# HP Fortran Programmer's Reference 

Second Edition

Product Number: B3909DB
HP Fortran Compiler for HP-UX
Document Number: B 3908-90003
$J$ une 2001

## Edition: Second

Document Number: B3908-90003
Remarks: Released J une 2001.

## Edition: First

Document Number: B3908-90002
Remarks: Released October 1998. Initial release.

Parts of the Itanium-based compiler were generated by the iburg codegenerator generator, described at http://www.cs.princeton.edu/software/ iburg.

## Contents

Preface ..... xix
New in HP Fortran v2.5 ..... xX
Scope ..... xxi
Notational conventions ..... xxii
Command syntax ..... xxiii
Associated documents ..... xxiv
1 Introduction to HP Fortran ..... 1
HP Fortran features .....  2
Source format .....  2
Data types .....  2
Pointers ..... 3
Arrays ..... 3
Control constructs .....  3
Operators ..... 4
Procedures. ..... 4
Modules ..... 5
I/O features ..... 5
Intrinsics .....  6
2 Language elements ..... 7
Character set .....  8
Lexical tokens ..... 9
Names ..... 9
Program structure ..... 10
Statement labels ..... 10
Statements ..... 11
Source format of program file ..... 13
Free source form ..... 13
Fixed source form .....  16
INCLUDE line ..... 19
3 Data types and data objects ..... 21
Intrinsic data types ..... 22
Type declaration for intrinsic types. ..... 24
Implicit typing ..... 28
Constants ..... 29
Character substrings ..... 36
Character strings as automatic data objects ..... 37
Derived types ..... 39
Defining a derived type. ..... 40
Sequence derived type ..... 41
Structure component ..... 41
Declaring a derived type-object ..... 43
Structure constructor ..... 43
Alignment of derived-type objects ..... 44
A derived-type example ..... 45
Pointers ..... 47
Pointer association status. ..... 48
4 Arrays ..... 51
Array fundamentals ..... 52
Array declarations ..... 54
Explicit-shape arrays ..... 55
Assumed-shape arrays ..... 56
Deferred-shape arrays ..... 58
Assumed-size arrays ..... 61
Array sections ..... 63
Subscript triplet ..... 64
Vector subscripts ..... 65
Array-valued structure component references ..... 68
Array constructors ..... 71
Array expressions. ..... 74
Array-valued functions ..... 76
I ntrinsic functions. ..... 76
U ser-defined functions ..... 76
Array inquiry intrinsics ..... 78
5 Expressions and assignment ..... 79
Expressions ..... 80
Operands ..... 80
Operators ..... 81
Special forms of expression ..... 89
Assignment ..... 95
Assignment statement ..... 95
Pointer assignment ..... 97
M asked array assignment ..... 99
6 Execution control ..... 103
Control constructs and statement blocks ..... 104
CASE construct ..... 105
DO Construct ..... 107
IF construct ..... 111
Flow control statements ..... 112
CONTINUE statement ..... 113
CYCLE statement ..... 113
EXIT statement ..... 114
Assigned GO TO statement ..... 115
Computed GO TO statement ..... 116
Unconditional GO TO statement ..... 117
Arithmetic IF statement ..... 117
Logical IF statement ..... 118
PAUSE statement ..... 118
STOP statement ..... 119
7 Program units and procedures ..... 121
Terminology and concepts ..... 122
Program units ..... 122
Procedures ..... 123
Scope ..... 123
Association ..... 124
Main program ..... 125
External procedures ..... 128
Procedure definition ..... 128
Procedure reference ..... 130
Returning from a procedure reference ..... 132
Alternate entry points ..... 133
Internal procedures ..... 135
Statement functions ..... 137
Arguments ..... 139
Argument association ..... 139
K eyword option ..... 144
Optional arguments ..... 145
Duplicated association ..... 146
INTENT attribute ..... 148
\%VAL and \%REF built-in functions ..... 148
Procedure interface ..... 151
Interface blocks ..... 152
Generic procedures ..... 154
Defined operators ..... 155
Defined assignment ..... 157
Modules ..... 161
M odule program unit ..... 161
USE statement ..... 163
Program example ..... 165
Block data program unit ..... 169
8 I/O and file handling ..... 171
Records ..... 172
Formatted records ..... 172
Unformatted records ..... 172
End-of-file record. ..... 172
Files ..... 173
External files ..... 173
Internal files ..... 174
Connecting a file to a unit ..... 175
Connecting to an external file ..... 175
Performing I/O on internal files ..... 176
Preconnected unit numbers ..... 176
Automatically opened unit numbers ..... 177
File access methods ..... 178
Sequential access ..... 178
Direct access ..... 185
Nonadvancing I/O. ..... 187
I/O statements ..... 188
Syntax of I/O statements ..... 190
I/O specifiers ..... 190
I/O data list ..... 192
ASA carriage control ..... 197
Example programs ..... 198
Internal file ..... 198
Nonadvancing I/O ..... 199
File access ..... 202
9 I/O formatting ..... 205
FORMAT statement ..... 206
Format specification ..... 207
Edit descriptors ..... 208
Character string ('...' or "...") edit descriptor ..... 210
Newline (\$) edit descriptor ..... 211
Slash (/) edit descriptor ..... 212
Colon (:) edit descriptor. ..... 212
A and R (character) edit descriptors ..... 213
$B$ (binary) edit descriptor ..... 216
BN and BZ (blank) edit descriptors. ..... 218
D, E, EN, ES, F, G, and Q (real) edit descriptors ..... 219
H (Hollerith) edit descriptor ..... 225
I (Integer) edit descriptor ..... 226
L (Logical) edit descriptor ..... 228
O (Octal) edit descriptor ..... 229
$P$ (scale factor) edit descriptor ..... 231
Q (bytes remaining) edit descriptor ..... 233
S, SP, and SS (plus sign) edit descriptors ..... 233
T, TL, TR, and X (tab) edit descriptors ..... 234
Z (hexadecimal) edit descriptor ..... 234
E mbedded format specification ..... 237
Nested format specifications ..... 238
Format specification and I/O data list ..... 239
10 HP Fortran statements ..... 241
Attributes ..... 242
Statements and attributes ..... 244
ACCEPT (extension) ..... 245

## Preface

The HP Fortran Programmer's R eference is a language reference for programmers using HP Fortran V2.0 and higher. It describes the features and requirements of the HP Fortran programming language.

The HP Fortran Programmer's Reference is intended for use by experienced Fortran programmers who are interested in writing or porting HP Fortran applications. This manual includes information on the parallel concepts and directives, as well as optimization of programs that use them.

You need not befamiliar with the HP parallel architecture, programming models, or optimization concepts to understand the concepts introduced in this book.

## New in HP Fortran v2.5

HP Fortran v2.5 introduces a port of the HP-UX PA-RISC Fortran product to the Itanium-based systems. It is source compatible between PA-RISC and Itanium. However, Itanium Fortran will not run on PARISC based systems.

The HP Fortran v2.5 features described in this reference are upgrades from the previous version of HP Fortran v2.0, including:

- Full Fortran 95 compiler (based on International ANSI/ISO standards) for Itanium-based and PA-RISC systems
- Native subset OpenMP implementation
- Object-oriented Fortran feature optimizations
- Support for math intrinsic inlining

## Scope

This guide covers programming methods for the HP Fortran compiler on machines running:

- HP-UX 11.0 and higher (PA-RISC)
- HP-UX 11i Version 1.5 (Itanium)

HP Fortran supports an extensive shared-memory programming model. HP-UX 11.0 and higher includes the required assembler, linker, and libraries.

HP Fortran fully supports the international Fortran standards informally called Fortran 90 and Fortran 95 as defined by these two standards: ISO/ IEC 1539:1991(E) and ISO/ IEC 1539:1997(E).

## Notational conventions

This section discusses notational conventions used in this book.

| bold monospace | In command examples, bold monospace <br> identifies input that must be typed exactly as <br> shown. |
| :--- | :--- |
| monospace | In paragraph text, monospace identifies <br> command names, system calls, and data <br> structures and types. |
| In command examples, monospace identifies |  |
| italic | command output, including error messages. |
| In paragraph text, italic identifies titles of <br> documents. |  |

In command syntax diagrams, italic identifies variables that you must provide.

The fol lowing command example uses brackets to indicate that the variable output_file is optional:
command input_file[output_file]
Brackets ([ ]) In command examples, square brackets designate optional entries.

Curly brackets ( $\}$ ), Pipe(|)

In command syntax diagrams, text surrounded by curly brackets indicates a choice. The choices available are shown inside the curly brackets and separated by the pipe sign (|).

The following command example indicates that you can enter either a or b:
command $\{\mathrm{a} \mid \mathrm{b}\}$

| Horizontal ellipses <br> $(\ldots)$ | In command examples, horizontal ellipses <br> show repetition of the preceding items. |
| :--- | :--- |
| Vertical ellipses | Vertical ellipses show that lines of code have <br> been left out of an example. |
| Keycap | Keycap indicates the keyboard keys you must <br> press to execute the command example. |

References to man pages appear in the form mnpgname(1), where "mnpgname" is the name of the man page and is followed by its section number enclosed in parentheses. To view this man page, type:

## \% man 1 mnpgname

NOTE
A Note highlights important supplemental information.

## Command syntax

Consider this example:
COMMAND input_file [...] \{a | b\} [output_file]

- COMMAND must be typed as it appears.
- input_file indicates a file name that must be supplied by the user.
- The horizontal ellipsis in brackets indicates that additional, optional input file names may be supplied.
- Either $a$ or $b$ must be supplied.
- [output_file] indicates an optional file name.

## Associated documents

The following documents are listed as additional resources to help you use the compilers and associated tools:

- HP aC++Online Programmer's Guide—Presents reference and tutorial information on $\mathrm{aC}+$. This manual is only available in html format.
- HP C/ HP-UX Programmer's Guide—Contains detailed discussions of selected $C$ topics.
- HP C/ HP-UX Reference M anual - Presents reference information on the $C$ programming language, as implemented by HP.
- CXperf Command Reference-Provides both introductory and reference information for using the CXperf performance analyzer.
- CXperf User's Guide—Provides information on how to use the CXperf performance analysis tool.
- HP-UX Floating Point Guide—Describes how floating-point arithmetic is implemented on HP 9000 Series 700/800 systems. It discusses how floating-point behavior affects the programmer. Additional useful includes that which assists the programmer in writing or porting floating-point intensive programs.
- HP Fortran Programmer's Guide—Provides extensive usage information, including how to compile and link, migration tips and tools, and how to call C and HP-UX routines for HP Fortran.
- HP MPI User's Guide—Discusses message-passing programming using HP's M essage-Passing Interface library.
- HP MLIB User's GuideVECLIB and LAPACK—Provides usage information about mathematical software and computational kernels for engineering and scientific applications.
- HP-UX Linker and Libraries User's Guide—Describes how to develop software on HP-UX using the HP compilers, assemblers, linker, libraries, and object files.
- Parallel Programming Guidefor HP-UX Systems-Describes efficient methods for shared-memory programming using the HP-UX suite of compilers: HP Fortran, HP aC++(ANSI C ++ ), and HP C. This guide is intended for use by experienced Fortran, C , and $\mathrm{C}++$ programmers and is intended for use on HP-UX 11.0 and higher.

Preface

## 1 <br> Introduction to HP Fortran

This chapter summarizes standard features of HP Fortran that are not found in FORTRAN 77. This includes the following topics:

- Source format
- Data types
- Pointers
- Arrays
- Control constructs
- Operators
- Procedures
- Modules
- I/O features
- Intrinsics

## HP Fortran features

The following summarizes features of HP Fortran that are not in standard FORTRAN 77 and indicates where they are described in this manual.

## Source format

The fixed source form of F ORTRAN 77 is extended by the addition of the semicolon (;) statement separator and the exclamation point (!) trailing comment.

HP Fortran also supports free format source code. The format used in a source program file is normally indicated by the file suffix, but the default format can be overridden by the + source compile-line option.
For information about source format, see "Source format of program file" on page 13.

## Data types

- Data declarations can include a kind type parameter-an integer value that determines the range and precision of values for the declared data object. The kind type parameter value is the number of bytes representing an entity of that type, except for COMP LEX entities, where the number of bytes required is double the kind type value.

In principle, multibyte character data for languages with large character sets can be implemented in Fortran by means of a kind type parameter for the CHARACTER data type. HP Fortran, however, uses the Extended Unix Code (EUC) characters in file names, comments, and string literals.

- Fortran supports derived types, which are composed of entities of the intrinsic types (INTEGER, REAL, COMP LEX, LOGICAL, and CHARACTER) or entities of previously defined derived types. You declare derivedtype objects in the same way that you declare intrinsic-type objects.

For information about intrinsic and derived types, see "I ntrinsic data types" on page 22 and "Derived types" on page 39.

## Pointers

Pointers are variables that contain addresses of other variables of the same type. Pointers are declared in Fortran 90 with the POINTER attribute. A pointer is an alias, and the variable (or allocated space) for which it is an alias is its target. The pointer enables data to be accessed and handled dynamically. For more information, see "Pointers" on page 47.

## Arrays

The Fortran 90 standard has defined these new array features:

- Array sections that permit operations for processing whole arrays or a subset of array elements; expressions, functions, and assignments can be array-valued. The where construct and statement are used for masked-array assignment.
- Array constructors-unnamed, rank-one arrays whose elements can be constants or variables. You can use the reshape intrinsic function to transform the array constructor to an array value of higher rank.
- New types of array:
- Assumed-shape arrays are dummy arguments that take on the size and shape of the corresponding actual arguments.
- Deferred-shape arrays become defined when they are associated with target array objects.
- Automatic arrays have at least one bound that is not a constant.

Arrays are discussed in Chapter 4, "Arrays," on page 51.

## Control constructs

Control constructs

- The CASE construct selects and executes one or more associated statements on the basis of a case selector value, which can be of type INTEGER, CHARACTER or LOGICAL.
- Additional forms of the do statement allow branching to the end of a Do loop and branching out of a Do loop.

Introduction to HP Fortran

## HP Fortran features

These constructs are described in "Control constructs and statement blocks" on page 104.

## Operators

You can write your own procedures to define new operations for intrinsic operators, including assignment, for use with operands of intrinsic data types or derived data types; see "Defined operators" on page 155 and "Defined assignment" on page 157.

## Procedures

- Fortran 90 includes a feature called the procedure interface block, which provides an explicit interface for external procedures. The names and properties of the dummy arguments are then available to the calling procedure, allowing the compiler to check that the dummy and actual arguments match. For information about interface blocks, see "Procedure interface" on page 151.
- Actual arguments can be omitted from the argument list or can be arranged in a different order from the dummy arguments.
- You can implement user-defined operators or extend intrinsic operators, including the assignment operator; see "Defined operators" on page 155 and "Defined assignment" on page 157.
- Dummy arguments to procedures can be given an INTENT attribute (IN, OUT or INOUT); see "INTENT attribute" on page 148.
- Subprograms can appear within a module subprogram, an external subprogram, or a main program unit; see "Internal procedures" on page 135.
- Recursive procedures (an extension in HP F ORTRAN 77) are a standard feature of Fortran 90. For more information, see "Recursive reference" on page 131.

## Modules

A module is a program unit that can be used to spedify data objects, named constants, derived types, procedures, operators, and namelist groups. Partial or complete access to these module entities is provided by the uSE statement. An entity may be declared PRIVATE to limit visibility to the module itself.

One use of the module is to provide controlled access to global data, making it a safer alternative to the COMM ON block. The module also provides a convenient way to encapsulate the specification of derived types with their associated operations.
For information about modules, see "M odules" on page 161.

## I/O features

- Nonadvancing I/O

After a record-based I/O operation in FORTRAN 77, the file pointer moves to the start of the next record. In Fortran 90, you can use the ADVANCE=NO specifier to position the file pointer after the characters just read or written rather than at the start of the next record. Nonadvancing I/O thus allows you to determine the length of a variable-length record. See "Nonadvancing I/O" on page 187 for more information.

- Namelist-directed I/O

Namelist-directed I/O—previously available as an extension to FORTRAN 77-is a standard feature of Fortran 90. This feature enables you to perform repeated I/O operations on a named group of variables. See "Namelist-directed I/O" on page 183 for more information.

Introduction to HP Fortran

## HP Fortran features

## Intrinsics

Fortran 90 provides a large number of new intrinsic procedures for manipulating arrays. Many of them are elemental, taking either scalar or array arguments. In the latter case, the result is as if the procedure were applied separately to each element of the array.

Other additions include transformational functions that operate on arrays as a whole, and inquiry functions that return information about the properties of the arguments rather than values computed from them.
Table 9 on page 78 lists the array-inquiry intrinsic functions. For descriptions of all intrinsic procedures, see Chapter 11, "I ntrinsic procedures," on page 475.

## 2 Language elements

This chapter describes the basic elements of an HP Fortran program. This includes the following topics:

- Character set
- Lexical tokens
- Program structure
- Statement labels
- Statements
- Source format of program file
- INCLUDE line

## Character set

The Fortran 90 standard character set, shown in Table 1, consists of letters, digits, the underscore character, and special characters. The HP Fortran character set consists of the Fortran 90 character set, plus:

- Control characters (Tab, N ewline, and Carriage return). Carriage return and Tab are usually treated as "white space" in a source program. You can use them freely to make the source easier to read.
- The pound sign (\#) character in column 1 to initiate a comment. This is an HP extension that allows C preprocessor directives embedded in source files to be treated as comments.
- Any other characters in the HP character set listed in Appendix B. These characters may be used in character constants, character string edit descriptors, comments, and I/O records.

## Table 1 <br> Fortran $\mathbf{9 0}$ character set

| Category | Characters |
| :---: | :---: |
| Letters | A to z , a to z |
| Digits | 0 to 9 |
| Underscore | - |
| Special characters |  |

Lowercase al phabetic characters are equivalent to uppercase characters except when they appear in character strings or H ol lerith constants.

HP Fortran supports only the default character type,
CHARACTER (KIND=1), as described in "Type declaration for intrinsic types" on page 24. Support is provided, however, for Extended Unix Code (EUC) and Shift-J IS encoding.

## Lexical tokens

Lexical tokens consist of sequences of characters and are the building blocks of a program. They denote names, operators, literal constants, labels, keywords, delimiters, and may also include the following characters and character combinations:
, $=\quad=>$ : : ; \%

## Names

In Fortran 90, names denote entities such as variables, procedures, derived types, named constants, and COM MON blocks. A name must start with a letter but can consist of any combination of letters, digits, and underscore (_) characters. As an extension in HP Fortran, the dollar sign may al so be used in a name, but not as the first character.

The Fortran 90 Standard allows a maximum length of 31 characters in a name. In HP Fortran this limit is extended to 255 characters, and all are significant-that is, two names that differ only in their 255th character are treated as distinct. Names and keywords are case insensitive: for example, Title\$23_Name and TITLE\$23_NAME are the same name.

The CASE, IF, and DO constructs can optionally be given names. The construct name appears before the first statement of the construct, followed by a colon (:). The same name must appear at the end of the final statement of the construct. For more information about these constructs, refer to "Control constructs and statement blocks" on page 104.

## Program structure

A complete executable Fortran program contains one and only one main program unit and may also contain one or more of the following other types of program units:

- External function subprogram unit
- External subroutine subprogram unit
- Block data program unit
- M odule program unit

Each program unit can be compiled separately. Execution of the program starts in the main program. Control may be passed to other program units.

The Fortran 90 program units, and the transfer of control between them, are described in Chapter 7, "Program units and procedures," on page 121.

## Statement labels

A Fortran 90 statement may have a preceding label, composed of one to five digits. All statement labels in the same scoping unit must be unique; leading zeroes are not significant. Although most statements can be labeled, not all statements can be branched to.

The format statement must have a label. The include line, which is not a statement but a compiler directive, must not have a label.

## Statements

All HP Fortran statements are fully described in alphabetical order in Chapter 10, "H P Fortran Statements."

The required order for statements in a standard Fortran 90 program unit is illustrated in Table 2. Vertical lines separate statements that can be interspersed, and horizontal lines separate statements that cannot be interspersed. For example, the DATA statement can appear among executable statements but may not be interspersed with CONTAIN statements. Also, the USE statement, if present, must immediately follow the program unit heading.

## Table 2 <br> Statement order in a program unit

| PROGRAM, FUNCTION, SUBROUTINE, MODULE, or BLOCK DATA statement |  |  |
| :---: | :---: | :---: |
| USE statement |  |  |
| FORMAT <br> and <br> ENTRY <br> statements | IMPLICIT NONE statement |  |
|  | PARAMETER statement | IMPLICIT statement |
|  | PARAMETER and DATA statements | Derived-type definitions, Interface blocks, <br> Type declarations, <br> Statement functions, and <br> Specification statements |
|  | DATA statements | Executable constructs |
| Contains statement |  |  |
| Internal subprograms or module subprograms |  |  |
| End statement |  |  |

## Language elements

## Statements

Table 2 does not show where comments, the include line, and directives may appear. Comments may appear anywhere in a source file, including after the END statement. The INCLUDE line may appear anywhere before the END PROGRAM statement.

Table 3 identifies which statements may appear within a scoping unit; a check mark indicates that a statement is allowed in the specified scoping unit. For the purpose of this table, type dedarations include the PARAMETER statement, the IMPLICIT statement, type declaration statements, derived-type definitions, and specification statements.

Table 3
Statements allowed in scoping units

| Statements | Scoping units |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\begin{aligned} & \frac{0}{5} \\ & \frac{\square}{\mathbf{O}} \\ & \frac{\square}{\Sigma} \end{aligned}$ |  |  |  |  |
| CONTAINS | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |  |  |  |
| DATA | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |  | $\checkmark$ |
| Entry |  | $\checkmark$ |  | $\checkmark$ |  |  |  |
| Executable | $\checkmark$ | $\checkmark$ |  | $\checkmark$ | $\checkmark$ |  |  |
| FORMAT | $\checkmark$ | $\checkmark$ |  | $\checkmark$ | $\checkmark$ |  |  |
| Interface block | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |  |
| Statement function | $\checkmark$ | $\checkmark$ |  | $\checkmark$ | $\checkmark$ |  |  |
| Type declaration | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| USE | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |

## Source format of program file

The HP Fortran compiler accepts source files in fixed form (the standard source form for FORTRAN 77 programs) or free form. The following sections describe both forms.

The compiler assumes that source files whose names end in the .f90 extension are in free source form and that files whose names end in the . f or . F extension are in fixed form. You can override these assumptions by compiling with the + source=free or + source=free option. See the HP Fortran Programmer's Guide for more information.
Although the two forms are quite different, you can format a Fortran 90 source file so that the compiler would accept it as either fixed or free form. This would be necessary, for example, when preparing a source file containing code that will be inserted through the include line into a file for which the form is not known. To format a source file to be acceptable as either free or fixed source form, use the following rules:

- Put labels in columns1-5.
- Put statement bodies in columns 7-72.
- Begin comments with an exclamation mark in anycolumn except column 6.
- Indicate all continuations with an ampersand character ( $\&$ ) in column 73 of the line to be continued and an ampersand character in col umn 6 of the continuing line.
- Do not insert blanks in tokens.
- Separate adjacent names and keywords with a space.

## Free source form

In free source form, the source line is not divided into fields of predefined width, as in the fixed form. This makes entering text at an interactive terminal more convenient.

Language elements
Source format of program file

## Source lines

Freeform lines can contain from 0 to 132 characters. The +extend_source option extends the line to column 254. This is described in the HP Fortran Programmer's Guide. Several statements can appear on a single source line, separated by semicolons. A single Fortran 90 statement can extend over more than one source line, as described below in "Statement continuation" on page 15.

Multiple statements may appear on the same line, separated by a semicolon (; ).

## Statement labels

Statement labels are not required to be in columns 1-5, but must be separated from the statement by at least one space.

## Spaces

Spaces are significant:

- They may not appear within a lexical token, such as a name or an operator.
- In general, one or more spaces are required to separate adjacent statement keywords, names, constants, or labels. Within the keyword pairs listed in Table 4, however, the space is optional. The keyword following END can be: BLOCK DATA, DO, FILE, FUNCTION, IF, INTERFACE, MAP, MODULE, PROGRAM, SELECT, SUBROUTINE, STRUCTURE, TYPE, UNION, Or WHERE.

## Table 4

## Keywords allowing optional spacing

```
BLOCK DATA
GO TO
DOUBLE PRECISION
IN OUT
ELSE IF SELECT CASE
END keyword
```

- Spaces are not required between a name and an operator because the latter begins and ends with special symbols that cannot be part of a name. Multiple spaces, unless in a character context, are equivalent to a single space.

Consider the spaces (designated by b) in the following statement:

```
IFbb(TEXT.EQ.'bbbYES') ... ! Valid
```

The two spaces after IF are valid and are equivalent to one space. No spaces are required before or after .EQ., because there is no ambiguity. However, the three spaces in the character constant are significant.

In the next example

```
IF(MbARY.bGE.MIKE) ... ! Faulty in free source form
```

the spaces are invalid in free source form but valid in fixed source form.

## Comments

An exclamation mark (!) indicates the beginning of a comment in free source form, except where it appears in a character context. The compiler considers the rest of the line following the exclamation mark as part of the comment. Embedding a comment inside program text within a single source line is not allowed, but it can fol low program text on a source line. A statement on a line with a trailing comment can be continued on subsequent lines.

## Statement continuation

A statement can be split over two or more source lines by appending an ampersand character ( $\varepsilon$ ) to each source line except the last. The ampersand must not be within a character constant.

A statement can occupy up to 40 source lines. As an extension, HP Fortran increases this limit to 100 source lines. The End statement cannot be split by means of a continuation line. Comments are not statements and cannot be continued.
The text of the source statement in a continuation line is assumed to resume from column 1. However, if the first nonblank symbol in the line is an ampersand, the text resumes from the first column after the ampersand.
Consider the following two statements:

```
INTEGER marks, total, difference,& ! work variables
    mean, average
INTEGER marks, total, difference, mean_& ! work variables
    &value, average
```

Language elements

## Source format of program file

The second statement declares the integer variable, mean_value. Any spaces appearing in the variable name as a result of the continuation would be invalid. This is the reason for the ampersand character in the continuation line. (Alternatively, value could have been positioned at column 1.) Using the ampersand character to split lexical tokens and character constants across source lines is permitted, but not recommended.

## Fixed source form

Statements or parts of statements must be written between character columns 7 and 72. Any text following column 72 is ignored. The + [no] extend_source option extends the statement to column 254. Columns 1-6 are reserved for special use.

Programs that depend on the compiler's ignoring any characters after column 72 will not compile correctly with the +extend_source option.

Multiple statements may appear on the same line, separated by a semicolon (; ).

## Spaces

Spaces are not significant except within a character context. For example, the two statements

RETURN
R E T U R N
are equivalent, but
c = "abc"
$c=" a b c "$
are not.

## Source lines

There are three types of lines in fixed source form:

- Initial line
- Continuation line
- Comment line

The following sections describe each type of source lines.

## Initial line

An initial line has the following form:

- Columns 1 to 5 may contain a statement label.
- Column 6 contains a space or the digit zero.
- Columns 7 to 72 (optionally, to 254) contain the statement.

## Continuation line

A continuation line has the following form:

- Columns 1 to 5 are blank.
- Column 6 contains any character other than zero or a space. One practice is to number continuation lines consecutively from 1.
- Columns 7 to 72 (optionally, to 254) contain the continuation of a statement.

The Standard specifies that a statement must not have more than 19 continuation lines. As an extension to the Standard, HP Fortran allows as many as 99 continuation lines.

## Comment line

Comment lines may be included in a program. Comment lines do not affect compilation in any way, but usually include explanatory notes. The letter c, or c, or an asterisk (*) in column 1 of a line, designates that line as a comment line; the comment text is written in columns 1 to 72. The compiler treats a line containing only blank characters in columns 1 to 72 as a comment line. In addition, a line is considered to be a comment when there is an exclamation mark (!) in column 1 or in any column except column 6.

The following are HP extensions to the comment:

- A line with D or din col umn 1 is by default treated as a comment. The + dlines option causes the compiler to treat such lines as statements to be compiled. This extension to the comment-called debugging lines-is useful for including PRINT statements that are to be compiled during the debugging stage to display the program state.

Language elements

## Source format of program file

- A line with a pound sign (\#) character in column 1 is treated as a comment. This extension allows compilation of source files that have been preprocessed with the C preprocessor (cpp).
- HP F ortran allows tab formatting. That is, a tab character may be entered in the first column of a line to skip past the statement label columns. If the character following the tab character is a digit, this digit is assumed to be in column 6, the continuation indicator column. Any other character following the tab character is assumed to be in column 7, the start of a new statement. A tab character in any other column of a line is treated as a space.

## INCLUDE line

The include line is a directive to the compiler, not a Fortran 90 statement. It causes the compiler to insert text into a program before compilation. The inserted text is substituted for the include line and becomes part of the compilable source text. The format of an INCLUDE line is:

## INCLUDE char-literal-const

where char-literal-const is the name of a file containing the text to be included. The character literal constant must not have a kind parameter that is a named constant.

If char-literal-const is only a filename (in other words, no pathname is specified), the compiler searches a user-specified path. You can use the Idir option to tell the compiler where to search for files to be included.

The include line must appear on one line with no other text except possibly a trailing comment. There must be no statement label. This means, for example, that it is not possible to branch to it, and it cannot be the action statement that is part of an IF statement. Putting a second include or another Fortran 90 statement on the same line using a semicolon as a separator is not permitted. Continuing an InClude line using an ampersand is also not permitted.
The text of the included file must consist of complete Fortran 90 statements.
include lines may also be nested. That is, a second include line may appear within the text to be included, and the text that it includes may also have an include line, and so on. HP Fortran has a maximum include line nesting level of 10 . However, the text inclusion must not be recursive at any level; for example, included text A must not include text $B$ if $B$ includes text $A$.

The following are example include lines:

```
INCLUDE "MY_COMMON_BLOCKS"
INCLUDE "/usr/include/machine_parameters.h"
```

Language elements
INCLUDE line

In the next example, the INCLUDE line occurs in the executable part of a program and supplies the code that uses the input value from the preceding READ statement:

```
READ *, theta
```

INCLUDE "FUNCTION_CALCULATION"

## 3 Data types and data objects

This chapter describes how data is represented and stored in HP Fortran programs, and includes the following topics:

- Intrinsic data types
- Derived types
- Pointers

Arrays are described in Chapter 4, "Arrays," on page 51. The RECORD and STRUCTURE statements—HP Fortran extensions—are fully described in Chapter 10, "HP Fortran Statements." I ntrinsics procedures are described in Chapter 11, "Intrinsic procedures," on page 475.

## Intrinsic data types

The intrinsic data types are the data types predefined by the HP Fortran language, in contrast with derived types, which are user-defined (see "Derived types" on page 39). The intrinsic data types include numeric types:

- Integer
- Real
- Complex
and nonnumeric types:
- Character
- Logical

Each type allows the specification of a kind parameter to select a data representation for that type (see "Type declaration for intrinsic types" on page 24 for the format of the kind parameter). If the kind parameter is not specified, each type has a default data representation. Table 5 identifies the data representation for each type, including the default case where a kind parameter is not specified. The types are listed by keyword and applicable kind parameter. The table also includes the data representation for the HP extensions, byte and double complex.

As shown in Table 5, HP Fortran aligns data on natural boundaries. Entities of the intrinsic data types are aligned in memory on byte boundaries of $1,2,4$, or 8 , depending on their size. Array variables are aligned on an address that is a multiple of the alignment required for the scalar variable with the same type and kind parameters.
The ASCII character set uses only the values 0 to 127 (7 bits), but the HP Fortran implementation allows use of all 8 bits of a character entity. The processing of character sets requiring multibyte representation for each character makes use of all 8 bits.

For additional information about data representation models, see "Data representation models" on page 480.

## Table 5 <br> Intrinsic data types

| Type | Range of values | Precision (in decimal digits) | Bytes | Alignment |
| :---: | :---: | :---: | :---: | :---: |
| INTEGER (1) | -128 to 127 | Not applicable | 1 | 1 |
| INTEGER (2) | $-2^{15}$ to $2^{15}-1$ | Not applicable | 2 | 2 |
| INTEGER(4) <br> (default) | $-2^{31}$ to $2^{31}-1$ | Not applicable | 4 | 4 |
| INTEGER (8) | $-2^{63}$ to $2^{63}-1$ | Not applicable | 8 | 8 |
| REAL (4) (default) | $\begin{aligned} & -3.402823 \times 10^{38} \text { to } \\ & -1.175495 \times 10^{-38} \\ & 0.0 \\ & +1.175495 \times 10^{-38} \text { to } \\ & +3.402823 \times 10^{38} \end{aligned}$ | approximately 6 | 4 | 4 |
| REAL (8) | $\begin{aligned} & -1.797693 \times 10^{+308} \text { to } \\ & -2.225073 \times 10^{-308} \\ & 0.0 \\ & +2.225073 \times 10^{-308} \text { to } \\ & +1.797693 \times 10^{+308} \end{aligned}$ | approximately 15 | 8 | 8 |
| REAL (16) | $\begin{aligned} & -1.189731 \times 10^{+4932} \text { to } \\ & -3.362103 \times 10^{-4932} \\ & 0.0 \\ & +3.362103 \times 10^{-4932} \text { to } \\ & +1.189731 \times 10^{+4932} \end{aligned}$ | approximately 33 | 16 | 8 |
| DOUBLE <br> PRECISION | Same as for REAL (8) | approximately 15 | 8 | 8 |
| COMPLEX (4) | Same as for REAL (4) | Same as for REAL (4) | 8 | 4 |
| COMPLEX (8) | Same as for REAL (8) | Same as for <br> REAL (8) | 16 | 8 |

Data types and data objects
Intrinsic data types

| DOUBLE <br> COMPLEX | Same as for REAL (8) | Same as for <br> REAL (8) | 16 | 8 |
| :--- | :--- | :--- | :--- | :--- |
| CHARACTER (1) <br> (default) | ASCII character set | Not applicable | 1 | 1 |
| LOGICAL (1) | .TRUE . and .FALSE . | Not applicable | 1 | 1 |
| LOGICAL (2) | .TRUE . and .FALSE . | Not applicable | 2 | 2 |
| LOGICAL (4) <br> (default) | .TRUE . and .FALSE . | Not applicable | 4 | 4 |
| LOGICAL (8) | .TRUE. and .FALSE. | Not applicable | 8 | 8 |

## Type declaration for intrinsic types

The following is the general form of a type declaration statement for the intrinsic data types:
type-spec [ [, attribute-spec] . . . : : ] entity-list
type-spec
is one of :

- INTEGER [kind-selector]
- REAL [kind-selector]
- DOUBLE PRECISION [kind-selector]
- CHARACTER [char-selector]
- LOGICAL [kind-selector]
- COMPLEX [kind-selector]
- DOUBLE COMPLEX
- BYTE

BYTE and DOUBLE COMPLEX areHP extensions. BYTE is equivalent to INTEGER (KIND=1). DOUBLE PRECISION is equivalent to REAL (KIND=8), and DOUBLE COMPLEX is equivalent to COMPLEX (KIND=8), except when +autodbl or +autodbl 4 is used. Refer to the HP Fortran Programmer's Guide for information
about using these options to increase sizes. Refer to Chapter 10, "HP Fortran Statements" for information about each type-spec.
If type-spec is present, it overrides the implicit-typing rules; see "Implicit typing" on page 28.
As an HP extension to the Standard, type-spec can also take the form:
type^length
where type is an intrinsic type excluding BYTE, CHARACTER, DOUBLE COMPLEX, and DOUBLE PRECISION; and length is the number of bytes of storage required, as shown in Table 5. Alternatively, *length may appear after the entity name. If the entity is an array with an array specification following it, *length may appear after the array specification. If *length appears with the entity name, it overrides the length specified by kind-selector.
kind-selector
is
([KIND=]scalar-int-init-expr)
scalar-int-init-expr
is a scalar integer initialization expression that must evaluate to one of the kind parameters available (see Table 5). For information about initialization expressions, see "Initialization expressions" on page 90.
char-selector
specifies the length and kind of the character variable, when typespec is CHARACTER.
attributespec
is one or more of the attributes listed in Table 6. Some attributes are incompatible with others; for information about which attributes are compatible as well as full descriptions of all the attributes, see Chapter 10, "HP Fortran Statements."

Data types and data objects
Intrinsic data types
entity-list
is a comma-separated list of entity names of the form:

- var-name [(array-spec)] [*char-len] [ = init-expr]
- function-name[ (array-spec )] [*char-len]
wherearray-spec is described in "Array declarations" on page 54; char-len is described with the CHARACTER statement in Chapter 10; and init-expr is described in "I nitialization expressions" on page 90. If you include init-expr in entity, you must also include the double colon (: :) separator.
As an extension to the Standard, HP Fortran permits the use of slashes to delimit init-expr. The double col on separator, array constructors, and structure constructors are not allowed in this form of initialization. Arrays may be initialized by defining a list of values that are sequence associated with the elements of the array.
Table 6 Attributes in type declaration statement

| Attribute | Description |
| :--- | :--- |
| AUTOMATIC | Makes procedure variables automatic (extension). |
| ALLOCATABLE | Declares an array that can be allocated during execution. |
| DIMENSION(array- <br> Spec) | Declares an array; see "Array declarations" on page 54. If entity- <br> list also includes an array-spec, it overrides the DIMENSION <br> attribute. |
| EXTERNAL | Specifies a subprogram or block data located in another program <br> unit. |
| INTENT | Defines the mode of use of a dummy argument. |
| INTRINSIC | Allows a specific intrinsic name as an actual argument. |
| OPTIONAL | Declares the presence of an actual argument as optional. |
| PARAMETER | Defines named constants. |
| POINTER | Declares the entity to be a pointer. |

| Attribute | Description |
| :--- | :--- |
| PRIVATE | Inhibits visibility outside a module. |
| PUBLIC | Provides visibility outside a module. |
| SAVE | Ensures the entity retains its value between calls of a procedure. |
| STATIC | Ensures the entity retains its value between calls of a procedure <br> (extension). |
| TARGET | Enables the entity to be the target of a pointer. |
| VOLATILE | Provides for data sharing between asynchronous processes <br> (extension). |

The following are examples of type declaration statements:

```
! Default, KIND=4, integers i j k.
INTEGER i, j, k
! Using optional separator.
INTEGER :: i,j,k
! An 8-byte initialized integer.
INTEGER(KIND=8) :: i=2**40
! 10 element array of 8-byte integers.
INTEGER(8),DIMENSION(10) :: i
! Using an array constructor for initialization.
REAL, DIMENSION (2,2):: a = RESHAPE((/1.,2.,3.,4./),(/2,2/))
! Initialized complex.
COMPLEX :: z=(1.0,2.0)
! SYNTAX ERROR - no :: present.
COMPLEX z=(1.0,2.0) ! ILLEGAL
! Initialization using the HP slash extension
INTEGER i/1/,j/2/
REAL a(2,2)/1.1,2.1,1.2,2.2/ ! a(i,j)=i.j
! One character (default length).
CHARACTER(KIND=1) :: c
! A 10-byte character string.
CHARACTER(LEN=10) :: c
! Length can be * for a named constant; title is a 13-byte
! character string
CHARACTER(*),PARAMETER :: title='Ftn 90 MANUAL'
! next four declarations are all equivalent, but only the last
! is standard-conforming
REAL*8 r8(10)
```

Data types and data objects
Intrinsic data types

```
REAL r8*8(10)
REAL r8(10)*8
REAL(8), DIMENSION(10) :: r8
! If the statement is in a subprogram, n must be known at entry;
! otherwise, it must be a constant.
CHARACTER(LEN=n) :: c
SUBROUTINE x(c)
    CHARACTER*(*) :: c
    ! c assumes the length of the actual argument.
END
! A single entity, of derived type node.
TYPE(node):: list_element
! Declaration and initialization of a user-defined variable
TYPE(coord) :: origin = coord(0.0,0.0)
```

## Implicit typing

In Fortran 90, an entity may be used without having been declared in a type declaration statement. The compiler determines the type of the entity by applying implicit typing rules. The default implicit typing rules are:

- Names with initial letter A to H or o to z are of type real.
- Names with initial letter I to n are of type integer.

Because Fortran 90 is a case-insensitive language, the same rules apply to both uppercase and lowercase letters.

## The following statements

```
DIMENSION a(5), i(10)
k = 1
b}=\textrm{k
```

implicitly declare $a$ and $b$ as default reals and $i$ and $k$ as default integers.

As described in Chapter 10, the ImPLICIT statement enables you to change or cancel the default implicit typing rules. The IMPLICIT statement takes effect for the scoping unit in which it appears, except where overridden by explicit type statements.

You can override the implicit typing rules and enforce explicit typingthat is, declare entities in type declaration statements-with the IMPLICIT NONE statement. If this statement is included in a scoping unit, all names in that unit must have their types explicitly declared. You can also enforce explicit typing for all names within a source file by
compiling with the +implicit_none option. This option has the effect of including an IMPLICIT NONE statement in every program unit within a source file.

For a full description of the IMPLICIT and IMPLICIT NONE statements, see Chapter 10, "HP Fortran Statements." The +implicit_none option is described in the HP Fortran Programmer's Guide.

## Constants

Constants can be either literal or named. A literal constant is a sequence of characters that represents a value. A named constant is a variable that has been initialized and has the PARAMETER attribute. This section describes the formats of literal constants for each of the intrinsic data types. For more information about named constants and the PARAMETER statement and attribute, see Chapter 10.

## Integer constants

The format of a signed integer literal constant is:
[sign] digit-string [_kind-parameter]
sign
is either + or - .
digit-string
takes the form:
digit[digit] ...
kind-parameter
is one of:

- digit-string
- the name of a scalar integer constant

The following are examples of integer constants:

```
-123
123_1
123_ILEN
```

In the last example, ILEN is a named integer constant used as a kind parameter. It must have a value of $1,2,4$, or 8 .

Data types and data objects
Intrinsic data types

## BOZ constants

Fortran 90 allows DATA statements to include constants that are formatted in binary, octal, or hexadecimal base. Such constants are called BOZ constants.
A binary constant is:
leading-letter \{ ' digit-string' | "digit-string" \}
where leading-letter is the single character $\mathrm{B}, \mathrm{O}$, or z , indicating binary, octal, or hexadecimal base, respectively. digit-string must consist of digits that can represent the base, namely:

- Binary: 0 and 1.
- Octal: 0 through 7.
- Hexadecimal: 0 through 9, and A through F . The letters can be uppercase or lowercase.
In the following, the three DATA statements use BOZ constants to initialize $i, j$, and $k$ to the decimal value 74 :

```
INTEGER i, j, k
DATA i/B'01001010'/
DATA j/O'112'/
DATA k/Z'4A'/
```

As an extension, HP Fortran allows octal constants with a trailing 0 , and hexadecimal constants with a trailing $x$. The following data statements initialize j and k to the decimal value 74 :

```
DATA j/'112'O/
DATA k/'4A'X/
```

HP Fortran also allows the use of BOZ constants in contexts other than the dATA statement; see "Typeless constants" on page 31.

## Hollerith constants

Hollerith constants have the form:

## len Hstring

where len is the number of characters in the constant and string contains exactly len characters. The value of the constant is the value of the pattern of bytes generated by the ASCII values of the characters.

As an extension, HP Fortran allows Hollerith constants to appear in the same contexts as BOZ constants (see "Typeless constants" on page 31), as well as wherever a character string is valid. If len is greater than the number of characters in string, the constant is padded on the right with space characters. If len is less than the number of characters in string, the constant is truncated on the right.

If a Hollerith constant appears as an argument to the conversion functions INT and LOGICAL, the kind parameter is KIND=1 if the length of the constant is 1 byte, KIND=2 if the length is 2 bytes, KIND=4 if 3 Or 4 bytes, and KIND=8 if greater than 4.

Following are examples of Hollerith constants:
3HABC
5 HABCbb ! $\mathrm{bb}=$ two space characters, making the length equal to 5

## Typeless constants

HP Fortran extends the uses of binary, octal, and hexadecimal constants (BOZ) beyond those prescribed in the Fortran 90 Standard; see "BOZ constants" on page 30. HP Fortran allows BOZ constants to be used as typeless constants wherever an intrinsic literal constant of any numeric or logical type is permitted.

If possible, the type attached to a typeless constant is derived from the magnitude of the constant and the context in which it appears. When used as one operand of a binary operator, it assumes the type of the other operand. If it is used as the right-hand side of an assignment, the type of the object on the left-hand side is assumed. When used to define the value within a structure constructor, it assumes the type of the corresponding component. If appearing in an array constructor, it assumes the type of the first element of the constructor.
The following rules and restrictions also apply:

- If the context does not determine the type, a warning is issued and the type attached to the constant is:
- INTEGER (4) if the constant occupies 1-4 bytes.
- INTEGER (8) if the constant occupies more than 4 bytes.

Leading zeros are considered significant in determining the size.
For example, z'00000001' assumes INTEGER (4), and
Z'000000001' assumes INTEGER(8).

Data types and data objects
Intrinsic data types

- The compiler truncates and issues a warning if more than 8 bytes are required to represent a constant-for example, z'12345678123456781234'. The resulting truncated value differs from that specified in the source code.
- When the size of the type determined by context does not match the size of the actual constant, the constant is either extended with zeroes on the left or truncated from the left as necessary.
- If a single constant is assigned to a complex entity, it is assumed to represent the real part only and will assume the real type with the same length as the complex entity.
- When the compiler attempts to resolve a generic procedure, a BOZ constant in the argument list is considered to match a logical or numeric dummy argument. An ambiguous reference is likely to occur. See "Generic procedures" on page 154 for information about generic procedures.
- Except for the intrinsic conversion procedures, a BOZ constant used as an actual argument for an intrinsic procedure assumes the integer type.
- The intrinsic functions Int, LOGICAL, REAL, DBLE, DREAL, CMPLX, and DCMPLX are available to force a BOZ constant to a specific type. If a BOZ constant is specified as an argument to these functions, its assumed type is determined as follows:
- For functions INT and LOGICAL the assumed type will be (respectively) INTEGER (KIND=4) and LOGICAL (KIND=4), if the constant occupies 1 to 4 bytes; otherwise, the type is assumed to be INTEGER (KIND=8) and LOGICAL (KIND=8).
- For the functions REAL, DBLE, DREAL, CMPLX, and DCMPLX an argument of type REAL (KIND=4) is assumed if the constant occupies 1 to 4 bytes, REAL (KIND=8) if it occupies 5 to 8 bytes, and REAL (KIND=16) otherwise.

The following examples illustrate the extended use of BOZ constants:

```
! The value is 20 (constant treated as INTEGER(2) and
    truncated on the left).
10_2 + Z'1000A'
LOGICAL(2) :: lgl2
! Constant treated as LOGICAL(2), the type of the variable.
lgl2 = B'1'
```

```
! Constant treated as INTEGER(4); IABS is used.
ABS(Z'41')
! Constant treated as REAL(8) as it is more than 4 bytes.
REAL(Z'3FF0000000000000')
```

## Real constants

A signed real literal constant is one of:
[sign] digit-string [ [. [digit-string] ] ] [exponent] [_kind-parameter]
exponent
takes the form:
exponent-letter [sign] digit-string
exponent-letter
is the character $\mathrm{E}, \mathrm{D}$, or $\mathrm{Q} . \mathrm{Q}$ is an HP Fortran extension.
sign and digit-string
are explained in "Integer constants" on page 29.
If no kind parameter is present, or if the exponent letter E is present, the default kind representation is used; see Table 5. If the exponent letter is $D$, the kind parameter is 8 , and if the exponent letter is $Q$, the kind parameter is 16 . If both an exponent and a kind parameter are specified, the exponent letter must be e.
Following are examples of real constants:

| $3.4 \mathrm{E}-4$ | $!0.00034$ |
| :--- | :--- |
| $42 . \mathrm{E} 2$ | $!4200$ |
| $1.234 \_8$ | $!1.234$ with approximately 15 digits precision |
| $-2.53 Q-300$ | $!-2.53 \times 10$ to the -300 th, with approximately 34 |

Data types and data objects
Intrinsic data types

## Complex constants

A complex literal constant has the form:

```
(real-part, imaginary-part)
```

real-part and imagi nary-part
are each one of:

- signed-integer-literal-constant
- signed-real-literal-constant

The kind parameter of the complex value corresponds to the kind parameter of the part with the larger storage requirement.

Following are examples of complex constants:

```
(1.0E2, 2.3E-2) !default complex value
(3.0_8,4.2_4) !complex value with KIND=8
```

## Character constants

A character literal constant is one of:
[kind-parameter_] 'character-string'
[kind-parameter_] "character-string"
The delimiting characters are not part of the constant. If you need to place a single quote in a string delimited by single quotes, use two single quotes; the same rule applies for double quotes.
Following are examples of character constants:
1_'A.N.Other'

```
'Bach''s Preludes' ! actual constant is: Bach's Preludes
"" ! a zero length constant
```

For compatibility with C-language syntax, HP Fortran allows the backslash character ( $\backslash$ ) as an escape character in character strings. You must use the +escape option to enable this feature. When this option is enabled, the compiler ignores the backslash character and either substitutes an alternative value for the character following, or interprets the character as a quoted value. For example:
'ISN\'T'
is a valid string when compiled with the +escape option.

The backslash is not counted in the length of the string. Also, if $\backslash \&$ appears at the end of a line when the +escape option is enabled, the ampersand is not treated as a continuation indicator.

Table 7 lists recognized escape sequences.

## Table 7 <br> Escape characters

| Escape character | Effect |
| :--- | :--- |
| $\backslash \mathrm{n}$ | Newline |
| $\backslash \mathrm{t}$ | Horizontal tab |
| $\backslash \mathrm{V}$ | Vertical tab |
| $\backslash \mathrm{b}$ | Backspace |
| $\backslash \mathrm{f}$ | Form feed |
| $\backslash \mathrm{o}$ | Null |
| $\backslash \mathrm{l}$ | Apostrophe (does not terminate a string) |
| $\backslash \overline{\prime \prime}$ | Double quote (does not terminate a string) |
| $\backslash \backslash$ | $\backslash$ |
| $\backslash \mathrm{x}$ | X, where x is any character other than 1 |

## Logical constants

The format of a logical literal constant is:
\{.TRUE.|.FALSE.\}[_kind-parameter]
The following are examples of logical constants:
.TRUE.
.FALSE._2
In standard-conforming programs, a logical value of . TRUE . is represented by 1 , and .FALSE. is represented by 0 . In nonstandardconforming programs involving arithmetic operators with logical operands, a logical variable may be assigned a value other than 0 or 1 . In this case, any nonzero value is .TRUE., and only the value zero is . FALSE.

Data types and data objects
Intrinsic data types

## Character substrings

A character substring is a contiguous subset of a character string. The substring is defined by the character positions of its start and end within the string, formatted as follows:

```
string ([ starting-position ] : [ ending-position ])
```

starting-position
is a scalar expression. If starting-position is omitted, a value of 1 is assumed. The starting-position must be greater than or equal to 1 , unless the substring has zero length.
ending-position
is a scalar integer expression. If ending-position is omitted, the value of the length of the character string is assumed.
The length of the substring is:
MAX (ending-position - starting-position $+1,0$ )
The following example, substring.f90, illustrates the basic operation on a substring.

## substring. 90

```
PROGRAM main
    CHARACTER(LEN=15) :: city_name
```

        city_name \(=\) 'CopXXXagen'
        PRINT *, "The city's name is: ", city_name
        city_name (4:6) = 'enh' ! assign to a substring of city_name
        PRINT *, "The city's name is: ", city_name
    END PROGRAM main

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 substring.f90
$ a.out
The city's name is: CopXXXagen
The city's name is: Copenhagen
```

For information about substring operations on an array of strings, see "Array sections" on page 63.

## Character strings as automatic data objects

An automatic data object can be either an automatic array (see "Explicitshape arrays" on page 55) or a character string that is local to a subprogram and whose size is nonconstant. The size of a character string is determined when the subprogram is called and can vary from call to call.

An automatic character string must not be:

- A dummy argument
- Declared with the SAVE attribute
- Initialized in a type declaration statement or DATA statement

The following example, swap_names.f90, illustrates the use of automatic character strings:

## swap_names.f90

```
PROGRAM main
    ! actual arguments to pass to swap_names
    CHARACTER(6) :: n1 = "George", n2 = "Martha"
    CHARACTER(4) :: n3 = "pork", n4 = "salt"
    PRINT *, "Before: n1 = ", n1, " n2 = ", n2
    CALL swap_names(n1, n2)
    PRINT *, "After: n1 = ", n1, " n2 = ", n2
    PRINT *, "Before: n3 = ", n3, " n4 = ", n4
    CALL swap_names(n3, n4)
    PRINT *, "After: n3 = ", n3, " n4 = ", n4
END PROGRAM main
! swap the arguments - two character strings of the same length
SUBROUTINE swap_names (name1, name2)
    CHARACTER(*) :: name1, name2 ! the arguments
    ! declare another character string, temp, to be used in the
    ! exchange. temp is an automatic data object, its length
        can vary from call to call
    CHARACTER(LEN(name1)) :: temp
    ! the exchange
    temp = name1
    name1 = name2
    name2 = temp
END SUBROUTINE swap_names
```

Data types and data objects
Intrinsic data types

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
£90 swap_names.f90
$ a.out
    Before: n1 = George n2 = Martha
    After: n1 = Martha n2 = George
Before: n3 = pork n4 = salt
After: n3 = salt n4 = pork
```

## Derived types

Derived types are user-defined types that are constructed from entities of intrinsic data types (see "I ntrinsic data types" on page 22) or entities of previously defined derived types. For example, the following is a definition of a derived type for mani pulating coordinates consisting of two real numbers:

```
TYPE coord
    REAL :: x,y
END TYPE coord
x and y are the components of the derived type coord.
```

The next statement declares two variables ( a and b ) of the derived type coord:

TYPE (coord) : : a, b
The next statement copies the values of a to b, as in any assignment statement:

$$
a=b
$$

The components of $a$ and $b$ are referenced $a s a \% x, a \% y, b \% x$, and $b \% y$. By using the defined operation facility of Fortran 90, it is possible to extend the standard operators to work with derived types. For example, if the + and = operators were redefined to operate on derived type operands, the following statement
$a=a+b$
would be equivalent to

```
a%x = a%x + b%x; a%y = a%y + b%y
```

The following sections describe:

- The syntax of defining a derived type
- Sequence types
- Structure constructors
- Referencing a structure component
- Alignment of derived type objects

The last section provides an example program that illustrates different features of derived types.

Data types and data objects
Derived types

## Defining a derived type

The format for defining a derived type is:

```
TYPE [[, access-spec] ::] typename
    [private-sequence-statement] . . .
    comp-definition-statement
    [comp-definition-statement] . . .
END TYPE [type-name]
access-spec
    is one of:
    - PRIVATE
    - PUBLIC
    access-spec is allowed only if the definition appears
    within a module. For more information about modules,
    see "Modules" on page 161. The PRIVATE and PUBLIC
    attributes are described in Chapter 10.
type-name
    is the name of the type being defined. type-name must
    not conflict with the intrinsic type names.
private-sequencestatement
    is a PRIVATE or SEQUENCE statement. The PRIVATE
    statement is allowed only if the definition appears
    within a module. For more information about the
    SEQUENCE statement, see "Sequence derived type" on
    page 41. Both statements are fully described in
    Chapter 10.
comp-definition-statement
    takes the form:
    type-spec [[comp-attr-list] : :] comp-decl
    N otice that the syntax does not allow for initialization.
    comp-attr-list
    can only contain the DIMENSION and POINTER
    attributes. A component array without the POINTER
    attribute must have an explicit-shape specification
    with constant bounds. If a component is of the same
```

derived type as the type being defined then the component must have the POINTER attribute. Both attributes are fully described in Chapter 10.
comp-declaration
takes the form:
comp-name [ (array-spec) ] [ *char-len]
where array-spec is an array specification, as described in "Array declarations" on page 54; and char-len is used when comp-name is of type character to specify its length.

## Sequence derived type

As shown in "Defining a derived type" on page 40, the SEQUENCE statement may appear in the definition of a derived type. When storage for a variable of derived type is allocated, the presence of the SEQUENCE statement in the definition of the derived type causes the compiler to arrange all components in a storage sequence that is the same as the order in which they are defined. Such a derived type is called a sequence derived type.

A sequence derived type may appear in a common block or in an equivalence set. The Standard makes requirements about the typenumeric or character-of the components in a sequence type. As an extension, HP Fortran makes no restrictions on the types of the components other than that the definition of the derived type must include the SEQUENCE statement.

## Structure component

A component of a derived-type object may be referenced and used like any other variable-in an expression, on the lefthand side of an assignment statement, or as procedure argument. It may be a scalar, an array, or itself a derived-type object. The component name has the same scope as the derived-type object in which it is declared.

Data types and data objects
Derived types

To reference a structure component, use the form:
parent-name[ \%comp-name] . . . \%comp-name
parent-name is a derived type. This part of a structure component reference is the parent and is joined to comp-name by the component selector operator ( $\%$ ). The comp-name component to which the parent is joi ned on its immediate right must be a component of parent-name. If parent-name has the INTENT, TARGET, or PARAMETER attribute, then the structure component being referenced-the rightmost comp-name-also has that attribute.
comp-name is the name of a component. If more than one compname appears in a structure component reference, the reference is to the rightmost comp-name. If more than one comp-name appears in the reference, each one (except the rightmost) must be a derived-type object, and the comp-name to its immediate right must be one of its declared components.

If parent-name and comp-name are arrays, each can be followed by a section-subscript-list enclosed in parentheses. See "Array sections" on page 63 for information about the syntax of section-subscript-list. The Standard imposes certain restrictions on structure component references that are array-valued, as described in "Array-valued structure component references" on page 68.
If the definition of a derived type contains a component that is of the same derived type, the component must have the POINTER attribute. The following example defines the derived type node, which includes a component (next) of the same derived type:

```
TYPE node ! for use in a singly linked list
    INTEGER :: value
    TYPE(node), POINTER :: next ! must have the POINTER attribute
END TYPE node
```

## Declaring a derived type-object

To declare an object of derived type, use the TYPE statement, as follows:
TYPE (typename) [ [, attrib-list] :: ] entity-list
where type-name, attrib-list, and entity-list all have the same meaning as in a type declaration statement that is used to declare an object of an intrinsic type; see "Type declaration for intrinsic types" on page 24.

## Structure constructor

A structure constructor constructs a scalar value of derived type. The value is constructed of a sequence of values for each component of the type. The syntax of a structure constructor is:
type-name ( expression-list )
type-name
is the name of the derived type. The name must have been previously defined.
expression-list
is a comma-separated list of expressions that must agree in number, order, and rank with the components in typename. For information about expressions, see "Expressions" on page 80 and "Special forms of expression" on page 89.
The following restrictions apply to the use of the structure constructor:

- If a component is of derived type, an embedded structure constructor must be used to specify a value for the derived-type component.
- If a component is an array, an array constructor must appear in expression-list that satisfies the array. For more information about array constructors, see "Array constructors" on page 71.
- If a component is a pointer, the corresponding expression in expression-list must evaluate to an allowable target.

Data types and data objects
Derived types

## Alignment of derived-type objects

Derived type objects have the same al ignment as the component that has the most restrictive alignment requirement. (This rule also applies to records.) To ensure natural alignment, the compiler may add padding to each element in an array of derived type.

