equipment require additional start/stop time (and consequently a longer inter-record gap). The different gap sizes and the time required to cross them during processing are listed in Table IV.

## Beginning and End of Tape

The first record on tape is recorded approximately 2.25 inches beyond the reflective spot located near the beginning of the tape. Succeeding records, normally separated by "short" interrecord gaps, are then recorded on the remainder of the tape. When the tape is positioned at the physical beginning of tape (the reflective spot), the Backspace, Rewind, and Read Reverse instructions do not move the tape or transfer data. A Rewind and Release instruction interlocks the tape unit at this point.

The physical end of tape is also marked by a reflective spot near the end of the tape. When either the physical beginning or end of tape is sensed, the corresponding indicator is turned on. Both the beginning-of-tape and the end-of-tape indicators can be tested by means of a PCB instruction.

## Simultaneity and Busy Conditions

Simultaneous operations can be performed by tape units connected to the same tape control, depending upon the instructions which the designated tape units are executing. These instructions can be divided into three groups, as shown in Table VII. Simultaneity exists between groups l, 2 , and 3; there is no simultaneity within a particular group except for group 3.

A PDT instruction issued to a particular tape unit places the designated unit in a busy condition. Group-l instructions place the input/output trunk assigned for reading in a busy condition, while group-2 instructions place the trunk assigned for writing in a busy condition. When an input/output trunk becomes busy, it remains busy until the inter-record gap is reached (in the case of group-l instructions), until an entire record is written (in the case of writing), or until 3-1/2 inches of tape is erased (in the case of an Erase operation). While a given trunk is busy, any other instruction addressed to the same trunk will stall in the central processor until that trunk becomes not busy, at which time the instruction will be accepted by the tape control.

Table VII. Tape Unit Simultaneity and Busy Conditions

| GROUP | STANDARD INSTRUCTIONS |  |  |  | OPTIONAL |
| :---: | :--- | :--- | :--- | :--- | :--- |

## Executable Instruction Sequences

Any sequence of PDT and PCB instructions may be issued to a tape control except for the sequence of Write (or Erase) followed by a Read Forward instruction.

## Use of the PCB Instruction

The test and control functions performed by a PCB instruction directed to a magnetic tape unit are defined in Table VIII. General specifications for the PCB instruction are on page 44.

Table VIII. Summary of Magnetic Tape PCB Functions (Series 204B)

| FUNCTION | DESCRIPTION | I/O CONTROL CHARACTERS |
| :---: | :---: | :---: |
| REWIND | Rewind the tape on the tape drive specified in control character 3. If the tape drive is busy, branch to the location specified in the address field. This operation will not move a rewound tape. |  |
| REWIND AND RELEASE | Same as rewind except that when rewind is completed, tape drive is disconnected from system and is not available again until operator restores ready status. |  |
| TEST FOR READ BUSY | Branch if specified tape control or tape unit is performing a read operation. |  |
| TEST FOR WRITE BUSY | Branch if specified tape control or tape unit is performing a write operation. |  |
| TEST FOR READ/ WRITE ERROR | Branch if error indicator is on. The error indicator is not reset by this operation but is reset by a subsequent PDT instruction. |  |
| TEST FOR PHYSICAL BEGINNING OF TAPE | Branch if beginning-of-tape indicator is on. |  |
| TEST FOR PHYSICAL END OF TAPE | Branch if end-of-tape indicator is on. |  |

Timing. 7 cycles, minimum.

## Notes.

1. The first I/O control character (Cl) is used to test the status of a read/write channel. If an RWC test is not desired, Cl must contain zeros.
2. A PCB instruction which tests for a read/write error condition or for beginning
or end of tape should not be issued until the completion of the read or write instruction. The completion of such a PDT instruction is indicated by testing the device for a busy condition. Therefore, the valid sequence of commands when testing for a read/write error or for beginning or end of tape is as follows: PDT (Read or Write) followed by PCB (test for read or write busy) followed by PCB (test for read/write error) or PCB (test for physical beginning or end of tape).

Use of the PDT Instruction
The magnetic tape data transfer operations that can be initiated by a PDT instruction are defined in Table IX.

Table IX. Summary of Magnetic Tape PDT Functions (Series 204B)

| OPERATION | FUNCTION | I/ O CONTROL CHARACTERS |
| :---: | :---: | :---: |
| READ <br> FORWARD | Read forward one record from tape into memory area whose leftmost location is specified by the $X$ address. Terminate the transfer when either an interrecord gap is sensed or the specified number of words is transferred. |  |
| - READ REVERSE | Same as Read Forward except that the direction of tape movement is backward and data is read into the memory area whose initial location is X . The order of information in memory is the same as in Read Forward. |  |
| WRITE | Transfer data from successive memory locations ( $\mathrm{X}, \mathrm{X}+1$, $X+2$, etc.) to magnetic tape. Terminate the transfer when the specified number of words has been transferred. |  |
| BACKSPACE | The tape drive specified in C3 backspaces over one tape record. No information is transferred as a result of this operation. |  |
| - Optional |  |  |

Timing. 7 cycles, minimum.

Notes.

1. If the number of characters read from tape is not a multiple of four, the contents of the main memory location which receives the last character read are completed with zeros.

## PRINT OPERATIONS, SERIES $2 \not 22$

Data to be printed on a high-speed printer is stored as standard Honeywell six-bit character codes in a print image area specified by the programmer. When a print instruction is executed, the contents of the print image area are transferred character-by-character to the printer control, which then directs the actual printing of the line. The transfer is terminated by either of two conditions: (1) a complete print image has been transferred, or (2) the specified number of words has been transferred. After the line has been printed, spacing occurs as specified either in the print instruction or in a separate PDT instruction.

Printing, like other input/output operations, is performed concurrently with central processor activities. The duration of a single print operation (i.e., printing a line and spacing once after the line has been printed) and the portion of this time in which central processor activity is suspended depend upon the printer model being used. Four high-speed printers (including printer controls) are available for use with the H-300.