The following illustrates the alignment of an array of derived type. The definition of the derived type includes the SEQUENCE statement to ensure the order in which components are laid out in memory is the same as in the definition. The sequence statement has no effect on alignment:

```
! definition of a derived type
TYPE t
    SEQUENCE
    CHARACTER(LEN=7) :: c
    INTEGER(2) :: i2
    REAL(8) :: r8
    REAL(4) :: r4
END TYPE t
! declaration of an array variable of derived type
TYPE (t), DIMENSION(5) :: ta
```

Each element of $t$ is allocated storage as shown in Table 8. The first component of $t$ starts at an address that is a multiple of 8 . The four trailing padding bytes are necessary to preserve the alignment of $r 8$ in each element of the array.
Table 8 Example of structure storage

| Component | Byte offset | Length |
| :--- | :--- | :--- |
| C | 0 | 7 |
| i2 | 8 | 2 |
| r8 | 16 | 8 |
| r4 | 24 | 4 |
| padding | 28 | 4 |

## A derived-type example

The example below, traffic.f90, illustrates how to define a derived type, declare a variable of the type, specify a value for the variable using the structure constructor, pass the variable as an argument to another procedure, and reference a structure component. The derived type is defined in a module so that it can be made accessible by use association.

For more information about modules and the USE statement, see "M odules" on page 161. The module and USE statements are also described in Chapter 10.
traffic. 990

```
PROGRAM traffic
! Illustrates derived types: defines a derived type, declares an
! to array variable of derived type, uses a structure constructor
! assign to its components, and passes a component which is
! itself another derived type to a subprogram.
! Make the definition of the derived type called hours accessible
! to this program unit
USE hours_def
LOGICAL :: busy
INTEGER :: choice
! Define another derived type that uses hours as a component
TYPE hiway
    INTEGER :: rte_num
    TYPE(hours) :: busy_hours
END TYPE hiway
! Declare an array of derived-type structures.
TYPE(hiway), DIMENSION(3) :: route
! Use the structure constructor to specify values for each
! element of route
route(1) = hiway(128, hours(.TRUE., .FALSE.))

Heavy commute on rte. 128

## Pointers

Pointers in Fortran 90 are more strongly typed than in other languages. While it is true that the Fortran 90 pointer holds the address of another variable (the target), it also holds additional information about the target. For this reason, declaring a pointer requires not only the POINTER attribute but also the type, kind parameter, and (if its target is an array) rank of the target it can point to.

If a pointer is declared as an array with the POINTER attribute, it is an array pointer. As explained in "Deferred-shape arrays" on page 58, the declaration for an array pointer specifies its specifies rank but not the bounds. Following is the declaration of the array pointer ptr:

```
REAL(KIND=16), POINTER, DIMENSION(:,:) :: ptr
```

To become assignable to an array pointer, a target must be declared with the TARGET attribute and must have the same type, kind parameter, and rank as the array pointer. Given the previous declaration of $p t r$, the following are legal statements:

```
! declare a target with the same type, kind parameter, and
! rank as ptr
REAL(KIND=16), TARGET, DIMENSION(4,3) :: x
ptr => x ! assign x to ptr in a pointer assignment statement
```

Once the assignment statement executes, you can use either ptr or x to access the same storage, effectively making ptr an alias of x .

You can also allocate storage to a pointer by means of the ALLOCATE statement. To deal locate that storage after you are finished with it, use the deallocate statement. Although allocating storage to a pointer does not involve a target object, the declaration of the pointer must still specify its type, kind parameter, and (if you want to allocate an array) rank. The allocate statement specifies the bounds for the dimensions. Here is an example of the ALlocate statement used to allocate storage for ptr:

```
INTEGER :: j = 10, k = 20
! allocate storage for ptr
ALLOCATE (ptr(j,k))
```

ptr can now be referenced as though it were an array, using Fortran 90 array notation.

## Data types and data objects

## Pointers

As an extension, HP Fortran provides the Cray-style pointer variables; for more information, see Chapter 10. For information about aspects of pointers, refer to:

- "Array pointers" on page 59 for information about allocating array pointers.
- "Pointer assignment" on page 97 for information about associating a pointer with a target by means of pointer assignment.
- Chapter 10, "HP Fortran Statements" for a full description of the ALLOCATE and DEALLOCATE statements as well as the POINTER and TARGET attributes.

The following section discusses pointer status and includes an example program.

## Pointer association status

Certain pointer operations can only be performed depending on the status of the pointer. A pointer's status is called its association status, and it can take three forms:
Undefined The status of a pointer is undefined on entry to the program unit in which the pointer is declared or if:

- Its target is never allocated.
- Its target was deallocated (except through the pointer.
- The target goes out of scope, causing it to become undefined.

If the association status is undefined, the pointer must not be referenced or deallocated. It may be nullified, assigned a target, or allocated storage with the ALLOCATE statement.

Associated The status of a pointer is associated if it has been allocated storage with the ALLOCATE statement or is assigned a target. If the target is allocatable, it must be currently allocated.
If the association status is associated, the pointer may be referenced, deallocated, nullified, or pointer assigned.

#### Abstract

Disassociated The status of a pointer is disassociated if the pointer has been nullified with the nuluify statement or deallocated, either by means of the DEALLOCATE statement or by being assigned to a disassociated pointer.

If the association status is disassociated, the same restrictions apply as for a status of undefined. That is, the pointer must not be referenced or deallocated, but it may be nullified, assigned a target, or allocated storage with the ALLOCATE statement.

You can use the ASSOCIATED intrinsic function to determine the association status of a pointer; see Chapter 11, "Intrinsic procedures," on page 475 for a description of this intrinsic.

## A pointer example

The example below, ptr_sts.f90, illustrates different pointer operations, including calls to the ASSOCIATED intrinsic to determine pointer status.

```
ptr_sts.f90
```

```
PROGRAM main
    ! This program performs simple pointer operations, including
    ! calls to the ASSOCIATED intrinsic to determine status.
    ! Declare pointer as a deferred shape array with POINTER
    ! attribute.
    REAL, POINTER :: ptr(:)
    REAL, TARGET :: tgt(2) = (/ -2.2, -1.1 /) ! initialize target
    PRINT *, "Initial status of pointer:"
    call get_ptr_sts
    ptr => tgt ! pointer assignment
    PRINT *, "Status after pointer assignment:"
    call get_ptr_sts
    PRINT *, "Contents of target by reference to pointer:", ptr
    ! use an array constructor to assign to tgt by reference to ptr
    ptr = (/ 1.1, 2.2 /)
    PRINT *, "Contents of target after assignment to pointer:", tgt
    NULLIFY(ptr)
    PRINT *, "Status after pointer is nullified:"
    call get_ptr_sts
    ALLOCATE(ptr(5)) ! allocate pointer
```

Data types and data objects

## Pointers

```
PRINT *, "Status after pointer is allocated:"
    ! To learn if pointer is allocated, call the ASSOCIATED
    ! intrinsic without the second argument
    IF (ASSOCIATED(ptr)) PRINT *, " Pointer is allocated."
    ptr = (/ 3.3, 4.4, 5.5, 6.6, 7.7 /) ! array assignment
    PRINT *, 'Contents of array pointer:', ptr
    DEALLOCATE (ptr)
    PRINT *, "Status after array pointer is deallocated:"
    IF (.NOT. ASSOCIATED(ptr)) PRINT *, " Pointer is deallocated."
CONTAINS
    ! Internal subroutine to test pointer's association status.
    ! Pointers can be passed to a procedure only if its interface
    ! is explicit to the caller. Internal procedures have an
    ! explicit interface. If this were an external procedure,
    ! its interface would have to be declared in an interface
    ! block to be explicit.
    SUBROUTINE get_ptr_sts
        IF (ASSOCIATED(ptr, tgt)) THEN
            PRINT *, " Pointer is associated with target."
        ELSE
            PRINT *, " Pointer is disassociated from target."
        END IF
    END SUBROUTINE get_ptr_sts
END PROGRAM main
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 ptr_sts.f90
```

\$ a.out

Pointer is allocated.
Contents of array pointer: 3.34 .45 .56 .67 .7
Status after array pointer is deallocated:
Pointer is deallocated.

## 4 Arrays

This chapter describes arrays and the array-handling features of HP Fortran. This includes the following topics:

- Array fundamentals
- Array declarations
- Array-valued structure component references
- Array constructors
- Array expressions
- Array-valued functions
- Array inquiry intrinsics

Arrays
Array fundamentals

## Array fundamentals

An array consists of a set of elements, each of which is a scalar and has the same type and type parameter as declared for the array. Elements are organized into dimensions. Fortran 90 allows arrays up to seven dimensions. The number of dimensions in an array determines its rank.

Dimensions have an upper bound and a lower bound. The total number of elements in a dimension-its extent-is calculated by the formula:

```
upper-bound - lower-bound + 1
```

The size of an array is the product of its extents. If the extent of any dimension is zero, the array contains no elements and is a zero-sized array.

Elements within an array are referenced by subscripts-one for each dimension. A subscript is a specification expression and is enclosed in parentheses. As an extension, HP Fortran allows a subscript expression of type real; the expression is converted to type integer after it has been evaluated.

The shape of an array is determined by its rank and by the extents of each dimension of the array. An array's shape may be expressed as a vector where each element is the extent of the corresponding dimension. For example, given the declaration:

REAL, DIMENSION $(10,2,5):: ~ x$
the shape of $x$ can be represented by the vector $[10,2,5]$.
Two arrays are conformable if they have the same shape, although the lower and upper bounds of the corresponding dimensions need not be the same. A scalar is conformable with any array.
A whole array is an array referenced by its name only, as in the fol lowing statements:

```
REAL, DIMENSION(10) :: x, y, z
PRINT *, x
x = y + z
```

Arrays
Array fundamentals

The array element order used by HP Fortran for storing arrays is column-major order; that is, the subscripts along the first dimension vary most rapidly, and the subscripts al ong the last dimension vary most slowly. For example, given the declaration:

```
INTEGER, DIMENSION(3,2) :: a
```

the order of the elements would be:

```
a (1, 1)
a (2,1)
a (3,1)
a(1,2)
a (2,2)
a(3,2)
```

The following array declarations illustrate some of the concepts presented in this section:
! The rank of al is 1 as it only has one dimension, the extent of ! the single dimension is 10, and the size of al is also 10.
! a1 has a shape represented by the vector [10].
REAL, DIMENSION(10) : : a1
! a2 is declared with two dimensions and consequently has a rank
! of 2 , the extents of the dimensions are 2 and 4
! respectively, and the size of a2 is 8.
! The array's shape can be represented by the vector [2, 4]. INTEGER, DIMENSION $(2,4)$ : a2
! a3 has a rank of 3, the extent of the first two dimensions is
! 5, and the extent of the third dimension is zero. The size of
! a3 is the product of all the extents and is therefore zero.
! The shape of a3 can be represented by the vector [5, 5, 0].
LOGICAL, DIMENSION (5,5,0) : : a3
! a and b are conformable, $c$ and d are conformable. The shape of
! $a$ and $b$ can be represented by the vector $[3,4]$. The shape of
! c and $d$ can be represented by the vector [6, 8].
REAL, DIMENSION : : $a(3,4), b(3,4), c(6,8), d(-2: 3,10: 17)$

Arrays
Array declarations

## Array declarations

An array is a data object with the dimension attribute. Its rank—and possibly the extents-are defined by an array specification. The array specification is enclosed in parentheses and can be attached either to the DIMENSION attribute, as in:

```
INTEGER, DIMENSION(17) :: a, b
```

or to the array name, as in:

```
REAL :: y (3,25)
```

If the array specification is attached both to the DIMENS ION attribute and to the array name in the same declaration statement, the specification attached to the name takes precedence. In the following example:

```
INTEGER, DIMENSION(4,7) :: a, b, c(15)
```

a and b are declared as two-dimensional arrays, but c is declared as a one-dimensional array.

An array specification can declare an array as one of the following:

- Explicit-shape array
- Assumed-shape array
- Deferred-shape array
- Assumed-size array

The following sections describe these types and the form of the array specification for each type. For information about initializing arrays with the array constructor, see "Array constructors" on page 71.

Arrays
Array declarations

## Explicit-shape arrays

An explicit-shape array has explicitly declared bounds for each dimension; the bounds are neither taken from an actual array argument ("assumed") nor otherwise specified prior to use ("deferred"). Each dimension of an explicit-shape array has the following form:
[lower-bound :] upper-bound
where lower-bound and upper-bound are specification expressions and may be positive, negative, or zero. The default for lower-bound is 1.
For a given dimension, the values of lower-bound and upper-bound define the range of the array in that dimension. Usually, lower-bound is less than upper-bound; if lower-bound is the same as upper-bound, then the dimension contains only one element; if it is greater, then the dimension contains no elements, the extent of the dimension is zero, and the array is zero-sized.

The simplest form is represented by an array declaration in which the name of the array is not a dummy argument and all bounds are constant expressions, as in the following example:

```
INTEGER :: a (100,4,5)
```

This form of array may have the SAVE attribute and may be declared in any program unit.

Other forms of the explicit-shape array include:

- An automatic array: An array that is declared in a subprogram but is not a dummy argument and has at least one nonconstant bound. Automatic arrays may be declared in a subroutine or function, but may not have the SAVE attribute nor be initialized.

Character strings can also be declared as automatic data objects; see "Character strings as automatic data objects" on page 37.

- A dummy array: An array that is identified by its appearance in a dummy argument list; its bounds may be constants or expressions. Dummy arrays may only be declared in a subroutine or function.
- An adjustable array: A particular form of a dummy array. Its name is specified in a dummy argument list, and at least one of its bounds is a nonconstant specification expression.

Arrays

## Array declarations

Explicit-shape arrays may also be used as function results, as described in "Array-valued functions" on page 76 and in "Array dummy argument" on page 140 .
The following code segment illustrates different forms of explicit-shape arrays:

```
SUBROUTINE sort(list1,list2,m,n)
! examples of arrays with explicit shape
INTEGER :: m,n
INTEGER :: cnt1(2:99)
! a rank-one array, having an explicit shape represented by
! the vector [98]
REAL :: list1(100), list2(0:m-1,-m:n)
! two dummy arrays with explicit shape: list1 is a rank-one
! array with an extent of 100; list2 is a rank-two array with an
! extent of m * (m+n+1). list2 is also an adjustable array.
REAL :: work(100,n)
! work is an automatic array; it does not appear in the dummy
! argument list and at least one of its bounds is not constant
INTEGER, PARAMETER :: buffsize = 0
REAL :: buffer (1: buffsize)
! buffer has explicit shape, but no elements and is zero-sized
    .
END SUBROUTINE sort
```

## Assumed-shape arrays

An assumed-shape array is a dummy argument that assumes the shape of the corresponding actual argument. It must not have the POINTER attribute. Each dimension of an assumed-shape array has the form:
[lower-bound] :
where lower-bound is a specification expression. The default for lowerbound is 1 .

The actual argument and the corresponding dummy argument may have different bounds for each dimension. An assumed-shape array subscript may extend from the specified lower-bound to an upper bound that is equal to lower-bound plus the extent in that dimension of the actual argument minus one.

Arrays
Array declarations

The fol lowing code segment illustrates different declarations of assumedshape arrays.

```
SUBROUTINE initialize (a,b,c,n)
! examples of assumed-shape arrays
INTEGER :: n
INTEGER :: a(:)
! the array a is a rank-one assumed-shape array, it takes its
! shape and size from the corresponding actual argument; its
! lower bound is 1 regardless of the lower bound defined for
! the actual argument
COMPLEX :: b (ABS (n) :)
! a rank-one assumed-shape array, the lower bound is ABS(n) and
! the upper bound will be the lower bound plus the extent of
! the corresponding actual argument minus one
REAL, DIMENSION(:,:,:,:,:) :: c
! an assumed-shape array with 5 dimensions; the lower bound for
! each dimension is 1
END SUBROUTINE initialize
```

If a procedure has an argument that is an assumed-shape array, its interface must be explicit within the calling program unit. A procedure's interface is explicit if it is an internal procedure within the caller procedure or if the interface is declared in an interface block within the caller.

For example, to call the external subroutine initialize in the previous example, its interface must appear in an interface block, as in the following:

```
PROGRAM main
INTEGER :: parts(0:100)
COMPLEX :: coeffs(100)
REAL :: omega(-2:+3, -1:+3, 0:3, 1:3, 2:3)
INTERFACE
    SUBROUTINE initialize (a,b,c,n)
            INTEGER :: n
            INTEGER :: a(:)
            COMPLEX :: b (ABS (n):)
            REAL, DIMENSION(:,:,:,:,:) :: c
    END SUBROUTINE initialize
END INTERFACE
CALL initialize(parts,coeffs,omega,lbound(omega,1))
    •
END PROGRAM main
```

## Arrays

## Array declarations

```
SUBROUTINE initialize (a,b,c,n)
    INTEGER :: n
    INTEGER :: a(:)
    COMPLEX :: b (ABS (n):)
    REAL, DIMENSION(:,:,:,:,:) :: c
•
END SUBROUTINE initialize
For more information about:
```

- Internal procedures, see "Internal procedures" on page 135
- Interface blocks, see "Procedure interface" on page 151
- Arrays used as dummy arguments, see "Array dummy argument" on page 140

## Deferred-shape arrays

A deferred-shape array has either the POINTER attribute or the Allocatable attribute. Its shape is not specified until the array is pointer assigned or allocated. Although a deferred-shape array can have the same form as an assumed-shape array, the two are different. The assumed-shape array is a dummy argument and must not have the POINTER attribute.
The array specification for a deferred-shape array has the form:
: [ , : ] ...
The specification for a deferred-shape array defines its rank but not the bounds. The bounds are defined either when the array is allocated or when an array pointer becomes associated with a target.
Array pointers and allocatable arrays are described in the following sections.

## Array pointers

An array pointer is a deferred-shape array with the POINTER attribute. Its bounds and shape are defined only when the array is associated with a target in a pointer assignment statement or in an ALLOCATE
statement. An array pointer must not be referenced until it is associated.
Following are example declarations of array pointers:

```
! p1 is declared as a pointer to a rank-one
! array of type real; p1 is not associated with any target
REAL, POINTER, DIMENSION(:) :: p1
! p2 is a pointer to an integer array of rank-two;
! it must be associated with a target before it can be referenced
INTEGER, POINTER :: p2(:,:)
! err is a pointer to a rank-3 array of type err_type
TYPE err_type
    INTEGER :: class
    REAL :: code
END TYPE err_type
TYPE(err_type), POINTER, DIMENSION(:,:,:) :: err
! The next statement is ILLEGAL: pointers cannot have an
! explicit shape.
INTEGER, POINTER :: p3(n)
```

For information about associating an array pointer with a target, see "Pointers" on page 47. For information about the pointer attribute and ALlocate statement, see Chapter 10, "HP Fortran Statements."

## Allocatable arrays

An allocatable array is a deferred-shape array with the ALLOCATABLE attribute. Its bounds and shape are defined when it is allocated with the allocate statement. Once allocated, the allocatable array may be used in any context in which any other array may appear. An allocatable array can also be deallocated with the DEALLOCATE statement.
An allocatable array has an allocation status that can be tested with the ALLOCATED intrinsic inquiry function. Its status is unallocated when the array is first declared and after it is deallocated in a DEALLOCATE statement. After the execution of the ALLOCATE statement, its status is allocated. An allocatable array with the unallocated status may not be referenced except as an argument to the ALLOCATED intrinsic or in an allocate statement. If it has the allocated status, it may not be referenced in the ALlocate statement. It is an error to allocate an allocatable array that is al ready allocated, or to deallocate an allocatable array either before it is allocated or after it is deallocated.

## Arrays

## Array declarations

In HP Fortran, an allocatable array that is unallocated, is local to a procedure, and does not have the SAVE attribute. It is automatically deallocated when the procedure exits.

The following example, alloc_array.f90, calls a subroutine that allocates and deallocates an allocatable array and uses the ALLOCATED intrinsic function to test its allocation status:

```
alloc_array.f90
PROGRAM main
! driver program for calling a subroutine that allocates and
! deallocates an allocatable array
    CALL test_alloc_array
END PROGRAM main
SUBROUTINE test_alloc_array
! demonstrate how to allocate and deallocate an allocatable array
    ! the array matrix is rank-2 allocatable array, with no
    ! shape or storage
    REAL, ALLOCATABLE, DIMENSION(:,:) :: matrix
    INTEGER :: n
    LOGICAL :: sts
    ! sts is assigned the value .FALSE. as the array is not yet
    ! allocated
    sts = ALLOCATED(matrix)
    PRINT *, 'Initial status of matrix: ', sts
    PRINT *, 'Enter an integer (rank of array to be allocated):'
    READ *,n
    ! dynamically create the array matrix; after allocation, array
    ! will have the shape [ n, n ]
    ALLOCATE (matrix(n,n))
    ! test allocation by assigning to array
    matrix(n,n) = 9.1
    PRINT *, 'matrix(',n,',',n,') = ', matrix(n,n)
    ! sts is assigned the value .TRUE. as the allocatable array
    ! does exist and its allocation status is therefore allocated
    sts = ALLOCATED(matrix)
    PRINT *, 'Status of matrix after ALLOCATE: ', sts
    DEALLOCATE (matrix)
    ! sts is assigned the value .FALSE. as the
    ! allocation status of a deallocated array
    sts = ALLOCATED (matrix)
    PRINT *, 'Status of matrix after DEALLOCATE: ', sts
END SUBROUTINE test_alloc_array
```

Arrays
Array declarations

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
$ f90 alloc_array.f90
$ a.out
    Initial status of matrix: F
    Enter an integer (rank of array to be allocated):
4
    matrix( 4 , 4 ) = 9.1
    Status of matrix after ALLOCATE: T
    Status of matrix after DEALLOCATE: F
```

For information about the ALLOCATABLE, ALLOCATE, DEALLOCATE statements, see Chapter 10, "HP Fortran Statements." See also "ALLOCATED(ARRAY)" on page 493.

## Assumed-size arrays

An assumed-size array is a dummy argument whose size is taken from the associated actual argument. Its declaration specifies the rank and the extents for each dimension except the last. The extent of the last dimension is represented by an asterisk (*), as in the following:

```
INTEGER :: a (2,5,*)
```

All dummy array arguments and their corresponding actual arguments share the same initial element and are storage associated. In the case of explicit-shape and assumed-size arrays, the actual and dummy array need not have the same shape or even the same rank. The size of the dummy array, however, must not exceed the size of the actual argument. Therefore, a subscript in the last dimension of an assumed-size array may extend from the lower bound to a value that does not cause the reference to go beyond the storage associated with the actual argument.
Because the last dimension of an assumed-size array has no upper bound, the dimension has no extent and the array consequently has no shape. The name of an assumed-size array therefore cannot appear in contexts in which a shape is required, such as a function result or a whol e array reference.

## Arrays

## Array declarations

The following example, assumed_size.f90, illustrates two assumed-size arrays: x (declared in subr) and i_array (declared in func):

## assumed_size. 990

```
PROGRAM main
    REAL :: a (2,3) ! an explicit-shape array, represented by the
    k = 0
    DO i = 1, 3
        DO j = 1, 2
            k = k + 1
            a(j, i) = k
        END DO
    END DO
    PRINT *, 'main: a =', a
    CALL subr (a)
END PROGRAM main
SUBROUTINE subr(x)
    REAL :: x(2,*) ! an assumed-size array; the subscript for the
                    ! last dimension may take any value 1 - 3
! PRINT *, x ! ILLEGAL, whole array reference not allowed
    PRINT *, `main: x(2, 2) = `, x(2, 2)
    PRINT *, 'returned by func: ', func(x), ', the value in x(2,3)'
END SUBROUTINE subr
REAL FUNCTION func(y)
    REAL :: y(0:*) ! an assumed-size array; the subscript may
    func = y(5)
END FUNCTION func
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 assumed_size.f90
$ a.out
main: a = 1.0 2.0 3.0 4.0 5.0 6.0
main: x(2, 2) = 4.0
returned by func: 6.0 , the value in x(2,3)
```

An assumed-size array is a FORTRAN 77 feature that has been superseded by the assumed-shape array; see "Assumed-shape arrays" on page 56.

## Array sections

An array section is a selected portion of another array (the parent) that is itself an array, even if it consists of only one element, or possibly none. An array section can appear wherever an array name is allowed.

The syntax for specifying an array section is:
array-name (section-subscript-list)[ (substring-range) ]
where:
section-subscript-list
is a comma-separated list of section-subscript.
section-subscript
is one of:

- subscript
- subscript-triplet
- vector-subscript
subscript
is a scalar integer expression.
subscript-triplet
takes the form:
[subscript]: [subscript] [:stride]
where stride is a scalar integer expression.
vector-subscript
is a rank-one integer array expression.
substring-range
specifies a character substring, as described in "Character substrings" on page 36. If substring-range is specified, array-name must be of type character.

Section-subscript-list must specify section-subscript for each dimension of the parent array. The rank of the array section is the number of subscript-triplets and vector -subscripts that appear in the section-subscript-list. Because an array section is also an array, at least one subscript-triplet or vector-subscript must be specified.

Arrays

## Array sections

The following sections provide more information about subscript-triplet and vector-subscript.

## Subscript triplet

A subscript triplet selects elements from the parent array to form another array. It specifies a lower bound, an upper bound, and a stride for any dimension of the parent array. Elements are sel ected in a regular manner from a dimension. The stride can, for example, select every second element.

All three components of a subscript triplet are optional. If a bound is omitted, it is taken from the parent array. H owever, an upper bound must be specified if a subscript triplet is used in the last dimension of an assumed-sized array.

A bound in a subscript triplet need not be within the declared bounds for that dimension of the parent array if all the elements selected are within its declared bounds. If the stride is omitted, the default is to increment by one.

The stride must not be zero. If it is positive, the subscripts range from the lower bound up to and including the upper bound, in steps of stride. When the difference between the upper bound and lower bound is not a multiple of the stride, the last subscript value selected by the subscript triplet is the largest integer value that is not greater than the upper bound. The array expression a (1: 9: 3) selects subscripts 1, 4, and 7 from a.

Strides may also be negative. A negative stride selects el ements from the parent array starting at the lower bound and proceeds backwards through the parent array in steps of the stride down the last value that is greater than the upper bound. For example, the expression a (9:1:- 3) selects the subscripts 9, 6, and 3 in that order from a.
If the section bounds are such that no elements are selected in a dimension (for example, the section a (2:1)), the section has zero-size.

Arrays
Array sections

The following example shows subscript triplet notation assigning the same value to a regular pattern of array elements.

```
INTEGER, DIMENSION(3,6) :: x,y,z ! declare 3 3x6 arrays
! initialize the arrays, using whole-array assignments.
x = 0; y = 0; z = 0
! assign to elements of x, y, and z, using subscript triplets
x(3,2:4:1) = 1
y(2,2:6:2) = 2
z(1:2,3:6) = 3
! The arrays x, y, and z now have the following values:
\begin{tabular}{lllllllllllllllll} 
! \\
\(!\) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 3 & 3 \\
3 & 3 \\
\(!\) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 2 & 0 & 2 & 0 & 0 & 3 & 3 \\
3 & 3
\end{tabular}
\begin{tabular}{lllllllllllllllllll}
1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{tabular}
```

In the following example of an array substring, the variable dates ( $5: 10$ ) is an array section that includes elements 5 through to 10 of the parent array dates, and the variable dates $(5: 10)(8: 11)$ is also an array section of the array dates but only contains the last 4 character positions of the elements 5 through to 10 .

```
CHARACTER(11) :: dates(20)
dates(5:10)(8:11) = "1776"
```

## Vector subscripts

A vector subscript is any expression that results in a rank-one array with integer value. The values of the array select the corresponding elements of the parent array for a given dimension. Vector subscripts can describe an irregular pattern and may be useful for indirect array addressing. For example, if v represents a rank-one integer array initialized with the values $4,3,1,7$, then the array section a (v) is a rank-one array composed of the array elements a (4) , a (3) , a (1), and a (7)-in that order.
Vector subscripts are commonly specified using array constructors, which are described in the next section. For example, the expressions a (v) and a( (/ 4, 3, 1, 7/)) reference the same section of the array a.

Arrays

## Array sections

Vector subscripts may not appear:

- On the right hand side of a pointer assignment statement.
- In an I/O statement as an internal file.
- As an actual argument that is associated with a dummy argument declared with INTENT (OUT) or INTENT (INOUT) or with no INTENT.

A vector subscript may specify the same element more than once. When a vector subscript of this form specifies an array section, the array section is known as a many-one array section. An example of a many-one array section is:

```
a( (/ 4, 3, 4, 7/) )
```

where element 4 has been selected twice. A many-one array section may not appear in either an input list or on the left-hand side of an assi gnment statement.

The following example, vector_sub.f90, illustrates an array section using a section subscript list.

```
vector_sub.f90
PROGRAM main
    ! m is a rank-1 array that has been
    ! initialized with the values of an array constructor
    INTEGER, DIMENSION(4) :: m = (/ 2, 3, 8, 1/)
    INTEGER :: i
    ! initialize a (a rank-1 array) with the values
    ! 1.1, 2.2, 3.3, 4.4, 5.5, 6.6, 7.7, 8.8, 9.9, 11.0
    REAL, DIMENSION(10) : : a = (/ (i*1.1, i=1,10) /)
    ! b is an uninitialized 4x2 array
    REAL, DIMENSION(4,2) :: b
    ! print a section of a, using a vector subscipt
    PRINT *,a(m)
    ! assign the values 5.5, 11.0, 6.6, and 5.5 to the first column
    ! b; this is an example of a many-one array
    b(:,1) = a( (/ 5, 10, 6, 5/) )
    ! the vector subscript MIN(m,4) represents a rank-1 array with
    ! the values 2, 3, 4, 1; the second column of b is assigned
    ! the values 11.0, 6.6, 5.5, 5.5
    b(:,2) = b(MIN (m,4),1)
    ! increment a(2), a(3), a(8), and a(1) by 20.0
```

```
    a(m)=a(m)+20.0
    ! print the new values in a
    PRINT *,a
END PROGRAM main
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
$ f90 vector_sub.f90
$ a.out
2.2 3.3 8.8 1.1
21.1 22.2 23.3 4.4 5.5 6.6 7.7 28.8 9.9 11.0
```

Arrays
Array-valued structure component references

## Array-valued structure component references

A structure component reference can specify an array or a scalar. If, for example, the parent in the reference is declared as an array and likewise one of the components is declared as an array, this makes possible an array-valued structure component reference. Conceptually, an arrayvalued structure component reference is similar to a reference to an array section (see "Array sections" on page 63).
Consider the following code:

```
TYPE student_data
    CHARACTER(25) :: name
    INTEGER :: average, test(4)
END TYPE student_data
TYPE course_data
    CHARACTER(25) :: course_title
    INTEGER :: course_num, class_size
    TYPE(student_data) :: student(10)
END TYPE course_data
TYPE (course_data) :: course(5)
```

These statements prepare a database for maintaining course information for 50 students- 10 students per course. The information about the students is held in student-an array of derived type. Likewise, the information about the five courses is held in course, which is also an array of derived type and which has student as one of its components. The following statement assigns a test score to a one student in one course, using a structure component reference:
course (5) \%student (7) \%test (4) $=95$
The reference is scalar-valued: 95 is assigned to a single element, test (4) of student (7) of course (5).

However, it is also possible to reference more than one element in a structure component reference. The following statement assigns the same score to one test taken by all students in one course:

```
course(4)%student%test(3) = 60
```

The structure component reference is array-valued because thirty elements are assigned with the one reference. The reference is to a section of the array course, rather than to the entire array.

The next statement also makes an array-valued structure component reference to initialize all the tests of one student in one course:

```
course(3)%student(3)%test = 0
```

The next statement uses a subscript triplet in an array-valued structure component reference to assign the same score to one test of three students in one course:

```
course(2)%student(1:3)%test(4) = 82
```

It would be convenient if we could initialize all tests of all students in all courses to 0 . But the Standard does not allow structure component references in which more than one of the parts specifies a rank greater than 0 . In other words, the following is not legal:

```
course%student%test = 0 ! ILLEGAL
```

The following example, array_val_ref.f90, contains the code examples listed in this section:

## array_val_ref.f90

```
PROGRAM main
! illustrates array-valued structure component references
    ! define a derived type that will be used to declare an
    ! object of this type as a component of another derived type
    TYPE student_data
        CHARACTER(25) :: name
        INTEGER :: average, test(4)
    END TYPE student_data
    TYPE course_data
        CHARACTER(25) :: course_title
        INTEGER :: course_num, class_size
        TYPE(student_data) :: student(10) ! an array of derived
    ! type
    END TYPE course_data
    TYPE (course_data) :: course(5) ! an array of derived
    ! type
    ! scalar-valued structure component reference
    course(5) %student(7)%test(4) = 95
    PRINT *, course(5)%student (7) %test (4)
    ! array-valued structure component reference
    course(4)%student%test(3) = 60
    PRINT *, course(4)%student%test(3)
    ! array-valued structure component reference
    course(3)%student (3)%test = 0
    PRINT *, course(3)%student (3)%test
```

## Arrays

## Array-valued structure component references

```
! array-valued structure component reference, using
! a subscript triplet to reference a section of the
! array component student
course(2)%student(1:3)%test(4) = 82
PRINT *, course(2) %student (1:3)%test(4)
! the following commented-out statement is illegal:
! only one part (of the combined components and
! parent) in a structure component reference
! may have a rank greater than 0.
! course%student%test = 0
END PROGRAM main
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
$ f90 array_val_ref.f90
```

\$ a.out
95
60606060606060606060
0000
828282

## Array constructors

An array constructor is used to assign values to an array. The generated values are supplied from a list of scalar values, arrays of any rank, and implied Do specifications. An array constructor may appear in any context in which a rank-one array expression is allowed. An array with a rank greater than one may be constructed by using the RESHAPE intrinsic function. The type of an array constructor is taken from the values in the list, which must all have the same type and type parameters (including character length). The extent is taken from the number of values specified.
The syntax of an array constructor is:
(/ ac-valuelist /)
where ac-valuelist is a comma-separated list of one or more ac-values. Each ac-value may be any of the following:

- Scalar expressions, for example:
(/ 1.2, 0.0, 2.3 /)
- An array expression, for example:
(/ x(0:5) /)
where the values in $\mathrm{x}(0)$ through $\mathrm{x}(5)$ become the values of the array constructor. If the array the value list has a rank greater than one, the values are generated in column-major order, as explained in "Array fundamentals" on page 52.
- An implied-do specification, taking the form:
(ac-valuelist, do-var $=$ expr1, expr2 [, expr3])
where do-var is the name of a scalar integer variable, expr1 is the initial value, expr2 is the final value, and expr2 is the stride (the default is 1 ). For example:

```
(/ i, i = 1, 10 )
```

Arrays

## Array constructors

When used to initialize an array in a type declaration or in an assi gnment statement, all elements in the array must be initialized. For example, the following is illegal:

```
INTEGER :: i(10) = (/ 1, 2, 3 /) ! ILLEGAL: too few
! initializers
```

If no values are supplied, the array constructor is zero-sized. For example, the size of the following array constructor:

```
(/ ( i, i=10,n) /)
```

depends on the value of the variable $n$; if the value of the variable is less than 10, then the constructor contains no values.

If the list contains only constant values, the array constructor may initialize a named constant or a type declaration statement. An array constructor may not initialize variables in a DATA statement, which may contain scalar constants only.
As an extension, HP Fortran allows the use of [ and ] in place of (/ and /).

The following are examples of array constructors:

```
! array x is assigned three real values.
x = (/19.3, 24.1, 28.6/)
! One vector, consisting of 16 integer values, is assigned to j
j = (/4, 10, k(1:5), 2 + l, (m(n), n = -7,-2),16, 1/)
assign 5 values
a = (/(base (k), k=1,5)/)
! The named constant t is a rank-one array initialized with
! the values 36.0 and 37.0
REAL,DIMENSION(2):: t
PARAMETER (t=(/ 36.0, 37.0/))
! the array constructor is reshaped as 1 3 5 7
2466
and is then assigned to z
z=RESHAPE ((/1,2,3,4,5,6,7,8/), (/2,4/) )
an array constructor is used for the second component of
! the structure constructor
alaska = site("NOME",(/-63,4/))
diagonal = (/ (b(i,i), i=1,n) /)
hilbert = RESHAPE( (/ ((1.0/(i+j), i=1,n), j=1,n) /), (/ n,n /) )
ident = RESHAPE ( (/ (1, (0, i=1,n), j=1,n-1), 1 /), (/ n,n /) )
```

Arrays
Array constructors

As shown in last three examples, an array constructor with implied- Do loops and the RESHAPE function permit construction of arrays that cannot otherwise be expressed conveniently with alternative notations.

Arrays
Array expressions

## Array expressions

Array operations areperformed in parallel. That is, an operation is performed on each element independently and in any order. The practical effect of this is that, because an assignment statement may have the same array on both the left and right-hand sides, the right-hand side is fully evaluated before any assignment takes place. This means that in some cases the compiler may create temporary space to hold intermediate results of the computation.

A scalar may appear in an array expression. If the scalar is used in an expression containing whole array references-for example

```
a = b + 2.0 ! a and b are conformable arrays of type real
```

then the effect is as if the scalar were evaluated and then broadcast to form a conformable array of elements, each having the value of the scalar. Thus, a scalar used in an array context is conformable with the array or arrays involved.

Zero-sized arrays may also appear in an array expression. Although they have no el ements, they do have a shape and must therefore follow the rule of conformable arrays. Because scalars are conformable with any array, they may therefore appear in an operation involving a zero-sized array.

The following illustrates valid and invalid array expressions.

```
SUBROUTINE foo(a,b,c)
! a is an assumed-shape array with rank-one
REAL :: a(:)
! b is a pointer to a rank-two array
REAL, POINTER :: b(:,:)
! c is an assumed-size array
REAL :: c(*)
! d is an allocatable array; its shape can only be defined in an
! ALLOCATE statement
REAL, ALLOCATABLE :: d(:)
! create the array d with the same size as a; a and d have
! the same shape and are therefore conformable
ALLOCATE(d(SIZE (a)))
! copy the array a into d
d = a
```

## Array expressions

```
! sets each element of the array associated with b to 0.0;
! the effect is as if the scalar were broadcast into a
! temporary array, with the same shape as b; b is then assigned
! to theleft-hand side
b}=0.
! corresponding elements of a and d are added together and then
! stored back into the corresponding array element of d
d = a + d
! conceptually the operand SQRT(d) is evaluated into an
! intermediate array with the same shape as d; each element of
! the intermediate array will be added to the corresponding
! element of a and stored into the corresponding element of d
d=a + SQRT(d)
DEALLOCATE (d)
! examples of illegal uses of arrays:
! ILLEGAL - c is an assumed-size array and so has no shape;
! an assumed-size array may not be used as a whole array
! operand(except in an argument list)
a = c
! ILLEGAL - the arrays a and b do not have the same shape and are
! therefore not conformable
a = a + b
! ILLEGAL - d was previously deallocated and must not be
! referenced subsequently
a = a + d
END SUBROUTINE foo
```

## Array-valued functions

A function may be array-valued; that is, its return value may evaluate to an array of values rather than to a scalar. Array-valued functions may appear in any array expression except:

- In an input list
- On the left side of an assignment statement (unless returning the result from within a function)

Array-valued functions may also be used in an array expression wherever a scalar function reference is allowed but must be conformable - that is, the function result must have the same shape as the expression.

The following sections describe intrinsic functions and user-defined functions that are array-valued.

## Intrinsic functions

Elemental procedures and transformation procedures have particular relevance to array expressions. Elemental procedures-for example, SQRT and SIN-are specified for scalar arguments, but with an array argument they return an array-valued result with the same shape as the argument. Each el ement of the result is as if the function were applied to each corresponding element of the argument.

A transformational procedure-for example, RESHAPE, SUM, and MATMUL-generally has one or more array arguments that the procedure operates on as a whole, and usually returns an array-valued result whose elements may depend not only on the corresponding elements of the arguments but also on the values of other elements of the arguments.

## User-defined functions

User-defined functions can return either a scalar-valued result or an array-valued result. A scalar function can appear in an array expression; its effect is to broadcast its value throughout a conformable array. A reference to a user-defined array-valued function must obey the rules for functions in general, and must also conform to the shape of the expression in which it appears.

## User-defined functions are described in "External procedures" on

 page 128.The following code segment illustrates two array-valued functions, genrand (user-defined) and RESHAPE (intrinsic):

```
PROGRAM main
! The following interface block describes the characteristics of
! the function genrand; the function inputs a single integer
! scalar and returns a real array of rank-one with an extent
! equal to the value of its argument
INTERFACE
    FUNCTION genrand(n)
    INTEGER:: n
    REAL, DIMENSION (n)::genrand
    END FUNCTION genrand
END INTERFACE
REAL :: a(100)
REAL :: b (10,10)
! set array a to the result returned by the function genrand;
! note that the left and right hand side are conformable
a = genrand(SIZE(a))
! add each element of a to the corresponding element of the
! result returned by genrand, forming an intermediate rank-one
! result that is passed into the intrinsic function RESHAPE.
! This intrinsic transforms its argument into a 10 by 10 array.
! Again, the left and right hand side are conformable.
b}=\operatorname{RESHAPE}(\textrm{a}+\operatorname{genrand(100),(/ 10, 10 /))
    .
END PROGRAM main
```

## Array inquiry intrinsics

Table 9 lists and briefly describes the inquiry intrinsic functions that return the properties of an array. For a full description of these intrinsics, see Chapter 11, "Intrinsic procedures," on page 475.

Table 9
Array inquiry intrinsic functions

| Intrinsic | Description |
| :--- | :--- |
| ALLOCATED | Returns the allocation status of an allocatable array; <br> see "Allocatable arrays" on page 59. |
| ASSOCIATED | Returns the association status of an array pointer; <br> see "Pointer association status" on page 48. |
| LBOUND | Returns either the lower bound of a specified <br> dimension or the lower bounds of the array as a <br> whole. |
| SHAPE | Returns the shape of the array as a rank-one integer <br> array. |
| SIZE | Returns the size of the array or the extent of a <br> particular dimension. |
| UBOUND | Returns the upper bound of a specified dimension or <br> the upper bounds of the array as a whole. |

## 5 <br> Expressions and assignment

This chapter describes expressions and assignment. M ore specifically, it covers the following topics:

- Expressions, including their components:
- Operands
- Operators
- Special forms of expression
- Assignment, including the following topics:
- Assignment statement
- Pointer assignment
- M asked array assignment

NOTE
This chapter discusses intrinsic operators and assignment only. For information about user-defined operators and assignment, see "Defined operators" on page 155 and "Defined assignment" on page 157.

## Expressions

An expression is the specification of data and, possibly, a set of operations that enable the computer to evaluate the expression and produce a value. Because an expression results in a value, it has a type, kind, and shape. If an expression is of the character type, it also has a length parameter.

The general form of an expression is:
[operand1] operator operand2
operand1, operand2
are data objects or expressions that evaluate to data.
They may be array-valued or scalar-valued.
operator
is either an intrinsic or defined operator. If operator is unary, operand1 must not be specified.
The following sections describe operands, operators, and expressions in more detail.

## Operands

An operand may be any of the following:

- A constant or a variable, such as $1.0,{ }^{\prime} \mathrm{ab}{ }^{\prime}$, or a
- An array element or an array section, such as a $(1,3)$ or a $(1,2: 3)$
- A character substring or a structure component, such as ch (1:3) or employee\%name
- An array constructor, such as (/1.0,2.0/)
- A structure constructor, such as employee(8, "Wilson", 123876)
- A function reference, such as $\operatorname{SQRT}(x)$
- An expression in parentheses, such as (b + SIN (y) **2)

Any variable or function reference used as an operand in an expression must have been previously defined. Likewise, any pointer must have been previously associated with a target. If an operand has the POINTER attribute, the target associated with it is the operand.

When an operand is a whole array reference, the complete array is referenced. An assumed-size array variable cannot be an operand. An array section of an assumed-size array can be an operand if the extent of the last dimension of the section is defined by the use of a subscript, a section subscript with an extent for the upper bound, or a vector subscript. (Assumed-size arrays are discussed in "Assumed-size arrays" on page 61, and array sections in "Array sections" on page 63.)

If two operands in an expression are arrays, they must have the same shape. If one operand is a scalar, it is treated as if it were an array of the same shape as the other operand, in which all elements have the value of the scalar. The result of the operation is an array in which each element is the result of applying the operator repeatedly to corresponding elements of the two operands.

The rules governing how the use of operands in an expression vary, depending on the type of expression. For example, some operands that may appear on the right-hand side of an assignment statement but not in an initialization expression. See "Special forms of expression" on page 89 for detailed information about the different forms of an expression and the restrictions that those forms impose on operands.

## Operators

HP Fortran recognizes the following types of operators:

- Arithmetic operators
- Relational operators
- Concatenation operator
- Logical operators
- Bitwise operators
- Defined operators

All of these except the last are intrinsic operators-that is, the operations they perform are defined by HP Fortran. Intrinsic operators are described in the following sections. Defined operators are those that

## Expressions

the programmer defines-or overloads, if the operator already has already been defined-using the INTERFACE statement. Defined operators and overloading are discussed in "Defined operators" on page 155.

## Arithmetic operators

The arithmetic operators are:

- Additive operators (+ and -). These can be used either as unary operators or binary operators.
- Multiplicative operators (/, *, and **). These are binary.

Two operands joined by a binary operator can be of different numeric types or different kind type parameters. The type of the result is:

- If the type and kind type parameters of the operands are the same, the result has the same type and kind type parameter.
- If the type of the operands is the same but the kind type parameters differ, the result has the same type and the larger kind type parameter.
- If either operand is of type complex, the result is of type complex.
- If either operand is of type real and the other operand is not of type complex, the result is of typereal.

Except for a value raised to an integer power, each operand that differs in type or kind type parameter from that of the result is converted to a value with the type and kind type of the result before the operation is performed.
Logical and integer operands can be combined with arithmetic operators. The logical operand is treated as an integer of the same kind type parameter, and the result of the operation is of type integer. If the operands have different kind type parameters, the shorter is considered to be extended as a signed integer. For information about logical values, see "L ogi cal operators" on page 84.

The arithmetic operators behave as expected, with the following qualifications:

- The division of an integer by an integer is defined to be the integer closest to the true result that is between zero and the true result.
- Exponentiation of an integer to a negative integer-i1**i2, where i2 is negative-is interpreted as 1/ (i1** (-i2)), where the division is interpreted as described for division of one integer by another.
- If $x 1$ and $x 2$ are real and $x 1$ is negative, then $x 1 * * x 2$ could be an invalid expression, as the result could be complex. Note, however, that CMPLX (x1) **x2 is valid; the result is the principal value.

The following are HP extensions to the Fortran 90 Standard:

- The exponentiation operator may be followed by a signed entity, as in the following example:

```
i ** -j
```

The Fortran 90 Standard does not allow adjacent operators.

- Operands of logical and integer types may be combined with the arithmetic operators. The logical variable is treated as an integer of equivalent size, and the result of the operation is an integer value. When different lengths of operands are involved, the shorter is considered extended as a signed integer. The following is an example:

```
LOGICAL(1) :: boolean1 = -4
LOGICAL(4) :: boolean4 = 2**16 + 27
INTEGER(1) :: flag1
INTEGER(4) :: flag4
flag4 = boolean4 - boolean1 !set flag4 to 2**16 + 31
! a relational operator with a logical operand
IF (boolean4 > 65536) THEN
    flag1 = -(boolean4/65536) !set flag1 to -1
ENDIF
```

## Relational operators

The relational operators are .EQ., .NE., .GT., .GE., .LT., .LE., ==, / $=,>,>=,<$, and $<=$. All relational operators are binary. The letter forms of the relational operators have the same meaning as the symbol forms. Thus, .EQ. is a synonym for $==$, . NE. is a synonym for $/=$, and so on.
If the operands in a relational operation are numerical expressions with different type or kind type parameters, the operands are converted to the type and kind type parameters that the sum of the operands would have and are then compared; see "Arithmetic operators" on page 82 for information about the result of mixed arithmetic expressions.

If the operands are character expressions, the shorter operand is blankpadded to the length of the other prior to the comparison. The comparison starts at the first character and proceeds until a character differs or equality is confirmed. See Appendix C for the collating sequence.

## Concatenation operator

The concatenation operator is //. It is binary.
In a concatenation operation, each operand of the concatenation operator must be of type character and have the same kind type parameter. The character length parameter of the result is the sum of the character length parameters of the operands.

## Logical operators

The logical operator are .AND., .OR., .EQV., .NEQV., .XOR., and .nOT.. The . NOT. operator is unary; the others are binary. The .xOR. is an HP extension having the same meaning as the .NEQV. operator.

As an HP extension, the operands of a logical expression may be of type integer. Functions returning integers may appear in logical expressions, and functions returning logicals may appear in integer expressions.
If the operands of a logical operation have different kind type parameters, the operand with the smaller parameter is converted to a value with the larger parameter before the operation is performed. The result has the larger kind type parameter.

Table 10 shows the behavior of the logical operators for the different permutations of operand values. Note that the .xor. operator is a synonym for the . NEQV. operator and behaves similarly.

## Table 10 Logical operators

| opnd1 | opnd2 | .AND. | . OR. | . EQV . | . NEQV | .NOT. opnd1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| . TRUE. | . TRUE. | . TRUE. | . TRUE. | . TRUE. | .FALSE. | .FALSE. |
| . TRUE. | . FALSE. | . FALSE. | . TRUE. | .FALSE. | . TRUE. | .FALSE. |
| . FALSE. | . TRUE. | . FALSE. | . TRUE. | .FALSE. | . TRUE. | . TRUE. |
| .FALSE. | . FALSE. | .FALSE. | .FALSE. | . TRUE. | . FALSE. | . TRUE. |

## Bitwise operators

As an extension to the Standard, HP Fortran allows logical operators to be used as bitwise operators on integer operands. The logical operations are bitwise; that is, they are performed for each bit of the binary representations of the integers. When the operands are of different lengths, the shorter is considered to be extended to the length of the other operand as if it were a signed integer, and the result has the length of the longer operand.

When logical operators are used on integer operands, any nonzero value is considered . TRUE., and a zero value is considered . FALSE . .

In general, an actual argument of type integer may not be used in a reference to a procedure when the corresponding dummy argument is of type logical, nor may an actual argument of type logical be used when the dummy argument is of type integer. As an HP extension, logical and integer arguments may be used interchangeably in calls to bit manipulation intrinsics. See Chapter 11, "Intrinsic procedures," on page 475 for information about the bit manipulation intrinsics.
The following example shows the use of the . And . operator to perform a bitwise AND operation:

```
INTEGER i, j
i = 5
j = 3
PRINT *, i .AND. j
! Output from the PRINT statement: 1
```

The next example shows the use of logical operators to perform bitmasking operations.

```
INTEGER(2) mask2
INTEGER(4) mask4
DATA mask2/ -4 /
DATA mask4/Z"ccc2"/
mask4 = mask4 .NEQV. mask2
mask2 = .NOT. mask4
```

```
!set mask4 to Z"ffff333e"
```

!set mask4 to Z"ffff333e"
!set mask2 to Z"ccc1"

```
    !set mask2 to Z"ccc1"
```

The next example makes a standard-conforming reference to a bit manipulation intrinsic:

```
INTEGER :: mask = 65535
LOGICAL :: is_even = .FALSE.
IF (IAND (mask,1) /= 0) is_even = .TRUE.
```

HP Fortran allows the following nonstandard version of the preceding example:

```
LOGICAL :: mask = z"ffff"
INTEGER :: is_even = .FALSE.
IF (IAND(mask,1)) is_even = .TRUE.
```

## Operator precedence

When an expression expands to operand1 operator 1 operand2 operator2 operand3 ...
each operator is assigned a precedence. The defined order of evaluation is that any subexpressions containing an operator with higher precedence than the adjacent operators is evaluated first. Where operators are of equal precedence, evaluation is from left to right. The exception to this rule is the exponentiation operator (**), which is evaluated from right to left.

Any expression or subexpression may be enclosed in parentheses. These expressions are always evaluated first, using the rules explained above. This usage of parentheses is therefore equivalent to normal mathematical usage.

Table 11 lists the precedence of the operators, and Table 12 gives example expressions that illustrate operator precedence.

Table 11
Operator precedence

| Precedence | Operators |
| :---: | :---: |
| Highest | U ser defined unary operators |
| - | ** |
| - | * / |
| - | Unary + Unary - |
| - | + - |
| - | / / |
| - | $\begin{aligned} & \text {.EQ. .NE. .LT. .LE. .GT. .GE. } \\ & ==/=\ll=\gg= \end{aligned}$ |
| - | . NOT. |
| - | . AND . |
| - | . OR. |
| - | .EQV. .NEQV. . XOR . |
| Lowest | User-defined binary operators |

Table 12
Examples of operator precedence

| Expression | How evaluated | Explanation |
| :---: | :---: | :---: |
| $a+b * c$ | $a+(b * c)$ | * has a higher precedence than +. |
| $a / b * c$ | $(\mathrm{a} / \mathrm{b}) * \mathrm{c}$ | / and * have the same precedence, and evaluation is left to right. |
| $a * *{ }^{\text {a }}$ ** $C$ | $a * *(b * * C)$ | ** evaluates right to left. |
| $\begin{aligned} & \text { a.AND.b.AND } \\ & \text {.c.OR.d } \end{aligned}$ | $\begin{aligned} & \text { ( (a.AND.b) .AND.c) } \\ & \text {.OR.d) } \end{aligned}$ | Logical operators evaluate left to right. |

Expressions and assignment
Expressions

The Standard allows the compiler to generate code that evaluates an expression by any sequence that produces a result mathematically equivalent to the sequence implied by the statement. This laxity permits code optimization, including (for example) the reordering of expressions and the promotion of common subexpressions.

Because the order of evaluation is not defined by the Standard, a function reference within an expression may not modify any of the other operands within the same expression. For example, fun (x) +x is indeterminate if the reference to fun modifies the value of the argument $x$.

## Special forms of expression

Certain language constructs allow only restricted forms of expressions. For example, the value specified for a named constant in a PARAMETER statement may be defined by an expression, but it must be possible to evaluate the expression at compile-time. This means that the expression must not contain any operands that depend on program execution for their value. To take another example, a bound of a dummy array argument may be specified as an expression, but it must be possible to evaluate this expression on entry to the subprogram.
There are special restrictions imposed on operands and operators that may appear in an expression, depending on whether the expression is one of the following:

- Constant expressions
- Initialization expressions
- Specification expressions

The following sections describe the special forms of expression.

## Constant expressions

A constant expression is either a constant or an expression containing only intrinsic operators and constant operands. This restriction also applies to any clearly defined part of a constant-for example, a substring with constant start and end points, or an array or structure constructor. A constant expression may include references to intrinsic functions that can be evaluated at compile-time. A constant expression may appear in any context in which any expression may appear.

Expressions and assignment
Expressions

The following are examples of constant expressions:

```
123 ! an integer literal
"Hello " // " World" ! a character constant expression
3.0_single ! a real literal constant where single is
    ! a named integer constant
coord(0.0,infinity) ! a structure constructor in which
    ! "infinity" is a named constant
(/ SQRT(x), x, x*x /) ! an array constructor in which x is a
    ! named real constant
x*x + 2*x*y + y*y ! a constant numeric expression where x
    ! and y are named constants
SUM(iterations,DIM=1) ! reference to a transformational
! intrinsic where iterations is an
! array-valued named constant
SHAPE(matrix) ! a reference to an inquiry intrinsic in
! which "matrix" is an array with
! constant bounds
```

## Initialization expressions

An initialization expression is a more specialized form of constant expression that can appear as the initial value in a declaration statement. Initialization expressions have these additional restrictions:

- Exponentiation is only allowed if the second operand is an integer.
- Any subexpression within the expression must itself be an initialization expression.
- All arguments to intrinsic function references must be initialization expressions.
- Only the following transformational intrinsic functions may be referenced:
- REPEAT
- RESHAPE
- SELECTED_INT_KIND
- SELECTED_REAL_KIND
- TRANSFER
- TRIM
- Any inquiry intrinsic that is referenced may interrogate a property of an entity (such as bounds or kind type parameter) only if the property is a constant.
- Any elemental intrinsic functions must have integer or character arguments and an integer or character result.

Initialization expressions are required for the following:

- Values of named constants. Any entity declared with the PARAMETER attribute must be initialized with an initialization expression.
- Kind parameter in a type specification statement.
- The KIND dummy argument of a type conversion intrinsic function.
- Initial values in type declaration statements.
- Expressions in structure constructors in DATA statements.
- Case values in CASE statements.
- Subscript expressions or substring ranges in EQUIVALENCE statements.

The following entities may not be initialized:

- Dummy arguments
- Function results
- Allocatable arrays
- Pointers
- External names
- Intrinsic names
- Automatic objects

Expressions and assignment

## Expressions

The following are examples of initialization expressions:

```
-456 ! an integer literal
("Hello "// "World") ! a character constant expression
pi * r ** 2 ! a constant numeric expression, where
    ! pi and r are named constants
ABS(i * j) ! reference to an elemental intrinsic,
        where i and j are named integer
        constants
SELECTED_REAL_KIND(7) ! reference to a transformational
intrinsic
```

The following are illegal initialization expressions:

```
x ** 2.5 ! the power operand is not an integer
LOG(10.0) ! the intrinsic function is neither
    ! integer nor character type
SUM( (/ i, 2 /) ) ! reference to a prohibited function
```

For information about initializing arrays with an array constructor, see "Array constructors" on page 71.

## Specification expressions

A specification expression has a scalar value, is of type integer, and can be evaluated on entry to the scoping unit in which it appears. A specification expression may appear (for example) as a bound in an array declaration or as the length in a ChARACTER type declaration.
An operand in a specification expression is one of the following:

- A literal or named constant or part of a constants.
- A variable that is available by argument, host, or use association or is in common.
- An array constructor or structure constructor where each element or component is also a specification expression or is a variablein an implied-Do loop appearing in the array constructor.
- A dummy argument having neither the OPTIONAL attribute nor the Intent (OUT) attribute.
- An argument to an intrinsic function.
- A reference to an elemental intrinsic function that returns an integer result.
- A reference to any of the following transformational intrinsic functions:
- REPEAT
- RESHAPE
- SELECTED_INT_KIND
- SELECTED_REAL_KIND
- TRANSFER
- TRIM
- Any inquiry intrinsic except ALLOCATED, ASSOCIATED, and PRESENT. Other inquiry intrinsics may be referenced so long as the property interrogated is not defined by either a pointer assignment or ALLOCATE statement. Furthermore, an inquiry intrinsic may not interrogate the following properties of an assumed size array:
- Upper bound of the last dimension
- Extent of the last dimension
- Size of the array
- Shape of the array

Expressions and assignment
Expressions

The differences between specification expressions and initialization expressions are summarized in Table 13.
Table 13 Initialization and specification expressions

| Initialization expression | Specification expression |
| :--- | :--- |
| Can be either scalar or array-valued. | Must be scalar-valued. |
| Can be of any type. | Must be of type integer. |
| M ust be a constant expression. | Can reference variables by host, argument, or <br> use storage association; can reference <br> variables in common. |
| ExCept for ALLOCATED, ASSOCIATED, and <br> PRESENT, can reference inquiry intrinsics <br> to interrogate a property of an entity, <br> provided that the property is constant. | Can reference inquiry intrinsic functions, <br> except for ALLOCATED, ASSOCIATED, and <br> PRESET. The arguments must be <br> specification expressions or variables whose <br> bounds or type parameters inquired about are <br> not assumed, are not defined by the <br> ALLOCATE statement, or are not defined by <br> pointer assignment. |

The following are examples of specification expressions:

```
789
MAX (m+n,0) ! m and n are integer dummy arguments
LEN(c) ! c is a character variable accessible via
! host association
SELECTED_INT_KIND(5) ! reference to a transformational
! intrinsic
UBOUND(arr,DIM=n) ! reference to an array inquiry
! intrinsic in which arr is an array
! accessible via USE and n is a
! variable in common
```

## Assignment

An assignment operation defines a variable by giving it a value. In HP Fortran, there are four types of assignment:

- Intrinsic assignment (also known as the assignment statement)
- Pointer assignment
- Masked-array assignment (also known as the where construct)
- Defined assignment

The following sections describe the first three assignment types. The last-defined assignment-is defined by the programmer, using the interface statement. For information about defined assignment, see "Defined assignment" on page 157.