Models 222-1, 222-2, and 222-3
The model 222-1 printer is equipped to print 96 characters per line, model 222-2 prints 108 characters per line, and model 222-3 can print 120 characters per line (standard) or 132 characters per line (optional). These printers operate at the rate of 650 lines per minute (one line every 92 milliseconds) when the output data uses a standard set of any 51 contiguous drum characters and at the rate of 550 lines per minute (one line every 110 milliseconds) when all of the 63 characters on the drum are used.

Figure 5. Print Operation for Models 222-1, 222-2, and 222-3

A processing interval of 92 milliseconds (see Figure 5) is in effect at the single-spacing speed of 650 lines per minute when the printer output uses any 51 contiguous characters on the
drum. Printing begins immediately after a print instruction activates the printer control. Line spacing begins immediately after a line has been printed (at the 75 -millisecond point in the processing interval). During the first 75 milliseconds of the print operation, the printer control interrupts the central processor for a total of approximately 3 milliseconds. The central processor is therefore free to perform other activities during approximately $97 \%$ of the print operation.

A full line which uses all 63 drum characters is printed in a processing interval of 110 milliseconds ( 550 lines per minute). In this case, the central processor is alsofree for approximately $97 \%$ of the print operation. If the print record in the image area is logically less than the unit record length of the particular printer model (e.g., less than 108 characters when using the Model 222-2, etc.), the percentage of available processing time is even higher than stated above.

Model 222-4
The Model 222-4 is equipped to print 120 characters per line (standard) or 132 characters per line (optional). It operates at the rate of 950 lines per minute (one line every 63 milliseconds) when the output data uses a standard set of any 46 contiguous drum characters and at the rate of 750 lines per minute (one line every 80 milliseconds) when all of the 63 characters on the drum are used.

Figure 6. Print Operation for Model 222-4

A processing interval of 63 milliseconds (see Figure 6) is in effect at the single-spacing speed of 950 lines per minute when the printed output uses any contiguous 46 characters on the drum. Printing begins immediately after a print instruction activates the printer control. Line spacing begins immediately after a line has been printed (at the $46-$ millisecond point in the processing interval). During the first 46 milliseconds of the print operation, the printer control interrupts the central processor for a total of approximately 3 milliseconds. The central processor is therefore free to perform other activities for $95 \%$ of the print operation.

A full line which uses all 63 drum characters is printed in a processing interval of 80 milliseconds ( 750 lines per minute). Again, the central processor is free to perform computations and other I/O operations during $95 \%$ of the print operation. As noted previously, the
percentage of available time is even higher if the print record is logically less than the unit record length.

## Programming Considerations

The following points must be considered when programming print operations:
l. The printer control contains two indicators: a control unit busy indicator and a print error indicator. The busy indicator remains on during the printing portion of the entire processing interval. If a print error is detected, line spacing is suppressed and the error indicator is turned on when printing terminates (at the end of the printing portion of the cycle). The status of either indicator can be tested by a PCB instruction. However, the print error indicator should be tested after the control unit busy indicator is found to be off and before a subsequent print instruction addresses the same control unit ( $\bar{a}$ new print operation will automatically reset the error indicator).
2. Continuous printing at the rated printing speed can be achieved if a print instruction is issued before the preceding print operation terminates. However, to avoid stalling the central processor, a new print instruction should be initiated during the line-spacing portion of a print operation.
3. The performance of the system is unspecified if the programmer attempts to manipulate the contents of the print image area during the line-printing interval.

## Use of the PCB Instruction

This instruction tests the status of the printer as specified in control character 3. If the condition tested exists, the program branches to the location specified by the address field of the instruction.

Timing. 7 cycles, minimum.

Table X. Summary of Printer PCB Functions (Series 222)

| Control Character C3 <br> (Octal) | Test Function |
| :---: | :--- |
| 10 | Branch if device busy. <br> Branch if print error. <br> Branch if channel two of <br> the format tape was the <br> last channel in which a <br> hole occurred (end of <br> form). |
| 02 | Branch if channel one of <br> the format tape was the <br> last channel in whicha hole <br> occurred (head of form). |

## Notes

The first I/ O control character (Cl) is used to test the status of a read/write channel. If an RWC status test is not desired, Cl must be zero.

Use of the PDT Instruction
This instruction causes the contents of the main memory area whose initial location is specified in the address field to be printed. The operation is terminated when a complete print image has been printed or when the specified number of words has been transferred.

Timing. 7 cycles, minimum.

Table XI. Summary of Printer PDT Functions (Series 222)

| Control Character C3 (Binary) | Operation |
| :---: | :---: |
| 00 nnnn | Print, then space the number of lines specified by nnnn (0-15). |
| 01 nnnn | Print, then space to channel one of the format tape (head of form) if channel two of the format tape (end of form) is sensed; otherwise space the number of lines specified by nnnn ( $0-15$ ). |
| 11 nnnn | Do not print; space the number of lines specified by nnnn (0-15). |
| 100xxx | Print, then space to channel xxx. |
| 101 xxx | Do not print; space to channel xxx. |
| xxx: |  |
| 000 | Channel 3 |
| 001 | Channel 4 |
| 010 | Channel 5 |
| 011 | Channel 1 (head of form) |
| 100 | Channel 6 |
| 101 | Channel 7 |
| 110 | Channel 8 |
| 111 | Channel 1 (head of form) |

## SECTION VIII

PERIPHERAL DEVICES

## DIRECT INPUT/OUTPUT DEVICES

Devices that may be connected to the direct input/output channel include the Model 309 Paper Tape Reader ( 300 characters per second) , the Model 310 Paper Tape Punch (120 characters per second), and the Model 320 Keyboard Printer ( 10 characters per second).

PAPER TAPE READER, MODEL 309
The Model 309 Paper Tape Reader is capable of reading up to 300 characters per second. The reader stops on a single character. Standard five-, six-, seven-, or eight-channel (plus sprocket channel) tapes may be used. Tapes may be dry, oiled, or Mylar* and may have up to $40 \%$ transmissivity. The reader can be adjusted to operate with tapes of from .0025 to .008 inches thickness. The variable tape guides may be adjusted to $11 / 16,7 / 8$, or 1 inch tape width.

PAPER TAPE PUNCH, MODEL 310
The Model 310 Paper Tape Punch is capable of punching 120 characters per second. Standard five-, six-, seven-, or eight-channel (plus sprocket channel) tapes may be used. Tapes may be dry, oiled, or Mylar. The variable tape guides may be adjusted to $11 / 16$, $7 / 8$, or 1 inch tape width. The supply and take up reels accommodate up to 1,000 feet of tape.

## KEYBOARD PRINTER, MODEL 320

The Model 320 Keyboard Printer consists of a keyboard and a page printer which operates at the rate of 10 characters per second. The keyboard printer may be used to interrogate the contents of memory and to start and stop programs. The page printer produces a printed record of communication with the central processor.

## BUFFERED INPUT/OUTPUT DEVICES

Buffered input/output devices operate semi-independently of the central processor. That is, after they have been addressed by an instruction, these devices require access to main memory only during data transfer. Data validity checks and hardware checks are performed by the control units and do not interrupt computing.

[^3]The buffered input/output devices are used with one or more read/write channels, as described in Section II. Generally, each device is connected to the central processor by means of its own control unit. ${ }^{l}$ Any configuration of peripheral controls can be connected to the buffered input/output trunks according to the following rules:

1. Any trunk can be connected to an input control.
2. Any trunk can be connected to an output control.
3. Two trunks must be connected to any control that is used for both input and output (e.g., a magnetic tape control).

The trunks are the half-duplex type, each capable of both input and output but not both simultaneously.

## MAGNETIC TAPE UNIT, SERIES 204

Magnetic tape (and its associated tape control) provides compact storage and high-speed data transfer in response to programmed instructions. It is used for high-speed input of programs and data files, for temporary storage of intermediate computations, and for storage of output. The $1 / 2$-inch and the $3 / 4$-inch tape units are summarized in the following tables.
Detailed programming considerations for the $1 / 2$-inch tape units are presented in Section VII.

## Operating Characteristics

A magnetic tape unit operates in the following manner:

1. A programmed instruction prepares the tape unit to transfer or receive data. The instruction addresses a specific unit, designates the direction of transfer (read or write), and indicates the memory location at which the transfer is to begin. The magnetic tape control directs the operation from this point.
2. Data transfer proceeds until an interrecord gap is sensed on the tape or until the number of words specified by the programmer have been transferred. The transferred block of information is called a record.

[^4]Table XII. I/2-Inch Magnetic Tape Units, Series 204B

| Characteristics | $\begin{gathered} \text { Model } \\ 204 \mathrm{~B}-1,2 \end{gathered}$ | $\begin{gathered} \text { Model } \\ 204 \mathrm{~B}-3,4 \end{gathered}$ | $\begin{gathered} \text { Model } \\ \text { 204B-5 } \end{gathered}$ | $\begin{array}{r} \text { Model } \\ 204 \mathrm{~B}-6 \end{array}$ | $\begin{array}{r} \text { Model } \\ 204 \mathrm{~B}-7 \end{array}$ |

PAPER TAPE READER AND CONTROL, MODEL 209
The Model 209 Paper Tape Reader and Control reads paper tape at the rate of 600 frames (characters) per second in response to programmed instructions. The control unit can be programmed to process either codes of 5 to 6 levels or codes of 7 to 8 levels. This facility minimizes the amount of central processor time required for data transfer when 5-or 6-level codes are used. Paper tape is an ideal medium for recording data that originates at locations distant from the central processor. Paper tape can be used to record data originating from a variety of source devices each having its own data transfer characteristics.

## Operating Characteristics

The reader operates as follows:

1. A programmed instruction prepares the reader to read tape in the forward or reverse direction. The control directs the operation from this point.
2. Information is transferred in the transcription mode: a punch in the tape generates a binary $l$ in memory and an unpunched position generates a
binary 0. Information is transferred to the control a frame at a time until a stop character is encountered or until the number of words specified by the programmer have been transferred.
3. The stop distance is less than the length of a frame. Tape can be rewound by program or run out manually.

## Checking

Frame parity can be checked by the program when frames are read into memory. The reader can also be equipped to check each frame for odd or even parity and to set a programaccessible indicator if this check fails.

Table XIV. Paper Tape Reader and Control, Model 209

| Tape Speed | 60 inches per second |
| :---: | :---: |
| Recording Density | 10 frames per inch. |
| Transfer Rate | 600 characters per second. |
| Transfer Time | $0.437 \mu \mathrm{~s}$ for 5 - or 6 -level characters; $0.875 \mu \mathrm{~s}$ for 7 - or 8-level characters. |
| Cycle Time | 1.667 ms |
| Cycle Available For Other Operations | 99.9\%. |
| Code | 5- through 8-level. Transcription mode. |
| Checking | Parity read into memory for program check. Optional reader check for odd or even parity. |
| Programmed Operations | Read tape forward or backward until stop character or until character count, rewind, and runout. |
| Tape Type | 5- through 8-channel $11 / 16^{\prime \prime}, 7 / 8^{\prime \prime}$, or $l^{\prime \prime}$ chadded tape in rolls up to 700 feet or in strips; dry or oiled paper, Mylar*, metallic. |
| Mechanism | Photoelectric. |
| *Mylar is a registered trademark of E. I. DuPont de Nemours and Co., Inc. |  |

## PAPER TAPE PUNCH AND CONTROL, MODEL 210

The Model 210 Paper Tape Punch punches alphanumeric information at the rate of 120 frames per second. The control unit can be programmed to process either codes of 5 to 6 levels or codes of 7 to 8 levels. This facility minimizes the amount of central processor time required for data transfer when 5 - or 6-level codes are used.

## Operating Characteristics

The punch operates as follows:

1. A programmed instruction prepares the punch to punch the contents of an output area onto tape. The control directs the operation from this point.
2. Information is transferred in the transcription mode: a binary lin memory generates a punch in the tape, and a binary 0 generates no punch. Information is transferred a frame at a time until a stop character is encountered or until the number of words specified by the programmer has been transferred.
3. The stop distance is less than the length of a frame.