## Assignment statement

An assignment statement gives the value of an expression to a variable. It has the following syntax:
variable $=$ expression
variable may be any nonpointer variable or a pointer variable that is associated with a target. (If variable is a pointer, expression is assigned to the target.) The valid combinations of types for variableand expression are given in Table 14. The intrinsic functions that document the conversions are described in Chapter 11.
Table 14 Conversion of variable=expression

| Variable <br> type | Expression type | Conversion |
| :--- | :--- | :--- |
| Integer | Integer, real, or complex | INT (expression, KIND (variable) ) |
| Real | Integer, real, or complex | REAL (expression, KIND (variable) ) |
| Character | Character (same kind <br> parameters) | CMPLX (expression, KIND (variable) ) |

## Assignment

| Variable <br> type | Expression type | Conversion |
| :--- | :--- | :--- |
| Logical | Logical | Truncate expression if its length is greater <br> than that of variable otherwise, pad value <br> assigned to variable, with blanks. |
| Logical | Logical | LOGICAL (expression, KIND (variable) ) |
| Derived type | Same derived type | None |

As described in "Bitwise operators" on page 85, HP Fortran allows integer and logical operands to be used interchangeably. HP Fortran also allows logical expressions to be assigned to integer variables and integer expressions to logical variables. As shown in Table 14, a logical expression may also be assigned to real or complex variables, and similarly, a real or complex expression may be assigned to a logical variable.

If variable is a scalar, expression must be scalar. If variableis an array or an array section, expression must be either an array-valued expression of the same shape or a scalar. If variableis an array or an array section, and expression is a scalar, the value of expression is assigned to all elements of variable. If variable and expression are both arrays, the assignment is carried out element by element with no implied ordering.

The expression is evaluated completely before the assignment is started. For example, the following code segment:

CHARACTER (LEN=4): C
c $(1: 4)=$ 'abcd'
$c(2: 4)=c(1: 3)$
sets c (2:4) to "abc", not to "aaa", which might result from a left-toright character-by-character assignment.

The following examples illustrate assignments of different data types:

```
! declarations of the variables used in the assignment statements
    to follow
integer icnt
type circle
    real radius
    real xreal y
end type
type (circle) circle1, circle2
real area, pi
logical boolx, booly, pixel(10,10)
integer a(10,5)
integer, dimension (10,10):: matrix1, matrix2
character*3 initials
character*10 surname
character*20 name
icnt = icnt + 1 ! integer assignment
circle1 = circle2 ! derived-type assignment
area = pi * circle%radius**2 ! real assignment
pixel(x,y) = boolx .AND. booly ! assigns a logical expression to
    ! an element of the logical
    ! array pixel
a(:,1:2)=0 ! first two columns of a are set to zero
maxtrix1 = maxtrix2 ! each element of maxtrix2 is assigned to
    ! the corresponding element of maxtrixl
name = initials // surname ! character assignment using the
        ! concatenation operator
```

## Pointer assignment

Pointer assignment establishes an association between a pointer and a target. Once the association is established, if the pointer is referenced on the left-hand side of an assignment statement, it is the target to which the assignment is made. And if the pointer is referenced in an expression, the target is taken as the operand in the expression.

The syntax of a pointer assignment is:
pointer-object => target-expression
pointer-object
is a variable with the POINTER attribute.

Expressions and assignment

## Assignment

## target-expression

is one of the following:

- A variable with the TARGET or POINTER attribute
- A function reference or defined operation that returns a pointer result

The type, kind, and rank of pointer-object and target-expression must be the same. If target-expression is an array, it cannot be an assumed-size array or an array section with a vector subscript. For information about assumed-size arrays, see "Assumed-size arrays" on page 61. For information about array sections with vector subscripts, see "Vector subscripts" on page 65.

If target-expression is a pointer already associated with a target, then pointer-object becomes associated with the target of target-expression. If target-expression is a pointer that is disassociated or undefined, then pointer-object inherits the disassociated or undefined status of targetexpression. For information about pointer status, see "Pointer association status" on page 48.

The following example, ptr_assign.f90, illustrates association of scalar and array pointers with scalar and array targets:

```
ptr_assign.f90
PROGRAM main
    INTEGER, POINTER :: p1, p2, p3(:) ! declare three pointers, p3
    INTEGER, TARGET :: t1 = 99, t2(5) = (/ 1, 2, 3, 4, 5 /)
    ! p1, p2 and p3 are currently undefined.
    p1 => t1 ! p1 is associated with t1.
    PRINT *, 'contents of t1 referenced through p1:', p1
    p2 => p1 ! p2 is associated with t1.
            ! p1 remains associated with t1.
    PRINT *, 'contents of t1 referenced through p1 through p2:', p2
    p1 => t2(1) ! p1 is associated with t2(1)
            ! p2 remains associated with t1.
    PRINT *, 'contents of t2(1) referenced through p1:', p1
    p3 => t2 ! p3 is associated with t2.
    PRINT *, &
        'contents of t2 referenced through the array pointer p3:', p3
    p1 => p3(2) ! p1 is associated with t2(2).
    PRINT *, &
```

```
    'contents of t2(2) referenced through p3 through p1:', p1
    NULLIFY(p1) ! p1 is disassociated.
    IF (.NOT. ASSOCIATED(p1)) PRINT *, "p1 is disassociated."
    p2 => p1 ! Now p2 is also disassociated.
    IF (.NOT. ASSOCIATED(p2)) PRINT *, &
    "p2 is disassociated by pointer assignment."
END PROGRAM main
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 ptr_assign.f90
$ a.out
contents of t1 referenced through p1: 99
contents of t1 referenced through p1 through p2: 99
contents of t2(1) referenced through p1: 1
contents of t2 referenced through the array pointer p3: 1 2 3
4
contents of t2(2) referenced through p3 through p1: 2
p1 is disassociated.
p2 is disassociated by pointer assignment.
```

## Masked array assignment

In a masked array assignment, a logical expression-called a maskcontrols the selection of array elements for assignment. Masked array assignment is implemented by the where statement and the where construct. The syntax of the WHERE statement is:
wHERE (array-logical-expression) array = array-expression
where array-logical-expression, array, and array-expression must all be conformable. The array-logical-expression (the mask) is evaluated for each element and the outcome(.TRUE. or .FALSE.) determines whether an assignment is made to the corresponding element of array.

The syntax of the where construct is:

```
WHERE ( array-logical-expression )
    array = array-expression
    [array = array-expression] ...
[ELSEWHERE
    array = array-expression
    [array = expression] . . . ]
END WHERE
```

## Assignment

The WHERE construct is similar to the WHERE statement, but more general in that several array = array-expression statements can be controlled by one array-logi cal-expression. In addition, an optional ELSEWHERE part of the construct assigns array el ements whose corresponding array-logicalexpression elements evaluate to .FALSE..

When a WHERE construct is executed, array-logi cal-expression is evaluated just once and therefore any subsequent assignment in a WHERE block (the block following the WHERE statement) or ELSEWHERE block to an entity of array-logical-expression has no effect on the masking. Thereafter, successive assignments in the WHERE block are evaluated in sequence as if they were specified in a wHERE statement, as follows:

WHERE (array-logical-expression) array = array-expression
Each assignment in the ELSEWHERE is executed as if it were:

## WHERE (. NOT . array-logical-expression) array =array-expression

For example, the following wHERE construct:

```
WHERE (a > b)
    a = b
    b}=
ELSEWHERE
    b}=\textrm{a
    a = 0
END WHERE
```

is evaluated as if it was specified as:

```
mask = a > b
WHERE (mask) a = b
WHERE (mask) b = 0
WHERE (.NOT.mask) b = a
WHERE (.NOT.mask) a = 0
```

Only assignment statements may appear in a WHERE block or an ELSEWHERE block. Within a WHERE construct, only the WHERE statement may be the target of a branch.

The form of a wHERE construct is similar to that of an IF construct, but with this important difference: no more than one block of an IF construct may be executed, but in a WHERE construct at least one (and possibly both) of the WHERE and ELSEWHERE blocks will be executed. In a WHERE construct, this difference has the effect that results in a WHERE block may feed into, and hence affect, variables in the ELSEWHERE block. Notice, however, that results generated in an ELSEWHERE block cannot feed back into variables in the WHERE block.

The following example score2grade.f90 illustrates the use of a masked assignment to find the letter-grade equival ent for each test score in the array test_score. To do the same operation without the benefit of masked array assignment would require a Do loop iterating over the array either in an IF-ELSE-IF construct or in a CASE construct, testing and assigning to each element at a time.

## score2grade.f90

```
PROGRAM main
    ! illustrates the use of the WHERE statement in masked array
    ! assignment
    ! use an array constructor to initialize the array that holds
    ! the numerical scores
    INTEGER, DIMENSION(10) :: test_score = &
        (/75,87,99,63,75,51,79,85,93,80/)
    ! array to hold the equivalent letter grades (A, B, C, etc.)
    CHARACTER, DIMENSION(10) :: letter_grade
    ! because the array arguments are declared in the procedure
    ! as assumed-shape arrays, the procedure's interface must
    ! be explicit
    !
    INTERFACE
        SUBROUTINE convert(num, letter)
            INTEGER :: num(:)
            CHARACTER :: letter(:)
        END SUBROUTINE convert
    END INTERFACE
    PRINT *, 'Numerical score:', test_score
    CALL convert(test_score, letter_grade)
    PRINT '(A,10A3)', ' Letter grade: ', letter_grade
END PROGRAM main
SUBROUTINE convert(num, letter)
    ! declare the dummy arguments as assumed-shape arrays
    INTEGER :: num(:)
    CHARACTER :: letter(:)
    ! use the WHERE statements to figure the letter grade
    ! equivalents
    WHERE (num >= 90) letter = 'A'
    WHERE (num >= 80 .AND. num < 90) letter = 'B'
    WHERE (num >= 70 .AND. num < 80) letter = 'C'
    WHERE (num >= 60 .AND. num < 70) letter = 'D'
    WHERE (num < 60) letter = 'F'
END SUBROUTINE convert
```

## Assignment

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 score2grade.f90
$ a.out
Numerical score: 75 87 99 63 75 51 79 85 93 80
Letter grade: C B A D C F C B A B
```

The next example is a subroutine that uses the wHERE construct to replace each positive el ement of array a by its square root. The remaining elements calculate the complex square roots of their values, which are then stored in the corresponding elements of the complex array ca. In the elsewhere part of the construct, the assignment to array a should not appear before the assignment to array ca; otherwise, all of ca will be set to zero.

```
SUBROUTINE find_sqrt(a, ca)
    REAL :: a(:)
    COMPLEX :: ca(:)
    WHERE (a > 0.0)
        ca = CMPLX(0.0)
        a = SQRT(a)
    ELSEWHERE
        ca = SQRT(CMPLX(a))
        a = 0.0
    END WHERE
END SUBROUTINE find_sqrt
```

## 6 <br> Execution control

The normal flow of execution in a Fortran 90 program is sequential. Statements execute in the order of their appearance in the program. However, you can alter this flow. The following topics, described in this chapter, describe how to achieve this:

- Control constructs and statement blocks
- Flow control statements

For a full description of each Fortran 90 control statement, see Chapter 10, "HP Fortran Statements." For information about the WHERE construct, see "Masked array assignment" on page 99.

## Control constructs and statement blocks

A control construct consists of a statement block whose execution logic is defined by one of the following control statements:

- CASE statement
- Do statement
- IF statement

A statement block is a sequence of statements delimited by a control statements and its corresponding terminal statement. A statement block consists of zero or more statements and can include nested control constructs. However, any nested construct must have its beginning and end within the same statement block.

Although the Standard forbids transferring control into a statement block except by means of its control statement, HP Fortran allows it. The Standard does permit the transferring control out of a statement block. For example, the following IF construct contains a GO TO statement that legally transfers control to a label that is defined outside the IF construct:

```
IF (var > 1) THEN
    var1 = 1
ELSE
    GO TO 2
END IF
2 var1 = var2
```

The next logical IF statement is nonstandard (but permitted by HP Fortran) because it would transfer control into the DO construct:

```
IF (.NOT.done) GO TO 4 ! nonstandard!
DO i}=1,10
    sum = b + c
4 b = b + 1
END DO
```

The following sections describe the operations performed by the three control constructs.

Execution control

## CASE construct

The CASE construct selects (at most) one out of a number of statement blocks for execution.

Syntax [construct-name : ] SELECT CASE ( case-expr )
[CASE ( caseselector ) [ construct-name ]
statement-block ]
[CASE DEFAULT [construct-name]
statement-block ]
END SELECT [ construct-name]
Notes on syntax caseselector is one of the following:

- case-value
- Iow :
- : high
- low : high
casese ectors must be mutually exclusive and must agree in type with case-expr.
caseexpr must evaluate to a scalar value and must be an integer, logical, or character type.
If construct-name is given in the SELECT CASE statement, the same name may appear after any CASE statement within the construct, and must appear in the END CASE statement. The construct name cannot be used as a name for any other entity within the program unit.

CASE constructs can be nested. Construct names can then be useful in avoiding confusion.

Although the Standard forbids branching to any statement in a CASE construct other than the initial SELECT CASE statement from outside the construct, HP Fortran allows it. The Standard allows branching to the END SELECT statement from within the construct.

## Execution control

## Control constructs and statement blocks

Execution logic The execution sequence of the CASE construct is as follows:
1 case-expr is evaluated.
2 The resulting value is compared to each casesel ector.
3 If a match is found, the corresponding statement-bl ock executes.
4 If no match is found but a CASE DEFAULT statement is present, its statement-block executes.

5 If no match is found and there is no CASE DEFAULT statement, execution of the CASE construct terminates without any block executing.

6 The normal flow of execution resumes with the first executable statement following the end select statement, unless a statement in statement-block transfers control.

Example
The following CASE construct prints an error message according to the value of ios_err:

INTEGER :: ios_err
SELECT CASE (ios_err)
CASE (:900)
PRINT *, "Unknown error"
CASE (913)

```
    PRINT *, "Out of free space"
```

CASE (963:971)
PRINT *, "Format error"
CASE (1100:)
PRINT *, "ISAM error"
CASE Default
PRINT *, "Miscellaneous Error"
End SELect

## DO construct

The do construct repeatedly executes a statement block. The syntax of the do statement provides two ways to specify the number of times the statement block executes:

- By specifying a loop count.
- By testing a logical expression as a condition for executing each iteration.

You can also omit all control logic from the do statement, in effect creating an infinite loop. The following sections describe the three variations of the DO construct.
You can use the CycLe and EXIT statements to alter the execution logic of the do construct. For information about these statements, see "Flow control statements" on page 112.

## Counter-controlled do loop

A counter-controlled Do loop uses an index variable to determine the number of times the loop executes.

```
[ construct-name : ] DO index = init, limit [ , step ]
```

    statement-block
    END DO [ construct-name ]

HP Fortran also supports the older, FORTRAN 77-style syntax of the Do loop:

```
DO labed index = init, limit [ , step ]
    statement-sequence
label terminal-statement
```

A third form, combining elements of the other two, is also supported:
[construct-name :] DO label index = init, limit [, step]

## Execution control

## Control constructs and statement blocks

Execution logic The following execution steps apply to all three syntactic forms, except as noted:

1 The loop becomes active, and index is set to init.
2 The iteration count is determined by the following expression:
MAX ( INT ( limit - init + step ) / step, 0 )
step is optional, with the default value of 1 . It may not be 0 .
N ote that the iteration count is 0 if either of the following conditions is true:

- step (if present) is a positive number and init is greater than limit.
- step is a negative number and init is less than limit.

3 If the iteration count is 0 , the construct becomes inactive and the normal flow of execution resumes with the first executable statement following the END DO or terminal statement.

4 statement-block executes. (In the case of the old-style syntactic form, both statement-sequence and terminal-statement execute.)

5 The iteration count is decremented by 1 , and index is incremented by step, or by 1 if step is not specified.

## 6 Goto Step 3.

NOTE

Examples This example uses nested Do loops to sort an array into ascending order:

```
INTEGER :: scores(100)
DO i = 1, }9
    DO j = i+1, 100
        IF (scores(i) > scores(j)) THEN
            temp = scores(i)
            scores(i) = scores(j)
            scores(j) = temp
        END IF
    END DO
END DO
```

The following example uses the older syntactic form. Note that, unlike the newer form, old-style nested Do loops can share the same terminal statement:

```
    DO 10 i = 1, 99
    DO 10 j = i+1, 100
        if (scores(i) <= scores(j)) GO TO 10
        temp = scores(i)
        scores(i) = scores(j)
        scores(j) = temp
10 CONTINUE
```

## Conditional Do loop

A conditional Do loop uses the while syntax to test a logical expression as a condition for executing the next iteration.

```
Syntax
Execution logic
Example
```

```
[ construct-name :] DO WHILE ( logical-expression )
```

[ construct-name :] DO WHILE ( logical-expression )
statement-block
statement-block
END DO [ construct-name ]
END DO [ construct-name ]
Fortran 90 also supports the older syntax of the DO WHILE loop:

```
```

DO label while ( logical-expression )

```
DO label while ( logical-expression )
    statement-sequence
    statement-sequence
label terminal-statement
```

label terminal-statement

```

\section*{Execution logic}
```

1 The loop becomes active.
2 The logical-expression is evaluated. If the result of the evaluation is false, the loop becomes inactive, and the normal flow of execution resumes with the first executable statement following the END DO statement, or in the old Do-loop syntax, the terminal statement.
3 statement-bl ock executes. (In the case of the old-style syntactic form, both statement-sequence and terminal-statement execute.)
4 Go to Step 2.
Example

```

\section*{Execution control}

\section*{Control constructs and statement blocks}
```

    money = money + (interest * money)
    END DO
PRINT *, "Years =", years

```

\section*{Infinite do loop}

The do statement for the infinite do loop contains no loop control logic. It executes a statement block for an indefinite number of iterations, until it is terminated explicitly by a statement within the block; for example, a RETURN or EXIT statement.

Syntax

Execution logic The execution sequence of an infinite Do loop is as follows:
1 The loop becomes active.
2 statement-bl ock executes.
3 Goto Step 2.
Example
```

! Compute the average of input values; press 0 to exit
INTEGER :: i, sum, n
sum = 0
n}=
average: DO
PRINT *,' 'Enter a new number or 0 to quit'
READ *, i
IF (i == 0) EXIT
sum = sum + i
n=n}+
END DO average
PRINT *, 'The average is ', sum/n

```

\section*{IF construct}

The IF construct selects betwen alternate paths of execution. The executing path is determined by testing logical expressions. At most, one statement block within the IF construct executes.

Syntax
Execution logic
```

[construct-name :] IF (logical-expression1) THEN
statement-block1
[ELSE IF (logical-expression2) THEN [construct-name]
statement-block2 ]
[ELSE [construct-name]
statement-block3]
END IF [construct-name]

```

1 logical-expression1 is evaluated. If it is true, statement-block1 executes.

2 If logical-expression1 evaluates to false and ELSE IF statements are present, the logical-expression for each ELSE IF statement is evaluated. The first expression to eval uate to true causes the associated statement-bl ock to execute.

3 If all expressions evaluate to false and the ELSE statement is present, its statement-bl ock executes. If the ELSE statement is not present, no statement block within the construct executes.

4 The normal flow of execution resumes with the first executable statement following the END IF statement.

Example
```

! Compare two integer values
IF ( num1 < num2 ) THEN
PRINT *, "num1 is smaller than num2."
ELSE IF ( num1 > num2 ) THEN
PRINT *, "num1 is greater than num2."
ELSE
PRINT *, "The numbers are equal"
END IF

```

\section*{F low control statements}

Flow control statements alter the normal flow of program execution or the execution logic of a control construct. For example, the GO то statement can be used to transfer control to another statement within a program unit, and the EXIT statement can terminate execution of a Do construct.

This section describes the operations performed by the following flow control statements:
- Continue statement
- CYCLE statement
- EXIT statement
- Assigned Go TO statement
- Computed go тo statement
- Unconditional GO TO statement
- Arithmetic If statement
- Logical If statement
- PAUSE statement
- STOP statement

For additional information about these statements, see Chapter 10, "HP Fortran Statements."

\section*{CONTINUE statement}

The continue statement has no effect on program execution. It is generally used to mark a place for a statement label, especially when it occurs as the terminal statement of a F ORTRAN 77-style Do loop.

Syntax
Execution logic No action occurs.
Example

Syntax
Execution logic
CONTINUE

\section*{CYCLE statement} do loop.

CYCLE [ do-construct-name ]
```

! find the 50th triangular number
triangular_num = 0
DO 10 i = 1, 50
triangular_num = triangular_num + i
10 CONTINUE
PRINT *, triangular_num

```

The CYCLE statement interrupts execution of the current iteration of a

1 The current iteration of the enclosing do loop terminates. Any statements following the CYCLE statement do not execute.

2 If do-construct-name is specified, the iteration count for the named Do loop decrements. If do-construct-name is not specified, the iteration count for the immediately enclosing Do loop decrements.

3 If the iteration count is nonzero, execution resumes at the start of the statement block in the named (or enclosing) Do loop. If it is zero, the relevant do loop becomes inactive.

\section*{Execution control}

\section*{Flow control statements}
```

Example LOGICAL :: even
INTEGER :: number
loop: DO i = 1, 10
PRINT *, "Enter an integer: "
READ *, number
IF (number == 0) THEN
PRINT *, "Must be nonzero."
CYCLE loop
END IF
even = (MOD (number, 2) == 0)
IF (even) THEN
PRINT *, "Even"
ELSE
PRINT *, "Odd"
END IF
END DO loop

```

\section*{EXIT statement}

The EXIT statement terminates a do loop. If it specifies the name of a Do loop within a nest of Do loops, the EXIT statement terminates all loops by which it is enclosed, up to and including the named Do loop.
```

Syntax EXIT [ do-construct-name ]
Execution logic If do-construct-name is specified, execution terminates for all Do loops do loop.
Example

```
```

DO

```
DO
    PRINT *, "Enter a nonzero integer: "
    PRINT *, "Enter a nonzero integer: "
    READ *, number
    READ *, number
    IF (number == 0) THEN
    IF (number == 0) THEN
        PRINT *, "Bye"
        PRINT *, "Bye"
        EXIT
        EXIT
        END IF
        END IF
        even_odd = MOD (number, 2)
        even_odd = MOD (number, 2)
        IF (even_odd == 0) THEN
        IF (even_odd == 0) THEN
            PRINT *, "Even"
            PRINT *, "Even"
        ELSE
        ELSE
            PRINT *, "Odd"
            PRINT *, "Odd"
        END IF
        END IF
END DO
```

END DO

``` that are within range, up to and including the do loop with that name. If no name is specified, execution terminates for the immediately enclosing

\section*{Assigned GO то statement}

The assigned GO TO statement transfers control to the statement whose statement label was assigned to an integer variable by an ASSIGN statement.

Syntax

Execution logic Control transfers to the executable statement at integer-variable.

\section*{Execution control}

\section*{Flow control statements}

\section*{Example}
```

INTEGER int_label
•
ASSIGN 20 TO int_label
.
GOTO int_label
.
20 ...

```

\section*{Computed GO то statement}

The computed GO TO statement transfers control to one of several labeled statements, as determined by the value of an arithmetic expression.

Syntax
Execution logic

\section*{Example}

GO TO ( label-list ) [ , ] integer-expression
1 integer-expression is evaluated.
2 The resulting integer value (the index) specifies the ordinal position of the label that is selected from label-list.

3 Control transfers to the executable statement with the sel ected label. If the value of the index is less than 1 or greater than the number of labels in label-list, the computed GO TO statement has no effect, and control passes to the next executable statement in the program.

DO
```

        PRINT *, "Enter a number 1-3: "
    ```
        READ *, k
        GO TO \((20,30,40) \mathrm{k}\)
        PRINT *, "Number out of range."
        EXIT
20 i \(=20\)
        GO TO 100
30 i \(=30\)
        GO TO 100
40 i \(=40\)
100 print *, i
    END DO

\section*{Unconditional GO TO statement}

The unconditional GO TO statement transfers control to the statement with the specified label.

Syntax
Execution logic
Example
Gо то labe

Control transfers to the statement at label.
Older, "dusty-deck" Fortran programs often combine the GO TO statement with the logical IF statement to form a kind of leap-frog logic, as in the following:
```

    IF ( num1 /= num2) GO TO 10
    PRINT *, "num1 and num2 are equal."
    GO TO 30
    10 IF ( num1 > num2 ) GO TO 20
PRINT *, "num1 is smaller than num2."
GO тO 30
20 PRINT *, "num1 is greater than num2."
30 CONTINUE

```

\section*{Arithmetic IF statement}

The arithmetic IF transfers control to one of three labeled statements, as determined by the value of an arithmetic expression.

Syntax
Execution logic

Example
IF ( arithmetic-expression ) label1, label2, label3
1 arithmetic-expression is evaluated.
2 If the resulting value is negative, control transfers to the statement at label 1.

3 If the resulting value is 0 , control transfers to the statement at label 2 .
4 If the resulting value is positive, control transfers to the statement at label 3.

As shown in this example, two or more labels in the label list can be the same.
```

i = MOD(total, 3) + 1
IF ( i ) 10, 20, 10

```

\section*{Flow control statements}

\section*{Logical If statement}

The logical IF statement executes a single statement, conditional upon the value of a logical expression. The statement it executes must not be:
- A statement used to begin a construct
- Any End statement
- Any IF statement

Syntax
Execution logic

Example

Execution logic 1 Execution of the program is suspended, and the following message is written to standard output:

> To resume execution, type 'go'.

If pause-code is specified, the following message is written:
To resume execution, type 'go'.
PAUSE pausecode

2 The normal flow of execution resumes after the user types the word go followed by return. If the user enters anything other than go, program execution terminates.
If the standard input device is other than a terminal, the message is:
```

To resume execution, execute a kill -15 pid
command.

```
pid is the unique process identification number of the suspended program. The kill command can be issued at any terminal at which the user is logged in.

\section*{Example}

PAUSE 999

\section*{STOP statement}

The STOP statement terminates program execution.
Syntax
STOP [ stop-code ]
where stop-code is a character constant, a named constant, or a list of up to 5 digits.

Execution logic Program terminates execution. If stop-code is specified, the following is written to standard output:
STOP stop-code
Example
STOP "Program has stopped executing."

Execution control
Flow control statements

\section*{\(7 \quad\) Program units and procedures}

This chapter describes the internal structure of each type of program unit, how it is used, and how information is communicated between program units and shared by them. This includes the following topics:
- Terminology and concepts
- Main program
- External procedures
- Internal procedures
- Statement functions
- Arguments
- Procedure interface
- Modules
- Block data program unit

For detailed information about individual statements that can be used to build program units and procedures, see Chapter 10, "HP Fortran Statements."

\section*{Terminology and concepts}

The following sections define the terms and explain the concepts that are mentioned throughout this chapter.

\section*{Program units}

A program consists of the following program units:
- Main program unit
- External procedure, which can be either a subroutine or a function
- Module program unit
- Block data program unit

A complete executable program contains one (and only one) main program unit and zero or more other program units, each of which is separately compilable. A program unit is an ordered set of constructs, statements, comments, and InCLUDE lines. The heading statement identifies the kind of program unit; it is optional in a main program unit only. An END statement marks the end of a program unit.

The only executable program units are the main program and external procedures. Program execution begins with the first executable statement in the main program and ends (typically) with the last. During execution, if the main program references an external procedure, control passes to the procedure, which executes and returns control to the main program. An executing procedure can also reference other procedures or even reference itself recursively.
The main program unit is described in "M ain program" on page 125, and external procedures are described in "External procedures" on page 128.
The nonexecutable program units are:
- The module program unit, which contains data declarations, userdefined type definitions, procedure interfaces, common block declarations, namelist group declarations, and subprogram definitions used by other program units. Modules are described in "M odules" on page 161.
- The block data program unit, which specifies initial values for variables in named common blocks. Block data program units are described in "Block data program unit" on page 169.

\section*{Procedures}

A procedure is a subroutine or function that contains a sequence of statements and that may be invoked during program execution. Depending on where and how it is used, a procedure can be one of the fol lowing:
- Intrinsic procedures are defined by the language and are available for use without any declaration or definition. Intrinsic procedures implement common computations that are important to scientific and engineering applications. Intrinsic procedures are described in detail in Chapter 11, "Intrinsic procedures," on page 475.
- An external procedure is a separately compilable program unit whose name and any additional entry points have global scope. External procedures are described in "External procedures" on page 128.
- An internal procedure has more limited accessibility than an external procedure. It can appear only within a main program unit or an external procedure and cannot be accessed outside of its hosting program unit. Internal procedures are described in "Internal procedures" on page 135.
- A module procedure can be defined only within a module program unit and can be accessed only by use association. Module procedures are described in "M odules" on page 161.

\section*{Scope}

All defined Fortran entities have a scope within which their properties are known. For example, a label used within a subprogram cannot be referenced directly from outside the subprogram; the subprogram is the scoping unit of the label. A variable declared within a subprogram has a scope that is the subprogram. A common block name can be used in any program unit, and it refers to the same entity-that is, the name has global scope. At the other extreme, the index variable used within an implied-Do loop in a DATA statement or array constructor has a scope consisting only of the implied-do loop construct itself.

Program units and procedures
Terminology and concepts

\section*{Association}

If the concept of scope limits the accessibility of entities, then the concept of association permits different entities to become accessible to each other in the same or different scope. The different types of association are:
- Argument association is the association that is established between actual arguments and dummy arguments during a procedure reference. For more information, see "Argument association" on page 139.
- Host association applies to nested scoping units, where the outer scoping unit (for example, an external procedure) plays host to the inner scoping unit (for example, an internal procedure). H ost association allows the host and its nested scoping units to share data. For information about internal procedures, see "Internal procedures" on page 135.
- Pointer association is the association between a pointer and its target that is established by a pointer assignment statement. For more information, see "Pointer association status" on page 48 and "Pointer assignment" on page 97.
- Sequence association is the association that is established between dummy and actual arguments when they are arrays of different rank. For more information, see "Array dummy argument" on page 140.
- Storage association is the association of different objects with the same storage area and is established by the eQuivalence and COMMON statements. For more information about storage association, refer to the descriptions of the EQUIVALENCE and COMMON statements in Chapter 10, "HP Fortran Statements." Derived-type objects that include the SEQUENCE statement in their definition can also be storage associated; see "Sequence derived type" on page 41.
- Use association allows different program units access to module entities by means of the USE statement. For more information about modules and the USE statement, see "M odules" on page 161.

\section*{Main program}

A main program is a program unit. There must be exactly one main program in an executable program. Execution always begins with the main program.

The main program can determine the overall design and structure of the complete program and often performs various computations by referencing procedures. A program may consist of the main program alone, in which case all the program logic is contained within it.

A main program has the form:
[PROGRAM program-name]
[specification-part]
[ execution-part]
[internal-procedurepart]
END [PROGRAM [program-name]]
program-name
i s the name of the program. program-name can appear on the END PROGRAM statement only if it also appears on the PROGRAM statement; the name must be the same in both places.
specification-part
is zero or more of the statements listed in Table 15 as well as any of the following:
- Type declaration statement
- Derived-type definition
- Interface block
- Statement function
- Cray-style pointer statement (HP extension)
- Structure definition (HP extension)
- Record declaration (HP extension)

Program units and procedures
Main program
execution-part
is zero or more of the statements or constructs listed in Table 16 as well as any of the following:
- Assignment statement
- Pointer assignment statement
internal-procedurepart
takes the form:

\section*{CONTAINS}
[internal-procedure] . . .
where internal-procedure is one or more internal procedures; see "Internal procedures" on page 135.

Table 15
Specification statements
\begin{tabular}{|lll|}
\hline ALLOCATABLE & FORMAT & POINTER \\
COMMON & IMPLICIT & SAVE \\
DATA & INTRINSIC & STATIC \\
DIMENSION & NAMELIST & USE \\
EQUIVALENCE & OPTIONAL & VIRTUAL \\
EXTERNAL & PARAMETER & VOLATILE \\
\hline
\end{tabular}

\section*{Table 16}

\section*{Executable statements}
\begin{tabular}{|lll|}
\hline ACCEPT & ELSE & ON \\
ALLOCATE & ELSE IF & OPEN \\
ASSIGN & ELSEWHERE & PAUSE \\
BACKSPACE & ENCODE & PRINT \\
CALL & END & READ \\
CASE COnstruct & ENDFILE & REWIND \\
CLOSE & EXIT & STOP \\
CONTINUE & FORMAT & TYPE (I/O) \\
CYCLE & GO TO & WHERE \\
DEALLOCATE & IF COnstruct & WHERE COnstruct \\
DECODE & INQUIRE & \\
DO & NULLIFY & \\
DO COnstruct & &
\end{tabular}

The only required component of a main program unit is the END statement. The following is therefore a valid, compilable program:

\section*{External procedures}

External procedures are implemented as either functions or subroutines. The major difference between the two is that a function subprogram returns a value and can therefore appear as an operand in an expression.

The following sections describe both types of external procedures, including the following topics:
- Procedure definition
- Procedure reference
- Returning from a procedure call
- Alternate entry points

For detailed information about any of the statements associated with procedures (for example, SUBROUTINE and FUNCTION), refer to Chapter 10, "HP Fortran Statements."

\section*{Procedure definition}

The definition of an external procedure takes the form:

\section*{external-procedurestatement}
[specification-part]
[execution-part]
[internal-procedure-part]
end-external-procedurestatement
external-procedurestatement
takes one of the following forms, depending on whether the procedure is a subroutine or function
- [RECURSIVE] SUBROUTINE name \&
[ ([dummy-arg-list])]
- [RECURSIVE][typespec] FUNCTION name \&
([dummy-arg-list]) [RESULT (result-name)]
where name is the name of the procedure; typespec is the type of the function's result value; and dummy-arg-list is a commaseparated list of dummy arguments, as described in
"Arguments" on page 139. The subroutine and function statements are fully described in Chapter 10, "HP Fortran Statements."
specification-part
is zero or more of the statements listed in Table 15 as well as the AUTOMATIC statement.
execution-part
is zero or more of the statements listed in Table 16 as well as the following statements:
- ENTRY statement
- RETURN statement
internal-procedure-part
takes the form:
CONTAINS
[internal-procedure] . . . internal-procedure
is the definition of an internal procedure; see "Internal procedures" on page 135.
end-external-procedurestatement takes one of the following forms, depending on whether the procedure is a subroutine or function:
- END [SUBROUTINE [subroutine-name]]
- end [function [function-name]]

Program units and procedures
External procedures

\section*{Procedure reference}

A procedure reference-also known as a procedure call—occurs when a procedure name is specified in an executable statement, which causes the named procedure to execute. The following sections describe references to subroutines and functions, and recursi ve references-when a procedure directly or indirectly calls itself.

\section*{Referencing a subroutine}

A reference to an external subroutine occurs in a CALL statement, which specifies either the subroutine name or one of its entry point names. The syntax of the CALL statement is:

CALL subroutine-name [([actual-argument-list])]
actual-argument-list
is a comma-separated list of the actual arguments that take the form:

\section*{[keyword =] actual-argument}

\section*{keyword}
is the name of a dummy argument that appears in the SUBROUTINE statement. For more information about keyword, see "K eyword option" on page 144.
actual-argument
is one of:
- Expression, including a variable name
- Procedure name
- Alternate return

For detailed information about arguments, see
"Arguments" on page 139.
alternatereturn
is one of:
- *label
- \&label
label must be a branch target in the same scoping unit as the CALL statement. The ampersand prefix ( \(\alpha\) ) is an HP extension and is permitted in fixed source form only. For information about alternate returns, see "Returning from a procedure reference" on page 132.
For information about referencing a subroutine that implements a defined assignment, see "Defined assignment" on page 157.

\section*{Referencing a function}

An external function subprogram is referenced either by its name or by one of its entry point names. The syntax of a function reference is:
name ([actual-argument-list])
where nameis the function name or the name of one of its entry points (see "Alternate entry points" on page 133). actual-argument-list has the same as it does in a subroutine reference (see "Procedure reference" on page 130), except that it may not include an alternate return.

For information about referencing a function that implements a defined operator, see "Defined operators" on page 155.

\section*{Recursive reference}

A procedure that directly or indirectly invokes itself is recursive. Such a procedure must have the word RECURSIVE added to the FUnCTION or SUBROUTINE statement.

If a function calls itself directly, both ReCURS IVE and a ReSUlt clause must be specified in the function statement, making its interface explicit.
The following is a recursive function:
```

RECURSIVE FUNCTION factorial (n) RESULT(r)
INTEGER :: n, r
IF (n.ne.0) THEN
r = n*factorial (n-1)
ELSE
r = 1
ENDIF
END FUNCTION factorial

```

Both internal and external procedures can be recursive.

\section*{External procedures}

\section*{Returning from a procedure reference}

When the EnD statement of a subprogram is encountered, control returns to the calling program unit. The RETURN statement can be used to the same effect at any point within a procedure. The syntax of the RETURN statement is:

\section*{RETURN [alt-return-arg]}
where alt-return-arg is a scalar integer expression that evaluates to the position of one of an alternate-return argument in the subroutine argument list. alt-return-arg is not permitted with RETURN statements appearing in functions.

By default, when control returns from a subroutine call, the next statement to execute is the first executable statement following the CALL statement. However, by specifying alternate returns as actual arguments in the subroutine call, the programmer can return control to other statements. The alternate returns are labels prefixed with an asterisk (*). Each label is inserted in the list of actual arguments in the position that corresponds to a placeholder-a simple asterisk (*) —in the dummy argument list. For example, if the subroutine subr has the following list of dummy arguments:

SUBROUTINE subr ( \(x, y, z, *, *)\)
then the actual arguments must include two labels for alternate returns, as in the following call:

CALL subr ( \(\mathrm{a}, \mathrm{b}, \mathrm{c}, ~ * 10, ~ * 20\) )
As a compatibility extension, HP Fortran allows the ampersand ( \(\&\) ) as a prefix character instead of the asterisk, but only in fixed source form. Alternate returns cannot be optional, and the associated actual argument cannot have keywords. For detailed information about the syntax of the alternate return argument, refer to the descriptions of the CALL and RETURN statements in Chapter 10, "HP Fortran Statements."

The following example, alt_return.f90, illustrates the alternate return mechanism. The referenced subroutine, subr, selects one of two alternate return arguments based on the value of the first argument, where_to.

\section*{alt_return.f90}
```

PROGRAM main
! illustrates alternate return arguments
INTEGER :: por ! point of return

```
```

    por = -1 ! interpreted by arithmetic IF
    CALL subr(por, *10, *15) ! executes first
    PRINT *, 'Default returning point'
    por = 0
    CALL subr(por, *10, *15) ! executes second
    GOTO 20 ! control should never reach here
    10 PRINT *, 'Line 10 in main'
por = 1
CALL subr(por, *10, *15) ! executes third
GOTO 20 ! control should never reach here
15 PRINT *, 'Line 15 in main'
20 CONTINUE
END PROGRAM main
SUBROUTINE subr(where_to, *, *)
! Argument list includes placeholders for two alternate returns;
! the third argument, where_to, is used to select a return
! argument
INTEGER :: where_to
! use arithmetic IF to select a return
IF (where_to) 25, 30, 35 ! labels to transfer control
PRINT *, 'Should never print'
25 PRINT *, 'Line 25 in subr'
RETURN ! default returning point
30 PRINT *, 'Line 30 in subr'
RETURN 1 ! select the first return argument
35 PRINT *, 'Line 35 in subr'
RETURN 2 ! select the second return argument
END SUBROUTINE subr

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
```

\$ f90 alt_return.f90
\$ a.out
Line 25 in subr
Default returning point
Line 30 in subr
Line 10 in main
Line 35 in subr
Line 15 in main

```

\section*{Alternate entry points}

When a procedure is referenced, execution normally begins with the first executable statement in the procedure. Using the Entry statement, however, the programmer can define alternate entry points into the

Program units and procedures

\section*{External procedures}
procedure and associate a name with each entry point. Each ENTRY statement within a procedure defines a procedure entry, which can be referenced by name as a separate, additional procedure.

The syntax for the ENTRY statement is:
entry entry-name ([dummy-arg-list]) [RESULT (result-name)]

\section*{Internal procedures}

An internal procedure is similar to an external procedure except that:
- It must be defined within a hosting program unit-a main, external, or module program unit-following the CONTAINS statement.
- It can be referenced by the host only.
- It can access other entities by host association within the host.
- It cannot have an Entry statement.
- It cannot be passed as an argument.
- It cannot contain an internal procedure.

The syntax of an internal procedure definition is the same as for an external procedure (see "Procedure definition" on page 128), except that it has no internal procedure part. The reference to an internal procedure is the same as for an external procedure; see "Procedure reference" on page 130.

The following example, int_func.f90, declares and references an internal function. Note that both the external procedure and the internal procedure have an assumed-shape array as a dummy argument, which requires the procedure to have an explicit interface (see "Procedure interface" on page 151). External procedures must be declared in an interface block to make their interface explicit; the interface of internal procedures is explicit by default.
```

int_func.f90
PROGRAM main
! declare and initialize an array to pass to an external
! procedure
REAL, DIMENSION(3) :: values = (/2.0, 5.0, 7.0/)
! Because the dummy argument to print_avg is an assumed-shape
! array (see the definition of print_avg below), the
! procedure interface of print_avg must
! be made explicit within the calling program unit.
INTERFACE
SUBROUTINE print_avg(x)
REAL :: x(:)
END SUBROUTINE print_avg

```

Program units and procedures

\section*{Internal procedures}
```

    END INTERFACE
    CALL print_avg(values)
    END PROGRAM main
! print_avg is an external subprogram
SUBROUTINE print_avg(x)
REAL :: x(:) ! an assumed-shape array
! reference the internal function get_avg
PRINT *, get_avg(x)
CONTAINS ! start of internal procedure part
REAL FUNCTION get_avg(a) ! get_avg is an internal procedure
! The interface of an internal procedure is explicit within
! the hosting unit, so this function may declare a as an
! assumed-shape array.
REAL a(:) ! an assumed-shape array
! references to the SUM and SIZE intrinsics
get_avg = SUM(a) / SIZE(a)
END FUNCTION get_avg
END SUBROUTINE print_avg

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
```

f90 int_func.f90

```
\$ a.out
4.66667

\section*{Statement functions}

If an evaluation of a function with a scal ar value can be expressed in just one Fortran assignment statement, such a definition can be included in the specification part of a main program unit or subprogram. This definition is known as a statement function. It is local to the scope in which it is defined. The syntax is:
function-name (dummy-argument-list) = scalar-expression
All dummy arguments must be scalars. All entities used in scalarexpression must have been declared earlier in the specification part. A statement function can reference another statement function that has already been declared. The name cannot be passed as a procedure-name argument. A statement function has an explicit interface.
The following example, stmt_func.f90, is the same as the one listed in "I nternal procedures" on page 135 except that it implements get_avg as a statement function rather than as an internal function. As noted in the comments to the program, the elements of the array x are passed to the statement function as separate arguments because dummy arguments of a statement function must be scalars.
```

stmt_func.f90
PROGRAM main
! declare and initialize an array to pass to an external
! procedure
REAL, DIMENSION(3) :: values = (/2.0, 5.0, 7.0/)
! Because the dummy argument to print_avg is an assumed-shape
! array (see the definition of print_avg below), the
! procedure interface of print_avg must be made
! explicit within the calling program unit.
INTERFACE
SUBROUTINE print_avg(x)
REAL :: x(:
END SUBROUTINE print_avg
END INTERFACE
CALL print_avg(values)
END PROGRAM main
! print_avg is an external subprogram
SUBROUTINE print_avg(x)
REAL :: x(:) ! an assumed-shape array

```

Program units and procedures

\section*{Statement functions}
```

    ! Define the statement function get_avg.
    ! Note that the dummy arguments must be scalar, so in order
    ! to find the average of the elements of the array, we must
    ! pass each element as a separate argument
    get_avg(x1, x2, x3) = (x1 + x2 + x3) / 3
    ! reference the statement function get_avg
    PRINT *, get_avg(x(1), x(2), x(3))
    END SUBROUTINE print_avg

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
\$ \(\mathbf{f 9 0}\) stmt_func.f90
\$ a.out
4.66667

\section*{Arguments}

Arguments data to be passed during a procedure call. Arguments are of two sorts: dummy arguments and actual arguments. Dummy arguments are specified in the argument list in a procedure definition. They define the number, type, kind, and rank of the actual arguments. The actual arguments are the arguments that appear in the procedure reference and are the actual entities to be used by the referenced procedure, even though they are known by the dummy argument names.
This section covers the following topics related to arguments:
- Argument association
- Keyword option
- Duplicated association
- intent attribute
- \%REF and \%VAL

\section*{Argument association}

Argument association is the linkage of actual argument to dummy argument that initially occurs when a procedure having arguments is invoked. During the execution of the referenced procedure, the dummy arguments are effectively aliases for the actual arguments. After control returns to the program unit making the reference, the dummy arguments and actual arguments are no longer associated, and the actual arguments may no longer be referenced by the dummy argument names.

The principle of argument association is positional: the first item in the list of actual arguments is associated with the first item in the list of dummy arguments, and so on with the remaining arguments in each list. However, the programmer can use the keyword option to override this positional correspondence; see "K eyword option" on page 144.
Dummy and actual arguments must agree in kind, type, and rank. The corresponding dummy and actual arguments must both be scalars or both arrays; if they are both arrays, they must have the same

\section*{Arguments}
dimensionality. Likewise, if an actual argument is an expression or a reference to a function, it must match the type and kind of the dummy argument.
The following sections provide more detailed information about these types of dummy arguments:
- Scalars
- Arrays
- Derived types
- Pointers
- Procedure names

\section*{Scalar dummy argument}

If the dummy argument is a scalar, the corresponding actual argument must be a scalar or a scalar expression, of the same kind and type. If the dummy argument is a character variable and has assumed length, it inherits the length of the actual argument. Otherwise, the length of the actual argument must be at least that of the dummy argument, and only the characters within the range of the dummy argument can be accessed by the subprogram. Lengths may differ for default character types only.

\section*{Array dummy argument}

If the dummy argument is an assumed-shape array, the corresponding actual argument must match in kind, type, and rank; the dummy argument takes its shape from the actual argument, resulting in an element-by-element association between the actual and dummy arguments.
If the dummy argument is an explicit-shape or assumed-size array, the kind and type of the actual argument must match but the rank need not. The el ements are sequence associated-that is, the actual and dummy arguments are each considered to be a linear sequence of elements in storage without regard to rank or shape, and corresponding elements in each sequence are associated with each other in array element order.

A consequence of sequence association is that the overall size of the actual argument must be at least that of the dummy argument, and only elements within the overall size of the dummy argument can be accessed by referenced procedure.

For example, if an actual argument has this declaration:
```

REAL a(0:3,0:2)

```
and the corresponding dummy argument has this declaration:
```

REAL d(2,3,2)

```
then the correspondence between elements of the actual and dummy arguments is as follows:
```

Dummy <=> Actual
_-_-_--_-_---_-------
d(1,1,1) <=> a(0,0)
d(2,1,1) <=> a(1,0)
d(1,2,1) <=> a (2,0)
d(2,3,2) <=> a(3,2)

```

When an actual argument and the associated dummy argument are default character arrays, they may be of unequal character length. If this is the case, then the first character of the dummy and actual arguments are matched, and the successive characters-rather than array elements-are matched.

The next example illustrates character sequence association. Assuming this declaration of the actual argument:
```

CHARACTER*2 a (3,4)

```
and this declaration of the corresponding dummy argument:
```

CHARACTER*4 d(2,3)

```
then the correspondence between elements of the actual and dummy arguments is as follows:
```

Dummy <=> Actual
d(1,1) <=> a(1,1)//a(2,1)
d(2,1) <=> a(3,1)//a(1, 2)
d(2,3) <=> a(2,4)//a(3,4)

```

An actual argument may be an array section, but associating an array section with any other but an assumed-shape dummy argument may cause a copy of the array section to be generated and is likely to result in a degradation in performance.

For information about the different types of arrays, see "Array declarations" on page 54.

\section*{Derived-type dummy argument}

When passing a derived-type object, the corresponding dummy and actual arguments of derived types are assumed to be of the same derived type. Unless the interface of the referenced procedure is explicit within the program unit that makes the reference, the compiler does not perform any type-checking. It is the programmer's responsibility to ensure that the types of the dummy argument and the actual argument are the same, such as by doing either of the following:
- Replicating the definition of the derived type in both subprograms
- Placing the definition in a module and making the definition available to both subprograms by use association

For information about explicit interface, see "Procedure interface" on page 151. For information modules and use association, see "M odules" on page 161.

\section*{Pointer dummy argument}

If the dummy argument has the POINTER attribute, the actual argument must also have the POINTER attribute. F urthermore, they must match in kind, type, and rank. If the dummy argument does not have the POINTER attribute but the actual argument is a pointer, the argument association behaves as if the pointer actual argument were replaced by its target at the time of the procedure reference.

\section*{Procedure dummy argument}

If a dummy argument is a procedure, the actual argument must be the name of an appropriate subprogram, and its name must have been declared as EXTERNAL in the calling unit or defined in an interface block (see "Procedure interface" on page 151). Internal procedures, statement functions, and generic names may not be passed as actual arguments.

If the actual argument is an intrinsic procedure, the appropriate specific name must be used in the reference. It must have the INTRINSIC attribute.

The following example, intrinsic_arg.f90, declares the intrinsics QSIN and QCOS with the INTRINSIC attribute so that they can be passed as arguments to the user-defined subroutine call_int_arg. Note that the dummy argument, trig_func, is declared in the subroutine with the

EXTERNAL attribute to indicate that it is a dummy procedure. This declaration does not conflict with the declaration of the actual arguments in the main program unit because each occurs in different scoping units.
intrinsic_arg.f90
```

PROGRAM main
! declare the intrinsics QSIN and QCOS with the INTRINSIC
! attribute to allow them to be passed as arguments
REAL(16), INTRINSIC :: QSIN, QCOS
CALL call_int_arg(QSIN)
CALL call_int_arg(QCOS)
END PROGRAM main
SUBROUTINE call_int_arg(trig_func)
! trig_func is an intrinsic function--see the declarations
! of the actual arguments in the main program. trig_func
! is declared here as EXTERNAL to indicate that it is a
! dummy procedure.
REAL(16), EXTERNAL :: trig_func
REAL(16), PARAMETER : : pi=3.1415926
INTEGER :: i
DO i = 0, 360, 45
! Convert degrees to radians (i*pi/180) and call the
! intrinsic procedure passed as trig_func.
WRITE(6, 100) i," degrees ", trig_func(i*pi/180)
END DO
100 FORMAT (I4, A9, F12.8)
END SUBROUTINE call_int_arg

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
\begin{tabular}{|c|c|c|}
\hline \multicolumn{3}{|l|}{\multirow[t]{2}{*}{\$ 990 intrinsic_arg. \(\mathbf{f 9 0}\)
\$ a.out}} \\
\hline & & \\
\hline 0 & degrees & 0.00000000 \\
\hline 45 & degrees & 0.70710675 \\
\hline 90 & degrees & 1.00000000 \\
\hline 135 & degrees & 0.70710686 \\
\hline 180 & degrees & 0.00000015 \\
\hline 225 & degrees & -0.70710665 \\
\hline 270 & degrees & -1.00000000 \\
\hline 315 & degrees & -0.70710697 \\
\hline 360 & degrees & -0.00000030 \\
\hline & degrees & 1.00000000 \\
\hline & degrees & 0.70710681 \\
\hline & degrees & 0.00000008 \\
\hline 135 & degrees & -0.70710670 \\
\hline 180 & degrees & -1.00000000 \\
\hline 225 & degrees & -0.70710691 \\
\hline & degrees & -0.00000023 \\
\hline
\end{tabular}

\section*{Arguments}
```

3 1 5 degrees 0.70710659
360 degrees 1.00000000

```

See Chapter 10, "HP Fortran Statements," for information about the external and Intrinsic statements. Intrinsic procedures are fully described in Chapter 11, "I ntrinsic procedures," on page 475.

\section*{Keyword option}

The keyword option allows the programmer to specify actual arguments in a procedure reference independently of the position of the dummy arguments. Using the keyword option, the programmer explicitly pairs an actual argument with its dummy argument, as shown by the syntax:
dummy-argument = actual-argument
If the keyword option is used for an argument, it must be followed by other arguments with the keyword option. If all arguments in the argument list use the keyword option, the actual arguments may appear in any order.
As an example of how to use the keyword option, consider the sum intrinsic function. As described in "SUM (ARRAY, DIM, MASK)" on page 577, this intrinsic has three arguments: array, dim, and mask, in that order; dim and mask are optional arguments. The following are therefore valid references to SUM:
```

SUM (a,2)
SUM(a,mask=a.gt.0)
SUM(dim=2, array=a)

```

The following is an invalid reference-the mask keyword must be specified:
```

SUM(a,dim=2,a.gt.0) ! ILLEGAL, mask keyword missing

```

\section*{Optional arguments}

An actual argument may be omitted from the argument list of a procedure reference if its corresponding dummy argument is optional. A dummy argument is optional if it is declared with the OPTIONAL attribute and appears at the end of the argument list. The procedure reference may also omit trailing arguments with the OPTIONAL attribute. Otherwise, keywords must be provided to maintain an identifiable correspondence (see "K eyword option" on page 144). Only procedures with an explicit interface may have optional arguments.
The following example, optional_arg.f90, references an internal function that declares one of its dummy \(\bar{a}\) guments with the OPTIONAL attribute. (Internal functions have an explicit interface, making them eligible for optional arguments; see "I nternal procedures" on page 135.) The function uses the PRESENT intrinsic to test whether or not the optional argument is present. If the intrinsic returns. TRUE. (an actual argument is associated with the optional dummy argument), the function returns the sum of the two arguments; otherwise, it returns the required argument incremented by 1.

\section*{optional_arg.f90}
```

PROGRAM main
! illustrates the optional argument feature
INTEGER :: arg1 = 10, arg2 = 20
PRINT *, add_or_inc(arg1) ! omit optional argument
PRINT *, add_or_inc(arg1, arg2)
CONTAINS ! internal procedure with explicit interface
INTEGER FUNCTION add_or_inc(i1, i2)
! return the sum of both arguments if the second argument
! (declared as optional) is present; otherwise, return the
! first argument incremented by 1
INTEGER :: i1
INTEGER, OPTIONAL :: i2 ! optional argument
! use PRESENT intrinsic to see if i2 has an actual
! argument associated with it
IF (PRESENT(i2)) THEN
add_or_inc = i1 + i2 ! add both arguments
ELSE
add_or_inc = i1 + 1 ! increment required argument
END IF
END FUNCTION add_or_inc
END PROGRAM main

```

\section*{Arguments}

Here are the command lines to compile and execute the program, along with the output from a sample run:
```

f90 optional_arg.f90
a.out
\$11

```

For information about the syntax, rules and restrictions governing the OPTIONAL statement and attribute, see "OPTIONAL (statement and attribute)" on page 387. For information about the PRESENT intrinsic see "PRESENT(A)" on page 559.

\section*{Duplicated association}

If a procedure reference would cause a data object to be associated with two or more dummy arguments, the object must not be redefined within the referenced procedure. Consider the following example:
```

PROGRAM p
CALL s (a,a)
CONTAINS
SUBROUTINE s (c,d)
c = 22.01 ! ILLEGAL definition of one of the dummy
! arguments associated with data object a
END SUBROUTINE
END PROGRAM
Both dummy arguments, c and d, are associated with the actual argument a. The procedure includes an assignment to c, the effect of which is to redefine a. This attempt to redefine a is invalid. This rule actual arguments that are overlapping sections of the same array.
Similarly, if a data object is available to a procedure through both argument association and either use, host, or storage association, then the data object must be defined and referenced only through the dummy argument.

```

In the following code, the data object a is available to the subroutine as a consequence of argument association and host association. The direct reference to a in the subroutine is illegal.
```

PROGRAM p
CALL s (a,b)
CONTAINS
SUBROUTINE s (c,d)
c = 22.01 ! valid definition of a through the dummy
d = 3.0*a ! direct reference to a is ILLEGAL
...
END SUBROUTINE
END PROGRAM

```

\section*{Arguments}

\section*{INTE NT attribute}

To enable additional compile-time checking of arguments and to avoid possibly unwanted side effects, the InTENT attribute can be declared for each dummy argument, which may be specified as INTENT (IN), INTENT (OUT) or INTENT (INOUT).

The values that may be specified for the intent attribute have the fol lowing significance:
- In is used if the argument is not to be modified within the subprogram.
- out implies that the actual argument must not be used within the subprogram before it is assigned a value.
- inout (the form in out is also permitted) implies that the actual argument must be defined on entry and is definable within the subprogram.

See "intent (statement and attribute)" on page 358 for more information about the Intent attribute.

\section*{\%VAL and \%REF built-in functions}

By default, HP Fortran passes noncharacter arguments by reference. Instead of passing the value of the actual argument to the referenced procedure, Fortran passes its address, with which the name of the dummy argument becomes associated-as explained in "Argument association" on page 139. When HP Fortran passes character arguments, it includes a hidden length parameter along with the address of the actual argument.
However, it is possible to change the way arguments are passed by using the \%VAL and \%REF built-in functions, which HP Fortran provides as extensions:
- \%VAL (arg) specifies that the value of arg-rather than its addressis to be passed to the referenced procedure. arg can be a constant variable, an array element, or a derived-type component.
- \%REF (arg) specifies that the address of arg is to be passed to the referenced procedure. Because this is how HP Fortran normally passes all noncharacter arguments, \(\%\) REF is useful only when arg is of type character. The effect of using \(\%\) REF with a character argument is to suppress the hidden length parameter.

These built-in functions are typically used to pass arguments from Fortran to a procedure written in another language, such as a \(C\) function. The following example illustrates this use. The program consists of a Fortran 90 main program unit and a \(C\) function. The main program calls the \(C\) function, passing 4 arguments: an integer constant, a real variable, a character variable, and an integer expression. The main program uses the built-in functions to change Fortran's argument-passing conventions to conform to C. C expects all arguments except the string-Fortran's character variable-to be passed by value. It expects the string to be passed by reference, without the hidden length parameter.
```

pass_args.f90

```
```

PROGRAM main
REAL :: x = 3.4
INTEGER :: i1 = 5, i2 = 7
! C expects strings to be null-terminated, so use the
! concatenation operator to append a null character.
CHARACTER(LEN=5) :: str = "Hi!"//CHAR(0)
! Pass 4 arguments--a constant, a variable, a character
! variable, and an expression--to a function written in C.
! Use HP Fortran's built-in functions to change the
! argument-passing conventions to conform to C.
CALL get_args(%VAL(20), %VAL(x), %REF(str), %VAL(i1+i2))
END PROGRAM main
get_args.c
\#include <stdio.h>
/* accept 4 arguments from a Fortran 90 program, which are
* passed as C expects them to be passed
*/
void get_args(int i1, float x, char *s, int i2)
{
/* display argument values */
printf("First argument: %i\n", i1);
printf("Second argument: %f\n", x);
printf("Third argument: %s\n", s);
printf("Fourth argument: %i\n", i2);
}

```

Here are the command lines to compile and link both files, and to execute the program, along with the output from a sample run:

Program units and procedures
Arguments
```

\$ cc -Aa -c get_args.c
\$ f90 pass_args.f90 get_args.o
\$ a.out
First argument: 20
Second argument: 3.400000
Third argument: Hi!
Fourth argument: 12

```

For additional information about multi-language programming, refer to the HP Fortran Programmer's Guide. The built-in functions can also be used with the ALIAS directive, where they have a slightly different syntax.

\section*{Procedure interface}

A procedure interface is the information specified in a procedure reference, including the name of the procedure, the arguments, and (if the procedure is a function) the result. If the interface is explicit, all of the characteristics of the arguments and the result-type, kind, attributes, and number-are defined within the scope of the reference. If the interface is implicit, the compiler may be able to make sufficient assumptions about the interface to permit the procedure reference.
All procedure interfaces are implicit except for the following:
- Intrinsic procedure
- Internal procedure
- Module procedure
- Recursive function that specifies a result clause
- External procedure whose interface is declared in an interface block

An explicit interface is required when:
- The procedure reference uses the keyword form of an actual argument.
- The procedure has OPtIONAL arguments.
- Any dummy argument is an assumed-shape array or a pointer.
- The result of a function is array-valued or a pointer.
- The procedure is a character function, the length of which is determined dynamically.
- The procedure reference is to a generic name.
- The procedure reference implements a user-defined operator or assignment.
- The procedure has the same name as an intrinsic procedure, but you want it to have precedence over the intrinsic; see "Availability of intrinsics" on page 476.

Program units and procedures

\section*{Procedure interface}
- You want the compiler to perform argument-checking at compiletime.

The following sections describe the interface block and its use for creating:
- Generic procedures
- Defined operators
- Defined assignment

\section*{Interface blocks}

An interface block is used to provide an explicit interface for external procedures or to define a generic procedure. An interface block may appear in any program unit, except a block data program unit. It is specified in the specification part of the program unit.

The syntax for an interface block is:
```

INTERFACE [generic-spec]

```
[interface-body]..
[MODULE PROCEDURE module-procedure-name-list]
END INTERFACE
generic-spec
is one of:
- generic-name
- OPERATOR (operator)
- ASSIGNMENT (=)

If generic-spec is omitted, then the module procedure statement must also be omitted.
generic-name
is the name of the generic procedure that is referenced in the subprogram containing the interface block.
operator
is a unary or binary operator-intrinsic or user-defined-of the form:
.letter[letter]... .

\section*{interface-body}
is:
function-statement
[ specification-part]
end-function-statement
or
subroutine-statement
[ specification-part]
end-subroutine-statement
module-procedurenamelist
is a comma-separated list of names of module procedures that have generic-spec as a generic interface. E ach module-procedure name must be accessible either by use association or-if this interface block is in a module that defines the module procedure-by host association.
If the MODULE PROCEDURE statement is present, then genericspec must also be present.
The following example, proc_interface.f90, uses an interface block in the main program unit to provide an explicit interface for the function avg.
```

proc_interface.f90
! Define an external function avg with one assumed-shape dummy
! argument. Note that the definition of the function must
! lexically precede its declaration in the interface block.
REAL FUNCTION avg(a)
REAL a(:)
avg = SUM(a)/SIZE(a)
END FUNCTION avg
PROGRAM main
REAL,DIMENSION(3) :: x
INTERFACE
REAL FUNCTION avg(a)
REAL, INTENT(IN) :: a(:)
END FUNCTION avg
END INTERFACE
x=(/2.0, 4.0, 7.0/)
PRINT *, avg(x)
END PROGRAM main

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
```

\$ f90 proc_interface.f90
\$ a.out
4.33333

```

Program units and procedures

\section*{Procedure interface}

\section*{Generic procedures}

The Fortran 90 concept of generic procedures extends the FORTRAN 77 concept of generic intrinsics to allow user-defined generic procedures. A procedure is generic if its name-a generic name-is associated with a set of specific procedures. Referencing the generic name allows actual arguments to differ in type, kind, and rank. The differences in the arguments determine which specific procedure is invoked.