## Checking

Data protection is achieved by means of program-generated frame parity.

Table XV. Paper Tape Punch and Control, Model 210

| Tape Speed | 12 inches per second. |
| :---: | :---: |
| Recording Density | 10 frames per inch. |
| Transfer Rate | 120 characters per second. |
| Transfer Time | $0.437 \mu \mathrm{~s}$ for 5 - or 6 -level characters; $0.875 \mu \mathrm{~s}$ for 7- or 8-level characters. |
| Cycle Time | 8.33 ms . |
| Cycle Available For Other Operations | 99.9\% |
| Code | 5- through 8-level. Transcription mode. |
| Checking | Data protection by means of program-generated frame parity. |
| Programmed Operations | Punch contents of output area onto tape. |
| Tape Type | 11/16', 7/8', or $1^{\prime \prime}$ non-metallic tape in reels up to 700 feet. |
| Mechanism | Die punch. |

PRINTERS AND CONTROLS, SERIES 222

Models 222-1, -2, - 3
These printers produce single-spaced copy at the rate of 650 lines per minute using a standard set of 51 characters. The three models are identical except for the number of print positions available.

Model 222-4 Printer

## Model 222-4

This printer produces single-spaced copy at the rate of 950 lines per minute using a standard set of 46 characters. By means of a manual control, the drum speed can be reduced to produce 633 lines per minute where extra fine print quality is required.

## Operating Characteristics (All Models)

1. A programmed instruction prepares the printer to print. The printer control directs the print operation from this point.
2. The printer control buffers the electronic speed of the central processor with the mechanical speed of the printer, limiting central processor interruptions due to data transfers to three milliseconds out of each print cycle. Data checking to insure correct transfer of information is automatic.
3. A total of 63 characters is available at each print position. Included are 26 alphabetic, 10 numeric, and 27 special characters. The characters are embossed on a drum in 63 axial rows. During print operations, the drum revolves at a constant speed, moving each row of characters past the print hammers. When the desired row passes the hammers, they are actuated and the characters are printed.

The print line contains 10 characters per inch. Manual selection of six or eight lines per inch vertical spacing is provided. Paper advance is under control of the program and/or an eight-channel paper tape loop. Form widths from 4 to $18-3 / 4$ inches are acceptable. Up to eight clean carbon copies can be printed, depending on the thickness of the stock. The type drum can be changed by an operator in two minutes to permit the use of another type drum having more or fewer print positions per line or a different type font.

Table XVI. Printers, Series 222

| Characteristics | Model 222-1 | Model 222-2 | Model 222-3 | Model 222-4 |

| Format Control | Paper tape loop |  |  |
| Reproducing <br> System | Hammer stroke against embossed drum |  |  |

CARD READER, MODEL 223
The Model 223 Card Reader reads standard 80 -column cards at a speed of 800 per minute by an end-feed process. This is a Honeywelldeveloped photoelectric device employing solidstate circuitry throughout.

## Operating Characteristics

The reader operates as follows:

1. Card acceleration begins immediately when the control receives a card read instruction. That is, the control does not have to wait for a clutching point in the operating cycle of the reader.
2. The card is read a column at a time by 12 photoelectric cells. Data transfer interrupts the central
 processor for 35 microseconds; computing may proceed during $99.9 \%$ of the 75 millisecond card read cycle.
3. The card passes to the output stacker and is stacked normally, or, if it is rejected, it is offset.

Cards may be loaded into the 3,000 -card input hopper or removed from the 2,500 -card output stacker without stopping the reader. Hollerith code is standard. Direct transcription is optional and is specified by program.

## Checking

Accuracy of input data is monitored by a validity check and a cycle check. The validity check detects illegal punches, and the cycle check detects failure of the photo-sensing system. Either type of failure automatically sets an indicator which may be tested by the program.

Table XVII. Card Reader, Model 223

| Reading Speed | 800 cards per minute. |
| :---: | :---: |
| Transfer Rate | 1,066 characters per second. |
| Cycle Time | 75 ms. |
| Cycle Available For Other Operations | 74.9 ms . |
| Code | Hollerith. Direct transcription is optional. |
| Checking | Hardware detection of illegal punches and of photosensing failure. Failure sets an indicator. |
| Programmed Operations | Read. |
| Card Type | 80- or 51-column. |
| Mechanism | Photoelectric reading. |

## CARD PUNCHES, SERIES 224

The punching speed of 224 series depends on the number of columns punched. The range for the model $224-1$ is from 50 cpm when all 80 columns are punched to 176 cpm when only the first ten columns are punched. Punching speed of the model 224-2 ranges from 9 l cpm when all 80 columns are punched to 265 cpm when only the first 10 columns are punched. As the number of columns punched decreases, punching speeds increase proportionately provided that the punched columns are grouped at the left side of the card.

## Operating Characteristics

The punch operates as follows:

1. A programmed instruction prepares the card punch to punch a card. The card punch control directs the punch operation from this point.
2. The card passes through a punch station. Information is punched onto the card column by column, beginning with column l. For both models, data transfer from the central processor interrupts computing for no more than 35 microseconds times the number of (left-justified contiguous) columns punched. Thus, computing proceeds during $99.9 \%$ of the card punching cycle.
3. The card is placed in one of two output stackers. The second stacker is optional on the model 224-1.

Either model may be equipped with a punch-feed read option which permits punching of additional information onto cards already containing information.

## Checking

An echo check in the 224-1 senses which punch dies have been actuated and performs an automatic comparison with the data specified for punching. In the 224-2 equipped with the punch-feed read option, data protection is provided by a check for illegal card codes and a read registration check.

Tablé XVIII. Card Punch, Models 224-1, -2

| Characteristics | Model 224-1 | Model 224-2 |
| :---: | :---: | :---: |
| Punching Speed | 50 to 176 cpm | 91 to 265 cpm |
| Cycle Time | 335 to $1,210 \mathrm{~ms}$ | 222. 5 to 660 ms |
| Cycle Available For Other Operations | (cycle time) - ( $\leq .035 \mathrm{ms}$. ) |  |
| Code | Hollerith. Direct transcription is optional. |  |
| Checking | Echo check. |  |
| Programmed Operations | Punch. |  |
| Card Type | 80 -column |  |
| Mechanism | Die punch. |  |

## CARD READER-CARD PUNCH, MODEL 227

The Model 227 Card Reader-Card Punch is a dualpurpose device. The reader portion reads standard 80column cards at the rate of 800 cards per minute. The card punch is capable of operating simultaneously with the reader and punches standard 80-column cards at the rate of 250 cards per minute.

## Operating Characteristics

The reader, which is on the right in the above
illustration, operates as follows:

1. A programmed instruction prepares the card reader to read a card. The card reader control directs the read operation from this point.
2. The card passes under two read stations. The first station counts the holes in the card for checking purposes. The second station reads the data from the card into the control.
3. The second read station also counts the holes in the card. This hole count is compared with the count obtained by the first read station. If the two counts are not equal, an error indicator is set which can be tested by the program.
4. The card is ejected into one of three output stackers.

The card punch, which is on the left in the above illustration, operates as follows:

1. A programmed instruction prepares the card punch to punch a card. The card punch control directs the punch operation from this point.
2. The card passes through a punch station consisting of 80 punch dies. The card is punched as directed by information transferred from memory.
3. The card is ejected into one of three output stackers.

The punch can be equipped with a punch-feed read option which permits punching of additional information into cards already containing information.

Table XIX. Card Reader - Card Punch, Model 227

| Speed (Cards/Minute) | Reading: 800. Punching: 250. |
| :---: | :---: |
| Cycle Time | Reading: 75 ms . Punching: 240 ms . |
| Cycle Available For Computing | Reading: 74.6 ms . Punching: 239.6 ms . |
| Code | Hollerith. Direct transcription is optional. |
| Checking | Illegal punch check on reading. Hole-count check on punching. |
| Programmed Operations | Read, Punch, Stacker Select. |
| Card Type | 80-column. |
| Mechanism | Reader: electromechanical. Punch: die punch. |

MICR SORTER-READER CONTROL, MODELS 233-1, - 2
Magnetic Ink Character Recognition (MICR) is a data input medium which was developed to enable data processing systems to handle such banking applications as check processing more efficiently. The MICR system permits direct entry of data into the computer without the necessity of converting it to another medium such as punched cards. Two types of MICR controls are offered. Model 233-1 is used in conjunction with an MICR sorter-reader capable of reading magnetically imprinted card or paper documents at the rate of 1600 documents per minute. The central processor stores the data, updates accounts, prepares reports, analyzes the data, and sorts the documents under program control. The model 233-2 performs the same functions in conjunction with an MICR sorter-reader capable of reading 1560 documents per minute.

RANDOM ACCESS DISC STORAGE

## AND CONTROL, SERIES 260

A Series 260 Random Access Disc Unit permits random access to any record in a file. (This is in direct contrast to the sequential access characteristic of magnetic tape.) Disc storage units are suited to applications requiring high-speed access and very large storage capacity. Each unit can be equipped with up to 24 magnetic discs, providing a storage capacity of up to 100.66 million characters.

## Operating Characteristics

1. A programmed instruction prepares the disc file for an information transfer. The instruction specifies an area on a disc, specifies the type of transfer (read or write), and indicates the memory location at which the transfer is to begin. The control unit directs the operation from this point.
2. Information transfer proceeds until an inter-record gap is sensed or until the number of words specified by the programmer have been transferred.

Table XX. Random Access Disc Units, Series 260

| STORAGE CAPACITY | 1 to 6 discs, each capable of storing $4,194,304$ characters, expandable to 12,18 , or 24 discs. |
| :---: | :---: |
| HEAD POSITIONING (track to track) | 60 milliseconds minimum. |
| LATENCY | 33.3 milliseconds average. |
| TRANSFER RATE | 23,550 to 64,300 characters per second. |
| DATA FORMAT | 128-character records standard, longer records can be handled. |
| CHECKING | Parity check. |
| PROGRAMMED OPERATIONS | Search and read, Search and write. |
| CODE | Same as central processor code. |
| DISC SPEED | 900 rpm . |

## RANDOM ACCESS DRUM STORAGE <br> AND CONTROL, SERIES 270

A Model 270 Random Access Drum Unit permits random access to any record in a file. Because of its extremely high access and transfer speeds, the drum storage unit is used in systems in which speed rather than capacity is a
 governing factor.

## Operating Characteristics

1. A programmed instruction prepares the drum for an information transfer. The instruction specifies an area on the drum, specifies the type of transfer (read or write), and indicates the memory location at which the transfer is to begin. The control unit directs the operation from this point.
2. Information transfer proceeds until an inter-record gap is sensed or until the number of words specified by the programmer have been transferred.

Table XXI. Random Access Drums, Series 270

| AVERAGE ACCESS TIME | 27.5 milliseconds. |
| :--- | :--- |
| TRANSFER RATE | 102,000 characters per second. |
| STORAGE CAPACITY | $2,621,440$ characters per drum; up to eight drums <br> per control. |
| DRUM SPEED | 1200 rpm. |
| RECORDING DENSITY | 580 bits per inch. |
| FILE PROTECTION | Protect/Permit switch. |
| DATA FORMAT | Variable-length records. |
| CHECKING | Parity checking. |
| PROGRAMMED OPERATIONS | Search and Read, Search and Write. |

## SINGLE-CHANNEL COMMUNICATION CONTROLS, SERIES 281

The Series 281 Communication Controls enable the central processor to receive and transmit data over a single toll or leased-wire line. The operations performed by the control include establishing synchronization with the remote equipment, controlling the flow of data between the central processor and the remote equipment, translating the Honeywell and communications codes, and implementing parity checking. The central processor is equipped with a priority interrupt system which automatically tests for the presence of incoming data or the readiness of the communication control to transmit data.