A generic procedure is defined in an interface block that specifies its name and the interfaces of the specific procedures; see "I nterface blocks" on page 152. The specific procedures within the interface block must all be subroutines or all functions. The interface for each procedure must differ from the others in one or more of the following ways:
- The number of dummy arguments must differ.
- Arguments that occupy the same position in the dummy argument lists must differ in type, kind, or rank.
- The name of a dummy argument must differ from the names of the other dummy arguments in the argument lists of the other procedures, or all dummy arguments with the same name must differ in type, kind, or rank.
There may be more than one interface block with the same generic name, but the specific procedures whose interfaces appear in all such interface blocks must be distinguishable by the above criteria.

The MODULE PROCEDURE statement can be used to extend the list of specific procedures to include procedures that are otherwise accessible to the program unit containing the interface block. The MODULE PROCEDURE statement specifies only the procedure names; the procedure interfaces are already explicit. The MODULE PROCEDURE statement may appear only in an interface block that has a generic specification. Furthermore, the interface block must be contained either in the same module that contains the definitions of the named procedures or in a program unit in which the procedures are accessible through use association.
The following example assumes that two subroutines have been coded for solving linear equations: rlineq for when the coefficients are real, and zlineq for when the coefficients are complex. A generic name, lineq, is
declared in the interface statement, enabling it to be used for referencing either of the specific procedures, depending on whether the arguments are real or complex:
```

INTERFACE lineq
SUBROUTINE rlineq(ra,rb,rx)
REAL,DIMENSION(:,:) :: ra
REAL,DIMENSION(:) :: rb,rx
END SUBROUTINE rlineq
SUBROUTINE zlineq(za,zb,zx)
COMPLEX,DIMENSION(:,:) :: za
COMPLEX,DIMENSION(:) :: zb,zx
END SUBROUTINE zlineq
END INTERFACE lineq

```

\section*{Defined operators}

The operator clause can be used with the interface statement either to define a new user-defined operator or to extend-or overload-the behavior of an already defined or intrinsic operator. This second use is similar to defining a generic procedure (see "Generic procedures" on page 154). The re-defined operator becomes associated with a generic operator.
When the operator clause is present in the Interface statement, the specific procedures within the interface block must all be functions. The functions can implement the operator for operands of different types, kinds, and ranks. These functions are restricted to one or two mandatory arguments, depending on whether the defined operator is unary or binary. The functions return the result of an expression of the form:
[operand] operator operand
Each dummy argument of the functions listed in the interface block must have the INTENT (IN) attribute. If operator is intrinsic, each specified function must take the same number of arguments as the intrinsic operator has operands. Furthermore, the arguments must be distinguishable from those normally associated with the intrinsic operation. However, argument keywords must not be used when the argument is specified as an operand to a defined operator.
If a user-defined operator is referenced by its generic name, the reference must resolve to a unique, specific function name. The selection of the function is accomplished by matching the number, type, kind, and rank of the operand with the dummy argument lists of the functions specified in the interface block. As with generic name references (see "Generic

Program units and procedures

\section*{Procedure interface}
procedures" on page 154), exactly one procedure must match the properties of the operands, and the matching function is selected and invoked.

The following program, def_op.f90, illustrates a defined operation. The operation, . inrect . , compares two derived-type operands. The one operand holds the \(x\) and \(y\) co-ordinates of a point on a graph, and the other holds the set of co-ordinates defining a rectangle. If the point is inside the rectangle, the operation evaluates to . TRUE.. The module in which the operation is defined also contains the definitions of the types of the operands.

As noted in the comments, when a module is defined in the same file as any USE statements that reference the module, the definition must lexically precede the USE statements. F or information about modules and the USE statement, see "M odules" on page 161.
```

def_op.f90
Note that, if a module definition and any USE statements that

```

\$ f90 def_op. f90
\$ a.out
Enter two co-ordinates (integers) in a graph:
4,8
The point lies inside the rectangle.

```

\section*{Defined assignment}

The ASSIGNMENT clause can be used with the Interface statement to specify one or more subroutines that extend-or overload-the assignment operator. Each subroutine must have exactly two arguments. The first argument can have either the Intent (OUT) or the INTENT (INOUT) attribute; the second argument must have the intent (IN) attribute. The first argument corresponds to the variable on the left-hand side of an assignment statement, and the second to the expression on the right-hand side.
Similarly to generic names and defined operators, there can be more than one defined assignment, but each occurrence of the assignment statement must resolve to a unique, specific subroutine. The subroutine

Program units and procedures

\section*{Procedure interface}
whose dummy arguments match the left-hand and right-hand sides of the assignment statement in kind, type, and rank is selected and invoked from the list of subroutines specified in the defined-assignment interface block.

The following example, def_assign.f90, illustrates defined assignment. The assignment consists of performing an elementary statistical analysis of the data on the right-hand operand and storing the results in the lefthand operand. As noted in the comments, when a module is defined in the same file as any USE statements that references the module, the definition must lexically precede the USE statements. For information about modules and the USE statement, see "M odules" on page 161.
```

def_assign.f90
! Note that, if a module definition and any USE statements that
! reference the definition are in the same file, then the
! definition must lexically precede the USE statements.

```

\section*{Modules}

A module is a nonexecutable program unit that contains-usually related-definitions and declarations that may be accessed by use association. Typically, modules are used for:
- Defining and declaring derived types
- Defining and declaring global data areas
- Defining operators
- Creating subprogram libraries

The definitions within a module are made accessible to other program units through use association. The program unit that requires access to the module must have a USE statement at the head of its specification part, and the statement must specify the name of the module.
The following sections describe the module program unit and the uSE statement. The last section gives an example program that uses a module.

Compiling programs that contain modules requires care to ensure that each module is compiled before the program unit that uses it. For detailed information about compiling programs that contain modules, refer to the HP Fortran Programmer's Guide.

\section*{Module program unit}

The syntax of a module program unit is:
```

MODULE modulename

```
    [specification-part]
    [module-procedurepart]
END [MODULE [modulename]]
where:
modulename
is the name of the module.

\section*{Modules}

\section*{specification-part}
is zero or more of the statements listed in Table 15 with the exception of the FORMAT statement. Also, specification-part must not contain statement function definitions or automatic objects. (Specifying the SAVE attribute within a module is unnecessary in HP Fortran as entities declared within a module retain their values by default.)
Each entity declared in specification-part and each of the procedure defined in moduleprocedure-part has either the PUBLIC or PRIVATE attribute. By default, all entities have the PUBLIC attribute and are thereby accessible by use association. Entities having the PRIVATE attribute are accessible from within the module only.
The pUBLIC and PRIVATE attributes and statements are fully described in Chapter 10, "HP Fortran Statements."
module-procedure-part
is:
CONTAINS
module-procedure[module-procedure. . .] module-procedure
is either a function or subroutine. module-procedure has the same structure as an external function or subroutine except that the END statement of module-procedure must include the SUBROUTINE or FUNCTION keyword, as appropriate; for an external procedurethis is optional. For information about external subroutines, see "E xternal procedures" on page 128. N ote the following about module procedures:
- They have an explicit interface within the using program unit. It is not necessary to create an interface block for a module procedure.
- They can also contain internal procedures.
- They can be passed as an actual argument.

The following may be contained in a module and be made accessible by use association:
- Declared variables
- Named constants
- Derived-type definitions
- Procedure interfaces
- Module procedures
- Generic names
- Namelist groups

\section*{USE statement}

The USE statement provides access to module entities within the using program unit-that is, the program unit in which the statement is specified. The USE statement specifies the name of the module that the program unit wants to access. The information in the specified module is made accessible to the program unit by use association. The USE statement must appear at the head of the specification part of a program unit.

The USE statement can take either of two forms:
- USE modulename[, renamelist]
- USE modulename, ONLY : access-list
where:
renamelist
is a comma separated list of:
local-name => moduleentity-name module-entity-name
is the name of a module entity.
local-name
is the name by which module-entity-name will be accessed within the using program unit.

Program units and procedures

\section*{Modules}
access-list
is a comma-separated list of:
[local-name =>] module-entity-name
As shown in the syntax description, the USE statement provides a renaming feature that allows module entities to be renamed within a using program unit. The association between local-name and module-entity-name is conceptually similar to argument association: the one name is an alias for the other, and the association between the two is in effect only within the using program unit.

The renaming feature can be used to resolve name conflicts when more than one module contains an entity with the same name. Consider a program unit that has access by use association to two modules: mod_defs1 mod_defs2. The names of the entities in mod_defs1 are a, b, and c; and the names of the entities in mod_defs 2 areb, c, and d. The following USE statements will avoid name conflicts within the using program unit:
```

USE mod_defs1
USE mod_defs2, b => local_b, c => local_c

```

The ONLY clause provides an additional level of control over access to module entities. As described in "M odule program unit" on page 161, the PRIVATE and PUBLIC attributes control access to module entities in all using program units. The onLY clause controls access within a specific program unit.

For example, consider a module named mod_defs that contains the entities ent_x, ent_y, and ent_z. If a program unit contains the following USE statement:
```

USE mod_defs, ONLY : ent_x, entry += local_Y

```
it has access to ent_x and ent_y only. Furthermore, it must access ent_y by the name local_y.

A program unit may have more than one USE statement specifying the same module:
- If one of the USE statements is without the ONLY clause, then all module entities with the PUBLIC attribute are accessible. F urthermore, all local-names from the rename-lists and access-lists are interpreted as a single concatenated renamelist.
- If all of the USE statements have the ONLY clause, all of the accesslists are interpreted as a single concatenated access-list.

For more information, see "USE" on page 461.

\section*{Program example}

The following example program consists of three files:
- main.f90
- precision.f90
- lin_eq_slv.f90

The file main. \(f 90\) is the driver that has access to entities in two modules-precision and linear_equation_solver-by use association. The modules are the other two files.

The purpose of precision is to communicate a kind type parameter to the other program units in the program, for the sake of precision portability. The second module-linear_equation_solver-contains three module procedures, the first of which, solve_linear_equations, uses the other two; solve_linear_equations is itself invoked by the main program.
Stated algebraically, the equations that main. \(£ 90\) provides as input for solution are:
```

2x+3y+4z=20
3x+4y+5z=26
4x+5y-6z=-4

```

\section*{main.f90}
```

PROGRAM main
! use the two modules defined in precision.f90 and
! lin_eq_slv.f90
USE precision
USE linear_equation_solver

DO \(k=n, 1,-1\)
\(x(k)=m(k, n+1)-\operatorname{SUM}(m(k, k+1: n) * x(k+1: n))\)
END DO
END SUBROUTINE back_substitution
END MODULE linear_equation_solver
Here are the command lines to compile and execute the program, along with the output from a sample run:
```

f90 precision.f90 lin_eq_slv.f90 main.f90
\$ a.out
The solution: 1.0 2.0 3.0

```

The order in which the files appear on the \(f 90\) command line is significant: files that contain modules must be compiled before files containing the program units that use the modules. For more information about compiling programs that use modules, see the HP Fortran Programmer's Guide

\section*{Block data program unit}

A block data program unit initializes data values in common blocks. The syntax of a block data program unit is:
```

BLOCK DATA [block-data-name]

```
    [ specification-part]
END [BLOCK DATA [block-data-name]]
block-data-name
is the name of the block data program unit. Note that the name is optional. If omitted, no more than one unnamed block data program unit may appear in an executable program.
specification-part
is zero or more of the following:
- Type dedaration statement
- USE statement
- IMPLICIT statement
- common statement
- DATA statement
- EQUIVALENCE statement
- Derived-type definition
- The following attribute-specification statements:
- DIMENSION
- INTRINSIC
- PARAMETER
- POINTER
- SAVE
- TARGET

If a USE statement appears in a block data program unit, it makes only the named constants accessible to the program unit.

Program units and procedures
Block data program unit

The block data program unit can initialize more than one common block. However, a common block can be initialized in only one block data program unit. It is not necessary to initialize every object within the common block, but the common block must be completely specified.
As an extension, HP Fortran allows the initialization of objects in blank-or unnamed-common. The following example illustrates this extension:
```

BLOCK DATA blank
COMMON//aa(3),ab(5) ! an unnamed common block
DATA aa/3*1.0/
DATA ab/1.0,2.0,3*4.0/
END BLOCK DATA blank

```

\section*{8 I/O and file handling}

This chapter describes input/output and file handling as supported by HP Fortran. This includes the following topics:
- Records
- Files
- Connecting a file to a unit
- File access methods
- Nonadvancing I/O
- I/O statements
- Syntax of I/O statements
- ASA carriage control
- Example programs

I/O and file handling
Records

\section*{Records}

The record is the basic unit of Fortran \(90 \mathrm{I} / \mathrm{O}\) operations. It consists of either characters or binary values, depending upon whether the record is formatted or unformatted. The following sections describe both formatted and unformatted records, plus the special case of the end-offile record.

Note that nonadvancing I/O makes it possible to read and write partial records. For more information, see "N onadvancing I/O" on page 187.

\section*{Formatted records}

A formatted record consists of characters that have been edited during list-directed or namelist-directed I/O, or by a format specification during a data transfer. (For information about format specifications, see "Format specification" on page 207.) The length of a formatted record is measured in characters; there is no predefined maximum limit to the length of a formatted record.

\section*{Unformatted records}

An unformatted record consists of binary values in machinerepresentable format. The length of an unformatted record is measured in bytes. Unformatted records cannot be processed by list-directed or namelist-directed I/O statements or by I/O statements that use format specifications to edit data.

\section*{End-of-file record}

The end-of-file record is a special case: it contains no data and is the last record of a sequential file. The end-of-file record is written:
- By the endfile statement
- When the file is closed-either explicitly by the close statement or implicitly when the program terminates-immediately following a write operation
- When a BACKSPACE statement executes after a write operation, before the file is backspaced

If the end-of-file record is encountered during the execution of the READ statement, the program execution will abort unless the READ statement includes the END= specifier, the IOSTAT= specifier, or both. For information about these specifiers, see the description of the READ statement in Chapter 10, "HP F ortran statements," on page 241.

\section*{Files}

A file is a collection of data, organized as a sequence of logi cal records. Records in a file must be either all formatted or all unformatted, except for the end-of-file record.

The following sections describe the two types of files, external files and internal files.

\section*{External files}

An external file is stored on disk, magnetic tape, or some other peripheral device. External files can be accessed sequentially or directly as described in "File access methods" on page 178.

\section*{Scratch files}

A scratch file is a special type of external file. It is an unnamed, temporary file that exists only while it is open-that is, it exists no longer than the life of the program. HP Fortran uses the tempnam (3S) system routine to name the scratch file. The name becomes unavailable through the file system immediately after it is created, and it cannot be seen by the Is (1) command and cannot be opened by any other process.
To create a scratch file, you must include the STATUS = ' SCRATCH ' specifier in the OPEN statement, as in the following:
```

OPEN (25, STATUS='SCRATCH')

```

In all other respects, a scratch file behaves like other external files. For an example of a program that uses a scratch file, see "File access" on page 202.

I/O and file handling
Files

\section*{Internal files}

An internal file is stored in a variable where it exists for the life of the variable. Its main use is to enable programs to transfer data internally between a machine representation and a character format, using edit descriptors to make the conversions. (F or more information about edit descriptors, see "E dit descriptors" on page 208.)

An internal file can be one of the following:
- A character variable
- A character array
- A character array element
- A character substring
- An integer or real array (HP Fortran extension)
- Any of the above that is either a field of a structure or a component of a derived type

Note, however, that a section of a character array with a vector subscript cannot be used as an internal file.

Accessing records in an internal file is analogous to accessing them in a formatted sequential file; see "Formatted I/O" on page 178. For an example program that uses an internal file, see "Internal file" on page 198.

\section*{Connecting a file to a unit}

Before a program can perform any I/O operations on an external file, it must establish a logical connection between the file and a unit number. Once the connection is established, the program can reference the file by specifying the associated unit number (a nonnegative integer expression). In the following example, the OPEn statement connects unit number 1 to the file my_data, allowing the WRITE statement to write the values in total_acct and balance to my_data:
```

OPEN (UNIT=1, FILE='my_data')

```
WRITE (1, '(F8.2)') total_acct, balance

The following sections describe three types of unit numbers:
- Those that are explicitly connected by means of the OPEN statement
- Preconnected unit numbers
- Automatically opened unit numbers

\section*{Connecting to an external file}

Typically, the connection between an external file and a unit number is established by the open statement. When the program is finished using the file, the connection is terminated by the CLOSE statement. Once the connection is terminated, the unit number can be assigned to a different file by means of another OPEN statement. Similarly, a file whose connection was broken by a CLOSE statement can be reconnected to the same unit number or to a different unit number.

A unit cannot be connected to more than one file at a time.
The following code establishes a connection between unit 9 and the external file first_file, which is to be by default opened for sequential access. When the program is finished with the file, the Close statement terminates the connection, making the unit number available for connection to other files. Following the close statement, the program connects unit 9 to a different external file, new_file:
```

! connect unit 9 to first_file
OPEN (9, FILE='first_file')
! process file

```

I/O and file handling
Connecting a file to a unit
```

terminate connection
CLOSE (9)
! connect same unit number to new_file
OPEN (9, FILE='new_file')
..
process file
...
terminate connection
CLOSE (9)

```

\section*{Performing I/O on internal files}

An internal file is not connected to a unit number and therefore does not require an OPEN statement. It is referenced as a character variable. In the following example, the WRITE statement transfers the data from char_var to the internal file int_file, using list-directed formatting. Because int_file is declared to be 80 characters long, it is assumed that the length of char_var will be no more than 80 characters.

CHARACTER (LEN=80) : : int_file
WRITE (FILE=int_file, FMT=*) char_var
For information about internal files, see "Internal files" on page 174.

\section*{Preconnected unit numbers}

Unit numbers 5, 6, and 7 are preconnected; that is, they do not have to be explicitly opened and are connected to system-defined files, as follows:
- Unit 5 is connected to standard input-by default, the keyboard of the machine on which the program is running.
- Unit 6 is connected to standard output-by default, the terminal/ display of the machine on which the program is running.
- Unit 7 is connected to standard error-by default, the terminal/ display of the machine on which the program is running.
Each predefined logical unit is automatically opened when a Fortran 90 program begins executing and remains open for the duration of the program. This means, for example, that standard output can be used by a PRINT statement without prior execution of an OPEN statement. Attempting to ClOSE a preconnected logical unit has no effect.
A preconnected unit number can be reused with an OPEN statement that assigns it to a new file. Once a preconnected unit number is connected to a new file, however, it cannot be reconnected to its original designation.

You can use theHP-UX input/output redirection (< and >) and piping (|) operators to redirect from standard input, standard output, or standard error to a file of your own choosing.

\section*{Automatically opened unit numbers}

Unit numbers that have not been associated with a file by an OPEN statement can be automatically opened using the READ or WRITE statement. When a file is automatically opened, a string is created of the form:
ftn \(X X\)
where \(X X\) is replaced by the unit number in the range 01 to 99.
If you have made an environment variable assignment of the form \(\operatorname{ftn} X X=\) path, the file named in path is opened. Otherwise, the file whose name is \(\operatorname{ftn} X X\) is opened in the current directory. If the file does not exist, it is created.

The following program
```

PROGRAM Auto
WRITE (11,'(A)') 'Hello, world!'
END
writes the string
Hello, world!
to the file ftn11.
If this program is compiled to a. out and is run as follows (using /bin/
sh or /bin/ksh)
ftn11=datafile
export ftn11
a.out
the output string is written to the file datafile instead of $f t n 11$.
Automatically opened files are always opened as sequential files. Other characteristics of an automatically opened file, such as record length and format, are determined by the data transfer statement that creates the file. If the statement does not specify formatted, list-directed, or namelist-directed I/O, the file is created as an unformatted file.

```

I/O and file handling
File access methods

\section*{File access methods}

HP Fortran allows both sequential access and direct access. You specify the access method with the OPEN statement when you connect the file to a unit number. The following example opens the file new_data for direct access:
```

OPEN(40, ACCESS='DIRECT', RECL=128, FILE='new_data')

```

If you do not specify an access method, the file is opened for sequential access.

The following sections describe both sequential and direct methods.

\section*{Sequential access}

Records in a file opened for sequential access can be accessed only in the order in which they were written to the file. A sequential file may consist of either formatted or unformatted records. If the records are formatted, you can use list-directed, namelist-directed, and formatted I/O statements to operate on them. If the records are unformatted, you must use unformatted I/O statements only. The last record of a sequential file is the end-of-file record.

The following sections describe the types of I/O that can be used with sequential files, namely:
- Formatted I/O
- List-di rected I/O
- Namelist-directed I/O
- Unformatted I/O

\section*{Formatted I/O}

Formatted I/O uses format specifications to define the appearance of data input to or output from the program, producing ASCII records that are formatted for display. (Format specifications are described in detail in "Format specification" on page 207.) Data is transferred and converted, as necessary, between binary values and character format. You cannot perform formatted I/O on a file that has been connected for unformatted I/O; see "Unformatted I/O" on page 185.

Formatted I/O can be performed only by data transfer statements that include a format specification. The format specification can be defined in the statement itself or in a FORMAT statement referenced by the statement.
For an example of a program that accesses a formatted file, see "File access" on page 202.

\section*{List-directed I/O}

List-directed I/O is similar to formatted I/O in that data undergoes a format conversion when it is transferred but without the use of a format specification to control formatting. Instead, data is formatted according to its data type. List-directed I/O is typically used when reading from standard input and writing to standard output.
List-directed I/O uses the asterisk (*) as a format identifier instead of a list of edit descriptors, as in the following READ statement, which reads three floating-point values from standard input:
```

READ *, A, B, C

```

List-directed I/O can be performed only on internal files and on formatted, sequential external files. It works identically for both file types.

\section*{Input}

I nput data for list-directed input consists of values separated by one or more blanks, a slash, or a comma preceded or followed by any number of blanks. (No values may follow the slash.) An end-of-record also acts as a separator except within a character constant. Leading blanks in the first record read are not considered to be part of a value separator unless followed by a slash or comma.
Input values can be any of the values listed in Table 17. A blank is indicated by the symbol b.

I/O and file handling
File access methods

Table 17 Input values for list-directed I/O
\begin{tabular}{|l|l|}
\hline Value & \multicolumn{1}{|c|}{ Meaning } \\
\hline\(z\) & \begin{tabular}{l} 
A null value, indi cated by two successive separators with \\
zero or more intervening blanks (for example, , b/).
\end{tabular} \\
\hline c & \begin{tabular}{l} 
A literal constant with no embedded blanks. It must be \\
readable by an I, \(\mathrm{F}, \mathrm{A}\), or L edit descriptor. Binary, octal, and \\
hexadecimal data are illegal.
\end{tabular} \\
\hline \(\mathrm{r}^{*} \mathrm{C}\) & \begin{tabular}{l} 
Equivalent tor (an integer) successive occurrences of c in the \\
input record. For example, \(5 * 0.0\) is equivalent to 0.00 .0 \\
\(0.0 \quad 0.0 \quad 0.0\).
\end{tabular} \\
\hline\(r^{*} z\) & Equivalent to r successive occurrences of z. \\
\hline
\end{tabular}

Reading always starts at the beginning of a new record. Records are read until the list is satisfied, unless a slash in the input record is encountered. The effect of the slash is to terminate the READ statement after the assignment of the previous value; any remaining data in the current record is ignored.

Table 18 outlines the rules for the format of list-directed input data.
Format of list-directed input data
\begin{tabular}{|l|l|}
\hline \multicolumn{1}{|c|}{ Data type } & \multicolumn{1}{c|}{ Input format rules } \\
\hline Integer & Conforms to the same rules as integer constants. \\
\hline \begin{tabular}{l} 
Real and \\
double \\
precision
\end{tabular} & \begin{tabular}{l} 
Any valid form for real and double precision. In \\
addition, the exponent can be indicated by a signed \\
integer constant (the, , D, or E can be omitted), and \\
the decimal point can be omitted for those values \\
with no fractional part.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline \multicolumn{1}{|c|}{ Data type } & \multicolumn{1}{c|}{ Input format rules } \\
\hline \(\begin{array}{l}\text { Complex and } \\
\text { double } \\
\text { complex }\end{array}\) & \(\begin{array}{l}\text { Two integer, real, or double precision constants, } \\
\text { separated by a comma and enclosed in parentheses. } \\
\text { The first number is the real part of the complex or } \\
\text { double complex number, and the second number is } \\
\text { the imaginary part. E ach of the numbers can be } \\
\text { preceded or followed by blanks or the end of a record. }\end{array}\) \\
\hline Logical & \(\begin{array}{l}\text { Consists of a field of characters, the first nonblank } \\
\text { character of which must be a T for true or an F for } \\
\text { false (excluding the optional Ieading decimal point). } \\
\text { Integer constants may also appear. }\end{array}\) \\
\hline Character & \(\begin{array}{l}\text { Same form as character constants. Delimiting with } \\
\text { single or doublequotation marks is needed only if the } \\
\text { constant contains any separators; delimiters are } \\
\text { discarded upon input. Character constants can be } \\
\text { continued from one record to the next. The end-of- } \\
\text { record does not cause a blank or any other character } \\
\text { to become part of the constant. If the length of the } \\
\text { character constant is greater than or equal to the } \\
\text { length, Ien, of the list item, only the leftmost len } \\
\text { characters of the constant are transferred. If the }\end{array}\) \\
length of the constant is less than len, the constant is \\
left-justified in the list item with trailing blanks.
\end{tabular}\(\}\)\begin{tabular}{l} 
(
\end{tabular}

\section*{Output}

The format of list-directed output is determined by the type and value of the data in the output list and by the value of the DELIM= specifier in the open statement. For information about the DELIM= specifier, see the description of the open statement in Chapter 10, "HP Fortran statements," on page 241.

I/O and file handling
File access methods

Table 19 summarizes the rules governing the display of each data type.
Table \(19 \quad\) Format of list-directed output data
\begin{tabular}{|l|l|}
\hline \multicolumn{1}{|c|}{\begin{tabular}{c} 
Data \\
type
\end{tabular}} & \multicolumn{1}{c|}{ Output format rules } \\
\hline Integer & Output as an integer constant. \\
\hline \begin{tabular}{l} 
Real and \\
Double \\
Precision
\end{tabular} & \begin{tabular}{l} 
Output with or without an exponent, depending on the \\
magnitude. Also, output with field width and decimal \\
places appropriate to maintain the precision of the data \\
as closely as possible.
\end{tabular} \\
\hline Complex & \begin{tabular}{l} 
Output as two numeric values separated by commas and \\
enclosed in parentheses.
\end{tabular} \\
\hline Logical & \begin{tabular}{l} 
If the value of the list element is . TRUE., then T is \\
output. Otherwise, F is output.
\end{tabular} \\
\hline Character & \begin{tabular}{l} 
Output using the Alen format descriptor, where len is the \\
length of the character expression (adjusted for \\
doubling). If DELIM= 'NONE' (the default), no single (') or \\
double (") quotation marks are doubled, and the records \\
may not be suitable list-directed input. If the value \\
specified by DELIM= is not 'NONE ', only the specified \\
delimiter is doubled. Character strings are output \\
without delimiters, making them also unsuitable for list- \\
directed input.
\end{tabular} \\
\hline
\end{tabular}

With the exception of character values, all output values are preceded by exactly one blank. A blank character is also inserted at the start of each record to provide ASA carriage control if the file is to be printed; see "ASA carriage control" on page 197 for a description of this. For example, the following statement:
```

PRINT *, 'Hello, world!'

```
outputs the line (where b indicates a blank):
```

bHello,bworld!

```

If the length of the values of the output items is greater than 79 characters, the current record is written and a new record started.

Slashes, as value separators, and null values are not output by listdirected WRITE statements.

\section*{Namelist-directed I/O}

Namelist-directed I/O enables you to transfer a group of variables by referencing the name of the group, using the NML= specifier in the data transfer statement. The nAmelist statement specifies the variables in the group and gives the group a name.
Like list-directed I/O, namelist-directed I/O does not use a format specification when formatting data but uses default formats, as determined by the data types.

In the following example, the NAMELIST statement defines the group name_group, which consists of the variables \(i, j\), and \(c\). The READ statement reads a record from the file connected to unit number 27 into name_group. The PRINT statement then writes the data from the variables in name_group to standard output. (As an extension, HP Fortran allows this use of the PRINT statement in namelist I/O.)
```

INTEGER :: i, j
CHARACTER(LEN=10) :: C
NAMELIST /name_group/ i, j, c
READ (UNIT=27,NML=name_group)
PRINT name_group

```

Each namelist-directed output record begins with a blank character to provide for ASA carriage control if the records are to be printed (see "ASA carriage control" on page 197).

Namelist-directed I/O can be performed only on formatted, sequential external files.
The following program illustrates namelist-directed I/O:
```

PROGRAM namelist
INTEGER, DIMENSION(4) : : ivar
CHARACTER (LEN=3), DIMENSION (3,2) :: cvar
LOGICAL :: lvar
REAL :: rvar
NAMELIST /nl/ ivar, cvar, lvar, rvar
READ (*,nl)
PRINT nl
END PROGRAM namelist

```

If the input data is:
```

\&nl
ivar = 4,3,2,1
lvar=toodles
cvar=,,'QRS',2*,2*'XXX'
rvar=5.75E25, cvar (3,2) (1:2) ='AB'
/

```

I/O and file handling
File access methods
then the output will be:
```

b\&NLbIVAR = 4 3 2 1bCVAR ='', 'QRS', '',
'', 'XXX', 'ABX'bLVAR = TbRVAR =
5.75000E+25b/

```

The following sections describe the format of namelist-directed input and output. See "NAMELIST" on page 373 for detailed information about the NAMELIST statement.

\section*{Input}

A namelist-directed input record takes the following form:
1 An ampersand character ( \(\&\) ) immediately followed by a namelist group name. The group name must have been previously defined by a NAMELIST statement.

As an extension, the dollar sign (\$) can be substituted for the ampersand.

2 A sequence of name-value pairs and value separators. A name-value pair consists of the name of a variable in the namelist group, the equals sign ( \(=\) ), and a value having the same format as for listdirected input ( \(z, c, r^{*} c\), and \(r^{*}\) ). A name-value pair can appear in any order in the sequence or can be omitted.

A value separator may be one of the following:
- Blanks
- Tabs
- Newlines
- Any of the above with a single comma

3 A terminating slash (/). As an extension, (\$END) can be substituted for the slash.

Names of character type may bequalified by substring range expressions and array names by subscript/array section expressions. If the name in a name-value pair is that of an array, the number of the values following the equals sign must be separated by value separators and must not exceed the number of elements in the array. If there are fewer values than el ements, null values are supplied for the unfilled elements.

Namelist-directed input values are formatted according to the same rules as for list-directed input data; see Table 18.

\section*{Output}

The output record for namelist-directed I/O has the same form as the input record, but with these exceptions:
- The namelist group name is always in uppercase.
- Logical values are either T or F .
- As in list-directed output, character values are output without delimiters by default, making them unsuitable for namelist-directed input. However, you can use the DELIM= specifier in the OPEN statement to specify the single or double quotation mark as the delimiter to use for character constants.
- Only character and complex values may be split between two records.

\section*{Unformatted I/O}

Unformatted I/O does not perform format conversion on data it transfers. Instead, data is kept in its internal, machine-representable format. You cannot perform unformatted I/O on files that have been connected for formatted I/O (see "Formatted I/O" on page 178).
Unformatted I/O is more efficient than formatted, list-directed, or namelist-directed I/O because the transfer occurs without the conversion overhead. However, because unformatted I/O transfers data in internal format, it is not portable.

\section*{Direct access}

When performing I/O on a direct-access file, records can be read or written in any order. The records in a direct-access file are all of the same length.
Reading and writing records is accomplished by READ and WRITE statements containing the REC= specifier. E ach record is identified by a record number that is a positive integer. For example, the first record is record number 1; the second, number 2; and so on. If REC= is not specified:
- The read statement inputs from the current record, and the file pointer moves to the next record.
- The WRITE statement outputs to the record at the position of the file pointer, and the file pointer is advanced to the next record.

I/O and file handling
File access methods

As an extension, HP Fortran allows sequential I/O statements to access a file connected for direct access.

Once established, a record number of a specific record cannot be changed or deleted, although the record may be rewritten. A direct-access file does not contain an end-of-file record as an integral part of the file with a specific record number. Therefore, when accessing a file with a directaccess read or write statement, the END= specifier is not valid and is not allowed.

Direct-access files support both formatted and unformatted record types. Both formatted and unformatted I/O work exactly as they do for sequential files. However, you cannot perform list-directed, namelistdirected, or nonadvancing I/O on direct-access files.
For an example program that uses direct access, see "File access" on page 202.

\section*{Nonadvancing I/O}

By default, a data transfer leaves the file positioned after the last record read or written. This type of I/O is called advancing. Fortran 90 also allows nonadvancing I/O, which positions the file just after the last character read or written, without advancing to the next record. It is character-oriented and can be used only with external files opened for sequential access. It cannot be used with list-directed or namelistdirected I/O.
To use nonadvancing I/O, you must specify ADVANCE=' NO ' in the READ or WRITE statement. The example program in "File access" on page 202 uses nonadvancing I/O in the first WRITE statement, which is reproduced here:
\(\operatorname{WRITE}(6, \operatorname{FMT}='(\mathrm{~A})\) ', ADVANCE='NO') \&
' Enter number to insert in list: '
The effect of nonadvancing I/O on theWRITE statement is to suppress the newline character that is normally output at the end of a record. This is the desired effect in the example program: by using a nonadvancing WRITE statement, the user input to the READ statement stays on the same line as the prompt.
You can get the same effect with the newline (\$) edit descriptor, an HP Fortran extension that also suppresses the carriage-return/linefeed sequence at the end of a record; see "Newline (\$) edit descriptor" on page 211.
For an example program that illustrates nonadvancing I/O in a READ statement, see "Nonadvancing I/O" on page 199. For more information about nonadvancing I/O and the ADVANCE= specifier, see the READ and WRIte statements in Chapter 10.

I/O and file handling
I/O statements

\section*{I/O statements}

HP Fortran supports three types of I/O statements:
- Data transfer statements (see Table 20)
- File positioning statements (see Table 21)
- Auxiliary statements (see Table 22)

For detailed information about all I/O statements, refer to Chapter 10, "HP Fortran statements," on page 241.
Table 20
Data transfer statements
\begin{tabular}{|l|l|}
\hline Statement & \multicolumn{1}{|c|}{ Use } \\
\hline ACCEPT & \begin{tabular}{l} 
Inputs data from the preconnected default input device \\
(standard input) (extension).
\end{tabular} \\
\hline DECODE & Inputs data from an internal file (extension). \\
\hline ENCODE & Outputs data to an internal file (extension). \\
\hline PRINT & \begin{tabular}{l} 
Outputs data to the preconnected default output device \\
file (standard output)
\end{tabular} \\
\hline READ & \begin{tabular}{l} 
Inputs data from a connected or automatically opened \\
unit.
\end{tabular} \\
\hline TYPE & Synonym for the PRINT statement (extension). \\
\hline WRITE & \begin{tabular}{l} 
Outputs data to a connected or automatically opened \\
unit.
\end{tabular} \\
\hline
\end{tabular}

NOTE
Although the DECODE and ENCODE statements are available as compatibility extensions for use with internal files, they are nonportable and are provided for compatibility with older versions of Fortran. To keep your programs standard-conforming and portable, you should use the READ and WRITE statements with both external and internal files.

ACCEPT and TYPE are also available as compatibility extensions for reading from standard input and writing to standard output. However, if you wish your program to be portable, you should use the READ and PRINT statements instead of the ACCEPT and TYPE statements.

Table 21
File positioning statements
\begin{tabular}{|l|l|}
\hline Statement & \multicolumn{1}{c|}{ Use } \\
\hline BACKSPACE & \begin{tabular}{l} 
Moves the file pointer of the connected sequential file to \\
the start of the previous record.
\end{tabular} \\
\hline ENDFILE & \begin{tabular}{l} 
Writes an end-of-file record as the next record of the \\
sequential file.
\end{tabular} \\
\hline REWIND & \begin{tabular}{l} 
Moves the file pointer of the connected file to the initial \\
point of the file.
\end{tabular} \\
\hline
\end{tabular}

\section*{Table 22}

Auxiliary statements
\begin{tabular}{|l|l|}
\hline Statement & \multicolumn{1}{c|}{ Use } \\
\hline CLOSE & Disconnects a unit from a file. \\
\hline INQUIRE & Requests information about a file or unit. \\
\hline OPEN & \begin{tabular}{l} 
Connects an existing file to a unit, creates a file and \\
connects it to a unit, or changes certain specifiers of a \\
connection between a file and a unit.
\end{tabular} \\
\hline
\end{tabular}

\section*{Syntax of I/O statements}

The general syntactic form of filepositioning and auxiliary statements is:
statement-name (io-specifier-list)
where
statement-name is one of the statements listed in Table 21 or Table 22.
io-specifier-list is a comma-separated list of I/O specifiers that control the statement's operation.

The general form of a data-transfer statement is:
statement-name (io-specifier-list) data-list
where
statement-name is one of the statements listed in Table 20.
io-specifier-list is a comma-separated list of I/O specifiers that control the data transfer.
data-list is a comma-separated list of data items.
The following sections describe the I/O specifiers and the form of datalist. For detailed information about the syntax of individual I/O statements, see Chapter 10, "HP F ortran statements," on page 241.

\section*{I/O specifiers}

I/O specifiers providel/O statements with additional information about a file or a data transfer operation. They can also be used (especially with the InQUIRE statement) to return information about a file. Table 23 lists all I/O specifiers supported by HP Fortran and identifies the statements in which each can appear. Note that the ACCEpt, Decode, encode, and type statements are not listed in the table as they are nonstandard. All I/O specifiers and statements are fully described in Chapter 10, "HP Fortran statements," on page 241. E ach I/O specifier is described under the I/O statement in which it may appear.

\end{tabular}

\section*{I／O data list}

The I／O data list can be used with any data transfer statement except namelist I／O；see＂Namelist－directed I／O＂on page 183 for a description of this．The general form of the I／O data list is：
item1［，item2．．．］
where item is a either a simple data element or an implied－do loop．
The following sections describe simple data elements and the implied－DO loop．

\section*{Simple data elements}

In a read operation, the simple data element specifies a variable, which can include:
- A scalar
- An array
- An array element or section
- A character substring
- A structure
- A component of a structure
- A record
- A field of a record
- A pointer

In a write operation, the simple data element can include any variable that is valid for a read operation, plus most expressions. Note that, if the expression includes a function reference, the function must not itself perform I/O.

The output list in the following PRINT statement contains two simplelist elements, a variable named radius and an expression formed from radius:
```

99 FORMAT('Radius = ', F10.2, 'Area = ', F10.2)
PRINT 99, radius, 3.14159*radius**2

```

The next READ statement contains three simple elements: a character substring (name (1:10)), a variable (id), and an array name (scores):
```

88 FORMAT(A10,I9,10I5)
READ (5, 88) name(1:10), id, scores

```

If an array name is used as a simple data element in the I/O list of a WRITE statement, then every element in the array will be displayed. If a format specifi cation is al so used, then the format will be reused if necessary to display every element. For example, the following code
```

    INTEGER :: i (10) = (/1,2,3,4,5,6,7,8,9,10/)
    88 FORMAT(' N1:',I5, 'N2:',I5, 'N3:',I5)
PRINT 88, i

```

I/O and file handling
Syntax of I/O statements
will output the following:
\begin{tabular}{lrrr} 
N1: & 1 & N2: & 2 \\
N1: & 4 N2: & 3 & 3 \\
N1: & 7 N2: & 8 & 6 \\
N1: & 10 N2: & & \\
\end{tabular}

The following restrictions apply to the use of arrays in input and output:
- Sections of character arrays that specify vector-valued subscripts cannot be used as internal files.
- An assumed-size array cannot be referenced as a whol e array in an input or output list.

The following restrictions apply to the use of structures and records in input and output:
- All components of the structure or fiel ds of the record must be accessible within the scoping unit that contains the data transfer statement.
- Every component of the structure or field of the record is written.
- A structure in an I/O list must not contain a pointer that is an ultimate component-that is, the last component in a variable reference. In the expression \(a \% b \% c\), \(a\) and \(b\) can be pointers, but not \(c\).

\section*{Implied-DO loop}

An implied-do loop consists of a list of data elements to be read, written, or initialized, and a set of indexing parameters. The syntax of an implied-do loop in an I/O statement is:
(list , index = init , limit [, step ])
where
list
is an I/O list, which can contain other implied-Do loops.
index
is an integer variable that controls the number of times the elements in list are read or written. The use of real variables is supported but obsolescent.
\begin{tabular}{ll} 
init & \begin{tabular}{l} 
is an expression that is the initial value assigned to \\
index at the start of the implied-Do loop.
\end{tabular} \\
limit
\end{tabular}
is an expression that is the termination value for index.
step
is an expression by which index is incremented or decremented after each execution of the do loop. step can be positive or negative. Its default value is 1 .

Inner loops can use the indexes of outer loops.
The implied-Do loop acts like a do construct. The range of the implied-DO loop is the list of elements to be input or output. The implied-Do loop can transfer a list of data elements that are valid for a write operation. index is assigned the value of init at the start of the loop. Execution continues in the same manner as for DO loops (see "DO construct" on page 107).

The implied-do loop is generally used to transmit arrays and array elements, as in the following:
```

INTEGER :: b(10)
PRINT *, (b(i), i = 1,10)

```

If \(b\) has been initialized with the values 1 through 10 in order, the PRINT statement will produce the following output:
\(\begin{array}{llllllllll}1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10\end{array}\)
If an nonsubscripted array name occurs in the list, the entire array is transmitted at each iteration. For example:
```

REAL :: x(3)
PRINT *, (x, i=1, 2)

```

If \(x\) has been initialized to be [ \(\left.\begin{array}{llll}1 & 2 & 3\end{array}\right]\), the output will be:
\[
\begin{array}{llllll}
1.0 & 2.0 & 3.0 & 1.0 & 2.0 & 3.0
\end{array}
\]

The list can contain expressions that use the index value. For example:
```

REAL :: x (10) = (/.1, .2, .3, .4, . 5, .6, . 7, . 8, . 9, 1 /)
PRINT *, (i*2, x(i*2), i = 1, 5)

```
print the numbers
\(\begin{array}{llllllllll}2 & .2 & 4 & . & 6 & 6 & . & 8 & 8 & 10\end{array}\)

I/O and file handling
Syntax of I/O statements

Implied-DO loops can also be nested. The form of a nested implied-Do loop in an I/O statement is:
( ( list, index1 = init1, limit1, step1), index2 = init2, limit2, step2) ... indexN = initN, limitN, stepN)
Nested implied-Do loops follow the same rules as do other nested Do loops. For example, given the following statements:
```

REAL :: a (2,2)

```
\(a(1,1)=1\)
\(a(2,1)=2\)
\(a(1,2)=3\)
\(a(2,2)=4\)
WRITE \((6, *)((a(i, j), i=1,2), j=1,2)\)
the output will be:
1.02 .03 .04 .0

The first, or nested Do loop, is completed once for each execution of the outer loop.

\section*{ASA carriage control}

The program asa(1) processes the output of a F ortran 90 program that uses ASA carriage control characters so that it can be properly handled by many printers.

The syntax of asa is:
asa [filenames]
where filenames is a list of file names to be output with carriage control characters interpreted according to ASA rules.

Table 24 describes the ASA carriage-control characters.

\section*{Table 24}

ASA carriage-control characters
\begin{tabular}{|l|l|}
\hline Character & \multicolumn{1}{c|}{ Meaning } \\
\hline blank & Advance one line. \\
\hline 0 & Advance two lines. \\
\hline 1 & Advance to top of next page. \\
\hline+ & Do not advance; overstrike previous line. \\
\hline
\end{tabular}
asa reads input from filenames or from standard input if filenames is not specified. The first character of each line is interpreted as a control character. Lines beginning with any character other than those listed in Table 24 are interpreted as if they began with a blank, and an appropriate diagnostic appears on standard error. The first character of each line is not printed. The asa program interprets input lines and sends its output to standard output. Each input file begins on a new page.

To properly view the output of programs that use as a carriage control characters, asa should be used as a filter. For example, the following example pipes the output of fortran_asa, an executableHP Fortran program that outputs lines with ASA carriage control characters, through the asa filter to the line printer command, lp:
```

fortran_asa | asa | lp

```

\section*{Example programs}

This section gives example programs that illustratel/O and file-handling features of HP Fortran.

\section*{Internal file}

The following example, int_file.f90, illustrates how internal files can use edit descriptors internally. The comments within the program explain in detail what the program does.
```

int_file.f90
! The main program is a driver for the function roundoff, which
truncates and rounds a floating-point number to a requested
! number of decimal places. The main program prompts for two
! numbers, a double-precision number and an integer. These are
passed to the function roundoff as arguments. The
double-precision argument (x) is the value to be rounded, and
the integer (n) represents the number of decimal places for
rounding. The function converts both arguments to character
format, storing them in separate internal files. The function
! uses the F edit descriptor (to which n in character format has
! been appended) to round x. This rounded value is finally
! converted back from a character string to a double-precision
! number, which the function returns.
PROGRAM main
REAL (KIND=8) :: x, y, roundoff
! Use nonadvancing I/O to suppress the newline and keep the
! prompt on the same line as the input.
WRITE (6, '(X, A)', ADVANCE='NO') 'Enter a real number: '
READ (5, '(F14.0)') x
WRITE (6, '(A)') 'How many significant digits (1 - 9) to the'
WRITE (6,'(X, A)',ADVANCE='NO') 'right of the decimal point? '
! Don't enter a number greater than you input into x!
READ (5, '(I1)') n
y = roundoff(x, n)
PRINT *, Y
END PROGRAM main
! This function truncates and rounds x to the number of decimal
! places specified by n. The function performs no error
! checking on either argument.
REAL (KIND=8) FUNCTION roundoff(x, n)
INTEGER :: n
REAL (KIND=8) :: x
CHARACTER (LEN=14) :: dp_val
CHARACTER :: dec_digits

```
```

! Use an edit descriptor to convert the value of n to a
character; write the result to the internal file
dec_digits.
WRITE (dec_digits, '(I1)') n
! Concatenate dec_digits to the string 'F14.'. The complete
! string forms an edit descriptor that will convert the
! binary value of }x\mathrm{ to a formatted value of }x\mathrm{ to a
! formatted character string that formats the
! value. The character represents the requested level of
! precision. The formatted number is stored in the internal
! file dp_val.
WRITE (dp_val, '(F14.'//dec_digits//')') x
! Re-convert the formatted record in dp_val to a binary
! value that the function will return.
READ (dp_val, '(F14.0)') roundoff
END FUNCTION roundoff

```

Here are the command lines to compile and execute the program, along with the output from a sample run:
```

\$ f90 int_file.f90
\$ a.out
Enter a real number: 3.1415927
How many significant digits (1 - 9) to the
right of the decimal point? 3
3.142

```

\section*{Nonadvancing I/O}

The following program reads a formatted sequential file as a set of records divided into an arbitrary number of fields. The program uses nonadvancing I/O to read and process each field. The comments explain what the program does. Included with the is a listing of the data file, grades, read by the program.

\section*{nonadvance.f90}
```

! This program uses nonadvancing I/O to read a series of
! sequential-file records, character by character. Each
! record is divided into fields. The first field is the name
! of a student and is 20 characters log. Each of the
! remaining fields s a numeric test score and is 3
! i characters long. The name score fields. The program
! reads the name field, then reads each score field
! until it encounters end-of-record. When the
! program encounters end-of-record, it starts a new record.
! When it encounters and end-of-file,
! the program is done. For the sake of simplicity, the
! program does no error-checking.

```

I/O and file handling
Example programs
```

PROGRAM main
INTEGER :: grade, count, sum, average
CHARACTER(LEN=20) name
OPEN(20, FILE='grades')
WRITE (6, 10) "Name", "Average"
WRITE (6, *) "---------------------------"
DO ! read and process each record
sum = 0
count = 0
! Read the first field of each record, using nonadvancing
! I/O so as not to advance beyond that field. The END=
! specifier causes the program to exit the loop and branch
! to the statement at }999\mathrm{ when it detects end-of-file.
READ(20, "(A20)", ADVANCE='NO', END=999) name
! Read each of the score fields of the record, using
! nonadvancing I/O to avoid advancing to the next record
! after each read. The EOR= specifier causes the program
! to break out of the loop and resume
! execution at the statement labeled 99.
DO ! inner loop to read scores
! read a score and convert it to integer
READ(20, "(I3)", ADVANCE='NO', EOR=99) grade
count = count + 1
sum = sum + grade
END DO
! calculate average
99 average = sum/count
WRITE(6, 20) name, average ! write student name and average
END DO
10 FORMAT (X, A, T21, A)
20 FORMAT (X, A, I3)
999 CLOSE (20)
END PROGRAM main

```

\section*{grades}
```

I/O and file handling
Example programs

\section*{File access}

The following example, file_access.f90, illustrates both sequential and direct access on external files. The file opened for direct access is a scratch file. The comments explain what the program does.

\section*{file_access.f90}
```

This program uses an external file and a scratch file to
insert a number into a list of numerically sorted numbers.
! The sorted list is held in a external file. The program uses
! the scratch file as a temporary holding place. The program
! uses direct access method with the scratch file.
PROGRAM main
REAL :: number_to_insert, number_in_list
INTEGER :: rec_num, ios1, ios2, i
! Initialize counter.
rec num = 0
! ios1 must be initialized to 0 so that the error-handling
! section at the end of the program will work correctly
ios1= 0
! Open the scratch file and the sequential data file
OPEN (18, FILE='list', STATUS='UNKNOWN', IOSTAT=ios1, ERR=99)
OPEN (17, STATUS='SCRATCH', ACCESS='DIRECT', FORM='FORMATTED'
\&
IOSTAT=ios1, ERR=99, RECL=16)
! Use nonadvancing I/O to suppress newline at the end of output
record, thus keeping the prompt on the same line with the
input.
WRITE (6, FMT='(A)', ADVANCE='NO') \&
' Enter number to insert in list: '
READ *, number_to_insert
! Read from sorted list and write to scratch file until we find
where to insert number; then, write number_to_insert, and
continue writing remaining sorted numbers to scratch file.
DO WHILE (ios1 >= 0) ! loop only if OPEN didn't encounter EOF
! The END=15 specifier in the READ statement gets us out of
! the loop, once we're in it.
READ (18, *, END=10, IOSTAT=ios2, ERR=99) number_in_list
IF (number_to_insert <= number_in_list) THEN
rec_num = rec_num + 1 ! add the new record
WRITE(17, 100, REC=rec_num) number_to_insert
DO
rec_num = rec_num + 1
WRITE(17, 100, REC=rec_num) number_in_list
READ (18, *, END=15, IOSTAT=ios2, ERR=99) number_in_list
END DO
ELSE
rec_num = rec_num + 1
WRITE (17, 100, REC=rec_num) number_in_list
END IF

```
```

    END DO
    ! The file is empty or the item goes at the end of file. Add 1
    ! to rec_num for the record to be inserted.
    10 rec_num = rec_num + 1
WRITE (17, 100, REC=rec_num) number_to_insert
! Copy the scratch file to the data file. But first rewind
! so that we start writing at beginning of the data file.
15 REWIND 18
! Read from scratch file and write to data file
DO i = 1, rec_num
READ (17, 100, REC=i) number_in_list
WRITE (18, *) number_in_list
END DO
CLOSE (18)
CLOSE (17)
STOP 'Inserted!'
! Error handling section
99 IF (ios1 /= 0) THEN
WRITE (7, 200) "Open error = ", ios1
ELSE
WRITE (7, 200) "Read error = ", ios2
END IF
100 FORMAT (F16.6)
200 FORMAT (A, 2I6)
END PROGRAM main

```

Here are the command lines to compile and execute the program, along with the output from a sample run. Output from the cat command shows the contents of the list file before and after executing the program:
```

\$ f90 file_access.f90
\$ cat list
0.5
1.2
2.5
3.5
26.15
\$ a.out
Enter number to insert in list: 4.7
STOP Inserted!
\$ cat list
0.5
1.2
2.5
3.5
4.7
26.15

```

I/O and file handling
Example programs

\section*{9 I/O formatting}

I/O formatting occurs during data transfer operations when data is converted between its machine-readable binary representation and human-readable character format. Although unformatted data transfers are faster because they do not incur the overhead of data conversion, I/O formatting is useful for displaying data in a human-readable form and for transferring data between machines with different machine representations for a data type.

I/O formatting can be implicit or explicit. Implicit formatting occurs during list-directed and namelist-directed I/O: data is converted without programmer intervention, based on the data types of the I/O list items; see "List-directed I/O" on page 179 and "Namelist-directed I/O" on page 183. Explicit formatting occurs under the control of the programmer, who specifies how the data is to be converted.
This chapter describes explicit I/O formatting and includes information about the following:
- FORMAT statement
- Format specification
- Edit descriptors
- Embedded format specification
- Nested format specifications
- Format specification and I/O data list

\section*{FORMAT statement}

The function of the FORMAT statement is to specify formatting information that can be used by one or more of the following data transfer statements:
- ACCEPT (extension)
- DECODE (extension)
- ENCODE (extension)
- PRINT
- READ
- TYPE (extension)
- WRITE

The syntax of the FORMAT statement is:
```

labd FORMAT ( format-spec )

```
where:
\begin{tabular}{ll} 
Iabel & is a statement label. \\
format-spec & \begin{tabular}{l} 
is a format specification consisting of a comma- \\
separated list of edit descriptors. For detailed \\
information about edit descriptors, see the next section.
\end{tabular}
\end{tabular}

The FORMAT statement must includelabel so that the data transfer statements can reference it. One FORMAT statement can be referenced by many data transfer statements. In the following example, both the READ and WRITE statements reference the same FORMAT statement:
```

READ(UNIT=22, FMT=10)ivar, fvar
WRITE(17, 10)ivar, fvar
10 FORMAT(I7, F14.3)

```

For additional information about the FORMAT statement and data transfer statements, see Chapter 10, "HP Fortran statements," on page 241.

\section*{Format specification}

A format specification consists of a list of edit descriptors that define the format of data to be read with a READ statement, or written with a WRITE or PRINT statement. A format specification can appear either in a FORMAT statement or in a character expression in a data transfer statement.
The syntax of a format specification is:
[descriptor1[, descriptor2...]]
where:
descriptor is an edit descriptor that is used to convert data between its internal (binary) format and an external (character) format. Edit descriptors are described in detail in the following section.
Note that format specifications are not used in list-directed and namelist-directed \(\mathrm{I} / \mathrm{O}\).

\section*{Edit descriptors}

Edit descriptors are encoded characters that describe data conversion between an internal (binary) format and an external (character) format. There are three types of edit descriptors:
- Data edit descriptors define the format of data to be read or written, such as its type and width (in characters). All data edit descriptors are repeatable; that is, they can be preceded by a positive integer that specifies the number of times the edit descriptor is to be replicated.
- Control edit descriptors specify editing information, such as the number of spaces between input items, treatment of blanks in input, and scale factors. Of the control edit descriptors, only the slash (/) is repeatable.
- Character string edit descriptors output text. N one of these is repeatable.

All of the edit descriptors supported by HP Fortran are listed in Table 25. As indicated by the syntax descriptions included in the table, the field width specification (w) is optional for all data edit descriptors in HP Fortran. Note that the Fortran 90 Standard defines the field width specifier to be optional only for the A edit descriptor. The table also identifies which edit descriptors are repeatable and which can be used on input, output, or both.

Table 25 Edit descriptors
\begin{tabular}{|l|l|l|l|l|}
\hline Descriptor & \multicolumn{1}{|c|}{ Type } & Repeatable? & \multicolumn{1}{|c|}{ I/O use } & \multicolumn{1}{c|}{ Function } \\
\hline\("^{\prime \ldots}\) " or '...' & \begin{tabular}{l} 
Character \\
string
\end{tabular} & No & Output & Output enclosed string. \\
\hline\(\$\) & Control & No & Output & \begin{tabular}{l} 
Suppress newline at end of \\
output.
\end{tabular} \\
\hline / (slash) & Control & Yes & Input/output & \begin{tabular}{l} 
End current record and begin \\
new record.
\end{tabular} \\
\hline : (colon) & Control & No & Input/output & \begin{tabular}{l} 
Stop formatting if I/O list is \\
exhausted.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|}
\hline Descriptor & Type & Repeatable? & I/O use & Function \\
\hline \(\mathrm{A}[\mathrm{w}]\) or \(\mathrm{R}[\mathrm{w}]\) & Data & Yes & Input/output & Convert character data. \\
\hline \(\mathrm{B}[\mathrm{w}[. m]]\) & Data & Yes & I nput/output & Convert integer data, using binary base. \\
\hline BN & Control & No & Input/output & I gnore blanks in numeric input data. \\
\hline BZ & Control & No & Input/output & Treat blanks as zeroes in numeric input data. \\
\hline D[w.d] & Data & Yes & Input/output & Convert real type data with exponent. \\
\hline E[w.d[Ee]] & Data & Yes & Input/output & Convert real type data with exponent. \\
\hline En[w.d[Ee]] & Data & Yes & Input/output & Convert real type data, using engineering notation. \\
\hline Es[w.d[Ee]] & Data & Yes & Input/output & Convert real type data, using scientific notation. \\
\hline F[w.d] & Data & Yes & Input/output & Convert real type data without exponent. \\
\hline G[w.d[Ee]] & Data & Yes & Input/output & Convert numeric data, all types. \\
\hline Q[w.d] & Data & Yes & Input/output & Convert real type data with exponent. \\
\hline nHs & Character String & No & Output & Output following n characters. \\
\hline I[w[.m] \(]\) & Data & Yes & Input/output & Convert integer numeric data. \\
\hline L[w] & Data & Yes & Input/output & Convert logical data. \\
\hline O[w[.m]] & Data & Yes & Input/output & Convert integer data, using octal base. \\
\hline kP & Control & No & Input/output & Set scale factor to k. \\
\hline
\end{tabular}

I/O formatting
Edit descriptors
\begin{tabular}{|l|l|l|l|l|}
\hline Descriptor & Type & Repeatable? & \multicolumn{1}{c|}{ I/O use } & \multicolumn{1}{c|}{ Function } \\
\hline Q & Control & No & Input & \begin{tabular}{l} 
Return number of bytes \\
remaining to be read in \\
current input record.
\end{tabular} \\
\hline S or SP & Control & No & Output & Print optional plus sign. \\
\hline SS & Control & No & Output & Do not print optional plus sign. \\
\hline TC & Control & No & Input/output & Move to column c. \\
\hline TLC & Control & No & Input/output & Move c columns to the left. \\
\hline TRC or CX & Control & No & Input/output & Move c columns to the right. \\
\hline Z[w[.m]] & Data & Yes & Input/output & \begin{tabular}{l} 
Convert integer data, using \\
hexadecimal base.
\end{tabular} \\
\hline
\end{tabular}

The following sections describe the edit descriptors.
NOTE There is no single edit descriptor that defines a field for complex data. Instead, you must use two real edit descriptors-the first for the real part of the number, and the second for the imaginary part. The two edit descriptors may be different or the same, and you can insert control and character string edit descriptors between them.

Likewise, there are no edit descriptors for formatting derived types and pointers. For derived types, you must specify the appropriate sequence of edit descriptors that match the data types of the derived type's components. For pointers, you must specify the edit descriptor that matches the type of the target object.

\section*{Character string ('...' or "...") edit descriptor}

The character string edit descriptor is used to write a character constant to a formatted output record. It cannot be used to format input. You can use either apostrophes or quotation marks to delimit the constant. Whichever you use, they must be balanced. That is, if you begin with an apostrophe, you must also end with it. If the enclosed character constant includes a delimiting character, it must be of the other type; or you can escape the delimiter by giving another of the same type. The width of the field is the number of characters enclosed by the character string edit descriptors, including any blanks.

Table 26 provides examples of the character string edit descriptor on output. Note that b represents a blank.

Table 26

NOTE

Character string edit descriptor output examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & Field width & \multicolumn{1}{|c|}{ Output } \\
\hline 'Enter data:' & 11 & Enter data: \\
\hline "David's turn" & 12 & David's turn \\
\hline "bbbspacesbbb" & 12 & bbbspacesbbb \\
\hline 'That''ll do.' & 11 & That'll do. \\
\hline """That'll do!""" & 13 & "That'll do!" \\
\hline """" & 1 & " \\
\hline '"' & 1 & \("\) \\
\hline
\end{tabular}

\section*{Newline (\$) edit descriptor}

The newline edit descriptor is an HP extension that suppresses the generation of the newline character (that is, the carriage-return/linefeed sequence) during formatted, sequential output. By default, the cursor moves to a newline after each output statement. The newline edit descriptor causes the cursor to remain on the same line, immediately to the right of the last character output.

Nonadvancing I/O also suppresses the newline at the end of a record. Unlike the newline (\$) edit descriptor, it is a standard feature of Fortran 90, and can be used on input and output. For more information, see "Nonadvancing I/O" on page 187 and the ADVANCE= I/O specifier in "OPEN" on page 379.

I/O formatting
Edit descriptors

\section*{Slash (/) edit descriptor}

The slash edit descriptor terminates the current record and begins processing a new record (such as a new line on a terminal). This edit descriptor has the same result for both input and output: it terminates the current record and begins a new one. For example, on output a newline character is printed, and on input a new line is read.

Keep in mind the following considerations when using the slash edit descriptor:
- If a series of two or more slashes are written at the beginning of a format specification, the number of records skipped is equal to the number of slashes.
- If \(n\) slashes appear other than at the beginning of a format specification (where \(n\) is greater than 1), processing of the current record terminates and \(\mathrm{n}-1\) records are skipped.
- If a format contains only n slashes (and no other format specifiers), n + 1 records are skipped.

The / edit descriptor does not need to be separated from other descriptors by commas.

\section*{Colon (:) edit descriptor}

The colon edit descriptor (: ) is used when performing formatted I/O to terminate format control when the I/O list has been exhausted. If all items in an I/O list have been read or written, the colon edit descriptor stops any further format processing. If more items remain in the list, the colon edit descriptor has no effect.

Consider the following example:
```

WRITE (*, 40) 1, 2
WRITE (*, 50) 1, 2
4 0 FORMAT (3(' value =', I2))
50 FORMAT(3(:, ' value =', I2))

```

The first wRITE statement outputs the line:
```

value = 1 value = 2 value =

```

The descriptor 'value \(=\) ' is repeated a third time because format control is not terminated until the descriptor 12 is reached and not satisfied.

The second WRITE statement outputs the line:
```

value = 1 value = 2

```

This time, the colon descriptor terminates format control before the string ' value=' is output a third time.

\section*{A and R (character) edit descriptors}

The A and \(R\) edit descriptors define fields for character data. The A edit descriptor specifies left-justification, and the \(R\) edit descriptor specifies right-justification.
The R edit descriptor is an HP extension.
The syntax for the character edit descriptors is:
[r]A[W]
[r]R[W]
where:
\(r\) is a positive integer constant, specifying the repeat factor.
w
is the field width. If w is not specified, the default is the length in bytes of the corresponding I/O list item.
As a portability extension, the list item can be of any data type.
When the A and R edit descriptors are used for input and output, the results can differ according to whether the width ( \(\mathrm{w} \mathrm{)} \mathrm{specified} \mathrm{for} \mathrm{the}\) edit descriptor is less than, greater than, or equal to the length of the I/O list item. The results on input are summarized in Table 27; the results on output are summarized in Table 28.

Edit descriptors

\section*{B (binary) edit descriptor}

The B edit descriptor defines a field for binary data. It provides for conversion between an external binary number and its internal representation.

The syntax for the binary edit descriptor is:
[r]B[w[.m] ]
where:
\(r \quad\) is a positive integer constant, specifying the repeat factor.
is a positive integer constant, specifying the field width.
is an unsigned integer constant, specifying the minimum number of digits that must be in the field and forcing leading zeroes as necessary up to the first nonzero digit. The \(m\) value is ignored on input. If \(m\) is not specified, a default value of 1 is assumed. If \(m\) is larger than w , the field is filled with w asterisks.

Input Variables to receive binary input must be of type integer. The only legal characters are 0s and 1 s . Nonleading blanks are ignored, unless the file is opened with BLANK='ZERO'.

If the file is opened with BLANK= 'ZERO' , nonleading blanks are treated as zeroes. For more information about the BLANK= specifier, see "OPEN" on page 379. Plus and minus signs, commas, or any other symbols are not permitted. If a nonbinary digit appears, an error occurs. The presence of too many digits for the integer variable (or I/O list item) is illegal.

Table 31 provides examples of the binary edit descriptor on input.
Table 31
B Edit descriptor: input examples
\begin{tabular}{|l|l|l|}
\hline Descriptor & Input field (binary) & Value stored (binary) \\
\hline B8 & 1111 & 1111 \\
\hline B8 & 01111 & 1111 \\
\hline B4 & 10101 & 1010 \\
\hline B8 & 1.1 & error: illegal character \\
\hline
\end{tabular}

Output
Unlike input, list items on output may be of any type, though character values are output only as the binary equivalent of their ASCII representation (without a length descriptor). If \(w\) is greater than the number of converted binary digits (excluding leading zeroes), the binary digits are right-justified in the output field.
If \(w\) is less than the number of converted binary digits, the field is filled with \(w\) asterisks. This primarily affects the output of negative values. Because negative values are output in twos complement form, their highorder bits are nonzero and cause the field to be filled with asterisks when w is less than the number of binary digits in the entire output value.

The field width required to fully represent the binary value of an item is eight times its size in bytes. For example, an integer* 4 item could require a field \(w\) of up to 32 characters.

Only 1 s and 0 s are printed on output.
Table 32 provides examples of the binary edit descriptor on output.
Table 32
B Edit descriptor: output examples
\begin{tabular}{|l|l|l|}
\hline Descriptor & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{|c|}{ Output } \\
\hline B5 & 27 & 11011 \\
\hline B8 & 27 & bbb11011 \\
\hline B8.6 & 27 & bb011011 \\
\hline B8 & -27 & \(\star * * * * * * *\) \\
\hline
\end{tabular}

I/O formatting
Edit descriptors

\section*{BN and BZ (blank) edit descriptors}

The BN and BZ edit descriptors control the interpretation of embedded and trailing blanks in numeric input fields. The syntax of the blank edit descriptors is:

BN
BZ
At the beginning of the execution of an input statement, blank characters within numbers are ignored except when the unit is connected with BLANK= ' ZERO' specified in the OPEN statement. BN and \(B Z\) override the BLANK=I/O specifier for the current READ statement. For more details about the BLANK= I/O specifier, see "OPEN" on page 379.

If a BZ edit descriptor is encountered in the format specification, trailing and embedded blanks in succeeding numeric fields are treated as zeroes. The BZ edit descriptor remains in effect until a BN edit descriptor or the end of the format specification is encountered. If BN is specified, all embedded blanks are removed and the input number is right justified within the field width.

The BN and BZ edit descriptors affect only I, B, O, F, D, E, EN, ES, G, and Z format descriptors during the execution of an input statement. The BN and BZ edit descriptors do not affect character and logical edit descriptors.

Table 33 provides examples of the BN and BZ edit descriptors on input.
Table 33
BN and BZ edit descriptors: input examples
\begin{tabular}{|l|l|l|l|}
\hline Descriptor & \multicolumn{1}{|c|}{\begin{tabular}{c} 
Input \\
characters
\end{tabular}} & \begin{tabular}{c} 
BN editing in \\
effect
\end{tabular} & \multicolumn{1}{c|}{\begin{tabular}{c} 
BZ editing in \\
effect
\end{tabular}} \\
\hline I4 & 1b2b & 12 & 1020 \\
\hline F6.2 & b4b. b2 & 4.2 & 40.02 \\
\hline E7.1 & \(5 \mathrm{~b} . \mathrm{bE1b}\) & \(5.0 \times 10^{1}\) & \(5.0 \times 10^{11}\) \\
\hline E 5.0 & 3 E 4 bb & \(3.0 \times 10^{4}\) & \begin{tabular}{l}
\(3.0 \times 10^{400}\) \\
(overflow)
\end{tabular} \\
\hline
\end{tabular}

The BN and BZ edit descriptors are ignored during the execution of an output statement.

\section*{D, E, EN, ES, F, G, and Q (real) edit descriptors}

The D, E, EN, ES, F, G, and \(Q\) edit descriptors define fields for real numbers. The I/O list item corresponding to a real descriptor must be a numeric type. (The Standard permits real and complex types only; as an extension, HP Fortran allows integers.)
The syntax for these edit descriptors is:
```

[r]D[w.d]
[r]E[w.d[{E|D|Q}e]]
[r]EN[W.d[Ee] ]
[r]ES [W.d [Ee] ]
[r]F [w.d]
[r]G[w.d[{E|D|Q}e]]
[r]Q [w.d]
where:

```
\(r\) is a positive integer constant, specifying the repeat
w is a positive integer constant, specifying the field width.
d is a nonnegative integer constant, specifying the number of decimal places on output.
e
is a positive integer constant, specifying the number of digits in the exponent.
For formatting complex data, you can use two real edit descriptors-the first for the real part of the number and the second for the imaginary part. The two edit descriptors may be different or the same, and you can insert control and character string edit descriptors between them.

I/O formatting
Edit descriptors

\section*{Real edit descriptors on input}

The input field for the real descriptors consists of an optional plus or minus sign followed by a string of digits that may contain a decimal point. If the decimal point is omitted in the input string, then the number of digits equal to \(d\) from the right of the string are interpreted to be to the right of the decimal point. If a decimal point appears in the input string and conflicts with the edit descriptor, the decimal point in the input string takes precedence. This basic form can be followed by an exponent in one of the following forms:
- A signed integer constant
- An e followed by an optionally signed integer constant
- A D followed by an optionally signed integer constant
- A Q followed by an optionally signed integer constant

All four exponent forms are processed in the same way. Note, however, that ehas no effect on input.

The en and es edit descriptors are the same as the F edit descriptor on input. The e edit descriptor (an HP Fortran extension) is the same as the E edit descriptor on input.
Table 34 provides examples of the real edit descriptors on input. The BZ edit descriptor listed in the "Descriptor" column treats nonleading blanks in numeric fields as zeroes.

Table 34
D, E, F, and G edit descriptors: input examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Input field } & \multicolumn{1}{|c|}{ Value stored } \\
\hline F6.5 & 4.51 E 4 & 45100 \\
\hline G4.2 & \(51-3\) & .00051 \\
\hline E8.3 & 7.1 bEb 5 & 710000 \\
\hline D9.4 & bbb45E+35 & \(.0045 \times 10^{35}\) \\
\hline BZ, F6.1 & -54 E 3 b & \(-5.4 \times 10^{30}\) \\
\hline
\end{tabular}

\section*{Real edit descriptors on output}

The output field for the real descriptors consists of w character positions, filled with leading blanks (if necessary) and an optionally signed real constant with a decimal point, rounded to d digits after the decimal point. The following sections describe the real edit descriptors on output in detail.

\section*{D and E edit descriptors}

The \(D\) and \(E\) edit descriptors define a normalized floating-point field for real and complex values. The value is rounded to digits. The exponent part consists of edigits. If Eeis omitted in a D or e edit descriptor, then the exponent occupies two or three positions, depending on its magnitude. The field width, \(w\), should follow the general rule: \(w\) is greater than or equal to \(d+7\). If Ee is used, \(w\) is greater than or equal to \(\mathrm{d}+\mathrm{e}+5\). This rule provides positions for a leading blank, the sign of the value, the decimal point, d digits, the exponent letter ( \(\mathrm{D}, \mathrm{E}\), or Q ), the sign of the exponent, and the exponent. The Ee, De, and ee specifications, which are available with the e edit descriptor, control which exponent letter is output.

Table 35 provides examples of the E and D edit descriptors on output.

\section*{Table 35} D and E edit descriptors: output examples
\begin{tabular}{|l|l|l|}
\hline Descriptor & Internal value & \multicolumn{1}{|c|}{ Output } \\
\hline D 10.3 & +12.342 & bb. 123D+02 \\
\hline E 10.3 E 3 & -12.3454 & \(-.123 \mathrm{E}+002\) \\
\hline E 12.4 & +12.34 & bbb.1234E+02 \\
\hline D 12.4 & -.00456532 & \(\mathrm{bb}-.4565 \mathrm{D}-02\) \\
\hline D 10.10 & +99.99913 & \(\star * * * * * * * * *\) \\
\hline E 11.5 & +999.997 & \(\mathrm{~b} .10000 \mathrm{E}+04\) \\
\hline E 10.3 E 4 & \(+.624 \times 10^{-30}\) & \(.624 \mathrm{E}-0030\) \\
\hline
\end{tabular}

I/O formatting
Edit descriptors

\section*{EN and ES edit descriptors}

The En and ES descriptors format floating-point values, using engineering and scientific notation, respectively. They are similar in form to the E descriptor, except:
- The field produced by the En descriptor has an exponent that is divisible by 3 and a significand that is in the range 1 to 999.
- The field produced by the ES descriptor has one digit before the decimal point.

Table 36 provides examples of the En and Es edit descriptors on output.
Table 36
EN and ES edit descriptors: output examples
\begin{tabular}{|l|l|l|}
\hline Descriptor & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{|c|}{ Output } \\
\hline EN12.3 & +3.141 & bbb3.141E+00 \\
\hline ES12.3 & +3.141 & bbb3.141E+00 \\
\hline EN12.3 & +.00123 & bbb1.230E-03 \\
\hline ES12.3 & +.00123 & bbb1.230E-03 \\
\hline EN12.3 & -.7 & \(-700.000 \mathrm{E}-03\) \\
\hline ES12.3 & -.7 & bb-7.000E-01 \\
\hline EN12.3 & +1234.5 & bbb1.235E+03 \\
\hline ES12.3 & +1234.5 & bbb1.235E+03 \\
\hline
\end{tabular}

\section*{F edit descriptor}

The F edit descriptor defines a field for real and complex values. The value is rounded to digits to the right of the decimal point. The field width, w , should be four greater than the expected length of the number to provide positions for a leading blank, the sign, the decimal point, and a roll-over digit for rounding if needed.
Table 37 provides examples of the F edit descriptor on output.

\section*{Table 37 F edit descriptor: output examples}
\begin{tabular}{|l|l|l|}
\hline Descriptor & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{|c|}{ Output } \\
\hline F5.2 & +10.567 & 10.57 \\
\hline F3.1 & -254.2 & \(\star * *\) \\
\hline F6.3 & +5.66791432 & b5.668 \\
\hline F8.2 & +999.997 & b1000.00 \\
\hline F8.2 & -999.998 & -1000.00 \\
\hline F7.2 & -999.997 & \(\star * * * * * *\) \\
\hline F4.1 & +23 & 23.0 \\
\hline
\end{tabular}

\section*{G edit descriptor}

The G edit descriptor can be used with any data type but is commonly used to define a field for real and complex values.

According to the magnitude of the data, the G edit descriptor is interpreted as either an E or F descriptor. (For moreinformation on these edit descriptors, refer to "D and E edit descriptors" on page 221 and "F edit descriptor" on page 223.) The e edit descriptor is used when one of the following conditions is true:
- The magnitude is less than 0.1 but not zero.
- The magnitude is greater than or equal to \(10 * * d\) (after rounding to \(d\) digits).

If the magnitude does not fit either of these rules, the F edit descriptor is used. When F is used, trailing blanks are included in the field where the exponent would have been.

I/O formatting
Edit descriptors

For fixed- or floating-point format descriptors, the field width is w. The value is rounded to d digits, and the exponent consists of edigits. If Eeis omitted, the exponent occupies two positions. If Ee is omitted and the exponent is greater than 99 (that is, it requires three digits), the exponent letter is dropped from the output. The field width, w, should follow the general rule: w is greater than or equal to the sum of \(d+7\); or, if Ee is specified, w is greater than or equal to the sum of d+e+5. This rule provides positions for a leading blank, the sign of the value, d digits, the decimal point, and, if needed, the exponent letter ( \(\mathrm{D}, \mathrm{E}\), or Q ), the sign of the exponent, and the exponent. Note that the Ee, de, and Qe specifications control which exponent letter is output.

When used to specify I/O fields for integer, character, and logical data, the \(G\) edit descriptor has the same syntax and same effect as the integer, character, and logical edit descriptors. The d and evalues (if specified) have no effect.

Table 38 provides examples of the G edit descriptor on output.
Table 38
G edit descriptor: output examples
\begin{tabular}{|l|l|l|l|}
\hline Descriptor & Internal value & Interpretation & \multicolumn{1}{c|}{ Output } \\
\hline G10.3 & +1234.0 & E 10.3 & \(\mathrm{~b} 0.123 \mathrm{E}+04\) \\
\hline G10.3 & -1234.0 & E 10.3 & \(-0.123 \mathrm{E}+04\) \\
\hline G12.4 & +12345.0 & E 12.4 & \(\mathrm{bb} 0.1235 \mathrm{E}+05\) \\
\hline G12.4 & +9999.0 & \(\mathrm{~F} 8.0,4 \mathrm{X}\) & \(\mathrm{bbb} 9999 . \mathrm{bbbb}\) \\
\hline G12.4 & -999.0 & \(\mathrm{~F} 8.1,4 \mathrm{X}\) & \(\mathrm{bb}-999.0 \mathrm{bbbb}\) \\
\hline G7.1 & +.09 & E 7.1 & \(0.9 \mathrm{E}-01\) \\
\hline G5.1 & -.09 & E 5.1 & \(\star * * * *\) \\
\hline G11.1 & +9999.0 & E 11.1 & \(\mathrm{bbbb} .1 \mathrm{E}+05\) \\
\hline G8.2 & +9999.0 & E 8.2 & \(0.10 \mathrm{E}+05\) \\
\hline G7.2 & -999.0 & E 7.2 & \(* * * * * * *\) \\
\hline
\end{tabular}

\section*{Q edit descriptor}

The \(Q\) edit descriptor (an HP extension) has the same effect as the E edit descriptor on output, except that it outputs \(a\), for the exponent instead of an E .
The \(Q\) edit descriptor can also be used to determine the number of bytes remaining to be read in an input record; see " Q (bytes remaining) edit descriptor" on page 233.

\section*{H (Hollerith) edit descriptor}

The н edit descriptor outputs a specified number of characters. The syntax is:

\section*{nhcharacter-sequence}
where:
n
is a positive integer that specifies the number of characters to output. This number must exactly match the actual number of characters in character-sequence.
character-sequence
is the string of representable characters (including blanks) to output.
Table 39 provides examples of the Hollerith edit descriptor on output.
Table \(39 \quad H\) edit descriptor: output examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Field width } & \multicolumn{1}{|c|}{ Output } \\
\hline 12 HbbbSpacesbb & 12 & bbbspacesbbb \\
\hline \(14 \mathrm{H}^{\prime \prime}\) Itbisn'tbso." & 14 & "Itbisn'tbso." \\
\hline
\end{tabular}

I/O formatting
Edit descriptors

\section*{I (Integer) edit descriptor}

The I edit descriptor defines a field for an integer number. As an HP extension, it can also be used on real and logical data. The corresponding I/O list item must be a numeric or logical type.

The syntax of the integer edit descriptor is:
[rI] [W [. m ]]
where:
r
w
is a positive integer constant, specifying the field width.
m
is a nonnegative integer constant, specifying the minimum number of digits that must be in the field and forcing leading zeroes as necessary up to the first nonzero digit. The \(m\) value is ignored on input. If \(m\) is not specified, a default value of 1 is assumed. If \(m\) is larger than w, the field is filled with w asterisks. If m= 0 and the list item is zero, only blanks are output.

The integer edit descriptor causes the interpretation of the next w positions of the input record. The number is converted to match the type of the list item currently using the descriptor. A plus sign is optional for positive values. A decimal point must not appear in the field.

Table 40 provides examples of the integer edit descriptor on input.
Table 40
I edit descriptor: input examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Input field } & \multicolumn{1}{c|}{ Value stored } \\
\hline I4 & b1 bb & 1 \\
\hline I5 & bbbbb & 0 \\
\hline I5 & bbbbb1 & 0 \\
\hline I2 & -1 & -1 \\
\hline I4 & -123 & -123 \\
\hline I3 & b12 & 12 \\
\hline
\end{tabular}

I/O formatting
Edit descriptors
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Input field } & \multicolumn{1}{c|}{ Value stored } \\
\hline I3 & 12 b & 12 \\
\hline I3 & 12 b & 120 \\
\hline I3 & 1.1 & error: illegal character \\
\hline
\end{tabular}

Output
The integer edit descriptor outputs a numeric variable as a rightjustified integer value (truncated, if necessary). The field width, w, should be one greater than the expected number of digits to allow a position for a minus sign for negative values. If \(m\) is set to 0 , a zero value is output as all blanks.

Table 41 provides examples of the integer edit descriptor on output.

\section*{Table 41}

I edit descriptor: output examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{c|}{ Output } \\
\hline I4 & +452.25 & b 452 \\
\hline I2 & +6234 & \(\star *\) \\
\hline I3 & -11.92 & -11 \\
\hline I5 & -52 & \(\mathrm{bb}-52\) \\
\hline I10 & 123456.5 & bbbb 123456 \\
\hline I6.3 & 3 & \(\mathrm{bbb0} 03\) \\
\hline I3.0 & 0 & bbb \\
\hline I3 & 0 & \(\mathrm{bb0}\) \\
\hline
\end{tabular}

I/O formatting
Edit descriptors

\section*{L (Logical) edit descriptor}

The l edit descriptor defines a field for logical data. Its syntax is:
[r]L[W]
where:
r

W
is a positive integer constant, specifying the repeat factor.
is a positive integer constant, specifying the field width.

The I/O list item corresponding to an L edit descriptor must be of type logical, short logical, or byte.

The field width is scanned for optional blanks followed by an optional decimal point, followed by T ( \(\circ \mathrm{r} \mathrm{t}\) ) for true or F ( \(\mathrm{or} f\) ) for false. The first nonblank character in the input field (excluding the optional decimal point) determines the value to be stored in the declared logi cal variable. It is an error if the first nonblank character is not \(\mathrm{T}, \mathrm{t}, \mathrm{F}, \mathrm{f}\), or a period(.).
Table 42 provides examples of the logical edit descriptor on input.
Table 42
L edit descriptor: input examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Input field } & \multicolumn{1}{c|}{ Value dtored } \\
\hline L1 & T & .TRUE . \\
\hline L1 & f & .FALSE . \\
\hline L6 & .TRUE . & .TRUE . \\
\hline L7 & .false. & .FALSE . \\
\hline L2 & .t & .TRUE . \\
\hline L8 & bbbbTRUE & .TRUE . \\
\hline L3 & ABC & error: illegal character \\
\hline
\end{tabular}

Output
The character T or F is right-justified in the output field, depending on whether the value of the list item is true or false. Table 43 provides examples of the logical edit descriptor on output.

\section*{Table 43 L edit descriptor: output examples}
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{c|}{ Internal value } & \multicolumn{1}{c|}{ Output (logical) } \\
\hline L5 & false & bbbbF \\
\hline L4 & true & bbbT \\
\hline L1 & true & T \\
\hline
\end{tabular}

\section*{O (Octal) edit descriptor}

The o edit descriptor defines a field for octal data. It provides conversion between an external octal number and its internal representation.

The syntax for the octal edit descriptor is:
```

[r]O[w[.m]]

```
where:
\(r \quad\) is a positive integer constant, specifying the repeat factor.
w
is a positive integer constant, specifying the field width.
\(\mathrm{m} \quad\) is a nonnegative integer constant, specifying the minimum number of digits that must be in the field and forcing leading zeroes as necessary up to the first nonzero digit. The \(m\) value is ignored on input. If \(m\) is not specified, a default value of 1 is assumed. If \(m\) is larger than w , the field is filled with w asterisks.

Input
The presence of too many digits for the integer variable (or list item) to receive produces undefined results. Legal octal digits are 0 through 7. Plus and minus signs are illegal.

I/O formatting
Edit descriptors

Table 44 provides examples of the octal edit descriptors on input.

Table 44

Output

Table 45

O edit descriptor: input examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & Input field (octal) & Value stored (octal) \\
\hline 08 & 12345670 & 12345670 \\
\hline 02 & 77 & 77 \\
\hline 03 & 064 & 64 \\
\hline 08 & \(45 r\) & error: illegal character \\
\hline
\end{tabular}

List items may be of any type, though character variables are output only as the octal equivalent of their ASCII representation (no length descriptor).
If \(w\) is greater than the number of converted octal digits (including blanks between words but excluding leading zeroes), the octal digits are right-justified in the output field. If \(w\) is less than the number of converted octal digits, the field is filled with asterisks. This primarily affects the output of negative values. Because negative values are output in twos complement form, their high-order bits are nonzero and cause the field to be filled with asterisks when \(w\) is less than the number of octal digits in the entire output value. If \(m\) is set to 0 , a zero value is output as all blanks.

Table 45 provides examples of the octal edit descriptors on output.
O edit descriptor: output examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{c|}{ Output (Octal) } \\
\hline 06 & 80 & bbb120 \\
\hline 02 & 80 & \(\star *\) \\
\hline 014 & -9 & bbb377777777767 \\
\hline 011 & 32767 & bbbbbb777777 \\
\hline 06.4 & 79 & \(b b 0117\) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{ Internal value } & \multicolumn{1}{|c|}{ Output (Octal) } \\
\hline 012 & 1.1 & bb7743146315 \\
\hline 012 & \(' A^{\prime}\) & b101 \\
\hline 012 & \(' \mathrm{ABC}^{\prime}\) & b101b102b103 \\
\hline
\end{tabular}

\section*{P (scale factor) edit descriptor}

The kp edit descriptor causes a scale factor of \(k\) to be applied to all subsequent F, D, E, EN, ES, and G edit descriptors in the format specification.

If the P edit descriptor does not precede an F, D, E, EN, ES, or G edit descriptor, it should be separated from other edit descriptors by a comma. If the P edit descriptor immediately precedes an F, D, E, EN, ES, or \(G\) edit descriptor, the comma is optional.

For example, the format specification
\[
(3 \mathrm{P}, \mathrm{I} 2, \mathrm{~F} 4.1, \mathrm{E} 5.2)
\]
is equivalent to
```

(I2, 3PF4.1, E5.2)

```

When a format specification is interpreted, the scale factor is initially set to 0 . When a P edit descriptor is encountered, the specified scale factor takes effect for the format specification and remains in effect until another \(P\) edit descriptor is encountered.

The effect of the scale factor differs for input and output as follows:

Input

Output

If the value in the input field does not have an exponent, the internal number is equal to the field value multiplied by 10-k. If the value in the input field has an exponent, the scale factor has no effect. See Table 46 for examples of the scale factor on input.

The scale factor has no effect on the En, ES, F and G (interpreted as F) edit descriptors. For the D, E, and G (interpreted as E) edit descriptors, the value of the list item is multiplied by 10k as it is output but the exponent part is decreased by \(k\).

I/O formatting
Edit descriptors

The value specified for the scale factor \((k)\) must be in the range:
\(-\mathrm{d}<\mathrm{k}<(\mathrm{d}+2)\)
where:
d is the number of digits in the fractional part of the number being written.
k
is a signed integer that specifies the scale factor.
Table 46 provides examples of the scale factor on output.
P edit descriptor: input and output examples
\begin{tabular}{|l|l|l|l|}
\hline \multicolumn{1}{|c|}{\begin{tabular}{c} 
Format \\
specification
\end{tabular}} & \multicolumn{1}{c|}{\begin{tabular}{c} 
Input \\
field
\end{tabular}} & Internal value & \multicolumn{1}{c|}{ Output } \\
\hline\((-2 \mathrm{PG} 15.5)\) & \(1.97 \mathrm{E}-4\) & \(1.97 \times 10^{-4}\) & bbbbb.00197E-01 \\
\hline\((2 \mathrm{P}, \mathrm{F} 15.5)\) & 27.982 & .2798199 & bbbbbbb27.98200 \\
\hline\((2 \mathrm{P}, \mathrm{ES} 15.5)\) & 3518. & 35.18 & bbbb3.51800E+01 \\
\hline\((-2 \mathrm{P}, \mathrm{EN} 15.5)\) & \(7.91 \mathrm{E}+5\) & \(7.91 \times 10^{5}\) & bb791.00000E+03 \\
\hline\((-2 \mathrm{PE} 15.5)\) & .17694 & 17.694 & bbbbb.00177E+04 \\
\hline
\end{tabular}

When part or all of a format specification is repeated, the current scale factor is not changed until another scale factor is encountered.

\section*{Q (bytes remaining) edit descriptor}

The 2 edit descriptor is an HP extension that returns the number of bytes remaining to be read in the input record, placing the result into the corresponding integer variable in the I/O list. The return value can be used to control the remaining input items.

The \(Q\) edit descriptor is valid on input only; it is ignored on output. It can be used for reading formatted, sequential, and direct-access files. The fol lowing program segment reads variable-length strings from a sequential file:
```

CHARACTER(LEN=80) :: string
INTEGER :: n, i
READ (11,'(Q,80A1)') n, (string (i:i), i=1, n)

```

For information about the ew.d edit descriptor for editing real data, see "D, E, EN, ES, F, G, and Q (real) edit descriptors" on page 219.

\section*{S, SP, and SS (plus sign) edit descriptors}

The \(\mathrm{S}, \mathrm{SP}\), and SS edit descriptors control printing of the plus sign character in numeric output. The default behavior of HP Fortran is not to print the plus sign. However, an SP edit descriptor in the format specification causes the plus sign to appear in any subsequent numeric output where the value is positive. The ss descriptor suppresses the plus sign in subsequent numeric output. The s edit descriptor restores the default behavior.

The sign edit descriptors have no effect on input.

\section*{T, TL, TR , and X (tab) edit descriptors}

The tab edit descriptors position the cursor on the input or output record. Their syntax is:

Tn
TLn
TRn
nx
where:
n is a positive integer constant, specifying the number of column positions to skip for positioning within the current output or input record.

The T edit descriptor references an absolute column number, while the descriptors TL and TR reference a relative number of column positions to the left (TL) or right (TR) of the current cursor position. Note that the TR descriptor is identical to the \(X\) edit descriptor.

\section*{Z (hexadecimal) edit descriptor}

The \(z\) edit descriptor defines a field for hexadecimal data. This descriptor provides for conversion between an external hexadecimal number and its internal representation.

The syntax for the hexadecimal edit descriptor is:
[r ]Z[W [.m] ]
where:
\(r\)
w
m
is a positive integer constant, specifying the repeat factor.
is a positive integer constant, specifying the field width.
is a nonnegative integer constant, specifying the minimum number of digits that must be in the field and forcing leading zeroes as necessary up to the first nonzero digit. The \(m\) value is ignored on input. If \(m\) is not specified, a default value of 1 is assumed. If \(m\) is larger than w , the field is filled with w asterisks.

Input \(\quad\) Variables to receive hexadecimal input must be of type integer. Legal hexadecimal digits are 0 through 9 , and \(A\) through \(F\) (or a through \(f\) ). Nonleading blanks are ignored, unless the file is opened with BLANK=' ZERO'. If the file is opened with BLANK='ZERO', nonleading blanks are treated as zeroes. For more information about the BLANK= specifier see "OPEn" on page 379. Plus and minus signs, commas, or any other symbols are neither permitted on input nor printed on output. The presence of too many digits for the integer variable (or list item) produces undefined results.

Table 47 provides examples of the hexadecimal edit descriptor on input.

\section*{Table 47}

Z edit descriptor: input examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{|c|}{\begin{tabular}{c} 
Input field \\
(hexadecimal)
\end{tabular}} & \multicolumn{1}{|c|}{\begin{tabular}{c} 
Value stored \\
(hexadecimal)
\end{tabular}} \\
\hline\(z 4\) & FF3B & FF 3B \\
\hline\(Z 4\) & fFfF & FFFF \\
\hline\(Z 2\) & ABCD & AB \\
\hline\(Z 3\) & 1.1 & error: illegal character \\
\hline
\end{tabular}

Output
List items may be of any type, though character variables are output only as the hexadecimal equivalent of their ASCII representation (without a length descriptor). If \(w\) is greater than the number of converted hexadecimal digits (excluding leading zeroes), the hexadecimal digits are right-justified in the output field. If w is less than the number of converted hexadecimal digits, the field is filled with asterisks. This primarily affects the output of negative values. Because negative values are output in twos complement form, their high-order bits are nonzero and cause the field to be filled with asterisks when \(w\) is less than the number of hexadecimal digits in the entire output value. If \(m\) is set to 0 , a zero value is output as all blanks.

The field width required to fully represent the hexadecimal value of an item is twice its size in bytes. For example, a ChARACTER*12 item would require a field width of 24 characters.
Table 48 provides examples of the hexadecimal edit descriptor on output.

I/O formatting
Edit descriptors

Table 48
Z edit descriptor: output examples
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ Descriptor } & \multicolumn{1}{c|}{ Internal value } & \multicolumn{1}{c|}{ Output } \\
\hline Z2 & 27 & 1 B \\
\hline Z6.4 & 27 & bb 001 B \\
\hline Z & 'A' & b 41 \\
\hline Z8 & 'ABCD' & 41424344 \\
\hline Z8 & 1.1 & \(3 F 8 C C C C D\) \\
\hline
\end{tabular}

\section*{E mbedded format specification}

A format specification can be embedded in a data transfer statement as a character expression. Parentheses are included in the expression, and the first nonblank character must be a left parenthesis. The matching right parenthesis must also be in the expression. A list of edit descriptors appears between the parentheses. Any characters appearing after the matching right parenthesis are ignored.
If the character expression is a character constant, it must be delimited by either apostrophes or quotation marks. If the character constant contains another character constant, the nested character constant must also be delimited. If the inner set of delimiters is the same as the outer set they must be doubled. E ach of the following statements is correct and will produce the same results:
```

PRINT "('i = ', i2)", i
PRINT "(""i = "", i2)", i
PRINT '("i = ", i2)', i
PRINT '(''i = '', i2)', i
WRITE (6, "('i = ', i2)") i

```

If the character expression is an array element, the entire specification must be within that element. If the expression is a whole character array, the format specification is the concatenation of the array elements in array element order. (As an extension, HP Fortran allows the use of an integer array to contain a format specification.)
The following illustrates the use of a character array to hold the format specification:
```

CHARACTER(LEN=6), DIMENSION(2) :: fspec
fspec(1) = '(F8.3,'
fspec(2) = ' I5)'
PRINT fspec, fvar, ivar

```

If the value of \(f\) var is 12.34567 and ivar is 123 , the output would be:
```

bb12.346bb123

```

I/O formatting
Nested format specifications

\section*{Nested format specifications}

A format specification can includea nested format specification (another set of edit descriptors, enclosed in parentheses). You can also precede the nested format specification with a repeat factor, as in the following example:
```

(1H , 2(I5, F10.5))

```

This is equivalent to:
```

(1H , I5, F10.5, I5, F10.5)

```

Each nested specification is known as a group at nested level n . The value of \(n\) begins at 1 . For each successive level of nesting, \(n\) is incremented by 1 . E ach group at nested level 1 can contain one or more groups at nested level 2, and so on.

For example:
```

(E9.3,I6,(2X,I4))

```
contains one group at nested level 1 .
(L2,A3/(E10.3,4 (A2,L4)))
has one group at nested level 1 and one at nested level 2.
```

(A, (3X, (I2, (A3)),I3),A)

```
contains one group at nested level 1 , one at level 2 , and one at level 3.
A nested format specification can be preceded by a repeat specification. For example, the following input record
```

b2 6b6.4336b373.86b39bb49.79bb4bbb4395.4972

```
could be accessed with the following FORMAT statement:
```

10 FORMAT (I3,F7.4,2(F7.2,I3),F12.4)

```

The list of variables following READ statement corresponds to the preceding FORMAT statement:

READ \(10, i, a, b, j, d, k, f\)
The READ statement would read values for \(i\) and \(a\); repeat the nested format specification F7. 2, I3 twice to read values for \(b, j, d\), and \(k\); and, finally, read a value for \(f\).

\section*{Format specification and I/O data list}

A formatted I/O statement references each item in an I/O list, and the corresponding format specification is scanned to find a format descriptor for each item. As long as an item is matched to an edit descriptor, normal execution continues.

If there are more edit descriptors than list items, format control terminates with the last list item. If there are fewer edit descriptors than list items, the following three steps are performed:

1 The current record is terminated.
2 A new record is started.
3 Format control is returned to the format specification based upon the following hierarchy:
a Control returns to the repeat specification for the rightmost group at nested level 1. For information about nested levels, see "Nested format specifications" on page 238.
b If no repeat specification exists in the rightmost group at nested level 1 , control returns to the group itself.
c If there is no group at nested level 1 , control returns to the first descriptor in the format specification.

I/O formatting
Format specification and I/O data list

Table 49 provides examples showing how control is returned to the format specification in different circumstances.

Table 49
Format control and nested format specifications
\begin{tabular}{|l|l|l|}

\hline
\end{tabular}

\section*{10 HP Fortran statements}

This chapter describes the HP Fortran statements and attributes, arranged in alphabetical order. The descriptions provide syntax information, applicable rules and restrictions, and examples.

The following descriptions for specific type declarations are located in this chapter. Generic type declaration information is described in "Type declaration for intrinsic types" on page 24:
- byte
- CHARACTER
- COMPLEX
- DOUBLE COMPLEX
- DOUBLE PRECISION
- integer
- LOGICAL
- REAL
- RECORD
- tYPE (typename)

This chapter does not describe the following:
- Assignment statements (instead, see "Assignment" on page 95)
- Statement functions (instead, see "Statement functions" on page 137)
- Constructs (instead, see "Data types and data objects" on page 21)

Attributes

\section*{Attributes}

Table 50 lists all the attributes that an HP Fortran entity can have and indicates their compatibility．If the box at the intersection of two attributes contains a check mark，the attributes are mutually compatible and can be held simultaneously by an entity．The attributes are referred to throughout this chapter as well as in the rest of the book．
Table 50

NOTE
AUTOMATIC，STATIC，and VOLATILE may be specified in a statement of the same name but not as attributes in a type declaration statement．

HP Fortran statements
Statements and attributes

\section*{Statements and attributes}

The remainder of this chapter describes all of the statements and attributes that you can use in an HP Fortran program. The statement and attribute descriptions are listed in alphabetical order. For general information about statements-including the order in which statements must appear in a legal program—see "Statements" on page 11.

\section*{ACCEPT (extension)}

Reads from standard input.

Syntax

Description

The syntax of the Accept statement can take one of two forms:
- Formatted and list-directed syntax:

ACCEPT format [, input-list ]
- Namelist-directed syntax:

ACCEPT name
format
is one of the following:
- An asterisk (*), specifying list-di rected I/O.
- The label of a FORMAT statement containing the format specification.
- An integer variable that has been assigned the label of a FORMAT statement.
- An embedded format specification.
input-list
is a comma-separated list of data items. The data items can include variables and implied-do lists.
name
is the name of a namelist group, as previously defined by a nAMELIST statement. Using this syntax, the ACCEPT statement accepts data from standard input and transfers it to the namelist group. To perform namelist-directed I/O with a connected file, you must use the READ statement and include the NML= specifier.

The Accept statement is an HP Fortran extension and is provided for compatibility with other versions of Fortran. The standard READ statement performs the same function, and standard-conforming programs should use it.

HP Fortran statements
ACCEPT (extension)

The ACCEPT statement transfers data from standard input to internal storage. (U nit 5 is preconnected to the HP-UX standard input.) The ACCEPT statement can be used to perform formatted, list-directed, and namelist-directed I/O only.

To read data from a connected file, use the READ statement.

Examples
The following example of the ACCEPT statement reads an integer and a floating-point value from standard input, using list-directed formatting:
```

INTEGER :: i
REAL :: x
ACCEPT *, i, x

```

Related statements FORMAT, NAMELIST, PRINT and READ

Related concepts
For related information, see the following:
- "List-directed I/O" on page 179
- "I mplied-DO loop" on page 194
- "E mbedded format specification" on page 237

\section*{ALLOCATABLE (statement and attribute)}

Declares an allocatable array with deferred shape.
Syntax
The syntax of a type declaration statement with the ALLOCATABLE attribute is:
type, attrib-list :: entity-list
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (typename) , etc.), as described in Chapter 3, "Data types and data objects," on page 21.
attrib-list
is a comma-separated list of attributes including ALLOCATABLE and optionally those attributes compatible with it, namely:
\begin{tabular}{lll} 
DIMENSION & PUBLIC & TARGET \\
PRIVATE & SAVE &
\end{tabular}
entity-list
is a comma-separated list of entities. Each entity is of the form: array-name [( deferred-shape-spec-list )]
If ( deferred-shape-spec-list ) is omitted, it must be specified in another declaration statement.
array-name
is the name of an array being given the attribute ALLOCATABLE.
deferred-shape-spec-list
is a comma-separated list of colons, each colon representing one dimension. Thus the rank of the array is equal to the number of colons specified.

HP Fortran statements

\section*{ALLOCATABLE (statement and attribute)}

The syntax of the ALLOCATABLE statement is:
ALLOCATABLE [::] array-name [(deferred-shape-spec-list)]
[, array-name [ (deferred-shape-spec-list)] ]...
If (deferred-shapespec-list) is omitted from the ALLOCATABLE statement, it must be specified in another declaration statement, such as a type or DIMENSION statement.

The ALLOCATED intrinsic inquiry function is described in "ALLOCATED(ARRAY)" on page 493. It can be used to determine whether an allocatable array is currently allocated.

Description

Examples

Related statements

Related concepts

The ALLOCATABLE attribute or statement is used to declare an array whose extents in all its dimensions will be specified when an ALLOCATE statement is executed at run-time; for this reason it is known as "deferred-shape". When an allocatable array is declared, only its name and rank are given.

The following statements declare a rank-one deferred-shape array and illustrate its use with different extents.
```

! mls is deferred shape.
INTEGER, ALLOCATABLE :: mls(:)
ALLOCATE (mls (3)) ! Allocate 3 elements.
DEALLOCATE (mls) ! mls is no longer allocated
ALLOCATE (mls (-n:n)) ! Allocate with different extent

```

ALLOCATE and DEALLOCATE

See "Allocatable arrays" on page 59 for more information about allocatable arrays and the conditions applying to their use.

Array pointers provide a more general mechanism for the manipulation of deferred-shape arrays; see "Array pointers" on page 59.

\section*{ALLOCATE}

Provides storage space for allocatable arrays and pointer targets.
Syntax
ALLOCATE (allocation-list[, sTAT= scalar-integer-variable])
allocation-list
is a comma-separated list of allocation.
allocation
is allocateobject [ (allocateshape-spec-list) ].
allocateobject
is variablename or derived-typecomponent. Each allocate-object must be an allocatable array or a pointer.
allocateshapespec-list
is a comma-separated list of allocate-shape-spec.
allocate-shapespec
is [lower-bound:]upper-bound. The bounds in an allocateshape-spec must be scalar integer expressions.

STAT=scalar-integer-variable
returns the error status after the statement executes. If given, it is set to zero if the statement successfully executed, and to one of the following nonzero values if an error occurred:

1 Error occurred after the array was allocated; for example, an attempt to allocate a previously allocated array.
2 Dynamic memory allocation failure (memory not available) or invalid size (array too large).

3 Errors of both types 1 and 2 have occurred. This kind of an error can only occur if the same ALLOCATE statement is used to allocate more than one array, and both kinds of errors occur.

If there is no scalar-integer-variable, the occurrence of an error causes the program to terminate.

HP Fortran statements
ALLOCATE

Description

Examples

The Allocate statement creates space for allocatable arrays and targets for variables (scalars or arrays) with the POINTER attribute. The ALLOCATE and DEALLOCATE statements give the user the ability to manage space dynami cally at execution time.
For allocatable arrays, an error occurs when an attempt is made to allocate an already allocated array or to deallocate an array that is not allocated. The ALLOCATED intrinsic function may be used to determine whether an allocatable array is allocated.

A pointer can be associated with a target, either with the pointer assignment statement or by use of the ALLOCATE statement. It is not an error to allocate an already associated pointer; its old target connection is replaced by a connection to the newly allocated space. H owever, if the previous target was allocated and no other poi nter became associated with it, the space is no longer accessible.

In the following example, a complex array with the POINTER attribute is declared. Target space is allocated to it at run-time, the amount being determined by two integer values read in. Later in the program, the space is recovered by use of the DEALLOCATE statement.
```

COMPLEX, POINTER :: hermitian (:, :)
READ *, m, n
ALLOCATE (hermitian (m, n))
DEALLOCATE (hermitian, STAT = ierr)

```

In the next example, a real allocatable array is declared. The amount of space allocated to it depends on how much is available.
```

! Rank-2 allocatable array
REAL, ALLOCATABLE :: intense(:,:)
CALL init_i_j(i, j)
DO
ALLOCATE (intense(i, j), STAT = ierr4)
! ierr4 will be positive if there is not enough space to
! allocate this array
IF (ierr4 == 0) EXIT
i = i/2; j = j/2
END DO

```

The derived type node in the next example is the basis of a binary tree structure. It consists of a real value component (val) and two pointer components, left and right, both of type node. The variable top (of type node) is declared, and space is allocated for targets for the pointers top\%left and top\%right.

The allocate and deallocate statements and pointer variables of type node make it possible to allocate space for nodes in such a tree structure, traverse it as required, and then recover the space when it is no longer needed.
```

TYPE node

```
    REAL val
    TYPE (node), POINTER : : left, right ! Pointer components
END TYPE node
TYPE (node) top
ALLOCATE (top \% left, top \% right)

In the final example, two CHARACTER arrays, para and key, are declared with the POINTER attribute. para is allocated space; key is made to point at a section of para.
! Pointers to char arrays
CHARACTER, POINTER : : para(:), key(:)
CALL init_k_m (k, m)
ALLOCATE (para(1000))
key => para (k : k + m)

- "Statement labels" on page 10
- "Assigned GO TO statement" on page 115

\section*{AUTOMATIC (extension)}

Makes procedure variables and arrays automatic.

Syntax

Description

Examples
Related statements

Related concepts

AUTOMATIC var-namelist
var-namelist
is a comma-separated list of names of variables and arrays to be declared as automatic. Array names may be followed by an optional explicit-shape-spec.

The Automatic statement is provided as an HP extension.
If a variable or array declared within a procedure is declared as automatic, then there is one copy of it for each invocation of the procedure. Space is allocated on entry to the procedure and deallocated on exit. This is also the default for variables that do not have the SAVE or STATIC attribute, unless the +save option has been specified.

If it is required to have the same copy of a variable available to each invocation of the routine (for example, to keep a record of the depth of recursion), then the variable should have the SAVE attribute.
Note the following:
- The automatic statement may only be used within a procedure.
- Local variables are automatic by default.
- Arguments and function values are Automatic.
- Automatic variables may not appear in EQUIVALENCE, DATA or SAVE statements.
- The automatic attribute is not the same as automatic arrays and automatic character strings.

AUTOMATIC r, s, u, v, w(10)
SAVE and STATIC
For information about automatic and static variables, refer to the HP Fortran Programmer's Guide.

HP Fortran statements
BACKSPACE

\section*{BACKSPACE}

Positions file at preceding record.
Syntax

Description The BACKSPACE statement causes the external file connected to unit to be positioned just before the preceding record of the file. The file must be connected for sequential access.

\section*{Examples \\ The following statement causes the file connected to unit 10 to be positioned just before the preceding record:}

BACKSPACE 10
The fol lowing statement causes the file connected to unit 17 to be positioned just before the preceding record. If an error occurs during the execution of the statement, control passes to the statement at label 99, and the error code is returned in ios:

BACKSPACE (17, ERR=99, IOSTAT=ios)

HP Fortran statements
BLOCK DATA

\section*{BLOCK DATA}

Introduces a block data program unit.
Syntax
Description

Examples

Related statements

Related concepts
BLOCK DATA [block-data-name]
block-data-name
is an optional name. If a name is given in the END BLOCK DATA statement terminating a block data program unit, it must be the same as the block-data-namegiven in the BLOCK DATA statement introducing the program unit.

A block data program unit is used to give initial values to variables in a named common blocks by means of DATA statements and must start with a BLock DATA statement. The block data program unit is an obsolescent feature of Fortran 90 and is effectively superseded by the module, as described in "Modules" on page 161.

As an extension, HP Fortran allows blank-or unnamed-common blocks to be initialized.

The following block data program unit gives initial values to variables in the common blocks cb1 and cb2. All variables in each common block are specified completely.
```

BLOCK DATA
REAL b(4) DOUBLE PRECISION z(3)
COMPLEX C
COMMON /cb1/c,a,b /cb2/z,y
DATA b, z, c/1.0, 1.2 , 2*1.3, 3*7.654321D0, (2.4,3.76)/
END

```

COMMON, DATA, and END
The structure and syntax of the block data program unit is described in "Block data program unit" on page 169.

\section*{BUFFER IN (extension)}

Provided for compatibility with the buFFer in Cray statement.
Asynchronous I/O with the BUFFER IN statements is not supported. HP Fortran 90 V2.0 supports these statements for synchronous I/O only.

Syntax

Description

Examples
The following program shows how to use the BUFFER IN and BUFFER OUT statements. The program must be compiled with the +autodbl option; see "Option Descriptions" on page 576.

\section*{HP Fortran statements \\ BUFFER IN (extension)}

PROGRAM bufferedIoTest
! buffered i/o example: compile with +autodbl
INTEGER a(10)
OPEN ( UNIT \(=7\), NAME \(=\) 'test.dat', FORM \(=\) 'UNFORMATTED' )
\(a=(/(i, i=1,10) /) \quad\) ! initialize the array A
BUFFER OUT ( 7, 0 ) ( a, a(10) ) write out A twice CALL unit ( 7 )
BUFFER OUT ( 7, 0 ) ( a, a(10) )
CALL unit ( 7 )
! now position the file 40 bytes (5 integer values) into the
file
CALL setpos ( 7, 5 )
! read the remainder of the 1 st record, and half of the second
BUFFER IN ( 7, 0 ) ( a, a(10) )
WRITE (6,*) a
CLOSE (7)
END PROGRAM bufferedIoTest

Related statements
BUFFER OUT

\section*{BUFFER OUT (extension)}

Provided for compatibility with Cray BUFFER OUT statement.

HP Fortran statements
BUFFER OUT (extension)

Related statements BUFFER IN

\section*{BYTE (extension)}

Declares entities of type integer.
Syntax
byte [ [, attrib-list] ::] entity-list
attrib-list
is a comma-separated list of one or more of the following attributes:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name [( array-spec )] [= initialization-expr]
where:
name
is the name of a variable or function
array-spec
is a comma-separated list of dimension bounds
initialization-expr
is a integer constant integer expression. If initialization-expr is present, entity-list must be preceded by the double colon.

HP Fortran statements
BYTE (extension)

Description

Example

The BYTE statement is an HP extension that is used to declare the properties of entities. The entities can take values that are whole numbers and can be represented in one byte. It is equivalent to the INTEGER (KIND=1) statement.

The BYTE statement is constrained by the rules for all type declaration statements, including the requirement that it precede all executable statements. Note, however, that the ByTE statement does not havea kind parameter.

The following are valid declarations:
```

BYTE i, j
BYTE :: k
BYTE, PARAMETER :: limit=120
! use an array constructor to initialize an array
BYTE, DIMENSION(4) :: bvec=(/1,2,3,4/)
! use slashes as initialization delimiters, an HP extension
BYTE b/12/, bb/27/ ! note, no double colon

```

INTEGER

Related concepts For related information, see the following:
- "Type declaration for intrinsic types" on page 24
- "I mplicit typing" on page 28
- "Array declarations" on page 54
- "Array constructors" on page 71
- "Expressions" on page 80

\section*{CAL工}

I nvokes a subroutine.
Syntax
CALL subr-name[([ subr-act-arg-spec-list ])]
subr-name
is the name of the subroutine being invoked.
actual-argument-list
is a comma-separated list of entities of the form:
[keyword = ] actual-argument
actual-argument
is one of the following:
- expression
- variable
- procedurename
- *label or \&label
keyword
is one of the dummy argument names of the subroutine being invoked. If any keyword is specified, the subroutine interface must be explicit.

A CALL statement is used to invoke (call) a subroutine, and to specify actual arguments, if any. Execution of the subroutine begins with the first executable statement. The following sequence of events occurs when a CALL statement executes:

1 Actual arguments that are expressions are evaluated.
2 The actual arguments are associated with the corresponding dummy arguments.

3 Control transfers to the subroutine being called, and the subroutine executes.

HP Fortran statements

\section*{CALL}

4 Control returns from the subroutine, normally to the statement following the CALL statement, or to a statement label indicated by an alternate return argument-*label or \&label. (The \& label form is provided as a compatibility extension and can be used in fixed source form only.)

A subroutine can call itself, directly or indirectly; in this case the keyword RECURSIVE must be specified in the SUBROUTINE statement of the subroutine definition.

The \%VAL and \%REF built-in functions are provided as HP extensions. They can be used to change argument-passing conventions calling a routine written in another language.

The only subroutine invocation other than by the CALL statement in Fortran 90 is through "defined assignment", where a defined type assignment operator that has been defined by means of a subroutine is used.

\section*{Examples}
```

! Interface for subroutine draw
INTERFACE
SUBROUTINE draw (x_start, y_start, x_end, y_end, form, scale)
REAL x_start, y_start, x_end, y_end
CHARACTER (LEN = 6), OPTIONAL :: form
REAL, OPTIONAL :: scale
END SUBROUTINE draw
END INTERFACE
! References to draw
! arguments given by position; optional argument scale omitted
CALL draw (5., -4., 2., .6, "DASHED")
! arguments given by keyword; optional argument form omitted
CALL draw (scale=.4, x_end=0., y_end=0., x_start=.5, y_start=.3)

```

\section*{CASE}

Marks start of statement block in a CASE construct.
Syntax

Description The CASE statement is used in a CASE construct to mark the start of a statement block. The CASE construct can consist of multiple blocks; at most, one is selected for execution. Selection is determined by comparing the case index produced by the SELECT CASE statement to the case selector in each CASE statement. If a match is found, the statement block

HP Fortran statements
CASE
under the matching case-selector executes. A match between the case index (c) and case-selector is determined for each form of case-selector, as follows:
case-value
For integer and character types, a match occurs if c . EQ. case value.
For logical types, a match occurs if c . EQV. case-value.
Iow:
For integer and character types, a match occurs if c. . GE. Iow.

For integer and character types, a match occurs if c . LE . high. low : high

For integer and character types, a match occurs if c. . GE. Iow . AND. C.LE. high.
DEFAULT
For integer, character, and logical types, a match occurs if no match is found with any other caseselector and DEFAULT is specified as a case-sel ector.
If CASE DEFAULT is not present and no match is found with any of the other CASE statements, none of the statement blocks within the CASE construct executes and execution resumes with the first executable statement following the END SELECT statement.
At most only one DEFAULT selector can appear within a CASE construct.
Each CASE statement must specify a unique value or range of values within a particular CASE construct. Only one match can occur, and only one statement block can execute.

All case-selectors and the case index within a particular CASE construct must be of the same type: integer, character, or logical. H owever, the lengths of character types can differ.

The colon forms—low : , : high, or low : high—are not permitted for a logical type.
Although putting the CASE statements in order according to range may improve readability, it is not necessary for correct or optimal execution of the CASE construct. In particular, DEFAULT can appear anywhere among the CASE statements and need not be the last.

CASE statements inside a named CASE construct need not specify construct-name; but if they do, the name they specify must match that of the SELECT CASE.

A CASE statement can have an empty statement block.
```