Table XXII. Single-Channel Communication Control, Series 281

| Model <br> Number | To Be Used With |  |  |  | Notes |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Service \& Line | Data Set | Speed | Terminal |  |

## MULTIPLE-CHANNEL COMMUNICATION CONTROL, SERIES 284

The Model 284 Communication Control enables the central processor to receive and transmit data over toll or leased-wire lines. The operations performed by the control include establishing synchronization with the remote equipment, controlling the flow of data between the central processor and the remote equipment, translating Honeywell and communications codes, and implementing parity checking. The central processor's priority interrupt system automatically tests for the presence of incoming data or the readiness of the control to transmit data. The control employs a series 285 Communication Adapter as interface between the control and each communication line. The basic control serves two communication lines. The following features are available for use with it:

| Feature | Description |
| :---: | :--- |
| $085-1$ | Expansion feature. Expands 284 line-handling capability <br> by l line. Up to 3 may be connected to a 284. |
| $085-13$ | Expansion feature. Expands 284 line-handling capability <br> by l3 lines. <br> $085-61$ <br> 086 <br> Expansion feature. Expands 284 line-handling capability <br> by 61 lines. <br> Parity check on reception and parity generation on trans- <br> mission. One per 284. <br> Long check. One per 284. Available only with 085-13 or <br> $085-61$. |

Expansion features (085-1, 085-13, 085-61) of different types cannot be attached to a single 284.

Figure 7. Multiple Communication Control, Series 284

## COMMUNICATION CONTROL ADAPTER, SERIES 285

When the 284 multiple-channel control is used, each communication line requires its own series 285 adapter unit as an interface between the control and the signal requirements of the communication line.

## FAMILY INTERFACE UNITS

The family interface (switching) units enable various combinations of Honeywell systems (H-200, H-2200, H-300) to share the same set of peripheral controls and devices and/or communications lines, to transfer data from memory to memory, and to switch various peripheral units among the peripheral control units of a single system.

## MAGNETIC TAPE SWITCHING UNITS, SERIES 205

The Model 205 Magnetic Tape Switching Unit switches a set of tape units between two tape controls, allowing the corresponding two computers to share one set of tape units (see Figure 11). A set may consist of up to eight $1 / 2$-inch tape units or up to four 3/4-inch tape units. All tape units connected to a switching unit are switched simultaneously.

As many tape units can be attached to a tape control by means of a switching unit as can be connected to the control directly (viz., eight $1 / 2$-inch tape units or four 3/4-inch tape units).

Up to eight switching units may be attached to a 203B (l/2-inch) tape control, and up to four switching units can be attached to a 203A (3/4-inch) tape control.

Conditions for switching are as follows:

1. An H-200, 2200, or 300 must be involved.
2. Only Honeywell tape units can be switched.
3. 3/4-inch and $1 / 2$-inch tape units cannot be intermixed on one switching unit.
4. If a switching unit is used with a $203 \mathrm{~B}-1$ tape control, and any one of the tape units connected to that control is not connected via the switching unit, all tape units attached to that control, either directly or by way of a switching unit, must be primary units.

Figure 8. Magnetic Tape Switching Units, Series 205

ON-LINE ADAPTER, MODEL 212-1
The Model 2l2-1 On-Line Adapter provides bi-directional data transfer between two central processors which may be any combination of $\mathrm{H}-200$, $\mathrm{H}-2200$, and $\mathrm{H}-300$ central processors. Data transfers are initiated and monitored under program control by means of standard input/output instructions. Data transfer is in one direction at a time at the rate of 167, 000 characters per second. Completion of the data path between the adapter and the two central processors is by means of read/write channels, as illustrated below.

COMMUNICATION SWITCHING UNITS, SERIES 215
A Model 215-1 or - 2 Communication Switching Unit switches either one group of communication lines between two model 284 Communication Controls (each of which is connected to its own H-200, H-2200, or H-300), or else it switches one such 284 between two groups of communication lines, as illustrated below, where a group contains up to eight lines.

Figure 9. Communication Switching Unit, Models 215-1, - 2

Each communication line requires its own series 285 adapter unit. The model 215-1 switching unit is used with the model 285-1 and -2 adapters, and the model 215-2 is used with the model 285-3 and -4 adapters.

By adding the appropriate 083 or 084 expansion features, the group switching capability can be expanded in increments of eight lines up to a total of 63 lines. All lines connected to a switching unit are switched simultaneously.

PERIPHERAL CONTROL SWITCHING UNITS, SERIES 216
The Models 216-1 and - 2 Peripheral Control Switching Units allow two central processors, which may be any combination of $\mathrm{H}-200, \mathrm{H}-2200$, and $\mathrm{H}-300$, to share the same set of peripheral controls and devices.

The model 216-1 switching unit accepts from one to eight standard peripheral controls (maximum of eight input/output assignments). In certain cases, attachment of a second 216-1 is possible and may be deemed practical. All units attached are switched simultaneously.

The basic model 216-2 unit also accepts from one to eight standard peripheral controls (maximum of eight input/output assignments), but up to three 053 modules can be added, each handling the switching of from one to eight standard peripheral controls. Each module and the basic unit may be switched independently, while all control units handled by any one such switching unit are switched simultaneously. In certain cases, an additional 216-2 (and 053 modules) may be added to the system for a total of eight switching units and even greater system flexibility.

## APPENDIX A

TWOS-COMPLEMENT ARITHMETIC

## COMPLEMENTATION

Two types of complements are commonly used for a number of given radix. ${ }^{l}$ These are the radix-minus-l complement and the true complement. It is the purpose of this appendix to demonstrate the distinction between the two and the use which the H-300 makes of the true complement.

TO FIND THE RADIX-MINUS-1 COMPLEMENT, SUBTRACT EACH DIGIT FROM THE RADIX MINUS 1. In the decimal system, the radix minus 1 is 9 . To find the radix-minus -1 complement of decimal 44, subtract 44 from 99, giving 55. A convenient property of the binary number system is that the radix-minus-l complement may be generated by changing all 0 's to l's and all l's to 0's, as illustrated below.

Specifically, the radix-minus-l complement of a binary number is called the ones complement, the radix-minus-l complement of an octal number is called the sevens complement, and the radix-minus-l complement of a decimal number is called the nines complement.