Examples The following example considers a person's credits and debits and prints
a message indicating whether a resulting account balance will be
overdrawn, empty, uncomfortably small, or sufficient:
INTEGER :: credits, debits
SELECT CASE (credits - debits)
CASE (:-1)
PRINT *, 'OVERDRAWN'
CALL TRANSFERFUNDS
CASE (0)
PRINT *, 'NO MONEY LEFT'
CASE (1:50)
PRINT *, 'BALANCE LOW'
CASE (51:)
PRINT *, 'BALANCE OKAY'
END SELECT
Related statements
Related concepts The CASE construct is described in "CASE construct" on page 105.

```

HP Fortran statements
CHARACTER

\section*{CHARACTER}

Declares entities of type character.
Syntax
CHARACTER [char-selector] [ [, attrib-list] ::] entity-list
char-sel ector
specifies the length and kind of the character variable. It takes one of the following forms:
- ([LEN=]len-spec[, KIND=kind-param])
- (len-spec, [KIND=]kind-param)
- (KIND=kind-param[, LEN=len-spec])
- *len-const [, ]
- * (len-spec[) , ]
where kind-param (if specified) must be 1, the default; len-spec is either an asterisk (*) or a specification expression; and len-const is an integer constant. In the last form, len-param is enclosed in parentheses, and the optional comma may be included only if the double colon does not appear in the type declaration statement. If Ien-spec evaluates to a negative value, a zero-length string is declared. If len-spec is unspecified, the default is 1.
attrib-list
is a list of one or more of the following attributes, separated by commas:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double col on. For information about individual attributes, see the corresponding statement in this chapter.
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name[(array-spec)][*len-spec][=initialization-expr]
where name is the name of a variable or function, array-spec is a comma-separated list of dimension bounds, len-spec is either an asterisk (*) or a specification expression, and initialization-expr is a character constant expression. If initialization-expr is present, entity-list must be preceded by the double colon.

\section*{Description}

Examples

The CHARACTER statement is used to declare the length and properties of character data. It is constrained by the rules for all type declaration statements, including the requirement that it precede all executable statements.

To indicate that the length of a character can vary, you may use an assumed character length parameter by specifying an asterisk (*) for len-param. The asterisk may be used only when doing the following:
- Declaring the type of a function. The function must not be an internal or module function, nor must it be array-valued, pointer-valued, or recursive.
- Declaring a dummy argument of a procedure.
- Declaring a named constant (see the PARAMETER statement).

The following are valid declarations:
```

CHARACTER c1, c2
CHARACTER(LEN=80) : : text (0:25)
CHARACTER(2, 1), PARAMETER :: limit='ZZ'
! initialize an array, using an array constructor
CHARACTER(4) :: response(3) = (/"Yes.", "No!!", "Huh?"/)
! use slashes as initialization delimiters, an HP extension
CHARACTER*10 c1/'Tom'/,c2/'Jones'/ ! note, no double colon

```

HP Fortran statements
CHARACTER

The following are valid uses of the assumed length parameter:
CHARACTER(*) dummy_arg_name
CHARACTER(*), PARAMETER : : hello="Hi Sam"
CHARACTER (LEN=*), PARAMETER : : hello="Hi Sam"
Assuming that cis an ordinary variable and not the dummy argument to a procedure, the following declaration is an illegal use of the assumed length parameter:
```

CHARACTER*(*) c ! illegal

```

- "Expressions" on page 80
- "LEN(STRING)" on page 539

\section*{CLOSE}

Terminates file connection.

Syntax ClOSE (io-specifier-list )
io-specifier-list
is a list of the following comma-separated I/O specifiers:
[UNIT=]unit
specifies the unit connected to an external file. unit must be a positive integer-valued expression. If the optional keyword UNIT= is omitted, unit must be the first item in io-specifier-list.

ERR=stmt-label
specifies the label of the executable statement to which control passes if an error occurs during statement execution. If neither IOSTAT= or ERR= is specified and an error occurs, the program aborts and a system error message is issued. stmt-label must be in the same scoping unit as the CLOSE statement with the ERR= specifier.
IOSTAT=integer-variable
returns the I/O status after the statement executes. If the statement executes successfully, integer-variable is set to zero. If an error occurs, it is set to a positive integer that indicates which error occurred. If neither IOSTAT = or ERR= is specified and an error occurs, the program aborts and a system error message is issued.

STATUS=character-expression
specifies the state of the file after it is closed. characterexpression can be one of the following arguments:
' KEEP ' Preserve the file after it is closed (default).
'DELETE ' Do not preserve the file after it is closed.

HP Fortran statements
CLOSE

The STATUS = specifier is ignored if the file was opened as a scratch file. See "OPEN" on page 379 for a description of the OPEN statement.

Description

Examples

Related statements

Related concepts

The CLOSE statement closes the file whose unit number was obtained from an OPEN statement. A CLOSE statement must contain a unit number and at most one each of the other I/O specifiers.

A CLOSE statement need not be in the same program unit as the OPEN statement that connected the file to the specified unit. If a CLOSE statement specifies a unit that does not exist or has no file connected to it, no action occurs.

The following examples illustrate different uses of the CLOSE statement. In the first example, the close statement closes the file connected to unit 10; after it is closed, the file will continue to exist, unless it was opened with the STATUS='SCRATCH' specifier:

CLOSE (10)
In the next example, after the file connected to unit 6 is closed, it will cease to exist:
```

CLOSE (UNIT=6,STATUS='DELETE')

```

The following code produces the same results as the previous example:
```

CHARACTER(LEN=6) cstat
cstat='delete'
CLOSE (UNIT=6,STATUS=cstat)

```

The following example doses the file connected to unit 5. If an error occurs, control is transferred to the executable statement labeled 100, and the error code is stored in the variable ios:
```

CLOSE(5,IOSTAT=ios,ERR=100)

```

OPEN

For information about I/O concepts, see Chapter 8, "I/O and file handling," on page 171, which also lists example programs that use I/O.

\section*{COMMON}

\section*{Specifies common blocks.}

Syntax

Description
```

COMMON [/[[common-block-name]]/] object-list
[,]/[common-block-name]/ object-list]...
common-block-name
is the name of a labeled common block.
object-list

```
    is a comma-separated list of scal ar variables, arrays, records,
    and derived-type objects. If an array is specified, it may be
    followed by an explicit-shape specification expression.

The COMMON statement defines one or more storage areas to be shared by different program units. It also identifies the objects-that is, variables, arrays, records, and derived-type objects-to be stored in those areas. Objects in common that are shared by different program units are made accessible by storage association.

Each object following a common-block name is declared to be in that common block. If /common-block-name/ is omitted, all objects in the corresponding object-list are specified to be in blank common. It is also possible to declare variables in blank common by specifying two slashes without common-block-name. Consider the following examples:
```

!Declare variables a, b, c in blank common.
COMMON a, b, c
! Declare pay and time in blank common,
! and red in the named common block color.
COMMON pay, time, /color/red
! Variables a1 and a2 are in common block a; array x and variable
! are in blank common; and variable d is in common block c
COMMON/a/a1,a2,//x(10),y,/c/d

```

Any common block name or blank common specification can appear more than once in one or more COMMON statements within the same program unit. The variable list following each successive appearance of the same common block name is treated as a continuation of the list for that common block name. For example, the following common statements:
```

COMMON a,b,c /x/y,x,d //w,r
COMMON /cap/hat,visor, //tax, /x/o,t

```

HP Fortran statements
COMMON
are equivalent to:
COMMON a,b,c,w,r,tax
COMMON /x/y,x,d,o,t
COMMON /cap/hat,visor
Unlike named common blocks, blank common can differ in size in different scoping units. However, blank common cannot be initialized.
As an extension, HP Fortran saves all common blocks in static memory.
The following restrictions apply to the use of common blocks:
- All common block names must be distinct from subprogram names.
- The size of a named common block must be the same in all program units where it is declared. Note, however, that the size of blank common can differ.
- The following data items must not appear in a common statement:
- Dummy arguments in a subprogram
- Functions, subroutines, or intrinsic functions
- Pointees declared by Cray-style pointers
- Variables accessible by use association
- Automatic entities, including automatic character strings
- Allocatable arrays
- Derived-type objects may appear in common if they have been defined with the SEQUENCE attribute.
- A variable can only appear in one Сомmon statement within a program unit.
- Zero-sized common blocks are allowed. Zero-sized common blocks with the same name are storage associated.
- Array bounds in a common statement must be constant specification expressions.
- A pointer may appear in common if it has the same type, type parameter, and rank in every instance of that common block.

\section*{Initializing common blocks}

As an extension to the Standard, HP Fortran allows common blocks to be initialized outside of a block data program unit; for example, in a subroutine. However, note that all data initialization for a given common block must occur in the same compilation unit.

HP Fortran also allows blank—or unnamed—common to be initialized.

\section*{Common block size}

The size of a common block is determined by the number and type of the variables it contains. In the following example, the common block my_block takes 20 bytes of storage: b uses 8 ( 2 bytes per element) and arr uses 12 (4 bytes per element):
```

INTEGER(2) b (4)
INTEGER(4) arr(3)
COMMON /cb/b, arr

```

Data space within the common area for arrays b and arr shown in this example is allocated as follows:
\begin{tabular}{|l|l|}
\hline \multicolumn{1}{|c|}{ Bytes } & Common block variables \\
\hline \(0,1,2,3\) & \(\mathrm{~b}(1), \mathrm{b}(2)\) \\
\hline \(4,5,6,7\) & \(\mathrm{~b}(3), \mathrm{b}(4)\) \\
\hline \(8,9,10,11\) & \(\operatorname{arr}(1)\) \\
\hline \(12,13,14,15\) & \(\operatorname{arr}(2)\) \\
\hline \(16,17,18,19\) & \(\operatorname{arr}(3)\) \\
\hline
\end{tabular}

\section*{Allocation common block storage}

Common block storage is allocated at link time. It is not local to any one program unit.

Each program unit that uses the common block must include a COMMON statement that contains the block name, if a name was specified. Variables assigned to the common block by the program unit need not correspond by name, type, or number of elements with those of any other program unit. The only consideration is the size of the common blocks

HP Fortran statements
COMMON
referenced by the different program units. Correspondence between objects in different instances of the same common block is established by storage association.
Note the following for HP Fortran: when types with different alignment restrictions are mixed in a common block, the compiler may insert padding bytes as necessary.

The following example illustrates how the same common block can be declared in different program units with different variables but the same size:
```

! common declaration for program unit 1
INTEGER i, j, k
COMMON /my_block/ i, j, k
! common declaration for program unit 2
INTEGER n(3)
COMMON /my_block/ n(3)

```

The variables \(i, j\), and \(k\) in program unit 1 share the same storage with the array n in program unit 2: i in program unit 1 matches up with n (1) in program unit 2 , \(j\) with \(n(2)\), and \(k\) with \(n(3)\).

Related statements

Related concepts

EQUIVALENCE
For information about data alignment, see Table 5 and "Alignment of derived-type objects" on page 44.

\section*{COMPLEX}

Declares entities of type complex.

Syntax COMPLEX [kind-spec] [[, attrib-list] ::] entity-list
kind-spec
is the kind type parameter that specifies the range and precision of the entities in entity-list. kind-spec takes the form:
([KIND =]kind-param)
where kind-param represents the kind of both the real and imaginary parts of the complex number. It can be a named constant or a constant expression that has the integer value of 4 or 8 . The size of the default type is 4 .

As an extension, kind-spec can take the form:
*len-param
where len-param is the integer 8 or 16 (default \(=8\) ), which represents the size of the whol e complex entity.
attrib-list
is a list of one or more of the following attributes, separated by commas:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.

HP Fortran statements
COMPLEX
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name [( array-spec )] [= initialization-expr]
where name is the name of a variable or function, array-spec is a comma-separated list of dimension bounds, and initialization-expr is a complex constant expression. If initialization-expr is present, entity-list must be preceded by the double col on.

Description

Examples

The COMPLEX statement is used to declare the length and properties of data that are approximations to the mathematical complex numbers. A complex number consists of a real part and an imaginary part. A kind parameter (if specified) indicates the representation method.

The COMP LEX statement is constrained by the rules for type declaration statements, including the requirement that it precede all executable statements.

As a portability extension, HP Fortran allows the following syntax for specifying the length of an entity:
name [*len] [ ( array-spec )] [= initialization-expr ]
If array-spec is specified, *len may appear on either side of array-spec. If name appears with *len, it overrides the length specified by kind-spec.

The following are valid declarations:
```

COMPLEX X, Y
COMPLEX(KIND=8) :: z
COMPLEX,PARAMETER : : t1 (2)=(/(3.2, 0), (.04, -1.1)/)
! initialize an array, using an array constructor
COMPLEX, DIMENSION(2) :: \&
cvec=(/(2.294, 6.288E-2), (-1.0096E7, 0)/)
! use slashes as initialization delimiters, an HP extension
COMPLEX cx/(2.294, 6.288E-2)/ ! note, no double colon
! the following declarations are equivalent; the second uses the
! HP length specification extension
COMPLEX(KIND = 8) x
COMPLEX(8) x*16

```

HP Fortran statements
CONTAINS

\section*{CONTAINS}

Introduces an internal procedure or a module procedure.

\section*{Syntax}

Description

Examples

CONTAINS
The contains statement introduces an internal procedure or a module procedure, separating it from the program unit that contains it. The statement can be used in:
- A main program, external subprogram, or module subprogram; in each case, it precedes one or more internal procedures.
- A module, where it precedes any module procedures.

When a contains statement is present, at least one subprogram must follow it.

The first example illustrates CONTAINS introducing an internal subroutine. It also illustrates how the internal subroutine mechanism can provide an alternative to the FORTRAN 77 statement function mechanism.
```

PRINT *, double_real(6.6)
CONTAINS
FUNCTION double_real (x); REAL x
double_real = 2.0 * x
END FUNCTION
END

```

The next example illustrates a main program with an internal procedure part.
```

PROGRAM electric ! Program header
REAL current ! Specification part
current = 100.5 ! Execution part begins
CALL compute_resistance( voltage, current, resistance )
CONTAINS ! Internal procedure part
SUBROUTINE compute_resistance( v, i, r )
REAL i
r = v / i
END SUBROUTINE
END PROGRAM electric

```

The third example is of a module that contains a module subprogram, which in turn contains an internal subprogram.
MODULE one
    CONTAINS
    SUBROUTINE two(x) ! Module subprogram
        CONTAINS
        LOGICAL FUNCTION three (y) ! Internal subprogram
        END FUNCTION three
    END SUBROUTINE two
END MODULE one

\section*{CYCLE}

Interrupts current iteration of a DO loop.

Syntax

Description

Examples

Related statements
Related concepts

CYCLE [ do-construct-name ]
do-construct-name
is the name of a do construct that must contain this CYCLE statement.

The CyCLE statement is used to control the execution of a do loop. When it executes, it interrupts a currently executing loop iteration and passes control to the next iteration, making the appropriate adjustments to the loop index. It may be used with either the do construct or the FORTRAN 77-style do loop.

A CyCle statement belongs to a particular Do loop. If do-construct-name is not given, the cycle statement resumes the immediately enclosing do loop. If do-construct-name is given, the cycle statement resumes an enclosing named Do loop with the same name.

The following example uses the CyCLE statement to control a bubble sort:
```

LOGICAL :: swap
INTEGER :: i, j
outer: DO i = 1, n-1
swap = .FALSE.
inner: DO j = n, i+1, -1
IF (a(j) >= a(j-1)) CYCLE inner
swap = .TRUE.
atmp = a(j)
a(j) = a(j-1)
a(j-1) = atmp
END DO inner
IF (.NOT. swap) EXIT outer
END DO outer

```

DO and EXIT

- "Flow control statements" on page 112

HP Fortran statements
DATA

\section*{DATA}

Initializes program variables.
Syntax DATA var-list1 / val-list1 / [ [,]var-list2 / val-list2 /]...
var-list
is a comma-separated list of entities, including the following:
- A variable name
- An array name
- An array triplet section; for example:
- points(1:10:2)
- An array element reference; for example:
- scores(0)
- A substring name; for example:
- name(1:10)
- An implied-do loop; for example:
- ((matrix \((i, j), i=0,5), j=5,10)\)
- An object of a derived type
- A component of a derived-type object

The following cannot appear in var-list:
- Pointer-based variables
- Records and record field references. However, you can initialize a record's fields in the record's structure definition. See "ReCord (extension)" on page 420.
- Automatic objects, including automatic character strings
- Dummy arguments
- Allocatable arrays: that is, arrays declared with a specified rank, but no specified bounds within each dimension
- The result variable of a function
- Objects made available by use or host association
- Procedure names
val-list
is a list of constant values, separated by commas. Each constant in the list represents a value to be assigned to the corresponding variable in var-list. A constant value can be optionally repeated by preceding the constant with a repetition factor. The syntax of a repeated constant is:
r*val
wherer is a positive integer specifying the number of times that val, the constant value, is to be specified.

\section*{Description}

The DATA statement initializes variables local to a program unit before the program unit begins execution. Initialization occurs as follows:

The var-list is expanded to form a sequence of scalar variables, and the val-list is expanded to form a sequence of scalar constants. The number of items in each expanded sequence must be the same, and there must be a one-to-one correspondence between the items in the two expanded lists. The variables in the expanded sequence of var-list are initialized on the basis of the correspondence.

If var-list contains an array name, the expanded sequence of constants must contain a constant for every element in the array.
A zero-sized array or an implied-Do list with an iteration count of zero in var-list contributes no variables to the expanded sequence of variables. However, a zero-length character variable does contribute a variable to the list.

If a constant is of any numeric or logical type, the corresponding variable can be of any numeric type. If an object is of derived type, the corresponding constant must be of the same type. If the type of the constant does not agree with the type of the variable, type conversion is performed, as described in Table 14.

Variables can be initialized with binary, octal, or hexadecimal constants.
A variable or array element must not appear in a DATA statement more than once. If two variables share the same storage space through an EQUIVALENCE statement, only one can appear in a DATA statement. If a

HP Fortran statements
DATA
substring of a character variable or other array element appears in a DATA statement, no overlapping substring (including the entire variable or array element) can appear in any DATA statement.

The length of a character constant and the declared length of its corresponding character variable need not be the same. If the constant is shorter than the variable, blank characters are placed in the remaining positions. If the constant is longer than the variable, the constant is truncated from the right until it is the same length as the variable

If a subscripted array element appears in var-list, then the subscript must be a specification expression.

DATA statements can be interspersed among executable statements. However, they initialize prior to runtime and, therefore, cannot be used as executable assignment statements.

\section*{Fortran 90 extensions}

A variable of type other than integer may be initialized with a binary, octal, or hexadecimal constant. The data type for a constant is determined from the type of the corresponding variable. The size (in bytes) of the variable determines how many digits of the octal or hexadecimal constant are used. If the constant lacks enough digits, the value is padded on the left with zeros. If the constant has too many digits, it is truncated on the left.

An integer, binary, octal, or hexadecimal constant can initialize a character variable of length one, as long as the value of the constant is in the range 0 to 255.

Examples
The following DATA statement initializes integer, logical, and character variables:
```

INTEGER i
LOGICAL done
CHARACTER(LEN=5) prompt
DATA i, done, prompt/10, .FALSE., 'Next?'/

```

The next DATA statement specifies a repetition factor of 3 to assign the value of 2 to all three elements of array i:
```

INTEGER, DIMENSION(3) :: i
DATA i/3*2/

```

The next DATA statement uses two nested implied-Do loops to assign the literal value \(x\) to each element of an array of 50 elements, \(k(10,5)\) :
```

CHARACTER, DIMENSION(10,5) :: k
DATA ((k(i,j),i=1,10),j=1,5)/50*'X'/

```

HP Fortran statements
DEALLOCATE

\section*{DEALLOCATE}

Deallocates allocatable arrays and pointer targets.
Syntax
DEALLOCATE (alloc-obj-list[, STAT=Scalar-int-var])
alloc-obj-list
is a comma-separated list of pointers or allocatable arrays.
STAT=scalar-int-var
returns the error status after the statement executes. If given, it is set to a positive value if an error is detected, and to zero otherwise. If there is no status variable, the occurrence of an error causes the program to terminate.

The DEALLOCATE statement deallocates allocatable arrays and pointer targets, making the memory available for reuse. A specified allocatable array then becomes not allocated (as reported by the ALLOCATED intrinsic), while a specified pointer becomes disassociated (as reported by the ASSOCIATED intrinsic).

An error occurs if an attempt is made to deallocate an allocatable array that is not currently allocated or a pointer that is not associated. Errors in the operation of DEALLOCATE can be reported by means of the optional STAT= specifier.

You can deallocate an allocatable array by specifying the name of the array with the DEALLOCATE statement. You cannot deallocate a pointer that points to an object that was not allocated.

Some or all of a target associated with a pointer by means of the ALLOCATE statement can also be associated subsequently with other pointers. However, it is not permitted to deallocate a pointer that is not currently associated with the whole of an allocated target object.

Deallocation of a pointer target causes the association status of any other pointer associated with all or part of the target to become undefined. When a pointer is deallocated, its association status becomes disassociated, as if a NULLIFY statement had been executed.
```

Examples The following example declares a complex array with the POINTER
attribute. The AlLOCATE statement allocates target space to the array at
run-time; the amount is determined by the input values to the READ
statement. Later in the program, the DEALLOCATE statement will
recover the space.

```
```

COMPLEX, POINTER :: hermitian (:, :)

```
COMPLEX, POINTER :: hermitian (:, :)
READ *, m, n
READ *, m, n
ALLOCATE (hermitian (m, n))
ALLOCATE (hermitian (m, n))
DEALLOCATE (hermitian, STAT = ierr)
```

DEALLOCATE (hermitian, STAT = ierr)

```

HP Fortran statements
DECODE (extension)

\section*{DECODE (extension)}

I nputs formatted data from internal storage.
Syntax DECODE (count, format, unit, io-specifier-list) [in-list]
count
is an integer expression that specifies the number of characters
(bytes) to translate from character format to internal (binary)
format. cnt must precede format.
format
specifies the format specification for formatting the data. format can be one of the following:
- The label of a FORMAT statement containing the format specification.
- An integer variable that has been assigned the label of a FORMAT statement.
- An embedded format specification.
format must be the second of the parenthesized items, immediately fol lowing count. Note that the keyword FMT = is not used.
unit
is the internal storage designator. It must be a scalar variable or array name. Assumed-size and adjustable-size arrays are not permitted. Note that char-var-name is not a unit number and that the keyword UNIT= is not used.
unit must be the third of the parenthesized items, immediately following format.
io-specifier-list
is a comma-separated list of I/O specifiers. N ote that the unit and format specifiers are required; the other I/O specifiers are optional. The following I/O specifiers can appear in io-specifierlist:

\section*{ERR=stmt-labe}
specifies the label of the executable statement to which control passes if an error occurs during statement execution.
```

IOSTAT=integer-variable

```
returns the I/O status after the statement executes. If the statement successfully executes, integer-variable is set to zero. If an end-of-file record is encountered without an error condition, it is set to a negative integer. If an error occurs, integer-variable is set to a positive integer that indicates which error occurred.
in-list
is a comma-separated list of data items for input. The data items can include expressions and implied-do lists.

\section*{Description}

Examples

The decode statement is an HP extension that is provided for compatibility with other versions of Fortran. The internal-I/O capabilities of the standard READ statement provide similar functionality and should be used to ensure portability.
The decode statement translates formatted character data into its binary (internal) representation.

The following example program illustrates the DECODE statement:
```

PROGRAM decode_example
CHARACTER(LEN=20) :: buf
INTEGER i, j, k
buf = 'XX1234 45 -12XXXXXX'
DECODE (15,'(2X,3I4,1X)', buf) i, j, k
! The equivalent READ statement is:
! READ (buf, '(2X,3I4,1X)') i, j, k
PRINT *, i, j, k
END PROGRAM decode_example

```

HP Fortran statements
DECODE (extension)

When compiled and executed, this program produces the following output:
```

1234 45 -12

```

\section*{DIMENSION (statement and attribute)}

Declares a variable to be an array.
Syntax
A type declaration statement with the DIMENSION attribute is:
type, dimension ( array-spec ) [[, attrib-list ]::] entity-list
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE ( typename), etc.).
array-spec
is one of the following:
- explicit-shapespec-list
- assumed-shapespec-list
- deferred-shapespec-list
- assumed-size-spec
explicit-shape-spec
is
[lower-bound :] upper-bound
lower-bound, upper-bound are specification expressions.
assumed-shape-spec
is
[lowe-bound] :
deferred-shape-spec
is

HP Fortran statements
DIMENSION (statement and attribute)
assumed-size-spec
is
[explicit-shapespec-list ,] [lower-bound :] *
That is, assumed-size-spec is explicit-shape-spec-list with the final upper bound specified as *.
attrib-list
is a comma-separated list of attributes including DIMENSION and optionally those attributes compatible with it, namely:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & PARAMETER & PUBLIC \\
INTENT & POINTER & SAVE \\
OPTIONAL & PRIVATE & TARGET \\
\hline
\end{tabular}
entity-list
is
object-name[ (array-spec) ]
If (array-spec) is present, it overrides the (array-spec) given with the DIMENSION keyword in attributelist; see the example below.

The syntax of the DIMENSION statement is:
```

DIMENSION [::] array-name (array-spec)
[, array-name (array-spec) ]...

```

An array consists of a set of objects called the array elements, all of the same type and type parameters, arranged in a pattern involving columns, and possibly rows, planes, and higher dimensioned configurations. The type of the array el ements may be intrinsic or userdefined. In HP Fortran, an array may have up to seven dimensions. The number of dimensions is called the rank of the array and is fixed when the array is declared. Each dimension has an extent that is the size in that dimension (upper bound minuslower bound plus one). The size of an array is the product of its extents. The shape of an array is the vector of its extents in each dimension. Two arrays that have the same shape are said to be conformable.

It is not necessary for the keyword DIMENSION to appear in the declaration of a variable to give it the DIMENSION attribute. This attribute, as well as the rank, and possibly the extents and the bounds of an array, may be specified in the entity declaration part of any of the fol lowing statements:
- type declaration
- DIMENSION
- ALLOCATABLE
- COMMON
- POINTER
- TARGET

The array-spec (see Syntax, above) determines the category of the array being declared. "Array declarations" on page 54, describes these categories as:
- Explicit-shape array
- Assumed-shape array
- Assumed-size array
- Deferred-shape array

Examples
```

! These 2 declaration statements are equivalent.
REAL a (20,2), b (20,2), c (20,2)
REAL, DIMENSION (20,2) :: a, b, c
DIMENSION x(100), y(100) ! x and y are 1-dimensional
! lower bounds specified for jj (if not given, they default to 1)
INTEGER jj (0:100, -1:1)
! l is a 4-dimensional, allocatable, deferred shape logical array
LOGICAL I
ALLOCATABLE l(:,:,:,:)
COMPLEX s ! s has explicit shape and
TARGET :: s(10,2) ! the target attribute
DOUBLE PRECISION d
! d has 5 dimensions and is declared in common
COMMON /stuff/ d(2,3,5,9,8)
! arr1 is an adjustable array, arr2 an automatic array

```
```

HP Fortran statements
DIMENSION (statement and attribute)

```
```

SUBROUTINE calc(arr1, ib1, ib2)

```
SUBROUTINE calc(arr1, ib1, ib2)
REAL, DIMENSION (ib1, ib2) :: arr1, arr2
REAL, DIMENSION (ib1, ib2) :: arr1, arr2
! arr3 is a deferred-shape array with the pointer attribute
! arr3 is a deferred-shape array with the pointer attribute
REAL, POINTER, DIMENSION(:,:) :: arr3
REAL, POINTER, DIMENSION(:,:) :: arr3
! all three arrays have explicit shape; array specifier (10,10)
! all three arrays have explicit shape; array specifier (10,10)
! overrides specifier (10,20) for tb declaration only
! overrides specifier (10,20) for tb declaration only
LOGICAL, DIMENSION (10,20) :: ta, tb (10,10), tc
```

LOGICAL, DIMENSION (10,20) :: ta, tb (10,10), tc

\section*{DO}

Controls execution of DO Ioop.

Syntax [ construct-name :] Do [ labe ] [ loop-control ]
construct-name
is the name given to the do construct. If construct-name is specified, an END DO statement must appear at the end of the DO construct and have the same construct-name
labe
is the label of an executable statement that terminates the DO loop. If you specify labed, you can terminate the do loop either with an END DO statement or with an executable statement; the terminating statement must include label. If you do not specify label, you must terminate the DO loop with the END DO statement.
loop-control
is information used by the Do statement to control the loop. It can take one of the following forms:
- index = init, limit [, step]
- while (logical-expression)
- loop-control is omitted

In the first form, index is a scalar variable of type integer or real; init, limit, and step are scalar expressions of type integer or real. In the second form, logical-expression is a scalar logical expression. In the third form, loop-control is omitted. If you use the second or third form, you must terminate the do loop with the END DO statement.

Description
The syntax of the do statement allows for the following types of Do loops:
- Counter-controlled loop: a loop count is calculated that controls the number of times the block is executed, unless a prior exit occurs. A loop variable is incremented or decremented after each execution.

HP Fortran statements
DO
- While loop: a condition (logical-expression) is tested before each execution of the block; when it is false, execution ceases. An exit may occur at any time.
- Infinite loop: there is no loop-control; repeated execution of the block ceases only when an exit from the loop occurs.
When labed is present in the do statement, it specifies the label of the terminating statement of the DO loop. The terminating statement cannot be any of the following statements:
- GO TO (unconditional)
- GO TO (assigned)
- If (arithmetic)
- If (block)
- ElSE or ElSE IF
- END, END If, END SELECT, or END WHERE
- Return
- STOP
- DO
- Any nonexecutable statement

Note, however, that the terminating statement can be an IF (logical) or an END DO statement.

To maintain compati bility with some older versions of Fortran, you can use the +onetrip compile-line option to ensure that every countercontrolled Do loop in the program executes at least once.

\section*{Extended-range DO loops}

Extended-range do loops-a compatibility extension-allow a program to transfer control outside the do loop's range and then back into the do loop. Extended-range do loops work as follows: if a control statement inside a Do loop transfers control to a statement outside the Do loop, then any subsequent statement can transfer control back into the body of the do loop.

For example, in the following code, the range of the do loop is extended to include the statement GOTO 20, which transfers control back to the body of the do loop:
```

    DO 50 i = 1, 10
    20 n = n + 1
IF (n > 10) GOTO 60
5 0 ~ C O N T I N U E ~ ! ~ n o r m a l l y , ~ t h e ~ r a n g e ~ e n d s ~ h e r e
6 0 \mathrm { n } = \mathrm { n } + 1 0 0 ! this is the extended range,
GOTO 20 ! which extends down to this line

```

Examples
The following do construct displays the integers 1 through 10:
```

DO i = 1, 10
WRITE (*, *) i
END DO

```

The next example is a F ORTRAN 77-style do loop that does the same as the preceding example:

DO 50 i \(=1,10\)
WRITE (*, *) i
50 CONTINUE
The following DO construct iterates 5 times, decrementing the loop index from 10 to 2:
```

DO i = 10, 1, -2
END DO

```

The following is an example of a do while loop:
```

DO WHILE (sum < 100.0)
sum = sum + get_num(unit)
END DO

```

The following example illustrates the use of the Exit statement to exit from a nested do loop. The loops are named to control which loop is exited. Note that loop-control is missing from both the inner and outer loops, which therefore can be exited only by means of one of the EXIT statements:
```

outer:DO
READ *, val
new_val = 0
inner:DO
new_val = new_val + proc_val(val)
IF (new_val >= max_val) EXIT inner
IF (new_val == 0) EXIT outer
END DO inner
END DO outer

```
```

    HP Fortran statements
    DO
    The next Do construct never executes:
DO i $=10,1$ END DO

```

\section*{DOUBLE COMPLEX (extension)}

Declares entities of type double complex.
Syntax
DOUBLE COMPLEX [ [, attrib-list ] ::] entity-list attrib-list
is a list of one or more of the following attributes, separated by commas:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name [( array-spec )] [= initialization-expr]
where:
name
is the name of a variable or function
array-spec
is a comma-separated list of dimension bounds
initialization-expr
is a complex constant expression. If initialization-expr is present, entity-list must be preceded by the double colon.

HP Fortran statements
DOUBLE COMPLEX (extension)

Description

Examples

Related statements

Related concepts

The DOUBLE COMPLEX statement is an HP Fortran extension that declares the properties of complex data that has greater precision than data of default type complex. The two parts of a double complex value are each a double precision value.
The DOUBLE COMPLEX statement is constrained by the rules for type declaration statements, including the requirement that it precede all executable statements. N ote however, that the double complex statement does not have a kind parameter.

The following are valid declarations:
```

DOUBLE COMPLEX x, y
DOUBLE COMPLEX, PARAMETER :: t1(2)=(/(1.2, 0), (-1.01, 0.0009)/)
! use an array constructor to initialize a double complex array
DOUBLE COMPLEX, DIMENSION(2) : : dc_vec = \&
(/(2.294D-8, 6.288D-4), (-4.817D4, 0)/)
! use slashes as initialization delimiters, an HP extension
DOUBLE COMPLEX dcx/(2.294D-8, 6.288D-4)/ ! note, no double colon

```

COMPLEX

\hline
\end{tabular}

HP Fortran statements
ELSE IF

\section*{ELSE IF}

Provides alternate path of execution for IF construct.
Syntax

Description

Examples
ELSE IF (logical-expression) THEN [construct-name]
logical-expression
is a scalar logical expression.
construct-name
is the name given to the IF construct. If construct-name is specified, the same name must also appear in the IF statement and in the END IF statement.

The ELSE IF statement executes the immediately following statement block, if the following conditions are met:
- N one of the logical expressions in the if statement and any previous ELSE IF statements evaluates to true.
- Iogical-expression evaluates to true.

Branching to an ELSE IF statement is illegal.
```

INTEGER temperature
INTEGER, PARAMETER :: hot=1, cold=2
IF (temperature == hot) THEN
PRINT *, 'Turn down your thermostat.'
ELSE IF (temperature == cold) THEN
PRINT *, 'Turn up your thermostat.'
ELSE
PRINT *, 'Your thermostat is working OK.'
END IF

```

Related statements ELSE, END IF, and IF (construct)
Related concepts See "IF construct" on page 111.

\section*{ELSEWHERE}

Introduces optional ELSEWHERE block within a WHERE construct.

Syntax

\section*{Description}

Examples

Related statements

Related concepts

ELSEWHERE
The ELSEWHERE statement introduces an ELSEWHERE block, which is an optional component of the WHERE construct. The ELSEWHERE statement executes on the complement of the WHERE condition. For additional information, see "WHERE (statement and construct)" on page 466.
```

WHERE( b .GE. 0.0 )

```
    ! Assign to sqrt_b only where logical array b is 0 or positive
    squt_b \(=\) SQRT (b)
ELSEWHERE
    sqrt_b \(=0.0 \quad\) ! Assign sqrt_b where b is negative
END WHERE

WHERE and END (construct)

For information about the WHERE construct, see "Masked array assignment" on page 99.

HP Fortran statements
ENCODE (extension)

\section*{ENCODE (extension)}

Outputs formatted data to internal storage.

Syntax ENCODE (count, format, unit, io-specifier-list) [out-list]
count
is an integer expression that specifies the number of characters
(bytes) to translate from character format to internal (binary)
format. count must precede format.
format
specifies the format specification for formatting the data. format can be one of the fol lowing:
- The label of a FORMAT statement containing the format specification.
- An integer variable that has been assigned the label of a FORMAT statement.
- An embedded format specification. For information about embedded format specifications, see "E mbedded format specification" on page 237.
format must be the second of the parenthesized items, immediately fol lowing count. Note that the keyword FMT= is not used.
unit
is the internal storage designator. It must be a scal ar variable or array name. Assumed-size and adjustable-size arrays are not permitted. Note that char-var-name is not a unit number and that the keyword Unit = is not used.
unit must be the third of the parenthesized items, immediately following format.
io-specifier-list
is a comma-separated list of I/O specifiers. Note that the unit and format specifiers are required; the other I/O specifiers are optional. The following I/O specifiers can appear in io-specifierlist:

\section*{ERR=stmt-label}
specifies the label of the executable statement to which control passes if an error occurs during statement execution.

IOSTAT=integer-variable
returns the I/O status after the statement executes. If the statement successfully executes, integer-variable is set to zero. If an end-of-file record is encountered without an error condition, it is set to a negative integer. If an error occurs, integer-variabl e is set to a positive integer that indicates which error occurred.
out-list
is a comma-separated list of data items for output. The data items can include expressions and implied-do lists (see "I mplied-DO loop" on page 194).

\section*{Description \\ Examples \\ The encode statement is a nonstandard feature of HP Fortran and is provided for compatibility with other versions of Fortran. The internal-I/O capabilities of the standard WRITE statement provide similar functionality and should be used to ensure portability. \\ The encode statement translates data from its internal (binary) representation into formatted character data. \\ The following example program uses the ENCODE statement to write to an internal file:}
```

PROGRAM encode_example
CHARACTER (LEN=20) :: buf
ENCODE (LEN(buf), '(2X, 3I4, 1X)', buf) 1234, 45, -12
PRINT *, buf
END PROGRAM encode_example

```

When compiled and executed, this program outputs the following (where b represents a blank character):
```

bb1234bb45b-12bbbbb

```

\section*{END}

Marks the end of a program unit or procedure.

Syntax END [keyword [name] ]
keyword
is one of the keywords BLOCK DATA, FUNCTION, MODULE, PROGRAM, or SUBROUTINE. When the END statement is used for an internal procedure or module procedure, the FUNCTION or SUBROUTINE keyword is required.
name
is the name given to the program unit. If name is specified, keyword must al so be specified.

The END statement is the last statement of a program unit (that is, a main program, function, subroutine, module, or block data subprogram), an internal procedure, or a module procedure. It is the only statement that is required within a program unit.

Examples
The following example illustrates the use of the EnD statement to indicate the end of a main program. Notice that, even though the main program unit is given a name, the END PROGRAM statement does not require it:
```

PROGRAM main_prog

```
END PROGRAM

In the next example, the END statement marks the end of an internal function and must therefore specify the keyword Function. However, it is not required that the name, get_args, be also specified:
```

FUNCTION get_args (arg1, arg2)
END FUNCTION get_args

```

The following example uses the END statement to indicate the end of a block data subprogram. Because the End statement specifies the program unit name, it must also specify the keyword BLOCK DATA:
```

BLOCK DATA main_data
END BLOCK DATA main_data

```

\footnotetext{

}

\section*{END (construct)}

Terminates a CASE, DO, IF, or WHERE construct.
Syntax construct-keyword [construct-name]
construct-keyword
is one of the keywords DO, IF, SELECT CASE, or where.
construct-name
is the name given to the construct terminated by this statement.

Description

Examples

Related statements
Related concepts

The END (construct) statement terminates a CASE, DO, IF, or where construct. If construct-name appears in the statement that introduces the construct, the same name must also appear in the END statement. If no construct-name is given in the introducing statement, none must appear in the end statement.

For examples of the end (construct) statement, seethe descriptions of the DO, IF, SELECT, or WHERE statements throughout this chapter.

DO, IF, SELECT CASE, and WHERE

\end{tabular}

\section*{END INTERFACE}

Terminates a procedure interface block.

Syntax
Description

Examples

END INTERFACE
In Fortran 90, external procedures may be given explicit interfaces by means of procedure interface blocks. Such a block is always terminated by the END INTERFACE statement.

The following makes the interface of function \(r\) _ave explicit, giving it the generic name g_ave.
```

INTERFACE g_ave
FUNCTION r_ave(x)
! get the size of array x from module ave_stuff
USE ave_stuff, ONLY: n
REAL r_ave, x(n)
END FUNCTION r_ave
END INTERFACE
INTERFACE
I nterface blocks are described in "I nterface blocks" on page 152.

```

Related statements

END TYPE

\section*{END TYPE}

Terminates a derived type definition.

Syntax

Description
Examples

Related statements

Related concepts

END TYPE [typename]
typename
is the name of the derived type being defined. typename is optional. If given, it must be the same as the type-name specified in the TYPE statement introducing the derived type definition.

The END TYPE statement terminates the definition of a derived type.
The following is a simple example of a derived type with two components, high and low:
```

TYPE temp_range
INTEGER high, low
END TYPE temp_range

```

TYPE (definition)

Derived types are described in "Derived types" on page 39.

\section*{ENDFILE}

Writes end-of-file record to file.
Syntax The syntax of the ENDFILE statement can take one of the following forms:
- Short form: ENDFILE integer-expression
- Long form:

ENDFILE (io-specifie-list)
integer-expression
is the number of the unit connected to a sequential file.
io-specifier-list
is a list of the following comma-separated I/O specifiers:
[UNIT=] unit
specifies the unit connected to a device or external file opened for sequential access. unit must be an integer expression that evaluates to a nonnegative number. If the optional keyword UNIT= is omitted, unit must be the first item in io-specifier-list.

\section*{ERR=stmt-label}
specifies the label of the executable statement to which control passes if an error occurs during statement execution.

\section*{IOSTAT=integer-variable}
returns the I/O status after the statement executes. If the statement executes successfully, integer-variable is set to zero. If an error occurs, it is set to a positive integer that indicates which error occurred.

Description
The ENDFILE statement writes an end-of-file record to the file or device connected to the specified unit at the current position and positions the file after the end-of-file record.

HP Fortran statements
ENDFILE

An end-of-file record can occur only as the last record of a disk file. After execution of an ENDFILE statement, the file is positioned beyond the end-of-file record; any records beyond the current position are lost-that is, the file is truncated.

Some devices (for example, magnetic tape units) can have multiple end-of-file records, with or without intervening data records.

An end-of-file record can be written to a sequential file only.
The following statement writes an end-of-file record to the file connected to unit 10:

\section*{ENDFILE 10}

The following statement writes an end-of-file record to the file connected to unit 17. If an error occurs during the execution of the statement, control passes to the statement at label 99, and the error code is returned in ios:
```

INTEGER :: ios
ENDFILE (17, ERR=99, IOSTAT=ios)

```

\section*{ENTRY}

Provides an additional external or module subprogram entry point.

Syntax
```

ENTRY entry-name [([dummy-arg-list])
[RESULT (result-name)]]
entry-name

```
is the name of the entry point (subroutine or function) defined by the ENTRY statement. It must differ from the original subroutine or function name, and from other ENTRY statement entry-names specified in the subprogram in which it appears.
dummy-arg-list
is a comma-separated list of dummy arguments for the subroutine or function defined by the ENTRY statement. The same rules and restrictions apply as for subroutine dummy arguments or function dummy arguments, as appropriate.
result-name
is the result variable for a function defined by an ENTRY statement. result-name is optional; if not specified, the result variable is entry-name

The RESULT (result-name) clause can only be specified when the ENTRY statement is included in a function subprogram.

\section*{Description}

When an entry statement appears in a function subprogram, it effectively provides an additional FUNCTION statement in the subprogram: execution starts from the ENTRY statement when the entryname is invoked (by being used). Similarly, an ENTRY statement in a subroutine subprogram effectively provides an additional SUBROUTINE statement in the subprogram, and execution starts from the ENTRY statement when the entry-nameis called.

The following restrictions apply to the ENTRY statement:
- The Entry statement can appear in an external subprogram or a module subprogram; it may not appear in an internal subprogram. If the ENTRY statement appears in a function subprogram, it defines an additional function; if it appears in a subroutine subprogram, it defines an additional subroutine. The entry points thus defined can be referenced in the same way as for a normal function name or subroutine name, as appropriate. Execution starts at the ENTRY

HP Fortran statements
ENTRY
statement, and continues in the normal manner, ignoring any ENTRY statements subsequently encountered, until a RETURN statement or the end of the procedure is reached.
- The RESULT (result-name) clause can only be specified when the ENTRY statement is included in a function subprogram. If specified, result-name must differ from entry-name, and entry-name must not appear in any specification statement in the scoping unit of the function subprogram; entry-name assumes all the attributes of resultname. The RESULT clause in an Entry statement has the same syntax and semantics as in a FUNCTION statement.
- If the ENTRY statement appears in a function, the result variable is that specified in the FUNCTION statement; if none is specified, the result variable is entry-name.
- If the characteristics of the result variable specified in the Entry statement are the same as those of the result variable specified in the FUNCTION statement, then the result variable is the same, even though the names are different. If the characteristics are different, then the result variables must be:
- Nonpointer scalars of intrinsic type
- Storage associated
- If any is of character type, they must all be of character type and must all have the same length. If any is of noncharacter type, they must all be of noncharacter type.
- The result variable may not appear in a COMMON, DATA, or EQUIVALENCE statement. Also, the result variable may not have the ALLOCATABLE, INTENT, OPTIONAL, PARAMETER, or SAVE attribute.
- If RECURSIVE is specified on thefUNCTION statement at the start of a function subprogram, and RESULT is specified on an ENTRY statement within the subprogram, then the interface of the function defined by the ENTRY statement is explicit within the function subprogram; the function can thus be invoked recursively. (Note that the keyword RECURSIVE is not given on the ENTRY statement, but only on the FUNCTION statement.)
- If RECURSIVE is specified on the SUBROUTINE statement at the start of a subroutine subprogram, the interface of the subroutine defined by an ENTRY statement within the subprogram is explicit within the subprogram; the subroutine can thus be called recursively.
- A dummy argument in an Entry statement must not appear in an executable statement preceding the ENTRY statement, unless it also appears in a FUNCTION, SUBROUTINE, or ENTRY statement preceding the executable statement.
- If a dummy argument in a subprogram-that is, as specified in a FUNCTION or SUBROUTINE statement at the start of the subprogram or in any Entry statements within the subprogram-is used in an executable statement, then the statement may only be executed if the dummy argument appears in the dummy argument list of the procedure name actually referenced in the current call. The same restrictions apply when you use a dummy argument in a specification expression to specify an array bound or character length.
- A procedure defined by an Entry statement may be given an explicit interface by use of an INTERFACE block. The procedure header in the interface body must be a FUNCTION statement for an entry to a function subprogram, and a SUBROUTINE statement for an entry to a subroutine subprogram.

The EnTRY statement was often used in FORTRAN 77 programs in situations where a set of subroutines or functions had slightly different dummy argument lists but entailed computations involving identical data and code. In Fortran 90 the use of the ENTRY statement in such situations can be replaced by the use of optional arguments.

Examples
The following example defines a subroutine subprogram with two dummy arguments. The subprogram also contains an ENTRY statement that takes only the first dummy argument specified in the SUBROUTINE statement.
```

SUBROUTINE Full_Name (first_name, surname)
CHARACTER(20) :: first_name, surname
ENTRY Part_Name (first_name)

```

The following example creates a stack. It shows the use of ENTRY to group the definition of a data structure together with the code that accesses it, a technique known as encapsulation. (This example could alternatively be programmed as a module, which would be preferable in that it does not rely on storage association.)

\section*{HP Fortran statements}

\section*{ENTRY}
```

SUBROUTINE manipulate_stack
IMPLICIT NONE
INTEGER size, top /0/, value
PARAMETER (size = 100)
INTEGER, DIMENSION(size) :: stack
SAVE stack, top
ENTRY push(value) ! Push value onto the stack
IF (top == size) STOP 'Stack Overflow'
top = top + 1
stack(top) = value
RETURN
ENTRY pop(value) ! Pop top of stack and place in value
IF (top == 0) STOP 'Stack Underflow'
value = stack(top)
top = top - 1
RETURN
END SUBROUTINE manipulate_stack

```

Here are examples of CALL statements associated with the preceding example:
```

CALL push(10)
CALL push(15)
CALL pop(I)
CALL pop(J)

```

\section*{EQUIVALENCE}

Associates different objects with same storage area.

Syntax EQUIVALENCE (equivalence-list1) [, (equivalencelist2)]...
equivalencelist
is a comma-separated list of two or more object names to be storage associated. Objects can include simple variables, array elements, array names, and character substrings.

Description All objects in each equivalencelist share the same storage area. Such objects become storage associated and are equivalenced to each other. Equivalencing may also cause other objects to become storage associated.

The following items must not appear in equivalencelist:
- Automatic objects, including character variables whose length is specified with a nonconstant
- Allocatable arrays
- Function names, result names, or entry names
- Dummy arguments
- Records or record field references
- Nonsequenced derived-type objects
- Derived-type components
- Pointers or derived-type objects containing pointers
- Named constants

Derived-type objects may appear in an EQUIVALENCE statement if they have been defined with the SEQUENCE attribute.

The following restrictions apply to objects that can appear in an EQUIVALENCE statement:
- Objects in the same equivalence-list must be explicitly or implicitly declared in the same scoping unit.

HP Fortran statements
EQUIVALENCE
- The name of an equivalenced object must not be made available by use association.

The Fortran 90 standard imposes the following type restrictions on equivalenced objects:
- If one of the objects in equivalence-list is of type default integer, default real, double precision real, default complex, double complex, default logical, or numeric sequence type, then all objects in equivalence-list must be one of these types.

HP Fortran relaxes this restriction and allows character and noncharacter items to be equivalenced. Note, however, that use of this extension can impact portability.
- If one of the objects in equivalence-list is of derived type that is not a numeric sequence or character sequence type, then all objects in equivalence-list must be of the same type.
- If one of the objects in equivalence-list is of intrinsic type other than default integer, default real, double precision real, default complex, double complex, default logical, or default character, then all objects in equivalence-list must be of the same type with the same kind type parameter value.

HP Fortran relaxes this restriction.
The EQUIVALENCE statement does not cause type conversion or imply mathematical equivalence. If an array and a scalar share the same storage space through the EQUIVALENCE statement, the array does not have the characteristics of a scalar and the scalar does not have the characteristics of an array. They only share the same storage space.
Care should be taken when data types of different sizes share the same storage space, because the EQUIVALENCE statement specifies that each data item in equivalence-list has the same first storage unit. For example, if a 4-byte integer variable and a double-precision variable are equivalenced, the integer variable shares the same space as the 4 most significant bytes of the 8-byte double-precision variable.
Proper alignment of data types is always enforced. The compiler will issue a diagnostic if incorrect alignment is forced through an EQUIVALENCE statement. For data type alignment rules, see "I ntrinsic data types" on page 22.

The lengths of the equivalenced objects need not be the same.

\section*{Equivalencing character data}

An equivalence statement specifies that the storage sequences of character data items whose names are specified in equivalencelist have the same first character storage unit. This causes the association of the data items in equivalencelist and can cause association of other data items as well. Consider the following example:
```

CHARACTER(LEN=4) : : a, b
CHARACTER(LEN=3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))

```

As a result of this EQUIVALENCE statement, the fourth character in a, the first character in b, and the first character in c (2) share the same storage.

Strings of the same or different lengths can be equivalenced to start on the first element, and you can use substring notation to specify other associations, as in the following:
```

CHARACTER (10) :: s1, s2
EQUIVALENCE (s1(2:2), s2(3:3)

```

Substring subscripts must be integer initialization expressions, and the substring length must be nonzero.

\section*{Equivalencing arrays}

To determine equivalence between arrays with different dimensions, HP Fortran views all elements of an array in linear sequence. Each array is stored as if it were a one-dimensional array. Array elements are stored in ascending sequential, column-major order; for information about how arrays are laid out in memory, see "Array fundamentals" on page 52.

Array elements can be equivalenced with elements of a different array or with scal ars. No equivalence occurs outside the bounds of any of the equivalenced arrays.

If equivalenced arrays are not of the same type, they may not line up element by element.

If an array name appears without subscripts in an EQUIVALENCE statement, it has the same effect as specifying an array name with the subscript of its first element.

It is illegal to equivalence different elements of the same array to the same storage area. For example, the following is illegal:
```

INTEGER :: a(2), b
EQUIVALENCE (a(1), b), (a(2), b)

```

HP Fortran statements
EQUIVALENCE

Likewise, it is illegal to use the EQUIVALENCE statement to force consecutive array elements to be noncontiguous, as in the following example:
```

REAL :: a(2), r(3)
EQUIVALENCE (a(1),r(1)), (a(2), r(3))

```

Array subscripts must be integer initialization expressions.

\section*{Equivalence in common blocks}

An EQUIVALENCE statement must not cause two common blocks to be associated. However, you can use the EQUIVALENCE statement to place objects in common by equivalencing them to objects already in common. If one element of an array is equivalenced to an object in common, the whole array is placed in common with equivalence maintained for storage units preceding and following the data element in common. The common block is always extended when it is necessary to fit an array that shares storage space in the common block. It may be extended after the last entry, but not before the first.

Consider the following example, which puts array i in blank common and equivalences array element \(j(2)\) to \(i(3)\) :
```

INTEGER :: i(6), j(6)
COMMON i
EQUIVALENCE (i(3), j(2))

```

The effect of the EQUIVALENCE statement is to extend blank common to include element \(j(6)\). This is entirely legal because the extension occurs at the end of the common block.

But if the EQUIVALENCE statement were changed as follows:
```

EQUIVALENCE (i(1), j(2)) ! illegal

```
it would result in an illegal equivalence, because storage would have to be inserted in front of the block in order to accommodate element \(j\) (1).

Examples
In the following example, the variables \(a, b\), and c share the same storage space; array elements d (2) and e (5) share the same storage space; variables \(f, g\), and \(h\) share the same storage:
```

INTEGER :: a, b, c, d(20), e(30), f, g, h
EQUIVALENCE (a, b, c), (d(2), e(5)), (f, g, h)

```

HP Fortran statements
EXTERNAL (statement and attribute)

\section*{EXTERNAL (statement and attribute)}

Declares a name to be external.
Syntax

Description
A type declaration statement with the EXTERNAL attribute is:
type, attrib-list :: function-namelist
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (name), etc.).
attrib-list
is a comma-separated list of attributes including EXTERNAL and optionally those attributes compatible with it, namely:
```

OPTIONAL PRIVATE PUBLIC

```
function-namelist
is a comma-separated list of function names to be designated EXTERNAL.
The syntax of the external statement is:
EXTERNAL external-namelist
Note that the syntax of the external statement does not permit optional colons.

An external attribute or statement specifies that a name may be used as an actual argument in subroutine calls and function references. The name is either an external procedure, a dummy procedure, or a block data program unit.
A name that appears in a type statement specifying the EXTERNAL attribute must be the name of an external procedure or of a dummy argument that is a procedure.
The following rules and restrictions apply:
- A name can appear once in an External statement, in a declaration statement with an External attribute, or in an interface body, but not in more than one of these.
- The external attribute cannot be used with subroutines. To declare a subroutine as EXTERNAL, use the statement form.
- If the name is a dummy argument, an external statement declares it to be a dummy procedure.
- If a user-defined procedure or library routine has the same name as an intrinsic procedure, then it must either be declared to have the external attribute or have an explicit interface. The intrinsic procedure is then no longer available in such program units.
- The intrinsic and External attributes are mutually exclusive.

\section*{Examples}

Related statements
SUBROUTINE sub (fourier)
! fourier is a dummy procedure; actual argument corresponding to
! to fourier can be external, intrinsic, or module procedure REAL fourier

HP Fortran statements
FORMAT

\section*{FORMAT}

Describes how I/O data is to be formatted.
Syntax labd FORMAT (format-list)
labe
is a statement label.
format-list
is a comma-separated list of format items, where each item in the list can be either one of the edit descriptors described in Table 25 or (format-list). If format-list is a list item, it may be optionally preceded by a repeat specification-a positive integer that specifies how may times format-list is to be repeated.

\section*{Examples}

The format statement holds the format specification that indicates how data in formatted I/O is to be translated between internal (binary) representation and formatted (ASCII) representation. The translation makes it possible to represent data in a humanly readable format.
Although a format specification can be embedded within a data transfer statement, the point to using a FORMAT statement is to make it available to any number of data transfer statements. Several data transfer statements can use the same format specification contained in a FORMAT statement by referencing label.

Another advantage of the FORMAT statement over the use of embedded format specifications is that it is "pre-compiled", reducing the runtime overhead of processing the format specification and providing compiletime error checking of the FMT= specifier.
```

    PROGRAM format_example
    WRITE (15,FMT=20) 1234, 45, -12
    20 FORMAT (I6, 2I4)
END PROGRAM format_example

```

When compiled and executed, this program outputs the following (where b represents the blank character):
```

bb1234bb45b-12

```

Related statements READ and WRITE
Related concepts For information about I/O formatting, see Chapter 9, "I/O formatting," on page 205.

HP Fortran statements
FUNCTION

\section*{FUNCTION}

Introduces a function subprogram.
Syntax
[RECURSIVE] [type-spec] FUNCTION
function-name ([dummy-arg-namelist])
[RESULT (result-name)]
RECURSIVE
is a keyword that must be specified in the FUNCTION statement if the function is either directly or indirectly recursive. The RECURSIVE clause can appear at most once, either before or after type-spec. It is not an error to specify RECURSIVE for a nonrecursive function.
A recursive function that calls itself directly must also have the RESULT clause specified (see below).
typespec
is a valid type specification (INTEGER, REAL, LOGICAL, ChARACTER, TYPE (name), etc.). The type and type parameters of the function result can be specified by typespec or by declaring the result variable within the function subprogram, but not by both. The implicit typing rules apply if the function is not typed explicitly.
If the function result is array-valued or a pointer, the appropriate attributes for the result variable (which is functionname, or result-name if specified) must be specified within the function subprogram.
function-name
is the name of the function subprogram being defined.
dummy-arg-namelist
is a comma-separated list of dummy argument names for the function.
result-name
is the result variable. If the Result clause is not specified, function-name becomes the result variable. If result-name is given, it must differ from function-name, and function-name must not then be declared within the function subprogram.
\begin{tabular}{|c|c|}
\hline Description & A FUNCTION statement introduces an external, module, or internal function subprogram. \\
\hline Examples & ```
PROGRAM main
...
CONTAINS
    ! f is an internal function
    FUNCTION f(x)
                f = 2*x + 3
    END FUNCTION f
    ! recursive function, which must specify RESULT clause
    RECURSIVE INTEGER FUNCTION factorial (n) &
                RESULT (factorial_value)
            IMPLICIT INTEGER (a-z)
        IF ( }\textrm{n}<= 0) THE
            factorial_value = 1
        ELSE
            factorial_value = n * factorial (n-1)
        END IF
    END FUNCTION factorial
END PROGRAM main
``` \\

Transfers control to one of several labels.
\begin{tabular}{|c|c|}
\hline \multirow[t]{5}{*}{Syntax} & GO TO ( labe-list ) [,] arithmetic-express \\
\hline & labe-list \\
\hline & is a list of statement labels, separated by commas. \\
\hline & arithmetic-expression \\
\hline & is a scalar integer expression. As an extension, HP Fortran also allows the expression to be of type real or double precision. \\
\hline \multirow[t]{2}{*}{Description} & The computed GO TO statement transfers control to one of several labeled statements, depending on the value of arithmetic-expression. After arithmetic-expression is evaluated (and, if necessary, truncated to an integer value), control transfers to the statement label whose position in labe-list corresponds to the truncated value of arithmetic-expression. \\
\hline & If the value of arithmetic-expression is less than 1 or greater than the total number of labels in label-list, control transfers to the executable statement immediately following the computed GO то statement. \\
\hline Examples & ```
index = 3
! Branch made to the statement labeled 30.
GO TO (10, 20, 30, 40) index
``` \\
\hline Related statements & SELECT CASE, GO TO (assigned), and GO TO (unconditional) \\
\hline Related concepts & For information about flow control statements, see "Flow control statements" on page 112. \\
\hline
\end{tabular}

HP Fortran statements
GO TO (unconditional)

\section*{GO TO (unconditional)}

Transfers control to a specified label.
\begin{tabular}{ll} 
Syntax & \begin{tabular}{l} 
GO TO label \\
label \\
\(\quad\) is the label of an executable statement.
\end{tabular} \\
Description & \begin{tabular}{l} 
The unconditional GO TO statement transfers control directly to the \\
statement at the specified label. The executable statement with label can \\
occur before or after the GO TO statement, but it must be within the \\
same scoping unit.
\end{tabular} \\
Examples & \begin{tabular}{l} 
GO TO 30 \\
30 CONT INUE
\end{tabular} \\
Related statements & \begin{tabular}{l} 
GO TO (assigned) and GO TO (computed)
\end{tabular} \\
Related concepts & \begin{tabular}{l} 
For information about flow control statements, see "F low control \\
statements" on page 112.
\end{tabular}
\end{tabular}

\section*{IF (arithmetic)}

Transfers control to one of three labels.
\begin{tabular}{ll} 
Syntax & \begin{tabular}{l} 
IF (arithmetic-expression) labelN, labelZ, labelP \\
arithmetic-expression \\
is an arithmetic expression of any numeric type except complex \\
and double complex.
\end{tabular} \\
Labe \(\quad\) is a label of an executable statement.
\end{tabular}

HP Fortran statements
IF (block)

\section*{IF (block)}

Begins an IF construct.
Syntax [construct-name :] IF (logical-expression) THEN
construct-name
is the name given to the IF construct. If construct-name is specified, the same name must also appear in the END IF statement.
logical-expression
is a scalar logical expression.

Description

Examples

Related statements
Related concepts For information about the IF construct, see "IF construct" on page 111.
\begin{tabular}{|c|c|}
\hline & IF (logical) \\
\hline & Conditionally executes a statement. \\
\hline \multirow[t]{6}{*}{Syntax} & IF (logical-expression) statement \\
\hline & logical-expression is a logical expression. statement \\
\hline & is any executable statement other than the following: \\
\hline & - A statement used to begin a construct \\
\hline & - Any END statement \\
\hline & - Any IF statement \\
\hline Description & The logical IF statement is a two-way decision maker. If logicalexpression evaluates to is true, statement executes and control passes to the next statement. If logical-expression evaluates to false, statement does not execute and control passes to the next statement in the program. \\
\hline Examples & IF (a .EQ. b) PRINT *, 'They are equal.' \\
\hline Related statements & IF (arithmetic) and IF (construct) \\
\hline Related concepts & For information about flow control statements, see "Flow control statements" on page 112. \\
\hline
\end{tabular}

HP Fortran statements
IMPLICIT

\section*{IMPLICIT}

Changes or voids default typing rules.
The IMPLICIT statement can take either of the following forms:
- First form:

IMPLICIT type (range-list) [, type (rangelist) ,]...
- Second form:

IMPLICIT NONE
type
is the data type to be associated with the corresponding letters in rangelist.
rangelist
is a comma-separated list of letters or ranges of letters (for example, \(\mathrm{A}-\mathrm{Z}\) or \(\mathrm{I}-\mathrm{N}\) ) to be associated with type. Writing a range of letters has the same effect as writing a list of single letters.

Description
The IMPLICIT statement can be used either to change or void the default typing rules within the program unit in which it appears, depending on which of the two forms the statement takes.

\section*{First form}

This form of the IMP LICIT statement specifies type as the data type for all variables, arrays, named constants, function subprograms, ENTRY names in function subprograms, and statement functions that begin with any letter in rangelist and that are not explicitly given a type.
Within the specification statements of a program unit, IMPLICIT statements must precede all other specification statements, except possibly the DATA and PARAMETER statements.
The same letter must not appear as a single letter or be included in a range of letters, more than once in all of the IMPLICIT statements in a scoping unit.

For information on how the IMPLICIT and PARAMETER statements interact, refer to "PARAMETER (statement and attribute)" on page 391.

\section*{Second form}

The IMPLICIT NONE statement disables the default typing rules for all variables, arrays, named constants, function subprograms, ENTRY names, and statement functions (but not intrinsic functions). All such objects must be explicitly typed. The IMPLICIT NONE statement must be the only IMPLICIT statement in the scoping unit, and it must precede any PARAMETER statement. Types of intrinsic functions are not affected.

You can also use the +implicit_none compile-line option to void the default typing rules. A program compiled with this option may include IMPLICIT statements, which the compiler will honor.

\section*{Examples}

The following statement causes all variables and function names beginning with \(I, ~ J\), or \(K\) to be of type complex, and all data items beginning with \(A, B\), or \(C\) to be of type integer:
```

IMPLICIT COMPLEX (I, J, K), INTEGER (A-C)

```

Related concepts For related information, see the following:
- "Implicit typing" on page 28

HP Fortran statements
INCLUDE

\section*{INCLUDE}

Imports text from a specified file.

Syntax

Description

INCLUDE character-literal-constant
character-literal-constant is the name of the file to include.

The keyword INCLUDE and character-literal-constant form an INCLUDE line, which is used to insert text into a program prior to compilation. The inserted text replaces the INCLUDE line; the INCLUDE line should therefore appear in your program where you want the inserted text. When the end of an included file is reached, the compiler continues processing with the line following the INCLUDE line.
character-literal-constant can be either a file name or a device name. It must not have a kind parameter that is a named constant.

The INCLUDE line must appear on one line with no other text except possibly a trailing comment. It should not have a statement label. Thus, you cannot branch to it, and it cannot be an action statement that is part of a Fortran 90 IF statement. You cannot use the "; " operator to add a second INCLUDE line, nor can you use the " \(\&\) " operator to continue it over another line.

The compiler searches directories for the named include files in the following order:

1 The current source directory
2 Directories specified by the -I compile-line option, in the order specified

3 The current working directory
4 The directory/usr/include
INCLUDE lines can be nested to a maximum of ten levels. However, they must be nested nonrecursively. That is, inserted text must not specify an INCLUDE line that was encountered at an earlier level of nesting.
Line numbering within the listing of an included file begins at 1 . When the included file listing ends, the include level decreases appropriately, and the previous line numbering resumes.

\title{
Examples INCLUDE 'my_common_blocks' INCLUDE "/my_stuff/declarations.h" \\ Related concepts For related information, see the following: \\ - "INCLUDE line" on page 19
}

HP Fortran statements
INQUIRE

\section*{INQUIRE}

Returns information about file properties.

Syntax
The syntax of the INQUIRE statement has two forms:
- Inquiry by output list:

INQUIRE ( IOLENGTH= integer-variable) output-list
- Inquiry by unit or file:

INQUIRE (io-specifier-list)
integer-variable
is the length of the unformatted record that would result from writing output-list to a direct-access file. The value returned in integer-variablecan be used with the RECL= specifier in an OPEN statement to specify the length of each record in an unformatted direct-access file that will hold the data in output-list.
output-list
is a comma-separated list of data items, similar to what would be included with the WRITE or PRINT statement. The data items can include variables and implied-Do lists (see "I mplied-DO loop" on page 194).
io-specifier-list
is a list of comma-separated I/O specifiers. As noted in the following descriptions, most of the specifiers return information about the specified unit or file. io-specifier-list must include either the UNIT= or FILE= specifier, but not both. The following paragraphs describe all the I/O specifiers that can appear in io-specifier-list:
[UNIT=] unit
specifies the unit connected to an external file. unit must be an integer expression that evaluates to a number greater than 0. If the optional keyword UNIT= is omitted, unit must be the first item in io-specifierlist. If unit appears in io-specifier-list, the FILE= specifier must not be used.

\section*{ACCESS=character}
returns the following values, indicating the method of access:
'SEQUENTIAL' Fileis connected for sequential access.
'DIRECT' File is connected for direct access.
'UNDEFINED' Fileis not connected.

ACTION=character-variable
returns the following values, indicating the direction of the transfer:
'READ' Fileis connected for reading only.
'WRITE' Fileis connected for writing only.
'READWRITE' Fileis connected for reading and writing.
'UNDEFINED' File is not connected.

BLANK=character-variable
returns the type of blank control that is in effect. For information about blank control, see the BLANK= specifier for the OPEN statement. The values returned by the BLANK= specifier are:
\begin{tabular}{ll} 
'NULL' & Null blank control is in effect. \\
' ZERO ' & Zero blank control is in effect. \\
'UNDEFINED' & \begin{tabular}{l} 
File is not connected for \\
formatted I/O.
\end{tabular}
\end{tabular}

HP Fortran statements

\section*{DELIM=character-variable}
returns the following values, indicating the character to use (if any) to delimit character values in listdirected and namelist formatting:
\begin{tabular}{ll} 
'APOSTROPHE ' & \begin{tabular}{l} 
An apostrophe is used as the \\
delimiter.
\end{tabular} \\
'QUOTE ' & \begin{tabular}{l} 
The double quotation mark is \\
used as the delimiter.
\end{tabular} \\
'NONE ' & \begin{tabular}{l} 
There is no delimiting \\
character.
\end{tabular} \\
'UNDEFINED' & \begin{tabular}{l} 
File is not connected for \\
formatted \(\mathrm{I} / \mathrm{O}\).
\end{tabular}
\end{tabular}

DIRECT=character-variable
returns the following values, indicating whether or not the file is connected for direct access:
'YES' File is connected for direct access.
'NO' File is not connected for direct access.
'UNKNOWN ' It cannot be determined whether or not file is connected for direct access.

ERR=stmt-labe
specifies the label of the executable statement to which control passes if an error occurs during statement execution.

\section*{EXIST=logical-variable}
returns the following values, indicating whether or not the file or unit exists:
\begin{tabular}{ll} 
'TRUE ' & File exists or unit is connected. \\
'FALSE ' & \begin{tabular}{l} 
File does not exist or unit is not \\
connected.
\end{tabular}
\end{tabular}

FILE=character-expression
specifies the name of a file for inquiry. The file does not have to be connected or even exist. If the FILE= specifier appears in io-specifier-list, the UNIT= specifier must not be used.

FORM=character-variable
returns the following values, indicating whether the file is connected for formatted or unformatted I/O:
\begin{tabular}{ll} 
'FORMATTED' & \begin{tabular}{l} 
File is connected for \\
formatted I/O.
\end{tabular} \\
'UNFORMATTED' & \begin{tabular}{l} 
File is connected for \\
unformatted I/O.
\end{tabular} \\
'UNDEFINED' & File is not connected.
\end{tabular}

HP Fortran statements

\section*{FORMATTED=character-variable}
returns the following values, indicating whether or not the file is connected for formatted I/O:
'YES' File is connected for formatted I/O.
'NO' File is not connected for formatted I/O.
' UNKNOWN ' It cannot be determined whether or not file is connected for formatted I/O.

IOSTAT=integer-variable
returns the I/O status after the statement executes. If the statement successfully executes, integer-variableis set to zero. If an error occurs, it is set to a positive integer that indicates which error occurred..

NAME=character-variable
returns the name of file connected to the specified unit. If the file has no name or is not connected, NAME= returns the string UNDEF INED.

NAMED=logical-variable
returns the following values, indicating whether or not the file has a name:
\begin{tabular}{ll} 
'TRUE ' & File has a name. \\
'FALSE & File does not have a name.
\end{tabular}

NEXTREC=integer-variable
returns the number of the next record to be read or written in a file connected for direct access. The value is the last record read or written +1 . A value of 1
indicates that no records have been processed. If the file is not connected or it is a device file or its status cannot be determined, integer-variable is undefined.

NUMBER=integer-variable
returns the unit number that is connected to the specified file. If no unit is connected to the named file, integer-variableis undefined.
```

OPENED=logical-variable

```
returns the following values, indicating whether or not the file has been opened (that is, is connected):
\begin{tabular}{ll} 
'TRUE' & File is connected. \\
'FALSE' & File is not connected.
\end{tabular}

PAD=character-variable
returns a value indicating whether or not input records are padded with blanks. For more information about padding, see the PAD= specifier for the OPEN statement. The return values are:
\begin{tabular}{ll} 
'YES' & \begin{tabular}{l} 
File or unit is connected with \\
PAD = 'YES' in OPEN statement.
\end{tabular} \\
'NO' & \begin{tabular}{l} 
File or unit is connected with \\
\\
\end{tabular}\(\quad\)\begin{tabular}{l} 
PAD = 'NO' in OPEN statement.
\end{tabular}
\end{tabular}

HP Fortran statements

\section*{POSITION=character-variable}
returns the following values, indicating the file position:
'REWIND' File is connected with its position at the start of the first record.
'APPEND ' File is connected with its position at the end-of-file record.
'ASIS' File is connected without changing its position.
'UNDEFINED' File is not connected or is connected for direct access.

READ=character-variable
returns the following values, indicating whether or not reading is an allowed action for the file:
\begin{tabular}{ll} 
'YES' & Reading is allowed for file. \\
'NO' & Reading is not allowed for file. \\
'UNKNOWN' & \begin{tabular}{l} 
It cannot be determined \\
whether or not reading is \\
allowed for file.
\end{tabular}
\end{tabular}

\section*{READWRITE=character-variable}
returns the following values, indicating whether or not reading and writing are allowed actions for the file:
\begin{tabular}{ll} 
'YES' & \begin{tabular}{l} 
Both reading and writing are \\
allowed for file.
\end{tabular} \\
'NO' & \begin{tabular}{l} 
Reading and writing are not \\
both allowed for file.
\end{tabular} \\
'UNKNOWN' & \begin{tabular}{l} 
It cannot be determined \\
whether or not reading and \\
writing are both allowed for file.
\end{tabular}
\end{tabular}

RECL=integer-variable
returns the record length of the specified unit or file, measured in bytes. The file must be a direct-access file. If the file is not a direct-access file or does not exist, integer-variable is undefined.

\section*{SEQUENTIAL=character-variable}
returns the following values, indicating whether or not the file is connected for direct access:
\begin{tabular}{ll} 
'YES' & \begin{tabular}{l} 
File is connected for sequential \\
access.
\end{tabular} \\
'NO' & \begin{tabular}{l} 
File is not connected for \\
sequential access.
\end{tabular} \\
'UNKNOWN' & \begin{tabular}{l} 
It cannot be determined \\
whether or not file is connected \\
for sequential access.
\end{tabular}
\end{tabular}

HP Fortran statements
INQUIRE

\section*{UNFORMATTED=character-variable}
returns the following values, indicating whether or not the file is connected for formatted I/O:
\begin{tabular}{ll} 
'YES' & \begin{tabular}{l} 
File is connected for \\
unformatted I/O.
\end{tabular} \\
'NO' & \begin{tabular}{l} 
File is not connected for \\
unformatted I/O.
\end{tabular} \\
'UNKNOWN' & \begin{tabular}{l} 
It cannot be determined \\
whether or not file is connected \\
for unformatted I/O.
\end{tabular}
\end{tabular}

WRITE=character-variable
returns the following values, indicating whether or not writing is an allowed action for the file:
\begin{tabular}{ll} 
'YES' & Writing is allowed for file. \\
'NO' & Writing is not allowed for file. \\
'UNKNOWN ' & \begin{tabular}{l} 
It cannot be determined \\
whether or not writing is \\
allowed for file.
\end{tabular}
\end{tabular}

The INQUIRE statement returns selected properties of a specified file or unit number. (It is illegal to include both the UNIT= specifier and the FILE= specifier in the same INQUIRE statement.) I nquiring by unit number should be used on connected files; inquiring by filename is typically used on unconnected files.
In addition, the INQUIRE statement can also be used to determine the record length of a new or existing file. That is, you can use INQUIRE to obtain the record length before creating the file and then use the return value as the argument to the RECL= specifier in an OPEN statement.

\section*{Examples}

The following examples illustrate different uses of the INQUIRE statement.

\section*{Inquiry by file}

The INQUIRE statement in this example returns the following information about the file named my_file:
- The EXIST= specifier determines if the file is connected.
- The DIRECT= specifier determines if it is connected for direct access.
- The READWRITE= specifier determines if it can be read and written.
```

LOGICAL :: exist
CHARACTER(LEN=9) :: dir_acc, rw_sts
INQUIRE (FILE='my_file', EXIST=exist, \&
DIRECT=dir_acc, READWRITE=rw__sts)

```

\section*{Inquiry by unit}

The following INQUIRE statement returns the following information about the file connected to the unit in u_num:
- The OPENED= specifier determines if the file is connected to u_num.
- The NAMED= specifier determines if it is a named file or a scratch file.
- The nAME = specifier returns its name.
```

LOGICAL :: opened, named
INTEGER : : u_num
CHARACTER(LEN=80) : : fname
INQUIRE (UNIT=u_num, NAMED=named, OPENED=opened, NAME=fname)

```

\section*{Inquiry by output list}

When using the OPEN statement to create a direct-access file, you must specify the record length for the file with the RECL= specifier. Previous to Fortran 90, you had to resort to a nonportable strategy to determine record length. The Fortran 90 INQUIRE statement provides a portable solution: use the INQUIRE statement to inquire by output list, and specify the return value from the INQUIRE statement as the argument to the OPEN statement. The following is an example:
```

INTEGER :: rec_len, ios
INQUIRE (IOLENGTH=rec_len) x, y, i, j
OPEN (UNIT=32, FILE='new_file', IOSTAT=ios, \&
ACCESS='DIRECT', RECL=rec_len)

```

HP Fortran statements
INQUIRE

Related statements
OPEN
Related concepts For information about I/O concepts, see Chapter 8, "I/O and file handling," on page 171.

\section*{INTEGER}

Declares entities of type integer.

Syntax INTEGER [kind-spec] [[, attrib-list] ::] entity-list
kind-spec
is the kind type parameter that specifies the range of the entities in entity-list. kind-spec takes the form:
([KIND =] kind-param)
where kind-param can be a named constant or a constant expression that has the integer value of 1,2 , 4 , or 8 . The size of the default type is 4 .

As an extension, kind-spec can take the form:
*len-param
where len-param is the integer \(1,2,4\), or 8 (default = 4).
attrib-list
is a list of one or more of the following attributes, separated by commas:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.

HP Fortran statements
INTEGER
entity-list
is a list of entities, separated by commas. Each entity takes the form:
```

name [(array-spec)] [= initialization-expr]

```
where:
name
is the name of a variable or function
array-spec
is a comma-separated list of dimension bounds
initialization-expr
is an integer constant expression. If initialization-expr is present, entity-list must be preceded by the double colon.

The INTEGER statement is used to declare the length and properties of data that are whole numbers. A kind parameter (if present) indicates the representation method.

The INTEGER statement is constrained by the rules for all type declaration statements, including the requirement that it precede all executable statements.

As a portability extension, HP Fortran allows the following syntax for specifying the length of an entity:
name [*len] [(array-spec)] [= initialization-expr]
If (array-spec) is specified, *len may appear on either side of (arrayspec). If name appears with *len, it overrides the length specified by INTEGER*size.

The following are valid declarations:
```

INTEGER i, j
INTEGER(KIND=2) :: k
INTEGER(2), PARAMETER :: limit=420
! initialize an array, using an array constructor
INTEGER, DIMENSION(4) :: ivec = (/1, 2, 3, 4 /)
! use the slash notation (an HP extension) to initialize
INTEGER i/-1/, j/-2/, k/-7/ ! note, no double colon
! the following declarations are equivalent; the second uses the
! HP length specification extension
INTEGER (KIND = 8) int1
INTEGER*4 int1*8

```

HP Fortran statements
INTENT (statement and attribute)

\section*{INTENT (statement and attribute)}

Specifies the intended use of dummy arguments.

Syntax

Description

A type dedaration statement with the intent attribute is:7
type, attrib-list :: dummy-arg-namelist
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (name), etc.).
attrib-list
is a comma-separated list of attributes including INTENT (intent-spec) and the optional attributes compatible with it, shown below:
DIMENSION OPTIONAL TARGET
intent-spec
is one of IN, OUT, or INOUT. (The form IN OUT is valid.)
dummy-arg-name-list
is a comma-separated list of subprogram dummy arguments to which intent-spec is to apply.
The syntax of the INTENT statement is:
INTENT (intent-spec) [::] dummy-arg-namelist
The INTENT attribute declares whether a dummy argument is intended for transferring a value into a procedure, or out of it, or both. The intent attribute helps detect the use of arguments inconsistent with their intended use, and may also assist the compiler in generating more efficient code.

If a dummy argument has intent In, the procedure must not change it or cause it to become undefined. If the actual argument is defined, this value is passed in as the value of the dummy argument.

If a dummy argument has intent out, the corresponding actual argument must be definable; that is, it cannot be a constant. When execution of the procedure begins, the dummy argument is undefined; thus it must be given a value before it is referenced. The dummy argument need not be given a value by the procedure.
If a dummy argument has intent InOut, the corresponding actual argument must be definable. If the actual argument is defined, this value is passed in as the value of the dummy argument. The dummy argument need not be given a value by the procedure.

The following points should also be noted:
- Intent specifications apply only to dummy arguments and may only appear in the specification part of a subprogram or interface body.
- If there is no intent specified for an argument in a subprogram, the limitations imposed by the actual argument apply to the dummy argument. For example, if the actual argument is an expression that is not a variable, the dummy argument must not redefine its value.
- The intent of a pointer dummy argument must not be specified.
```

! x, y, and z are dummy arguments
SUBROUTINE electric (x, y, z)
REAL, INTENT (IN) :: x, y ! x and y are used only for input
! z is used for input and output
COMPLEX, INTENT (INOUT), TARGET :: z(1000)
SUBROUTINE pressure (true, tape, a, b)
USE a_module
TYPE(ace), INTENT(IN) :: a, b ! a and b are only for input
INTENT (OUT) true, tape ! true and tape are for output
SUBROUTINE lab_ten (degrees, x, y, z)
COMPLEX, INTENT(INOUT) :: degrees
REAL, INTENT(IN), OPTIONAL :: x, y
INTENT(IN) z
PROGRAM pxx
CALL electric (a+1, h*c, d) ! First subroutine defined above
CALL lab_ten (dg, e, f, g+1.0)
END PROGRAM pxx

```

\section*{INTERFACE}

Introduces an interface block.
Syntax

Description

Examples

INTERFACE [generic-spec]
generic-spec
is one of:
- generic-name
- OPERATOR (defined-operator)
- ASSIGNMENT (=)
generic-name
is the name of a generic procedure.
defined-operator
is one of:
- An intrinsic operator
- . operator ., where operator is a user-defined name

The interface statement is the first statement of an interface block. Interface blocks constitute the mechanism by which external procedures may be given explicit interfaces and also provide additional functionality, as described below.

The interface generic-name form defines a generic interface for the procedures in the interface block.

The interface operator (defined-operator) form is used to define a new operator or to extend the meaning of an existing operator.
The INTERFACE ASSIGNMENT (=) form is used to extend the assignment operator so that it can be used (for example) with derived-type objects.

The following examples illustrate different forms of the interface block:
```

! make explicit the interfaces of external function spline
! and external subroutine sp2
INTERFACE
REAL FUNCTION spline(x,y,z)
END FUNCTION spline

```
```

    HP Fortran statements
    INTERFACE
    SUBROUTINE sp2(x,z)
    END SUBROUTINE sp2
    END INTERFACE
! it the generic name g_ave
INTERFACE g_ave
FUNCTION r_ave(x)
! Get the size of x from the module ave_stuff
USE ave_stuff, ONLY: n
REAL r_ave, x(n)
END FUNCTION r_ave
END INTERFACE
! Make the interface of external function b_or explicit, and
use! it to extend the + operator
INTERFACE OPERATOR ( + )
FUNCTION b_or(p,q)
LOGICAL b_or, p, q
INTENT (IN) p, q
END FUNCTION b_or
END INTERFACE

```

Related statements

\section*{INTRINSIC (statement and attribute)}

Identifies an intrinsic procedure.
Syntax

Description The Intrinsic statement and attribute identifies a specific or generic name as that of an intrinsic procedure, enabling it to be used as an actual argument. (Only a specific function name-or a generic name that is the same as the specific name-can be used as an actual argument; see "P rocedure dummy argument" on page 142.) The Intrinsic statement is necessary to inform the compiler that a name is intrinsic and is not the name of a variable. Whenever an intrinsic name is passed as an actual argument and no other appearance of the name in the same scoping unit

HP Fortran statements
INTRINSIC (statement and attribute)
indicates that it is a procedure, it must be specified by the calling program in an INTRINSIC statement, or (if a function name) in a type declaration statement that includes the INTRINS IC attribute.

Each name can appear only once in an INTRINSIC statement and in at most one INTRINSIC statement within the same scoping unit. Also, a name cannot appear in both an EXTERNAL and an INTRINSIC statement within the same scoping unit.
```

Examples
Related statements

```
```

\section*{LOGICAL}

Declares entities of type logical.
Syntax
LOGICAL [kind-spec] [[, attrib-list] ::] entity-list
kind-spec
specifies the size of the logical entity in bytes. kind-spec takes the form:
([KIND=] kind-param)
where kind-param can be a named constant or a constant expression that has the integer value of 1,2 , 4 , or 8 . The size of the default type is 4 .

As an extension, kind-spec can take the form:
*len-param
where len-param is the integer \(1,2,4\), or 8 (default \(=\) 4).
attrib-list
is a list of one or more of the following attributes, separated by commas:
\begin{tabular}{|lll|}
\hline ALLOCATABLE & INTRINSIC & PRIVATE \\
DIMENSION & OPTIONAL & PUBLIC \\
EXTERNAL & PARAMETER & SAVE \\
INTENT & POINTER & TARGET \\
\hline
\end{tabular}

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.

HP Fortran statements
LOGICAL
entity-list
is a list of entities, separated by commas. Each entity takes the form:
```

name [(array-spec)] [= initialization-expr]

```
where:
name
is the name of a variable or function
array-spec
is a comma-separated list of dimension bounds
initialization-expr
is a logical constant expression. If initialization-expr is present, entity-list must be preceded by the double colon.

Description

Examples

HP Fortran statements
MAP (extension)

\section*{MAP (extension)}

Defines a union within a structure.
Syntax

Description
The MAP statement is an HP compatibility extension that is used with the UNION statement to define a union within a structure. For detailed information about the MAP and UNION statements, see "STRUCTURE (extension)" on page 437.

\section*{MODULE}

Introduces a module.
Syntax

\section*{Description}

Examples
module modulename
modulename
is a unique module name.
Modules are nonexecutable program units that can contain type definitions, object declarations, procedure definitions (module procedures), external procedure interfaces, user-defined generic names, and user-defined operators and assignments. Any such definitions not specified to be private to the module containing them are available to those program units that specify the module in a USE statement. Modules provide a convenient sharing and encapsulation mechanism for data, types, procedures, and procedure interfaces.
```

! Make data objects and a data type sharable via a module
MODULE shared
COMPLEX gtx (100, 6)
REAL, ALLOCATABLE :: y(:), z(:,:)
TYPE peak_item
REAL peak_val, energy
TYPE(peak_item), POINTER :: next
END TYPE peak_item
END MODULE shared
! Define a data abstraction for rational arithmetic via a module
MODULE rational_arithmetic
TYPE rational
PRIVATE
INTEGER numerator, denominator
END TYPE rational ! Generic extension of =
INTERFACE ASSIGNMENT (=)
MODULE PROCEDURE eqrr, eqri, eqir
END INTERFACE
INTERFACE OPERATOR (+) ! Generic extension of +
MODULE PROCEDURE addrr, addri, addir
END INTERFACE
CONTAINS
FUNCTION eqrr (. . .) ! A specific definition of =
FUNCTION addrr (. . .) ! A specific definition of +
...
END MODULE rational_arithmetic

```

HP Fortran statements
MODULE

Related statements CONTAINS, END, PRIVATE, PUBLIC, and USE
Related concepts For more information about modules, see "Modules" on page 161.

\section*{MODULE PROCEDURE}

Specifies module procedures in a generic interface.
\begin{tabular}{ll} 
Syntax & \begin{tabular}{l} 
Module Procedure moduleprocedurenamelist \\
moduleprocedure-name-list \\
is a comma-separated list of moduleprocedurenames.
\end{tabular}
\end{tabular}

Description A module procedure statement appears within an interface block. It is used when the specification is generic and a specific procedure is defined within the module rather than as an external procedure. The module PROCEDURE Statement only names the subprograms; it does not contain the definition of the interface. The named subprograms must be defined within the current module or within another module that is accessible by use association.

\section*{Examples}
```

MODULE path
! module data environment; module procedures contained in this
! module have access to this data environment
REAL x, y, z
! Generic name substance for procedures air and water
INTERFACE substance
MODULE PROCEDURE air, water
END INTERFACE
INTERFACE OPERATOR (*)
MODULE PROCEDURE rational_multiply
END INTERFACE
...
! Module procedures are preceded by CONTAINS
CONTAINS
SUBROUTINE air (contents)
END SUBROUTINE air
SUBROUTINE water (x, a, z)
! x is a dummy argument, y is from the module data
! environment
a = x + y
END SUBROUTINE water
FUNCTION rational_multiply (x, y)
TYPE (rational) :: rational_multiply
TYPE (rational), INTENT (IN) :: x, y
rational_multiply = ...
...
END FUNCTION rational_multiply
END MODULE path

```

Related concepts For information about module procedures, see "Module program unit" on page 161.

\section*{NAMELIST}

Names a group of variables for I/O processing.
Syntax
NAMELIST /group-name/var-list [ [ , ]/group-name/var-list ]...
group-name
is a unique namelist group name.
var-list
is a comma-separated list of scal ar and array variable names.
Description
The nAmelist statement declares var-list as a namelist group and associates the group with group-name

Variables appearing in var-list may be of any type, including objects of derived types or their components, saved variables, variables on the local stack, and subroutine parameters. The following, however, are not allowed:
- Record or composite references
- Pointers or their targets
- Automatic objects
- Allocatable array
- Character substrings
- Assumed-size array parameters
- Adjustable-size array parameters
- Assumed-size character parameters
- Individual components of a derived type object

The var-list explicitly defines which items may be read or written in a namelist-directed I/O statement. It is not necessary for every item in varlist to be defined in namelist-directed input, but every input item must belong to the namelist group. The order of items in var-list determines the order of the values written in namelist-directed output.

HP Fortran statements
NAMELIST

More than one NAMELIST statement with the same group-name may appear within the same scoping unit. Each successive var-list in multiple NAMELIST statements with the same group-name is treated as a continuation of the list for group-name

The same variable name may appear in different NAMELIST statements within the same scoping unit.
```

Examples

```
```

PROGRAM

```
PROGRAM
    INTEGER i, j(10)
    INTEGER i, j(10)
    CHARACTER*10 C
    CHARACTER*10 C
    NAMELIST /n1/ i, j, c
    NAMELIST /n1/ i, j, c
    ! Define the namelist group n1
    ! Define the namelist group n1
    READ (UNIT=5,NML=n1)
    READ (UNIT=5,NML=n1)
    WRITE (6, n1)
    WRITE (6, n1)
END
END
When this program is compiled and executed with the following input record:
```

```
\&n1
```

\&n1
$j(8)=6,7,8$
$j(8)=6,7,8$
i $=5 \mathrm{c}=$ 'xxxxxxxxx'
i $=5 \mathrm{c}=$ 'xxxxxxxxx'
$j=5 * 0,-1,2$
$j=5 * 0,-1,2$
$c(2: 6)=$ 'abcde'
$c(2: 6)=$ 'abcde'
/
/
its output is:

```

```

ACCEPT, OPEN, INQUIRE, PRINT, READ, and WRITE
Namelist-directed I/O is described in "N amelist-directed I/O" on page 183.

```

\section*{NULLIFY}

Disassociates a pointer from a target.
Syntax nullify (pointer-object-list)
pointer-object-list
is a comma-separated list of variable names and derived-type components.

Description The nULLIFY statement disassociates a pointer from any target. A nULLIFY statement is also used to change the status of a pointer from undefined to disassociated.

Examples
The following example shows the declaration and use of a variable with the pointer attribute:
```

REAL, TARGET :: value ! value can be target
REAL, POINTER :: pt ! for the pointer
pt.pt => value ! Associate pt with value
NULLIFY (pt) ! Disassociate pt
! ASSOCIATED intrinsic is valid in next statement if (and only
! if) pt has been previously allocated, assigned (as above), or
! nullified (as above)
IF (.NOT.ASSOCIATED(pt)) pt => x

```

The next example shows how a derived type can be used in list processing applications:
```

TYPE list_node
INTEGER value
TYPE (list_node), POINTER : : next
END TYPE list_node
TYPE (list_node), POINTER : : list
ALLOCATE (list) ! Create new list node
list % value = 28 ! Initialize data field
NULLIFY (list % next) ! Nullify pointer to the next node

```

Related statements ALLOCATE, DEALLOCATE, POINTER, and TARGET
Related concepts
For information about pointers, see "Pointers" on page 47.

HP Fortran statements
ON (extension)

\section*{ON (extension)}

Specifies the action to take when program execution is interrupted.
Syntax ON interrupt-condition action
interrupt-condition
is the interrupt to be handled, either an arithmetic error or a keyboard interrupt.
action
is one of the following:
- CALL trap-routine
- ABORT
- IGNORE
where:
trap-routine
is an external subroutine name.

Description The on statement is an HP extension. It is an executable statement that specifies the action to be taken after the occurrence of an exception that interrupts program execution.

For each interrupt-condition, you can specify one of the following actions:
- CALL: specifies a subroutine to be called.
- ABORT: causes the program to abort.
- IGNORE: causes the interrupt to be ignored.

Table 51 lists the range of values for interrupt-condition. The first column identifies the type of trap; the second gives the keywords that must appear on the on statement, immediately following the word on; and the third column gives equivalent keywords you can specify instead of those in the second column. For example, the following on statement causes the program to trap an attempt to divide by zero with 8-byte floating-point operands, passing control to a user-written trap handler called div_zero_trap:

ON REAL (8) DIV 0 CALL trap_div_by_zero
The following on statement does the same thing, but it specifies the equivalent keywords from the third column of the table:

ON DOUBLE PRECISION DIV 0 CALL trap_div_by_zero
Table 51
Exceptions handled by the ON statement
\begin{tabular}{|c|c|c|}
\hline Exceptions & Exception keywords & Alternate keywords \\
\hline \multirow[t]{5}{*}{Division by zero} & REAL (4) DIV 0 & REAL DIV 0 \\
\hline & REAL (8) DIV 0 & DOUBLE PRECISION DIV 0 \\
\hline & REAL (16) DIV 0 & (none) \\
\hline & INTEGER(2) DIV 0 & INTEGER*2 DIV 0 \\
\hline & INTEGER (4) DIV 0 & INTEGER DIV 0 \\
\hline \multirow[t]{5}{*}{Overflow} & REAL (4) OVERFLOW & REAL OVERFLOW \\
\hline & REAL (8) OVERFLOW & DOUBLE PRECISION OVERFLOW \\
\hline & REAL (16) OVERFLOW & (none) \\
\hline & INTEGER(2) OVERFLOW & INTEGER*2 OVERFLOW \\
\hline & INTEGER(4) OVERFLOW & INTEGER OVERFLOW \\
\hline \multirow[t]{3}{*}{U nderflow} & REAL (4) UNDERFLOW & REAL UNDERFLOW \\
\hline & REAL (8) UNDERFLOW & DOUBLE PRECISION UNDERFLOW \\
\hline & REAL (16) UNDERFLOW & (none) \\
\hline \multirow[t]{3}{*}{I nvalid (illegal) operation} & REAL (4) ILLEGAL & REAL ILLEGAL \\
\hline & REAL (8) ILLEGAL & DOUBLE PRECISION ILLEGAL \\
\hline & REAL (16) ILLEGAL & (none) \\
\hline \multirow[t]{3}{*}{I nexact result} & REAL (16) INEXACT & (none) \\
\hline & REAL (4) INEXACT & REAL INEXACT \\
\hline & REAL (8) INEXACT & DOUBLE PRECISION INEXACT \\
\hline Control-C & CONTROLC & (none) \\
\hline
\end{tabular}

HP Fortran statements
ON (extension)

To use the on statement to trap for integer overflow, you must also include the \$HP \$ CHECK_OVERFLOW directive. This is described in the HP Fortran Programmer's Guide.
Using the on statement at optimization levels 2 and above is restricted. When compiling at optimization level 2 or above, the optimizer makes assumptions about the program that do not take into account the behavior of procedures called by the on statement. Such procedures must therefore be "well-behaved"-in particular, they must meet the following criteria:
- The ON procedure must not assume that any variable in the interrupted procedure or in its caller has its current value. (The optimizer may have placed the variable in a register to be stored there until after the call to the interrupted procedure is complete.)
- The ON procedure must not change the value of any variable in the interrupted procedure or in its caller if the effect of the ON procedure is to return program control to the point of interrupt.
```

NOTE
Examples
Related concepts
If you include the ON statement in a program that is compiled at optimization level 2 or higher and the program takes an exception, the results may vary from those you would get from the unoptimized program or from the same program without the ON statement.
The following example uses the on statement to call the procedure trap_div_by_zero if the function do_div is passed 0 in argument $y$. If trap_div_by_zero is called, it prints an error message and assigns 0 to the result.

```
```

REAL FUNCTION do_div(x, y)

```
REAL FUNCTION do_div(x, y)
    REAL :: x, y
    REAL :: x, y
    ON REAL DIV O CALL trap
    ON REAL DIV O CALL trap
    do_div = x/y ! causes an interrupt if y = 0
    do_div = x/y ! causes an interrupt if y = 0
    RETURN
    RETURN
END FUNCTION do_div
END FUNCTION do_div
SUBROUTINE trap(res)
SUBROUTINE trap(res)
    REAL :: res
    REAL :: res
    PRINT *, "Don't do that."
    PRINT *, "Don't do that."
    res = 0
    res = 0
END SUBROUTINE trap
END SUBROUTINE trap
Related concepts The HP Fortran Programmer's Guide provides detailed information about using the on statement, including example programs that use the on statement.
```

## OPEN

Connects file to a unit.
Syntax open (io-specifie-list)
io-specifier-list
is a list of the following comma-separated I/O specifiers:
[UNIT=]unit
specifies the unit to connect to an external file. unit must be an integer expression that evaluates to a number greater than 0. If the optional keyword UNIT= is omitted, unit must be the first item in io-specifierlist.

## ACCESS=character-expression

specifies the method of file access. character-expression can be one of the following arguments:
'DIRECT' Open file for direct access.
'SEQUENTIAL' Open file for sequential access (default).
' POSITION= To open a file for append (to APPEND' position the file just before the end-of-file record)

HP Fortran statements
OPEN

## ACTION=character-expression

specifies the allowed data-transfer operations. character-expression can be one of the following arguments:

| 'READ' | Do not allow WRITE and <br> ENDFILE statements. |
| :--- | :--- |
| 'WRITE' | Do not allow READ statements. |
| 'READWRITE' | Allow any data transfer <br> statement (default). |

BLANK=character-expression
specifies treatment of blanks within numeric data on input. This specifier is applicable to formatted input only. character-expression can be one of the following arguments:

| 'NULL' | Ignore blanks (default). |
| :--- | :--- |
| 'ZERO' | Substitute zeroes for blanks. |

## DELIM=character-expression

specifies the delimiter to use (if any) when delimiting character constants in list-directed and namelistdirected formatting. This specifier is applicable to formatted output only. character-expression can be one of the following arguments:

| 'APOSTROPHE ' | Use the apostrophe to delimit <br> character constants in list- <br> directed and namelist-directed <br> formatting. |
| :---: | :--- |
| 'QUOTE' | Use double-quotation marks to <br> delimit character constants in <br> list-directed and namelist- <br> directed formatting. |
| 'NONE ' | Use no delimiter to delimit <br> character constants in list- <br> directed and namelist-directed <br> formatting (default). |

ERR=stmt-labe
specifies the label of the executable statement to which control passes if an error occurs during statement execution.

FILE=character-expression
specifies the name of the file to be connected to unit. character-expression can also be the ASCII
representation of a device file. If this specifier does not appear in the OPEN statement, a temporary scratch file is created.

HP Fortran statements
OPEN

## FORM=character-expression

specifies whether the file is connected for formatted or unformatted I/O. character-expression can be one of the following arguments:

| 'FORMATTED' | Specify formatted I/O. If the file <br> is to be opened for sequential <br> access, this is the default. |
| :--- | :--- |
| 'UNFORMATTED' | Specify unformatted I/O. If the <br> file is to be opened for direct <br> access, this is the default. |

## IOSTAT=integer-variable

returns the I/O status after the statement executes. If the statement successfully executes, integer-variable is set to zero. If an error occurs, it is set to a positive integer that indicates which error occurred.

```
PAD=character-expression
```

specifies whether or not to pad the input record with blanks if the record contains fewer characters than required by the format specification. This specifier is applicable to formatted input only. character-expression can be one of the following arguments:

| 'YES' | Pad input records with blanks <br> (if necessary) to fill it out to <br> length required by format <br> specification (default). |
| :--- | :--- |
| 'NO' $^{\prime}$ | Do not pad input record with <br> blanks if it is not as long as <br> record specified by format <br> specification. |

## POSITION=character-expression

specifies the position of an existing file to be opened for sequential access. character-expression can be one of the following arguments:

| 'ASIS' | Leave file position unchanged <br> (default). |
| :--- | :--- |
| 'REWIND' | Position the file at its start. |
| 'APPEND' | Position the file just before the <br> end-of-file record. |

If the file to be opened does not exist, this specifier is ignored. New files are always positioned at their start.

RECL=integer-expression
specifies the length of each record in a file to be opened for direct access. The length is measured in characters (bytes). This specifier must be present when a file is opened for direct access and is ignored if file is opened for sequential access.

HP Fortran statements
OPEN

STATUS=character-expression
specifies the state of the file when it is opened. character-expression can be one of the following arguments:

| 'OLD' | Open an existing file. FILE= must also be specified and the named file must exist. |
| :---: | :---: |
| 'NEW' | Create a new file. FILE= must also be specified and the named file must not exist. |
| 'UNKNOWN ' | If the file named in FILE= exists, open it with the status of old; if it does not exist, open it with the status of NEW. This is the default status. |
| 'REPLACE ' | If the file does not exist, create it with a status of OLD; if it does exist, delete it and open it with a status of NEW. If STATUS='REPLACE' is specified, FILE= must also be specified. |
| 'SCRATCH ${ }^{\prime}$ | Create a scratch file. FILE= specifier must not be specified. For information about scratch files, see "Scratch files" on page 173. |

The OPEn statement connects a unit to a file so that data can be read from or written to that file. Once a file is connected to a unit, the unit can be referenced by any program unit in the program.
I/O specifiers do not have to appear in any specific order in the OPEN statement. However, if the optional keyword UNIT= is omitted, unit must be the first item in the list.

Only one unit can be connected to a file at a time. That is, the same file cannot be connected to two different units. Attempting to open a file that is connected to a different unit will produce undefined results.

However, multiple OPENS can be performed on the same unit. In other words, if a unit is connected to a file that exists, it is permissible to execute another OPEN statement for the same unit. If FILE= specifies a different file, the previously opened file is automatically closed before the second file is connected to the unit. If FILE= specifies the same file, the file remains connected in the same position; the values of the BLANK=, DELIM=, PAD=, ERR=, and IOSTAT= specifiers can be changed, but attempts to change the values of any of the other specifiers will be ignored.

## Examples

The following examples illustrate different uses of the OPEN statement.

## Opening a file for sequential access

The following open statement connects the existing file inv to unit 10 and opens it (by default) for sequential access. Only READ statements are permitted to perform data transfers. If an error occurs, control passes to the executable statement labeled 100 and the error code is placed in the variable ios:

```
OPEN(10, FILE='inv', ERR=100, IOSTAT=iOs, &
    ACTION='READ', STATUS='OLD')
```

Opening a file for direct access
The following OPEN statement opens the file whose name is contained in the variable next 1, connecting it to unit 4 as a formatted, direct-access file with a record length of 50 characters:

```
OPEN(ACCESS="DIRECT", UNIT=4, RECL=50, &
    FORM="FORMATTED", FILE=next1)
```

## Opening a device for I/O transfers

The next example connects the system device / dev/console to unit 6; all data transfers that specify unit 6 will go to this device:

```
OPEN(6,FILE='/DEV/CONSOLE')
```

HP Fortran statements
OPEN

## Opening a scratch file

The following two OPEN statements produce the same results: open a scratch file that is connected to unit 19 (if the FILE=name specifier had appeared in the first statement, the named file would have been opened instead):

```
OPEN (UNIT=19)
OPEN (UNIT=19, STATUS="SCRATCH")
```

## I/O specifiers in an OPEN statement

Because the l/O specifiers that can be used in an OPEN statement do not have to appear in any specific order, the following three OP EN statements are all equivalent:

```
OPEN(UNIT=3, STATUS='NEW', FILE='OUT.DAT')
OPEN(3, STATUS='NEW', FILE='OUT.DAT')
OPEN(STATUS='NEW', FILE='OUT.DAT', UNIT=3)
```

Note, however, that in the second open statement the number 3 must appear first because of the omission of the optional keyword UNIT=. Thus, the following OPEN statement is illegal:

```
OPEN(STATUS='NEW', 3, FILE='OUT.DAT') ! illegal
```

Related statements

Related concepts

CLOSE, INQUIRE, READ, and WRITE

For information about I/O concepts and examples of programs that perform I/O, see Chapter 8, "I/O and file handling," on page 171. For information about I/O formatting, see Chapter 9, "I/O formatting," on page 205.

## OPTIONAL (statement and attribute)

Identifies optional arguments for procedures.
Syntax
The syntax of the type dedaration statement with the OPTIONAL attribute is:
type , attrib-list :: dummy-argument-namelist
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE ( name), etc.).
attrib-list
is a comma-separated list of attributes including OPTIONAL and optionally those attributes compatible with it, namely:

| DIMENSION | INTENT | TARGET |
| :--- | :--- | :--- |
| EXTERNAL | POINTER | VOLATILE |

dummy-argument-namelist
is a comma-separated list of dummy-argument-names.
The syntax of the OPTIONAL statement is:
OPTIONAL [::] dummy-argument-namelist
Description If a dummy argument has the OPTIONAL attribute, the corresponding actual argument need not appear in a procedure reference. In cases where there are arguments that generally do not change from one reference to another, it is convenient to specify that the arguments are optional and provide default values for them. They can then be omitted from references in these general cases. The presence of an optional argument in a procedure may be determined by using the PRESENT intrinsic function.

Many uses of the Entry statement in FORTRAN 77 programs can be replaced by the use of optional arguments.
The following restrictions apply to the use of the OPTIONAL attribute:

HP Fortran statements
OPTIONAL (statement and attribute)

- The OPTIONAL attribute may be specified only for dummy arguments. It may occur in a subprogram and in any corresponding interface body.
- An optional dummy argument whose actual argument is not present may not be referenced or defined (or invoked if it is a dummy procedure), except that it may be passed to another procedure as an optional argument and will be considered not present.
- When an argument is omitted in a procedure reference, all arguments that follow it must use the keyword form.
- If a procedure has an optional argument, the procedure interface must be explicit.

## Examples

The following are two examples of the OPTIONAL statement. In the first example, the call to the subroutine trip can legally omit the path argument because it has the OPTIONAL attribute:

```
CALL TRIP ( distance = 17.0 ) ! path is omitted
SUBROUTINE trip ( distance, path )
    OPTIONAL distance, path
```

In the next example, the subroutine plot uses the present function to determine whether or not to execute code that depends on the presence of arguments that have the OPTIONAL attribute:

```
SUBROUTINE plot (pts, o_xaxis, o_yaxis, smooth)
    TYPE (point) pts
    REAL, OPTIONAL :: o_xaxis, o_yaxis
    ! Origin - default (0.,0.)
    LOGICAL, OPTIONAL :: smooth
    REAL Ox, OY
    IF (PRESENT (o_xaxis)) THEN
        ox = O_xaxis
    ELSE
        ox = 0.
    ! Note that the o_xaxis dummy argument cannot be referenced if
    ! the actual argument is not present. The same applies
    ! to o_yaxis (below).
    END IF
    IF (PRESENT (o_yaxis)) THEN
        oy = o_yaxis
    ELSE
        oy = 0.
    END IF
    IF (PRESENT(smooth)) THEN
            IF (smooth) THEN
                ! Smooth algorithm
                RETURN
            END IF
    END IF
```

HP Fortran statements

```
END SUBROUTINE plot
! Some valid calls to plot.
CALL plot (points)
CALL plot (observed, o_xaxis = 100., o_yaxis = 1000.)
CALL plot (random_pts, smooth = .TRUE.)
```

- The description of the PRESENT intrinsic in Chapter 11, "Intrinsic procedures," on page 475

HP Fortran statements
OPTIONS (extension)

## OPTIONS (extension)

Lowers the optimization level used by the HP Fortran compiler.
Syntax

Description

Examples In the following example, the first OPTIONS statement optimizes the subroutine go_fast at optimization level 3. The second OPTIONS statement lowers the optimization level to 2.

```
OPTIONS +O3
SUBROUTINE go_fast
END SUBROUTINE go_fast
OPTIONS +O2
SUBROUTINE not_so_fast
END SUBROUTINE not_so_fast
```

## PARAMETER (statement and attribute)

Defines a named constant.
Syntax A type declaration statement with the PARAMETER attribute is:
type, attrib-list :: cnamel = cexpr1[, cname2 = cexpr2]...
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (name), etc.).
attrib-list
is a comma-separated list of attributes including PARAMETER and optionally those attributes compatible with it, namely:

| DIMENSION | PUBLIC |
| :--- | :--- |
| PRIVATE | SAVE |

Specifying the SAVE attribute in a PARAMETER statement has no effect.
cname
is the name that will represent the constant.
cexpr
is an initialization expression that evaluates to the constant represented by cname. In the case of an array constant, cexpr must be an array constructor. In the case of a derived type constant, cexpr must be a structure constructor.
The syntax of the PARAMETER statement is:
PARAMETER (cnamel $=$ cexpr1 [, cname2 $=$ cexpr2]...)

HP Fortran statements
PARAMETER (statement and attribute)

Description
The PARAMETER statement associates a symbolic name with a constant. A symbolic name defined in a PARAMETER statement is known as a named constant. A named constant must not become defined more than once in a program unit. Once defined, it can be used only as a named constant. This means that a named constant cannot be assigned a valuelike a variable.

When the PARAMETER attribute is used, the value of the named constant must be provided by the initialization part of the statement in which the PARAMETER attribute appears.

The type of a named constant is determined by the implicit typing rules, unless its type is specified by a type declaration statement prior to its first appearance in a PARAMETER statement or by a type declaration statement that includes PARAMETER as one of its attributes. If a PARAMETER statement declares and implicitly types a named constant, the named constant may appear in a subsequent type declaration or IMPLICIT statement, but only to confirm the type of the named constant.

When the type of the symbolic name and the constant do not agree, the value of the named constant is assigned in accordance with assignment statement type-conversion rules, as given in Table 14.

The following rules apply to type agreement between the constant and the symbol ic name:

- If cnameis of numeric type, cexpr must be an arithmetic constant expression.
- If cname is of type character, the corresponding cexpr must be a character constant expression.
- If cname is of type logical, the corresponding cexpr may be either an arithmetic or logical constant expression.

Any symbolic name of a constant that appears in cexpr must have been defined previously in the same or a different PARAMETER statement in the same program unit. For example, the expression in the second PARAMETER statement below is built from the expression in the first PARAMETER statement, and is legal:

```
PARAMETER (limit = 1000)
PARAMETER (limit_plus_1 = limit + 1)
```

The logical operators(.EQ., .NE., .LT., .LE., .GT., and .GE.), as well as the following intrinsic functions, can appear in the PARAMETER statement:

| ABS | IAND | IXOR | MAX |
| :--- | :--- | :--- | :--- |
| CHAR | ICHAR | LEN | MIN |
| CMPLX | IEOR | LGE | MOD |
| CONJB | IMAG | LGT | NINT |
| DIM | IOR | LLE | NOT |
| DPROD | ISHFT | LLT |  |

If these intrinsic functions are used in a PARAME TER statement, their arguments must be constants.

If the named constant is of type character and its length is not specified, the length must be specified in a type declaration statement or IMP LICIT statement prior to the first appearance of the named constant. Its type and/or length must not be changed by subsequent statements, including IMP LICIT statements. If a symbolic name of type ChARACTER* (*) is defined in a PARAMETER statement, its length becomes the length of the expression assigned to it.
If the named constant is an array, the bounds must be explicit and determined by an initialization expression.
Once such a symbolic name is defined, that name can appear in any subsequent statement of the defining program unit as a constant in an expression or DATA statement.

```
Examples
! PARAMETER used in a type declaration statement as an attribute
REAL, DIMENSION(4), PARAMETER :: const = &
    (/1.2, 1.45, 0.9, 24.3/)
INTEGER year
! PARAMETER used as a statement
PARAMETER year = 1996
! Type declaration statement declaring a derived-type constant
TYPE (postal_info), PARAMETER :: package = &
    postal_info (9.5, (/10.0, 5.5, 2.25/) )
```

HP Fortran statements
PARAMETER (statement and attribute)

Related concepts For information about the type declaration statement, see "Type declaration for intrinsic types" on page 24.

## PAUSE

Temporarily stops program execution.

Syntax

Description

PAUSE pausecode
pausecode
is a character constant or a list of up to 5 digits.
The PAUSE statement suspends program execution and prints a message, depending on whether digits, characters, or nothing has been specified in the PAUSE statement:

- If digits, the message "PAUSE digits" is written to standard error.
- If a character expression, the message "PAUSE character-expression" is written to standard error.
- If nothing appears after PAUSE, the word "PAUSE" is written to standard error.
After displaying the appropriate message, the PAUSE statement writes to standard output one of two messages that give information on resuming the program. If the standard input device is a terminal, the message is:

```
To resume program execution, type GO.
```

At this point the program is suspended and remains so until the operator types the word GO and presses the Return key. The program will terminate if anything other than GO is entered.
If the standard input device is other than a terminal, the message is:
To resume execution, execute a kill -15 pid \&
command
where pid is the unique process identification number of the suspended program. This command can be issued at any terminal at which the user is logged in.

HP Fortran statements
PAUSE

| Examples | ! Write "PAUSE 7777 " to standard error <br> PAUSE 7777 |
| :--- | :--- |
| ! Write "PAUSE MOUNT TAPE" to standard error <br> PAUSE 'MOUNT TAPE' |  |
| ! Write "PAUSE" to standard error |  |
| PAUSE |  |

## POINTER (Cray-style extension)

Declares Cray-style pointers and their objects.
Syntax POINTER (pointer1, pointee1) [, (pointer2, pointe2)]...
pointer
is a pointer.
pointe
is a variable name or array declarator.

Description
HP Fortran supports both the standard Fortran 90 POINTER statement as well as the Cray-style POINTER statement. The Cray-style POINTER statement is supported for compatibility with older, F ORTRAN 77 programs. The following information applies only to the Cray-style POINTER statement; the Fortran 90 POINTER statement is described in "POINTER (statement and attribute)" on page 400.
The following restrictions apply to pointer:

- It should be of type Integer (4). If it is not, the compiler interprets its type as Integer (4) regardless of other implicit or explicit type declarations.
- It cannot be declared of any other data type.
- Another pointer cannot point to it.
- It cannot appear in a PARAMETER or DATA statement.
- It cannot be in a derived type object.

You can increase the size of pointer with the +autodbl or +autodbl4 option; see "Option Descriptions" on page 576.
pointee may be of any type, including an array, a derived type, a record, or a character string.
The following restrictions apply to pointee:

- It cannot be a dummy argument, function name, function value, common block element, automatic object, generic interface block name, or derived type.

HP Fortran statements
POINTER (Cray-style extension)

- It cannot be used in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement.
- It cannot have any of the following attributes: ALLOCATABLE, EXTERNAL, INTENT, INTRINSIC, OPTIONAL, PARAMETER, POINTER, SAVE, and target.
- Pointees that are arrays with nonconstant bounds can be used only in subroutines and functions, not in main programs.
- Variables used in an array-bound expression that appears in a POINTER statement must be either subprogram formal arguments or common block variables. The value of the expression cannot change after subprogram entry.
You associate memory with a pointer by assigning it the address of an object. Typically, this is done with the libu77 function, LOC. The LOC function returns the address of its argument, which can be assigned to a pointer. The following example assigns 0 to the pointee i:

```
INTEGER i, j
POINTER (p, i)
p = LOC(j)
j = 0
```

You can also use the MALLOC intrinsic to allocate memory from the heap and assign its return value to a pointer. Once you are done with the allocated memory, you should use the FREE intrinsic to rel ease the memory so that it is available for reuse.

If you are using the pointer to manipulate a device that resides at a fixed address, you can assign the address to the pointer, using either an integer constant or integer expression.

Under certain circumstances, Cray-style pointers can cause erratic program behavior-especially if the program has been optimized. To ensure correct behavior, observe the following:

- Subroutines and functions must not save the address of any of their arguments between calls.
- A function must not return the address of any of its arguments.
- Only those variables whose addresses are explicitly taken with the LOC function must be referenced through a pointer.

```
Examples
```

Related statements

Related concepts For related information, see the following:

- "Pointers" on page 47
- The description of the LOC routine in Table 64
- The descriptions of the malloc and FREE intrinsics in Chapter 11, "Intrinsic procedures," on page 475

HP Fortran statements
POINTER (statement and attribute)

## POINTER (statement and attribute)

Specifies variables with the POINTER attribute.
Syntax

| DIMENSION | PRIVATE | SAVE |
| :--- | :--- | :--- |
| OPTIONAL | PUBLIC |  |

dummy-argument-name-list
is a comma-separated list of dummy-argument-names.
The syntax of the pointer statement is:
POINTER [::] object-name [(deferred-shape-spec-list)]
[, object-name [(deferred-shape-spec-list) ] ] . . .
object-name
is a data object or function result.
deferred-shapespec-list
is a comma-separated list of colons.
Description A pointer attribute or statement specifies that the named variables may be pointers to some target object. Pointers provide a capability for creating dynamic objects, such as dynamic-sized arrays and linked lists. An object with a pointer attribute initially has no space reserved for its target. A pointer is assigned space for its target when an ALLOCATE statement is executed or when it is assigned to point to a target using a pointer assignment statement.

Examples In the first example, two array pointers are declared and used.

```
! Extents are not specified; they are determined during execution
REAL, POINTER :: weight (:,:,:)
REAL, POINTER :: w_reg (:,:,:)
READ *, i, j, k
ALLOCATE (weight (i, j, k)) ! create weight
! w_reg is an alias for an array section
w_reg => weight (3:i-2, 3:j-2, 3:k-2)
avg_w = sum (w_reg) / ((i-4) * (j-4) * (k-4))
DEALLOCATE (weight) ! weight no longer needed
```

The next example illustrates the use of pointers in a list-processing application.

```
TYPE link
    REAL value
    TYPE (link), POINTER :: next
END TYPE link
TYPE(link), POINTER :: list, save_list
NULLIFY (list) ! Initialize list
DO
    READ (*, *, IOSTAT = no_more) value
    IF (no_more /= 0) EXIT
    save_list => list
    ALLOCATE (list) ! Add link to head of list
    list % value = value
    list % next => save_list
END DO
! Linked list removed when no longer needed
DO
    IF (.NOT.ASSOCIATED (list) ) EXIT
    save_list => list % next
    DEALLOCATE (list)
    list => save_list
END DO
```

HP Fortran statements
PRINT

## PRINT

Writes to standard output.