TO FIND THE TRUE COMPLEMENT OF A NUMBER, ADD 1 TO ITS RADIX-MINUS-1 COMPLEMENT. As demonstrated above, the radix-minus-l complement of decimal 44 is 55; adding $l$ by the rules of decimal addition gives 56 , which is the true complement of decimal 44. Likewise, the true complement of binary 100 is 011 plus l, which, by the rules of binary addition, is binary 100.

Specifically, the true complement of a binary number is called the twos complement, the true complement of an octal number is called the eights complement, and the true complement of a decimal number is called the tens complement.

## TWOS-COMPLEMENT NOTATION

To clarify some essential properties of twos-complement numbers and twos-complement

[^5]arithmetic, a four-bit word is used below as a frame of reference. The properties of this word that are discussed apply as well to the 24 -bit Honeywell 300 word. The numbers that can be represented by a four-bit word are listed in Table A-1 below.

Table A-1. Twos-Complement Notation

| Decimal Number | Binary <br> Number | Decimal Number | (2's Complement) Binary Number |
| :---: | :---: | :---: | :---: |
| +7 +6 +5 +4 +3 +2 +1 +0 | $\begin{array}{llll} 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{array}$ | - 8 <br> - 7 <br> - 6 <br> - 5 <br> - 4 <br> - 3 <br> - 2 <br> $-1$ | $\begin{array}{llll} 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \end{array}$ |

The table shows that positive numbers are represented in main memory in pure binary, as distinguished from twos-complement binary. The high-order bit is always zero and can be interpreted as a plus sign. The rest of the word can be interpreted directly from binary to decimal using the rules of positional notation. For example, 0111 may be interpreted as plus $710^{\circ}$

There is only one zero in twos-complement notation. Therefore zero ambiguity is impossible.

Negative numbers are represented in twos-complement form. The high-order bit is always $l$ and can be interpreted as a minus sign. Such numbers, including the sign bit, must be recomplemented if they are to be interpreted directly from binary to decimal using the rules of positional notation. Any of the following equivalent methods may be used:

1. RECOMPLEMENT THE BINARY NUMBER (take the true complement). That is, invert all l's to 0 's and all 0 's to l's. Then add 1 to the low-order bit.
2. UNCOMPLEMENT THE BINARY NUMBER. That is, subtract from the loworder bit using the rules of binary subtraction. Then invert all l's to 0's and all 0 's to l's.
3. BINARY TRUE COMPLEMENTATION. Beginning with the low-order bit position, proceed to the high-order end of the number as follows. If the bit is 0 or the first-encountered l, put it in the corresponding position of the result; else invert it and put it in the corresponding position of the result.
4. OCTAL TRUE COMPLEMENTATION. Beginning with the low-order octal digit, proceed to the high-order end of the number as follows. If the digit is 0 , put it in the corresponding position of the result; else take the 8's complement of it, and take the 7 's complement of the remaining (higherorder) digits.
5. GENERAL TRUE COMPLEMENTATION. Beginning with the low-order digit, proceed to the high-order end of the number as follows. If the digit is 0 , put it in the corresponding position of the result; else take the true complement of it, and take the radix-minus-l complement of the remaining (higher order) digits.

## TWOS-COMPLEMENT ARITHMETIC

One of the advantages of twos-complement notation is that negative numbers stored in memory as twos-complement operands can be added together as full-word, unsigned integers during arithmetic operations. Yet the high-order bit of the result can be interpreted as the sign of the result, with the qualification, stated above, that a negative result must be recomplemented if it is to be interpreted directly by the rules of positional notation.

The first example in Figure A-l illustrates subtraction as it is normally performed using decimal arithmetic. The second example shows that the same problem can be solved by adding the true complement of the subtrahend instead of by subtracting the subtrahend itself. And the third example demonstrates that the same principle applies to binary numbers. Note that, when subtraction is performed by adding the true complement, all operands must have the same number of digits. The need for this can be understood by observing that the complement of, for example, $100_{2}$ is not identical to the complement of 01002 .

| Third Example: Binary Subtract by True Complementation |
| :---: |
| 1. Complement Subtrahend |
| 2. Add to Minuend $\begin{array}{lrl}\begin{array}{l}\text { minuend: } \\ \text { complemented }\end{array} & 1010=10 \\ \text { subtrahend: }\end{array} \quad \frac{+1100}{10110}$ |
| 3. Discard High-Order Carry <br> difference: $0110=6_{10}$ |

Figure A-1. Twos-Complement Arithmetic

The following examples illustrate the way in which the $\mathrm{H}-300$ performs arithmetic operations. Again, a four-bit word is used for brevity.

Example 1: $7+(-8)=-1$
Assume that -8 has been loaded into the accumulator ( $A$ ) and that +7 has been stored at address $x$. Then, using the $A D D$ (Add to Accumulator) instruction, (A) plus (x) replace (A) as follows:
(A):

1000 ("-8")
(x):
$0111(+7)$
new (A):
1111 ("-1")
The result, $111 l_{2}$, is minus one according to the twos-complement collating sequence (Table A-1). The quotation marks merely indicate that the number is in its twos-complement form.

Example 2: 2-(+3) = - 1
Assume that the minuend, +2 , is in the accumulator ( $A$ ) and that the subtrahend, +3 , has been stored at address $x$. Then, using the SUB (Subtract from Accumulator) instruction, the contents of $x$ are twos-complemented:
(x):
$0011(+3)$
complemented ( x ):
1101 ("-3")

The complemented subtrahend is then added to the contents of the accumulator. The sum replaces the contents of the accumulator.

| (A): | $0010(+2)$ |
| :--- | :--- |
| complemented (x): | $\left.\frac{1101}{(\prime \prime}-3^{\prime \prime}\right)$ |
| new (A): | $1111\left({ }^{\prime \prime}-1\right)$ |

## APPENDIX E

## OCTAL-DECIMAL FRACTION CONVERSION TABLES

The octal/decimal fraction conversion table is in two parts. The first part lists three octal digits of precision. The second part lists six octal digits of precision, the first three of which are always zero. Used together, these tables provide a fraction conversion capability of six digits.

| EBR | Equalize Bank Register (NAD) | 1 | 1 | 40 |
| LBR | Load Bank Register (NAD) | 1 | 1 | 40 |
| SBR | Store Bank Register | 2 | 2 | 41 |

Floating-Point Instructions

| FAD | Floating Add | $4+\frac{S}{7}$ | $4+\frac{S}{7}$ | 42 |
| :---: | :---: | :---: | :---: | :---: |
| FDV | Floating Divide | 26 | 26 | 42 |
| FMP | Floating Multiply | $9+\frac{S}{7}$ | $9+\frac{S}{7}$ | 42 |
| FSB | Floating Subtract | $4+\frac{S}{7}$ | $4+\frac{S}{7}$ | 43 |
| FUL | Floating Unload | 4 | 4 | 44 |
| Multiply/Divide Instructions |  |  |  |  |
| DIV | Divide | 12 | 12 | 41 |
| MPY | Multiply | 4 | 4 | 41 |
| Input/Output Instructions, Buffered |  |  |  |  |
| PCB | Peripheral Control and Branch | $3+4 w$ | $3+4 w$ | 44 |
| PDT | Peripheral Data Transfer | $3+4 w$ | $3+4 w$ | 47 |

Notes:

1. Where two timings are listed, the smaller one applies when the instruction does not branch.
2. The variable (s) in the Shift instruction timing represents the number of binary shifts specified in the instruction word.
3. The variable (w) in the Multiple Transfer instruction timing represents the number of words transferred.
4. The variable (S) in the floating-point timings represents the number of shifts required to justify the operands and/or to normalize the result.
5. The variable ( w ) in the timing formulas for the Peripheral Data Transfer and the Peripheral Control and Branch instructions represents the number of words containing the control characters.

The following additions and corrections apply to the Honeywell 300 Programmers' Reference Manual, DSI-297, effective immediately.

1. Page 5. Under "Standard Peripheral Control," the third sentence now reads as follows: "Up to seven additional peripheral controls servicing up to 508 additional devices may be attached to the direct input/output channel."
2. Page 15. Under "INDEXED ADDRESSING," the first sentence should read: "When indexed addressing is used, the variant character of the instruction word has a value of from one to six, specifying one of the six 24 -bit index registers."
3. Page 16. Under "EXPANDED MEMORY ADDRESSING," the fourth sentence should read: "The instructions are divided into two sets: those whose address field normally references the sequence register (namely, BAR, DJX, EXC, JAN, JAP, JAZ, JIX, JMP, SBR, STS, and $P C B$ ) and those whose address field normally references data (thatis, allother instructions).
4. Page 19. Under "Mnemonic Operation Code" the instructions having an octal variant of zero are: PAS, EBR, LBR, and RSS.
5. Page 20. Under "Mnemonic Operation Code" the instructions having an octal variant of seven are SRB and HLT. The first sentence should read: "Instructions having the same operation code and variant character (e.g., PAS, EBR, LBR, and RSS) are differentiated by means of bits in the address field of the instruction word."
6. Page 21. The HTJ instruction is deleted and is replaced by the following instruction. The HTJ entry in the index on page 105 is changed to HLT.

HLT - Halt (NAD)

An interruptable halt occurs. That is, an interrupt signal can cause a subsequence.
Timing. 1 cycle.
7. Page 26. Add the following instruction before the DJX instruction. The index on page 105 is updated accordingly.

AIX - Augment Index Immediate

The contents of register $v$ are incremented by $x$. The result replaces the contents of that register.

Timing. 1 cycle.
8. Page 26. Add the following instruction at the bottom of the page. The index on page 105 is updated accordingly.
SXI - Skip Immediate on Index High

If the contents of register $v$ are greater than $x$, (SR) are incremented by two (thus the next instruction is skipped); else (SR) are incremented by one.

Timing. 1 or 2 cycles.
9. Page 28. In the SKC instruction word diagram, bit positions 10 through 15 constitute the control field. Bit positions 16 through 24 constitute the address field.
10. Page 30. The SRB instruction word diagram contains a 1 bit in position 10.
11. Page 36. Insert the following instruction after the MTR instruction. The index on page 106 is updated accordingly.

RSS - Restore Status (NAD)

For each of bits 13-24 of $x$, if the bit is one, the corresponding indicator is set if installed in the system. The indicators are:

Bank Register
Carry
Divide Overcapacity
Exponential Overflow
Exponential Underflow
Overflow
Timing. 1 cycle.
12. Page 37. Delete the STZ instruction and add the following instruction in its place. The index on page 106 is updated accordingly.
STS - Store Status

For each of the following indicators that is set, a one replaces the corresponding bit in positions 13-24 of (x). Bits 1-12 are protected. All the indicators are set to zero when the instruction has been executed. This instruction can be used to load information into the address field of the RSS instruction word. The indicators are:

Bank Register
Carry
Divide Overcapacity
Exponential Overflow
Exponential Underflow
Overflow
Timing. 2 cycles. With interlace: 1 cycle.
13. Pages 44 and 47. Opposite " $w$ " in the PARAMETER column, the paragraph under "Second Word" in the INTERPRETATION column should read: "The number of control characters in the instruction. Each four control characters require one word of storage. Note that bit 7 of the second word of the instruction must be one."

[^0]:    (A, B) are treated as one 48-bit register, as are (x, x+1). (A, B) are multiplied by

[^1]:    ${ }^{1}$ Direct transcription reading is optional. In this mode, each possible punch position is read into memory individually: those with a punch are read as 1 ; those without a punch are read as 0 .

[^2]:    1
    Direct transcription mode punching is optional. In this mode, each possible punch position is punched individually: a l-bit results in a punch, and a 0 -bit results in no punch.

[^3]:    *Mylar is a registered trademark of E. I. DuPont de Nemours and Co., Inc.

[^4]:    ${ }^{1}$ A notable exception is that up to eight $1 / 2$-inch magnetic tape units can be connected to a single tape control.

[^5]:    $\overline{1}$
    The radix of a number system is the quantity of permissible symbols in the system.