Syntax

Description

The syntax of the PRINT statement can take one of two forms:

- Formatted and list-directed syntax:

PRINT format [, output-list ]

- Namelist-directed syntax:

PRINT name
format
is one of the following:

- An asterisk (*), specifying list-directed I/O.
- The label of a FORMAT statement containing the format specification.
- An integer variable that has been assigned the label of a FORMAT statement.
- An embedded format specification.
name
is the name of a namelist group, as previously defined by a NAMELIST statement. Using the namelist-directed syntax, the PRINT statement sends data in the namelist group to standard output. To direct output to a connected file, you must use the WRITE statement and include the NML= specifier.
output-list
is a comma-separated list of data items for output. The data items can include expressions and implied-Do lists.

The PRINT statement transfers data from memory to standard output. (U nit 6 is preconnected to the HP-UX standard output.) The PRINT statement can be used to perform formatted, list-directed, and namelistdirected I/O only.
To direct output to a connected file, use the WRITE statement.

## Examples

Related statements
FORMAT and WRITE

HP Fortran statements
PRIVATE (statement and attribute)

## PRIVATE (statement and attribute)

Prevents access to module entities by use association.
Syntax
The syntax of a type declaration statement with the PRIVATE attribute is:
type, attrib-list :: access-id-list
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE ( name), etc.).
attrib-list
is a comma-separated list of attributes including PRIVATE and optionally those attributes compatible with it, namely:

| ALLOCATABLE | INTRINSIC | SAVE |
| :--- | :--- | :--- |
| DIMENSION | PARAMETER | TARGET |
| EXTERNAL | POINTER |  |

access-id-list
is a comma-separated list of one or more of the following:

- constant-name
- variablename
- procedurename
- defined-typename
- namelist-group-name
- operator (operator)
- ASSIGNMENT ( = )

The syntax of the PRIVATE statement is:

```
PRIVATE [[::] access-id-list]
```

Description

Examples

The PRIVATE attribute may appear only in the specification part of a module. The default accessibility in a module is PUBLIC; it can be changed to PRIVATE using a statement without a list. However, only one PRIVATE accessibility statement without a list is permitted in a module.
The PRIVATE attribute in a type statement or in an accessibility statement restricts the accessibility of entities such as module variables, type definitions, functions, and named constants. USE statements may restrict accessibility further.

A derived type may contain a PRIVATE attribute or an internal PRIVATE statement, if it is defined in a module. The internal private statement in a type definition makes the components unavailable outside the module even though the type itself might be available.

The private statement may also be used to restrict access to subroutines, generic specifiers, and namelist groups.
The PRIVATE specification for a generic name, operator, or assignment does not apply to any specific name unless the specific name is the same as the generic name.

```
MODULE fourier
    REAL :: x, y, z ! PUBLIC (default)
    COMPLEX, PRIVATE :: fft ! PRIVATE, accessible only in module
    TYPE (structure_name), PRIVATE :: structure_a, structure_b
    ! a, b and c are accessible only within this module
    PRIVATE a, b, c
        ! r, s, and t are accessible outside the module
    PUBLIC r, s, t
END MODULE fourier
MODULE place
    PRIVATE ! Change default accessibility to PRIVATE
    INTERFACE OPERATOR (.st.)
            MODULE PROCEDURE xst
    END INTERFACE
        ! make .st. public; everything else is private
    PUBLIC OPERATOR (.st.)
    LOGICAL, DIMENSION (100) :: lt
    CHARACTER(20) :: name
    INTEGER ix, iy
END MODULE place
PUBLIC and USE
```

HP Fortran statements
PRIVATE (statement and attribute)

Related concepts For related information, see the following:

- "Type declaration for intrinsic types" on page 24
- "M odules" on page 161

## PROGRAM

Identifies the main program unit.
Syntax

Description The optional PROGRAM statement assigns a name to the main program unit. name does not have to match the main program's filename. However, if the corresponding END PROGRAM statement specifies a name, it must match name.

If the Program statement is specified, it must be the first statement in the main program unit.

Related statements END
Related concepts For information about the main program unit, see "Main program" on page 125 .

HP Fortran statements
PUBLIC (statement and attribute)

## PUBLIC (statement and attribute)

E nables access to module entities by use association.
Syntax
The syntax of a type declaration statement with the PUBLIC attribute is:
type, attrib-list :: access-id-list
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE ( name), etc.).
attrib-list
is a comma-separated list of attributes including PUBLIC and optionally those attributes compatible with it, namely:

| ALLOCATABLE | INTRINSIC | SAVE |
| :--- | :--- | :--- |
| DIMENSION | PARAMETER | TARGET |
| EXTERNAL | POINTER | VOLATILE |

access-id-list
is a comma-separated list of one or more of the following:

- constant-name
- variablename
- procedurename
- defined-typename
- namelist-group-name
- operator (operator)
- ASSIGNMENT ( = )

The syntax of the PUBLIC statement is:

```
PUBLIC [[::] access-id-list]
```

## Description

Examples

Related statements

The PUBLIC attribute may appear only in the specification part of a module. The default accessibility in a module is PUBLIC; it can be reaffirmed using a PUBLIC statement without a list. However, only one PUBLIC accessibility statement without a list is permit ted in a module.
The PUBLIC attribute in a type statement or in an accessibility statement permits access to entities such as module variables, type definitions, functions, and named constants. USE statements may control accessibility further.

A derived type may contain a PUBLIC attribute or an internal PUBLIC statement, if it is defined in a module.

The PUBLIC statement may also be used to permit access to sub routines, generic specifiers, and namelist groups.

The PUBLIC specification for a generic name, operator, or assignment does not apply to any specific name unless the specific name is the same as the generic name.

```
MODULE fourier
    PUBLIC ! PUBLIC unless explicitly PRIVATE
    COMPLEX, PRIVATE :: fft ! fft accessible only in module
    PRIVATE a, b, c ! accessible only in module
    PUBLIC r, s, t ! accessible outside the module
END MODULE fourier
MODULE place
    PRIVATE ! Change default accessibility to PRIVATE
    INTERFACE OPERATOR (.st.)
        MODULE PROCEDURE xst
    END INTERFACE
        ! Make .st. public; everything else is private
    PUBLIC OPERATOR (.st.)
    LOGICAL, DIMENSION (100) :: lt
    CHARACTER(20) :: name
    INTEGER ix, iy
END MODULE PLACE
```

PRIVATE and USE

HP Fortran statements
PUBLIC (statement and attribute)

- "Type declaration for intrinsic types" on page 24
- "M odules" on page 161

## READ

Inputs data from external and internal files.
Syntax
The syntax of the READ statement can take one of the following forms:

- Long form (for use when reading from a connected file):

READ (io-specifier-list) [input-list]

- Short form (for use when reading from standard input):

READ format [, input-list]

- Short namel ist-directed form (for use when reading from standard input into a namelist group):

READ name
io-specifier-list
is a list of the following comma-separated I/O specifiers:
[UNIT=] unit
specifies the unit connected to the input file. unit can be one of the following:

- The name of a character variable, indicating an internal file
- An integer expression that evaluates to the unit connected to an external file
- An asterisk, indicating a pre-connection to unit 5 (standard input)

If the optional keyword UNIT = is omitted, unit must be the first item in io-specifier-list.
[ $\mathrm{FMT}=$ ] format
specifies the format specification for formatting the data. format can be one of the following:

- An asterisk (*), specifying list-directed I/O.
- The label of a FORMAT statement containing the format specification.

HP Fortran statements
READ

- An integer variable that has been assigned the label of a FORMAT statement.
- A character expression that provides the format specification.

If the optional keyword FMT= is omitted, format must be the second item in io-specifier-list.

NOTE
The NML= and FMT = specifier may not both appear in the same io-specifier-list.
[NML=] name
specifies the name of a namelist group for namelistdirected input. name must have been defined in a NAMELIST statement. If the optional keyword NML= is omitted, name must be the second item in the list. The first item must be the unit specifier without the optional keyword UNIT=.
The NML = and FMT = specifier may not both appear in the same io-specifier-list.

ADVANCE=character-expression
specifies whether to use advancing I/O for this statement. character-expression can be one of the following arguments:

| 'YES' | U se advancing formatted <br> sequential I/O (default). |
| :--- | :--- |
| 'NO' | U se nonadvancing formatted <br> sequential I/O. |

If the ADVANCE= specifier appears in io-specifier-list, unit must be connected to an external file opened for formatted sequential I/O. Also, ADVANCE= ' NO ' must be specified if the EOR= or SIZE= specifier appear in the list. N onadvancing I/O is incompatible with listdirected and namelist I/O.

END=stmt-label
specifies the label of the executable statement to which control passes if an end-of-file record is encountered. This specifier is only valid for reading files opened for sequential access.

## EOR=stmt-label

specifies the label of the executable statement to which control passes if an end-of-record condition is encountered. This specifier may appear in io-specifierlist only if ADVANCE= ' NO ' also appears in the list.

## IOSTAT=integer-variable

returns the I/O status after the statement executes. If the statement successfully executes, integer-variable is set to zero. If an end-of-file record is encountered without an error condition, it is set to a negative integer. If an error occurs, integer-variable is set to a positive integer that indicates which error occurred.

REC=integer-expression
specifies the number of the record to be read from a file connected for direct access. This specifier cannot appear in io-specifier-list with the NML=, ADVANCE=, SIZE=, and EOR= specifiers, nor with FMT=* (for listdirected I/O).

## SIZE=integer-variable

returns the number of characters that have been read by this READ statement. This specifier may appear in io-specifier-list only if ADVANCE = ' NO' also appears in thelist.
input-list
is a comma-separated list of data items for input. The data items can include variables and implied-Do lists.

HP Fortran statements
READ
format
is one of the following:

- An asterisk (*), specifying list-di rected I/O.
- The label of a FORMAT statement containing the format specification.
- An integer variable that has been assigned the label of a FORMAT statement.
- An embedded format specification.
name
is the name of a namelist group, as previously defined by a NAMELIST statement. Using the namelist-directed syntax, the READ statement takes its input from standard input. To read from a connected file, you must use the NML= specifier with the full syntax form, as described below.

Description The READ statement transfers data from an external or internal file to internal storage. An external file can be opened for sequential access or direct access. If it is opened for sequential access, the READ statement can perform the following types of I/O:

- Formatted
- Unformatted
- List-directed
- Namelist-directed

If the file is opened for direct access, the READ statement can perform formatted or unformatted I/O.

READ statements operating on internal files can perform formatted or list-directed I/O.

The following examples illustrate different uses of the READ statement.

## Formatted sequential I/O

The following READ statement reads 10 formatted records from a file opened for sequential access, using an implied-Do list to read the data into the array x_array. If the end-of-file record is encountered before the array is filled, execution control passes to the statement at label 99.

```
READ (41, '(F10.2)', END=99) (x_array(i),i=1,10)
```

## Nonadvancing I/O

The following READ statement takes its input from a file that was opened for sequential access and is connected to unit 9. It uses nonadvancing I/O to read an integer into the variable key. If the statement encounters the end-of-record condition before it can complete execution, control will pass to the executable statement at label 100. After the statement executes, the number of characters that have been read will be stored in cnt.

```
INTEGER :: key
READ (UNIT=9, '(I4)', ADVANCE='NO', SIZE=cnt, EOR=100) key
```

## Internal file

The following statement inputs a string of characters from the internal file cfile, uses an embedded format specification to perform format conversion, and stores the results in the variables $i$ and $x$ :

```
READ (cfile, FMT='(I5, F10.5)') i, x
```

## Namelist-directed I/O

Each of the four READ statements in the next example uses a different style of syntax to do exactly the same thing:

```
NAMELIST /nl/ a, b, c
READ (UNIT=5, NML=nl) ! 5 = standard input
READ (5, nl)
READ (*, NML=nl) ! * = standard input
READ nl ! assume standard input
```

## List-directed I/O

The following statement takes its data from standard input, storing the converted value in int_var. The format conversion is based on the type of int_var.

```
READ *, int_var
```

HP Fortran statements
READ

If you knew the format, you could substitute for the asterisk one of the following:

- The label of the FORMAT statement with the format specification, as in the following:

```
READ 100, int_var
100 FORMAT(I4)
```

- An embedded format specification, as in the following:

```
READ '(I4)', int_var
```

## Unformatted direct-access I/O

The following statement takes its input from the file connected to unit 31. The REC= specifier indicates that the file has been opened for direct access and that this statement will read the record whose number is stored in the variable rec_num. If an I/O error occurs during the execution of the statement, an error number will be stored in ios, and execution control will branch to the executable statement at label 99.

READ (31, REC=rec_num, ERR=99, IOSTAT=ios) a, b

CLOSE, OPEN, and WRITE.
For more about I/O concepts, including information about files and different types of I/O, see Chapter 8, "I/O and file handling," on page 171. This chapter also lists example programs that usel/O. For information about I/O formatting, see Chapter 9, "I/O formatting," on page 205.

## REAL

Declares entities of type real.

Syntax REAL [kind-spec] [[, attrib-list] ::] entity-list
kind-spec
is the kind type parameter that specifies the range and precision of the entities in entity-list. kind-spec takes the form:
([KIND=] kind-param)
where kind-param can be a named constant or a constant expression that has the integer value of 4,8 , or 16 . The size of the default type is 4.

As an extension, kind-spec can take the form:

* len-param
where len-param is the integer 4,8 , or 16 (default $=4$ ).
attrib-list
is a list of one or more of the following attributes, separated by commas:

| ALLOCATABLE | INTRINSIC | PRIVATE |
| :--- | :--- | :--- |
| DIMENSION | OPTIONAL | PUBLIC |
| EXTERNAL | PARAMETER | SAVE |
| INTENT | POINTER | TARGET |

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.

HP Fortran statements
REAL
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name [( array-spec )] [ = initialization-expr ]
where name is the name of a variable or function, array-spec is a comma-separated list of dimension bounds, and initialization-expr is a real constant expression. If initialization-expr is present, entity-list must be preceded by the double col on.

```
Description
Examples
The REAL statement is used to declare the length and properties of data that approximate the mathematical real numbers. A kind parameter (if present) indicates the representation method.
The REAL statement is constrained by the rules for all type declaration statements, including the requirement that it precede all executable statements.
As a portability extension, HP Fortran allows the following syntax for specifying the length of an entity:
name [*len] [( array-spec )] [= initialization-expr]
If (array-spec) is specified, *len may appear on either side of (arrayspec). If name appears with *len, it overrides the length specified by REAL*size.
The following are valid declarations:
```

```
REAL, TARGET :: x, y
```

REAL, TARGET :: x, y
REAL(KIND=16) :: z
REAL(KIND=16) :: z
REAL(4), PARAMETER :: pi=3.14
REAL(4), PARAMETER :: pi=3.14
! initialize an array, using an array constructor

HP Fortran statements
RECORD (extension)

## RECORD (extension)

Declares a record of a previously defined structure.
Syntax
RECORD /struct-name/rec-name [, rec-name] ...
[/struct-name/rec-name [, rec-name ] ]...
struct-name
is the name of a structure declared in a previous structure definition.
rec-name
is a record name.
HP Fortran supports the RECORD statement as a compatibility extension. New programs should use the derived type, a standard feature of Fortran 90. For more information about derived types, see "Derived types" on page 39 and "TYPE (definition)" on page 457.

The RECORD statement declares a record variable of a structure that has been previously defined by a structure statement. A record variable can consist of multiple data items, called fields. The structure statement is described in "STRUCTURE (extension)" on page 437.

## Referencing record fields

The syntax for referencing a field in a record depends on whether the field itself is another record (a composite reference) or not (a simple reference). Composite references have the following syntax:
rec-name [. substruct-fieldname] . . .
Simple references have the following syntax:
rec-name [. substruct-fieldname] . . . simplefieldname
rec-name
is the name of the record in which a composite or simple field is being referenced.
substruct-field-name
is the name of a nested structure or nested record field name, if applicable.

## simplefield-name

is the name of a lowest-level field, defined with a type declaration statement. As indicated by the syntax, the field could be part of a nested structure or nested record.
Given the following structure definition and record declarations:

```
STRUCTURE /abc/
    REAL a, b, c(5)
    STRUCTURE /xyz/ xyz, xyzs(5)
        INTEGER x, y, z(3)
    END STRUCTURE
END STRUCTURE
RECORD /abc/ abc, abcs(100)
RECORD /xyz/ xyz
the following are composite references:
```

```
abc !composite record references
abcs(1)
xyz
abcs(idx)
abc.xyz !composite field references
abc.xyzs(3)
and the following are simple references:
abc.a
abc.c(1)
xyz.x
xyz.z(1)
abc.xyz.x
abcs(idx).xyz.y(1)
abcs(2).xyzs(3).z(1)
```

Composite references can be either to an entire record or to a record field that is itself a structure or record.

## Rules for record field

Arrays of records can be created as follows:

```
RECORD /student/ students(1000)
```

Or
RECORD /student/ students DIMENSION students (1000)
In either case a 1000-record array called students of structure student is declared.

HP Fortran statements
RECORD (extension)

Records can be placed in common blocks. The following code places the students array (declared above) in the common block frosh, along with variables $a, b$, and $c$ :

COMMON /frosh/ a, b, c, students
Simple field references can appear wherever a variable can appear. The following assigns values to the fields of record $r$ of structure struct:

```
STRUCTURE /struct/
    INTEGER i
    REAL a
END STRUCTURE
```

```
RECORD /struct/ r
```

RECORD /struct/ r
r.i = r.i + 1
r.i = r.i + 1
r.a = FLOAT(r.i) - 2.7

```
r.a = FLOAT(r.i) - 2.7
```

Composite assignment is allowed for two records or two composite fiel ds of the same structure-that is, the record declaration statements for both records must have specified the same struct-name. For example, the fol lowing is legal:

```
STRUCTURE /string/
    BYTE len
    CHARACTER*1 str(254)
END STRUCTURE
RECORD /string/ str1, str2
str1 = str2
```

The following example is also valid and uses composite assignment to assign the value of the record edate of structure date to a field of the same structure (when) in the record event:

```
STRUCTURE /event/
    CHARACTER*20 desc
    STRUCTURE /date/ when
        BYTE month, day
        INTEGER*2 year
    END STRUCTURE
END STRUCTURE
RECORD /date/ edate
RECORD /event/ event
edate.month = 1
edate.day = 6edate.year = 62
event.desc = 'Party for Joanne'
! composite assignment of record to field
! of record--both have same structure
event.when = edate
```

Even though the following records are of identical structures-that is, the fields of both structures have the same type, size, and format-the code is invalid because the structures have a different name:

```
STRUCTURE /intarray/
    BYTE elem_count
    INTEGER arr(100)
END STRUCTURE
STRUCTURE /iarray/
    BYTE elem_count
    INTEGER arr(100)
END STRUCTURE
RECORD /intarray/ iarray1
RECORD /iarray/ iarray2
! The next assignment won't work. The two
! records are not of the same structure.
iarray1 = iarray2 ! Invalid
```

When performing I/O on structures and records, composite record and field references can appear only in unformatted I/O statements. They are not allowed in formatted, list-directed, or namelist-directed I/O
statements. However, simple field references can appear in all types of I/ O statements. For information about I/O, see Chapter 9, "I/O formatting," on page 205.
A record name or composite field reference can appear as either a formal or an actual argument to a subroutine or function. Formal and actual arguments must have the same size as well as the same number, type, and order of fields.

Composite record and field arguments to subroutines and functions are passed by reference, just like other HP Fortran arguments.
Adjustable arrays are allowed in RECORD statements that declare formal arguments.

Do not name a field with any of the following:

- Logical constants, .true. and .FALSE.
- Logical operators, such as .OR., .AND ., and .nOt.
- Relational operators, such as .EQ., . LT ., and .NEQV.
- The name of a defined operator

|  | RETURN |
| :---: | :---: |
|  | Returns control from a subprogram. |
| Syntax | RETURN [scalar-integer-expression] |
|  | scal ar-integer-expression <br> is an optional scalar integer expression that is evaluated when the RETURN statement is executed. It determines which alternate return is used. |
| Description | A RETURN statement can appear only in a subprogram. |
|  | An expression may appear in a RETURN statement only if alternate returns (one or more asterisks) are specified as dummy arguments in the relevant FUnction, SUBROUTINE, or Entry statement of the subprogram. An expression with a value in the range will return to the ith asterisk argument (specified as *label) in the actual argument list. A normal return is executed if $i$ is not in the range 1 to $n$, where $n$ is the number of dummy argument alternate returns specified. |
| Examples | SUBROUTINE calc (y, z) <br> ! Subroutine calc checks the range of $y$. If <br> ! it exceeds the permitted range, it calls <br> ! an error handler and stops the program IF (y > ymax) GO TO 303 <br> RETURN <br> ! It returns to the caller of calc if the <br> ! calculation proceeds to normal completion. <br> 303 CALL err (3, "OUT OF RANGE") <br> STOP 303 <br> END |

| Related concepts | For more information about returning from a procedure call, see "Returning from a procedure reference" on page 132. |

HP Fortran statements
REWIND

## REWIND

Positions file at its initial point.

Syntax

Description The REWIND statement repositions the file connected to the specified unit at the start of the first record. If the file is already at its starting point or if the unit is not connected to a file, the REWIND statement has no effect.

## Examples

Related statements

Related concepts

The following example of the REWIND statement repositions the file connected to unit 10 to its initial point:

REWIND 10
The next example repositions to its initial point the file connected to unit 21. If an error occurs during the execution of the statement, control passes to the statement at label 99, and the error code is returned in ios:

REWIND (21, ERR=99, IOSTAT=ios)
BACKSPACE, ENDFILE, and OPEN

For information about I/O concepts, see Chapter 8, "I/O and file handling," on page 171. This chapter also lists example programs that use I/O.

HP Fortran statements
SAVE (statement and attribute)

## SAVE (statement and attribute)

Stores variables in static memory.
Syntax
A type declaration statement with the SAVE attribute is:
type, attrib-list :: savelist
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (name), etc.).
attrib-list
A comma-separated list of attributes including SAVE and optionally those attributes compatible with it, namely:

| ALLOCATABLE | PRIVATE | TARGET |
| :--- | :--- | :--- |
| DIMENSION | PUBLIC | VOLATILE |
| POINTER | STATIC |  |

savelist
is a comma-separated list of names of objects to save.
The syntax of the SAVE statement is:
SAVE [[::] savelist]
Description
The SAVE statement and attribute cause objects in a subroutine or function to be stored in static memory, instead of being dynamically allocated whenever the procedure is invoked (the default case). A saved object retains its value and definition, association, and allocation status between invocations of the program unit in which the saved object is declared.

If savelist is omitted, everything in the scoping unit that can be saved is saved. No other explicit occurrences of the SAVE attribute or the SAVE statement are allowed.

The names of the following may appear in savelist:

- Scalar variables
- Arrays
- Named common blocks
- Derived type objects
- Records

If the name of a common block appears in savelist, it must be delimited by slashes (for example, /my_block/); all variables in the named common block are saved. If a common block is saved in one program unit, it must be saved in all program units (except main) where it appears.

HP Fortran always saves all common blocks.
The following must not appear in savelist:

- Formal argument names
- Procedure names
- Selected items in a common block
- Variables declared with the AUTOMATIC statement or attribute
- Function results
- Automatic data objects (such as automatic arrays, allocatable arrays, automatic character strings, and Fortran 90 pointers)

Initializing a variable in a DATA statement or in a type declaration statement implies that the variable has the sAve attribute, unless the variable is in a named common block in a block data subprogram.

A SAVE statement in a main program unit has no effect.

## Examples

The save statement in the following example saves the variables $a, b$, and c, as well as the variables in the common block dot:

```
SUBROUTINE matrix
SAVE a, b, c, /dot/
RETURN
```

HP Fortran statements
SAVE (statement and attribute)

The SAVE statement in the next example saves the values of all of the variables in the subroutine fixit:

```
SUBROUTINE fixit
SAVE
RETURN
```

| SELECT CASE |
| :--- | :--- |
| Begins CASE construct. |$\quad$| [construct-name :] SELECT CASE (caseexpr) |
| :--- |
| construct-name |
| is the name given to the CASE construct. |
| caseexpr $\quad$ is a scalar expression of type integer, character, or logical. |

HP Fortran statements
SEQUENCE

## SEQUENCE

Imposes storage sequence on components of derived type object.

## Syntax

Description

SEQUENCE
The SEQUENCE statement can appear once within any derived type definition; its presence specifies that a storage sequence on the components that is the same as their definition order. A derived type that includes the SEQUENCE statement in its definition is known as a sequence derived type. Sequence derived types are used:

- To allow objects of sequence derived type to be storage associated with the COMMON and EQUIVALENCE statements.
- To allow actual and dummy arguments to have the same type without use or host association. The corresponding actual and dummy arguments of derived types are of the same derived type if the derived-type objects refer to the same type definition. Alternatively, they are of the same type if all of the following are true:
- They refer to different type definitions with the same name.
- They have the SEQUENCE statement in their definitions.
- The components have the same names and types and are in the same order.
- None of the components is of a private type or of a type that has private access.

The following restrictions apply to the use of the SEQUENCE statement:

- No more than one SEQUENCE statement may appear in the definition of a derived type.
- If a derived type definition includes the SEQUENCE statement, each component that is of derived type must also include the SEQUENCE statement.
Examples TYPE weather
! weather is a sequence derived type with two
! character components and two integer components SEQUENCE CHARACTER(LEN=32) place INTEGER high_temp, low_temp CHARACTER (LEN=16) conditions
END TYPE weather

Related statements

HP Fortran statements
STATIC (statement, attribute, extension)

## STATIC (statement, attribute, extension)

Gives variables and arrays static storage.
Syntax

| ALLOCATABLE | PRIVATE | VOLATILE |
| :--- | :--- | :--- |
| DIMENSION | SAVE |  |
| POINTER | TARGET |  |

entity-list
is a comma-separated list of variables and arrays.
The syntax of the STATIC statement is:
STATIC [::] entity-list

Description The STATIC statement and attribute is an HP Fortran extension. Variables possessing the STATIC attribute retain their storage location for the duration of the program. A static variable declared within a procedure will therefore retain its value between calls of the procedure.

The STATIC statement and attribute has the same functionality as the SAVE statement and attribute; it is provided for compatibility with other vendors' Fortran 90.

HP Fortran statements
STATIC (statement, attribute, extension)

```
Examples
    SUBROUTINE work_out(first_call)
        LOGICAL first_call
        INTEGER, STATIC :: ncalls
        IF (first_call) ncalls = 0
        ncalls = ncalls + 1 ! record how often work_out is called
END SUBROUTINE work_out
Related statements
AUTOMATIC and SAVE
For related information, see the following:
- "Type dedaration for intrinsic types" on page 24
- Information about automatic and static variables, in the HP Fortran Programmer's Guide
```

HP Fortran statements
STOP

## STOP

Terminates program execution.

Syntax

Description

STOP [stop-code]
stop-code
is a character constant, a named constant, or a list of up to 5 digits.

The Stop statement terminates program execution and optionally prints a message to standard error or standard list.
STOP al so sends a message to standard error, dependent on whether digits, characters, or nothing was specified with the STOP statement:

- If digits are specified, the message "stop digits" is written to standard error.
- If a character expression is specified, the message "stop characterexpression" is written.
- If nothing appears after STOP, nothing is written.

## Examples

Related statements

Related concepts

IF (b .LT. c) STOP 'BAD VALUE!'

PAUSE

For information about flow control statements, see "Flow control statements" on page 112.

## STRUCTURE (extension)

Defines a named structure.
Syntax

Description

```
STRUCTURE /struct-name/
```

    fiedd-def
    ...
    End STRUCTURE
struct-name
is the structure's name, delimited by slashes. struct-name can be used later to declare a record.
fiedd-def
is a field definition.
HP Fortran supports the STRUCTURE statement as a compatibility extension. New programs should use the derived type, a standard feature of Fortran 90; derived types provide the same functionality as named structures. For more information about derived types, see "Derived types" on page 39 and "TYPE (declaration)" on page 454.
The structure statement defines the type, size, and layout of a structure's fields, and assigns a name to the structure. Once a structure is defined, you can declare records of that structure using the RECORD statement and can manipulate the record's fields.
A structure definition pertains only to the program unit in which it is defined. For example, you cannot define a structure in the main program unit and then declare a record of that structure in a subprogram unit. Instead, the structure must be explicitly defined again in the subprogram unit.
fiedd-def can be any of the following:

- A type declaration statement
- A nested structure definition
- A nested record declaration
- A union definition

Each type of field definition is described in the remaining sections.

HP Fortran statements
STRUCTURE (extension)

## Field definition as type declaration

At the simplest level, field-def can be a type declaration statement. As such, field-def has the same syntax as a standard Fortran 90 type declaration statement, except that the only attribute that can be specified is the DIMENSION attribute. A variable defined with a type declaration statement is called a field.

The following code uses simple type declaration statements to define a structure named date with three fields: month and day of type BYTE, and year of type INTEGER (KIND=2) :

```
STRUCTURE /date/
    BYTE :: month, day
    INTEGER(KIND=2) :: year
END STRUCTURE
```

A type declaration statement in a structure definition can optionally define initial values for the fields. For example:

```
STRUCTURE /xyz/
    REAL :: x = 1.0, y = 2.0, z = 3.0
END STRUCTURE
```

Thereafter, any record declared of structure xyz will have its $x, y$, and $z$ fields initially set to $1.0,2.0$, and 3.0 respectively. Consider the following:

```
RECORD /xyz/ xyz
PRINT *, xyz.x, xyz.y, xyz.z
```

Even though no values have been assigned to the fields of $x y z$ with an assi gnment statement, the above code will display:

$$
1.02 .0 \quad 3.0
$$

Implicit typing is not allowed in a structure definition. For example, the following code would cause a compile error:

```
STRUCTURE /dimensions/
    x, y, z ! illegal
END STRUCTURE
```

A correct way to code this would be:

```
STRUCTURE /dimensions/
    REAL(KIND=8) :: x, y, z ! legal
END STRUCTURE
```

A field type declaration statement can also define an array, as in the fol lowing:

```
STRUCTURE /foo_bar/
    INTEGER foo(10)
END STRUCTURE
or, using Fortran 90 syntax:
```

```
STRUCTURE /foo_bar/
```

STRUCTURE /foo_bar/
REAL, DIMENSION(30, 50) :: bar
REAL, DIMENSION(30, 50) :: bar
END STRUCTURE

```
END STRUCTURE
```

The array's dimensions must in any case appear in the type statement. The dimension statement (but not the dimension attribute) is illegal in a structure definition. The following code defines the structure, string, which uses a type declaration statement to define an array field str of type CHARACTER (LEN=1), containing 254 elements:

```
STRUCTURE /string/
    CHARACTER(LEN=1) :: str(254)! Contains string
    INTEGER :: length ! string's length
END STRUCTURE
```

As mentioned, the DIMENSION statement cannot be used in a structure definition. For example, the following code would cause a compile-time error:

```
STRUCTURE /real_array/
    REAL :: rarray
    DIMENSION arr(100) ! illegal example
END STRUCTURE
```

A correct way to code this would be:

```
STRUCTURE /real_array/
    REAL :: rarray(100)
END STRUCTURE
Or
STRUCTURE /real_array/
    REAL, DIMENSION(100) :: arr
END STRUCTURE
```

Assumed-size and adjustable arrays are also illegal in structure definitions. For example, the following is illegal:

```
STRUCTURE /assumed_size/ ! illegal example
    CHARACTER*(*) :: carray
END STRUCTURE
```

HP Fortran statements
STRUCTURE (extension)

The following is also illegal:

```
STRUCTURE /adj_array/ ! illegal example
    INTEGER :: size
    REAL :: iarray(size)
END STRUCTURE
```

For alignment purposes, HP Fortran provides the $\%$ FILL field name. It enables the programmer to pad a record to ensure proper alignment. The padding does not have a name and is therefore not accessible. For example, the following structure, sixbytes, creates a 6-byte structure, of which 4 bytes are inaccessible filler bytes:

```
STRUCTURE /sixbytes/
    INTEGER(KIND=2) :: twobytes
    CHARACTER(LEN=4) :: %FILL
END STRUCTURE
```

\%FILL can be of any type and may appear more than once in a structure.
\%FILL should not be needed in normal usage. The compiler automatically adds padding to ensure proper alignment.

## Nested structures

A field-def can itself be a structure definition, known as a nested structure. The syntax of a nested structure definition is:

```
STRUCTURE /struct-name/struct-fidd-list
    field-def
END STRUCTURE
struct-name
```

is the structure's name (delimited by slashes), which can be
used later to declare a record.
struct-field-list
is a comma-separated list of one or more names of nested
structure field names.
fiedd-def
can be one of the following regular field definitions (defined in
the same way as an unnested structure field):

- A type declaration statement
- Another nested structure
- A nested record
- A union definition

Note that a structure definition allows multiple levels of nesting.
A nested structure definition is the same as an unnested structure definition, with two exceptions:

- /struct-name/ is optional in a nested structure.
- A nested structure definition must include a list of one or more structure field names (struct-field-list).

If /struct-name/ is present in a nested structure definition, the structure struct-name can also be used in subsequent record declarations. For example, the following code defines a structure named person, which contains a nested structure named name. The structure's field name is nm and contains three CHARACTER*10 fields: last, first, and mid.

```
STRUCTURE /person/
    INTEGER :: person_id
    ! Define the nested structure 'name' with the field name 'nm'.
    STRUCTURE /name/ nm
        CHARACTER(LEN=10) :: last, first, mid
    END STRUCTURE
END STRUCTURE
```

Given this definition, the following code defines the record p of structure person and the record $n$ of structure name:

```
RECORD /person/p
RECORD /name/n
```

If /struct-name/ is not present, then the structure can be used only in this declaration. For example, we could redefine the person structure so that the nested structure no longer has a name:

```
STRUCTURE /person/
    INTEGER :: person_id
    STRUCTURE nm
        CHARACTER(LEN=10) :: last, first, mid
    END STRUCTURE
END STRUCTURE
```

There is no way to declare a separate record of the nested structure because it has no name. N ote, however, that the nested structure still has a field name, nm. The field name is required.

To declare an array of nested structures, simply specify a dimension declarator with the structure's field name. For example, the following structure definition contains a nested, 3-element array of structures with field name phones of structure phone:

```
HP Fortran statements
STRUCTURE (extension)
```

```
STRUCTURE /person/
```

STRUCTURE /person/
INTEGER :: person_id
INTEGER :: person_id
! Define the nested structure 'name' with the field name 'nm'.
! Define the nested structure 'name' with the field name 'nm'.
STRUCTURE /name/ nm
STRUCTURE /name/ nm
CHARACTER(LEN=10) :: last, first, mid
CHARACTER(LEN=10) :: last, first, mid
END STRUCTURE
END STRUCTURE
! Nested array of structures.
! Nested array of structures.
STRUCTURE /phone/ phones(3)
STRUCTURE /phone/ phones(3)
INTEGER(KIND=2) :: area_code
INTEGER(KIND=2) :: area_code
INTEGER :: number
INTEGER :: number
END STRUCTURE
END STRUCTURE
END STRUCTURE

```
END STRUCTURE
```

## Nested records

A field-def can be a record declaration, known as a nested record. See "RECORD (extension)" on page 420 for information about record declarations.) A nested record declaration must use a structure that has already been defined. The following code first defines the structure date. It then declares the structure event, which contains the nested record when of structure date:

```
STRUCTURE /date/
    BYTE :: month, day
    INTEGER :: year
END STRUCTURE
STRUCTURE /event/
    CHARACTER :: what, where
    RECORD /date/ when
END STRUCTURE
```

A structure definition can also dedare an array of nested records. For example, the following code defines the structure calendar, which contains a 100-element array of records of structure event:

```
STRUCTURE /calendar/
    ! number of events
    INTEGER(KIND=2) :: event_count
    RECORD /event/ events(100) ! array of event records
END STRUCTURE
```

## Unions

A field-def can be a union-a form of nested structure in which two or more map blocks share memory space. The UNION and MAP statements together define a union. The syntax of a union definition is:

```
UNION
    map-block
    map-block
    ...
END UNION
```

where map-block is defined by a MAP statement and one or more field definitions. All map blocks within the encl osing UNION statement share the same memory space in a record. The syntax for defining a map block is:

```
MAP
    field-df
    MAP
```

where field-def can be one of the following:

- A type declaration statement
- Another nested structure
- A nested record
- A union definition

Note that a structure definition allows multiple levels of nesting.
For programmers who are familiar with C or Pascal, HP Fortran unions are similar to unions in C and variant records in Pascal. HP Fortran unions differ from C unions in that they must be defined inside a structure definition.

The structure below contains a union with two map blocks. The first contains the integer field int; the second contains the real field float.

```
STRUCTURE /var/
    INTEGER :: type ! 1=INTEGER, 2=REAL
    UNION
        MAP
            INTEGER :: int
        END MAP
        MAP
            REAL :: float
        END MAP
    END UNION
END STRUCTURE
```

HP Fortran statements
STRUCTURE (extension)

To declare a record of this structure named v, use the following RECORD statement:

```
RECORD /var/ v
```

The declaration of the record v reserves 8 bytes of storage: 4 bytes for the type field and 4 bytes to be shared by int and float. If you use the int field to access the 4 bytes, they will be interpreted as an integer; if you use the float field, they will be interpreted as a real.
It is the programmer's responsibility to ensure that appropriate values are assigned to each field in a union. For instance, given the previous declaration of $v$, the following assignments make sense:

```
v.type =1 ! set the type to integer
! access the storage shared by 'int' and 'float' as an integer
v.int = 3
```

In contrast, the following code would yield unexpected results, although it would compile without errors:

```
v.type = 1 ! set the type to integer
! the next statement contradicts the previous statement
v.float = 3.14
```

Once a value is assigned to a map block, all other map blocks become undefined. The reason is that all map blocks share memory space within a union; therefore, the values of one map block may become altered if you assign a value to a field in another map block. Consider the following definition of a structure called struct and the declaration of a record called rec:

```
STRUCTURE /struct/
    UNION
        MAP
            CHARACTER*8 :: s
        END MAP
        MAP
            CHARACTER*1 :: c(8)
        END MAP
    END UNION
END STRUCTURE
RECORD /struct/ rec
```

If we made the following assignment to the s field:

```
rec.s = 'ABCDEFGH'
```

and then executed the next two PRINT statements:

```
PRINT *, rec.s
PRINT *, rec.c
```

the output would be:

## ABCDEFGH

ABCDEFGH
Now, if we set values in the c field and display both fields again

```
rec.c(1) = '1'
rec.c(8) = '8'
PRINT *, rec.s
PRINT * rec.c
```

the output would be:

```
1BCDEFG8
1BCDEFG8
```

Note how the s field has changed, even though it was not directly assigned any new values. This is a result of the s and c field sharing the same storage space in the union. Although this is valid coding-that is, it will not cause a compiler or runtime error-it may cause unexpected results.

However, you can also use shared memory mapping to your benefit. The fact that map blocks share space within a union makes unions useful for equivalencing data within a record. For example, the following structure could be used to mask off individual bytes in a 4-byte word:

```
STRUCTURE /wordmask/
    UNION
        MAP
            INTEGER(KIND=4) :: word
        END MAP
        MAP
            BYTE :: byte0, byte1, byte2, byte3
        END MAP
    END UNION
END STRUCTURE RECORD /wordmask/ maskrec
```

If we assign a value to the word field of maskrec, we can then get the individual values of all four bytes in maskrec by looking at the fields byte0, byte1, byte2, and byte3. To see how the integer variable word maps onto the byte variables byte0, byte1, byte2, and byte3, use the fol lowing statements:

```
    maskrec.word = 32767
    WRITE(*, fmt=100) 'word = ', maskrec.word
    WRITE(*, 200) 'byte 0 = ', maskrec.byte0
    WRITE(*, 200) 'byte 1 = ', maskrec.byte1
    WRITE(*, 200) 'byte 2 = ', maskrec.byte2
    WRITE(*, 200) "byte 3 = ', maskrec.byte3
100 FORMAT(A, Z8.8)
200 FORMAT(A, Z2.2)
```

HP Fortran statements
STRUCTURE (extension)

This code displays the following output:
word $=00007 \mathrm{FFF}$
byte $0=00$
byte $1=00$
byte $2=7 \mathrm{~F}$
byte $3=\mathrm{FF}$
Such code, depending as it does on a specific word size, is inherently nonportable.

Related statements

Related concepts

RECORD and TYPE

Derived types are described in "Derived types" on page 39.

## SUBROUTINE

Begins the definition of a subroutine subprogram.

Syntax

Description
[RECURSIVE] SUBROUTINE subr-name [([dummy-arg-list])]
subr-name
is the name of a subroutine.
dummy-arg-list
is a comma-separated list of zero or more of dummy-arg-name or the asterisk character (*).
As indicated by the syntax, the parentheses surrounding the dummy arguments may be omitted if there are no dummy arguments.

The sUbrout Ine statement is the first statement of a subroutine subprogram.

The following rules and restrictions apply to subroutines:

- A subroutine is either an external, module, or internal subprogram.
- If a subroutine calls itself directly or indirectly, the word RECURSIVE must appear in the SUBROUTINE statement. If the keyword RECURSIVE is specified, the subroutine interface is explicit within the subprogram.
- The keyword subroutine must appear on the end statement if the subroutine is a module or internal procedure.
- An asterisk in a subroutine dummy argument list designates an alternate return.
- The interface of an internal subroutine is explicit in its host. The interface of a module subroutine is explicit within the module, and if it is public, it is explicit in all program units using the module. The interface of an external subroutine is implicit, but may be made explicit by the use of an interface block.

HP Fortran statements

## SUBROUTINE

## Examples Consider the following subroutines:

```
! A subroutine definition with two arguments.
SUBROUTINE exchange (x, y)
    temp = x; x = y; y = temp
END SUBROUTINE exchange
SUBROUTINE altitude (*, long, lat)
    ! asterisk (*) indicates alternate return
    IMPLICIT NONE
    INTEGER, OPTIONAL :: long, lat
    RETURN 1
END SUBROUTINE altitude
```

The preceding subroutines may be referenced with the CALL statement, as in the following program:

```
PROGRAM reject
    CALL exchange (a,t) ! A subroutine reference
    ! subroutine reference, including an alternate return label,
    ! missing optional argument, and an argument keyword
    CALL altitude (*90, lat = 49)
END PROGRAM reject
```

Following are some other examples of subroutine statements:

```
SUBROUTINE pressure_surface ! No arguments
SUBROUTINE taffy () ! Also no arguments
RECURSIVE SUBROUTINE fact (n, x)
CALL, END, ENTRY, FUNCTION, and RETURN
For related information, see the following:
```

- "External procedures" on page 128
- "Arguments" on page 139

## tARGET (statement and attribute)

Allows variables and arrays to be pointer targets.
Syntax
The syntax of a type declaration statement with the TARGET attribute is:
type, attrib-list :: entity-list
type
is a valid type specification (INTEGER, REAL, LOGICAL, CHARACTER, TYPE (name), etc.).
attrib-list
is a comma-separated list of attributes including target and optionally those attributes compatible with it, namely:

| ALLOCATABLE | OPTIONAL | SAVE |
| :--- | :--- | :--- |
| DIMENSION | PRIVATE |  |
| INTENT | PUBLIC |  |

entity-list
is a comma-separated list of entities. Each entity is of the form: array-name [ (deferred-shapespec-list)]
If ( deferred-shapespec-list ) is omitted, it must be specified in another declaration statement.
array-name
is the name of an array being given the attribute ALLOCATABLE.
deferred-shape-spec-list
is a comma-separated list of colons, each colon representing one dimension. Thus the rank of the array is equal to the number of colons specified.

HP Fortran statements
TARGET (statement and attribute)

The syntax of the TARGET statement is:

```
TARGET [::] object-name [(array-spec)]
    [, object-name [(array-spec)]]...
array-spec
```

| explicit-shapespec is | [lower-bound :] upper- <br> bound |
| :--- | :--- |
| assumed-shape-spec is | [lower-bound] : |
| deferred-shape-spec is | $:$ |
| assumed-size-spec is | [explicit-shapespec-list ,] |
|  | [lower-bound :] * |

That is, an assumed-size-spec is an explicit-shape-spec-list with the final upper bound given as *.

Examples

The TARGET attribute or statement specifies that name is a target that may be pointed at by a pointer. A target may be either a scalar or an array.

The TARGET attribute allows the compiler to generate efficient code because only those objects specified with the TARGET or POINTER attribute can be dynamically aliased.

If the target in a pointer assignment is a variable, then one of the following must be true:

- It must have the TARGET attribute.
- It must be the component of a derived-type, the element of an array variable, or the substring of a character variable that has the TARGET attribute.
- It must have the POINTER attribute.

If the target of a pointer assignment is an array section, the array must have either the TARGET or the POINTER attribute.

```
! p is a pointer array
INTEGER, POINTER, DIMENSION(:,:) :: p
! declare t as an array with the TARGET attribute
INTEGER, TARGET :: t(10, 20, 30)
! make p point to a rank-2 section of t
```

```
    p => t(10,1:10,2:5)
    REAL, POINTER :: nootka(:), talk(:)
    REAL, ALLOCATABLE, TARGET :: x(:)
    ALLOCATE (x(1:100), STAT = is)
    nootka => x(51:100)
    ! Pointer assignment statements
    talk => x(1:50)
    REAL r, p1, p2
    TARGET r
    POINTER p1, p2
    r = 4.7
! make both p1 and p2 aliases of r
    p1 => r
p2 => p1
ALLOCATE (p1)
p1 = 9.4
POINTER, ALLOCATE, DEALLOCATE, and NULLIFY
For related information, see the following:
```

## TASK COMMON (extension)

Dedlares a common block to be local to a thread during parallel execution.

NOTE | A program that uses the TASK COMMON statement should be compiled with |
| :--- |
| the +Oparallel or +parallel option; otherwise, the compiler treats the |
| TASK COMMON statement as a COMMON statement. |

Syntax $\quad$ TASK COMMON /cbn/nlist $[, / \mathrm{cbn} / \mathrm{nlist} . .$. cbn
is a symbolic name for a common block that is declared in a TASK COMMON statement. Unnamed common blocks are not allowed in a TASK COMMON statement.
nlist
is a list of variable names, array names, and array declarators. These variables cannot appear in a DATA statement, but otherwise can be used like other variables in common storage.

The TASK COMMON statement is an extension to the Fortran 90 standard and is provided for compatibility with programs that use the Cray TASK COMMON feature. TASK COMMON blocks can only be declared in functions and subroutines.

A program should already be running multiple threads before calling a subroutine that contains a TASK COMMON block.

When used in a program executing multiple threads, the TASK COMMON statement declares all variables in a common block as local to a thread (also called a task). If multiple threads execute code that uses the same TASK COMMON block, each thread has a private copy of the block.
All occurrences of the TASK COMMON block must be declared with the TASK COMMON statement; a common block cannot be declared in both a COMMON statement and a TASK COMMON statement.

HP Fortran statements
TYPE (declaration)

## TYPE (declaration)

Declares a variable of derived type.

Syntax TYPE (typename) [[, attrib-list] ::] entity-list type-name
is the name of a previously defined derived type.
attrib-list
is a comma-separated list of one or more of the following attributes:

| ALLOCATABLE | INTRINSIC | PRIVATE |
| :--- | :--- | :--- |
| DIMENSION | OPTIONAL | PUBLIC |
| EXTERNAL | PARAMETER | SAVE |
| INTENT | POINTER | TARGET |

If attrib-list is present, it must be followed by the double colon. For information about individual attributes, see the corresponding statement in this chapter.
entity-list
is a list of entities, separated by commas. Each entity takes the form:
name[(array-spec)] [=initialization-expr]
where:
name
is the name of a variable or function
array-spec
is a comma-separated list of dimension bounds

initialization-expr<br>is a structure constructor<br>initialization-expr<br>is present<br>entity-list<br>must be preceded by the double col on.

## Description

## Examples

The type declaration statement specifies the type and attributes of derived-type objects. A derived-type object may be an array, which may be deferred shape (pointer or allocatable), assumed shape (dummy argument), or assumed size (dummy argument).
Assignment is intrinsically defined for each derived type but may be redefined by the user. Operators appropriate to a derived type may be defined by procedures with the appropriate interfaces.
When a derived-type object is used as a procedure argument, the types of the associated actual and dummy arguments must be the same. For sequence derived types different physical type definitions may be used for the actual and dummy arguments, as long as both type definitions specify identical type names, components, and component order. For nonsequenced types the same physical type definition must be used, typically accessed via host or use association, for both the actual and dummy arguments.

```
! Weather is a simple derived type with two
! character components and two integer components.
TYPE Weather
    CHARACTER(LEN=32) Place
    INTEGER High_temp, Low_temp
    CHARACTER(LEN=16) Conditions
END TYPE Weather
TYPE (Weather) July(num_ws, 31)
! A two-dimensional Weather array for July
July(:,:) % Low_temp = -40
! Initialize all low temps in July
TYPE Polar
! Polar is a derived type with two real components that cannot be
! directly accessed in Polar objects outside the module
        PRIVATE
        REAL rho, theta
END TYPE Polar
! Point is a derived type with three components, one of which is
! itself of derived type
```

```
HP Fortran statements
TYPE (declaration)
TYPE Point
    REAL x, y
    TYPE (Polar) p
END TYPE Point
TYPE (Polar) r, q(500)
! Two variables of type Polar
TYPE (Point) a, b, t(100,100)
! Three variables of type Point
b = Point(0.,0.,Polar(0.,0.))
! Use of nested structure constructors.
Related statements INTERFACE, PRIVATE, PUBLIC, SEQUENCE, and TYPE (definition)
Related concepts For information about derived types, see "Derived types" on page 39.
```

## TYPE (definition)

The first statement of a derived type definition.
Syntax

Description

Examples
TYPE [[, access-spec ] ::] derived-typename
access-spec
is the keyword PUBLIC or PRIVATE.
derived-typename
is a legal Fortran 90 name.
The type statement introduces the definition of a derived type. A derived type name may be any legal Fortran 90 name, as long as it is not the same as an intrinsic type name or another local name (except component names and actual argument keyword names) in that scoping unit.

A derived type may contain an access specification (PUBLIC or PRIVATE attribute) or an internal PRIVATE statement only if it is in a module.

```
! This is a simple example of a derived type
! with two components, high and low.
TYPE temp_range
    INTEGER high, low
END TYPE temp_range
! This type uses the previous definition for one of its
! components
TYPE temp_record
    CHARACTER(LEN=40) city
    TYPE (temp_range) extremes(1950:2050)
END TYPE temp_record
! This type has a pointer component to provide links to other
! objects of the same type, thus providing linked lists.
TYPE linked_list
    REAL value
    TYPE(linked_list),POINTER : : next
END TYPE linked_list
! This is a public type whose components are private; defined
! operations provide all functionality.
TYPE, PUBLIC :: set; PRIVATE
    INTEGER cardinality
    INTEGER element ( max_set_size )
END TYPE set
! Declare scalar and array of type set.
TYPE (set) :: baker, fox(1:size(hh))
```

HP Fortran statements TYPE (definition)

Related statements INTERFACE, PRIVATE, PUBLIC, SEQUENCE, and TYPE (declaration)
Related concepts For information about derived types, see "Derived types" on page 39.

## тYре (I/O) (extension)

Writes to standard output.
Description
The type statement is a synonym for the print statement and has the same functionality and syntax. It is provided as an HP extension for compatibility with earlier versions of Fortran. For more information, see "PRINT" on page 402.

HP Fortran statements
UNION (extension)

## UNION (extension)

Defines a union within a structure.
Syntax

Description
UNION
map-block map-block

END UNIO
map-block
is one or more of the following:

- A type declaration statement
- Another nested structure
- A nested record
- A union definition

The union statement is an HP Fortran extension that is used with the MAP statement to define a union within a structure. For detailed information about the MAP and UNION statements, see "STRUCTURE (extension)" on page 437.

## USE

Provides controlled access to module entities.

Syntax A USE statement has one of the following forms:

- USE modulename [, renamelist ]
- USE modulename, ONLY : access-list
rename-list
is a comma-separated list of rename
rename
is local-name => module-entity-name
access-list
is a comma-separated list of the following:
- [local-name =>] module-entity-name
- OPERATOR (operator)
- ASSIGNMENT (=)

Description
The USE statement provides access to a module's public specifications and definitions. These include declared variables, named constants, derived-type definitions, procedure interfaces, procedures, generic identifiers, and namelist groups. The method of access is called use association. Such access may be limited by an only clause on the USE statement, or the accessed entities may be renamed.
All USE statements must appear after the program unit header statement and before any other statements. More than one USE statement may be present, including more than one referring to the same module.

M odules may contain USE statements referring to other modules; however, references must not directly or indirectly be recursive.

The local-name in a renaming operation is not declared: it assumes the attributes of the module entity being renamed.

HP Fortran statements
USE

The first two forms of the USE statement make available by use association all publidy accessible entities in the module, except that the USE statement may rename some module entities. The third form makes available only those entities specified in access-list, with possible renaming of some module entities.

Entities made accessible by a USE statement include public entities from other modules referenced by USE statements within the referenced module.

The same name or specifier may be made accessible by means of two or more USE statements. Such an entity must not be referenced in the scoping unit containing the USE statements, except where specific procedures can be distinguished by the overload rules. A rename or onLy clause may be used to restrict access to one name or to rename one entity so that both are accessible.

## Examples

```
MODULE rat_arith
    TYPE rat
        INTEGER n, d
    END TYPE
    ! Make all entities public except zero.
    TYPE (rat), PRIVATE, PARAMETER : : zero = rat (0,1)
    TYPE(rat), PUBLIC, PARAMETER : : one = rat (1,1)
    TYPE(rat) r1, r2
    NAMELIST /nml_rat/ r1, r2
    INTERFACE OPERATOR ( + )
        MODULE PROCEDURE rat_plus_rat, int_plus_rat
    END INTERFACE
CONTAINS
    FUNCTION rat_plus_rat(l, r)
    END FUNCTION
END MODULE
PROGRAM Mine
    ! From the module rat_arith, access only the entities rat,
    ! one, r1, r2, nml_rat but use the name one_rat for the
    ! rational value one.
    USE rat_arith, ONLY: rat, one_rat => one, r1, r2, nml_rat
    ! The OPERATOR + for rationals and the procedures rat_plus_rat
    ! and int_plus_rat are not available because of the ONLY
clause
    READ *, r2; r1 = one_rat
    WRITE( *, NML = nml_rat)
END PROGRAM
```

Related statements

Related concepts

MODULE

For information about modules, see "M odules" on page 161.

HP Fortran statements
VIRTUAL (extension)

## VIRTUAL (extension)

Declares an array.

| Syntax | VIRTUAL array-declarator-list <br> array-declarator-list <br> is a comma-separated list of array dedarators. |
| :--- | :--- |
| Description | The VIRTUAL statement is an HP extension in HP Fortran for <br> compatibility with earlier versions of Fortran. It is an alternative to the <br> DIMENSION statement. VIRTUAL cannot be used as an attribute in type <br> declaration statements. |
| Examples | VIRTUAL A(10), B (1:5, 2:6) |
| Related statements | DIMENSION |
| Related concepts | Arrays are discussed in Chapter 4, "Arrays," on page 51. |

## VOLATILE (extension)

Provides for data sharing between asynchronous processes.
Syntax VOLATILE [::] object-namelist
object-namelist
is a comma-separated list of the following:

- variablename
- array-name
- common-block-name

It is only necessary to declare an object as volatile when its value may be altered by an independent asynchronous process or event (for example, a signal handler). All optimization processes are inhibited for objects with the volatile attribute. Data objects declared as volatile are addressable by otherwise independent processes.
If an array or common block is declared as volatile, then all of the array elements or common block variables become volatile. Similarly, use of EQUIVALENCE with a volatile object implies that any associated object is also volatile.

```
INTEGER alarm, trem
EXTERNAL wakeup
COMMON/FLAGS/ialarm
VOLATILE ialarm
trem = ALARM(60,wakeup) ! Set an alarm to execute in 60 seconds
wakeup
IALARM = 0
DO
    IF (ialarm.NE.O) EXIT
END DO
SUBROUTINE wakeup
    COMMON/flags/ialarm
    VOLATILE ialarm
    ialarm=1
END
```

HP Fortran statements
WHERE (statement and construct)

## WHERE (statement and construct)

Performs masked array assignments.
Syntax

Description
If the optional array-assignment clause is present, the WHERE statement is syntactically complete and does not require the END WHERE statement.
If the array-assignment clause is not present, the WHERE statement is the first statement of a wHERE construct. The syntax of the wHERE construct is:

```
WHERE (array-logical-expr)
    array-assignment-statement
    ...
[ ELSEWHERE
    array-assignment-statement
    ... ]
END WHERE
array-logical-expr
            is a logical array expression.
array-assignment-statement
is an array assignment statement.
```

Certain array elements can be selected by a mask and assigned in arrayassignment statements using the where statement or where construct. array-logical-expr establishes the mask.
For any elemental operation in the array assignments, only the elements selected by the mask participate in the computation. The elemental operations include the usual intrinsic operations and the elemental intrinsic functions such as ABS. Masked array assignments are useful when certain elemental operations involving arrays need to be avoided because of program exceptions.

The following rules and restrictions apply:

- The shape of the result of array-logi cal-expr and the arrays in each array-assignment-statement must be the same; they may be of size zero.
- array-assignment-statement must be an intrinsic array assignment statement; no defined assignment statements are permitted.
- Each elemental operation in array-assignment-statement is masked by the array logical expression.
- The elements of the arrays that are used in the where part (the assignments after the where keyword) are those corresponding to the true elements of the array logical expression. The elements of the arrays that are used in the elsewhere part (the assignments after the ELSEWHERE keyword and before the End where keywords) are those corresponding to the false elements of the array logical expression.
- Each array-assignment-statement executes in the order in which it appears in both the where and elsewhere part of the where construct.
- In a where construct, only the where statement may be a branch target statement.

## Examples

```
REAL, DIMENSION(150) :: a, recip_a
REAL(DOUBLE), DIMENSION(10,20,30) :: b, sqrt_b
! Assign 1.0/a to recip_a only where a is nonzero
WHERE( a /= 0.0 ) recip_a = 1.0 / a
WHERE( b .GE. 0.0 )
        ! Assign to sqrt_b only where b is nonnegative
        sqrt_b = SQRT(b)
ELSEWHERE ! Set sqrt_b to 0.0 where b is -ve.
    sqrt_b = 0.0
END WHERE
```

```
INTEGER, DIMENSION(no_of_tests, student):: score
```

INTEGER, DIMENSION(no_of_tests, student):: score
CHARACTER, DIMENSION(no_Of_tests, student) :: letter_grade
CHARACTER, DIMENSION(no_Of_tests, student) :: letter_grade
! Assign letter grades for numeric scores
! Assign letter grades for numeric scores
WHERE( score >= 92 ) letter_grade = 'A'
WHERE( score >= 92 ) letter_grade = 'A'
WHERE( score >= 82 .AND. score <= 91 ) letter_grade = 'B'
WHERE( score >= 82 .AND. score <= 91 ) letter_grade = 'B'
WHERE( score >= 72 .AND. score <= 81 ) letter_grade = 'C'
WHERE( score >= 72 .AND. score <= 81 ) letter_grade = 'C'
WHERE( score >= 62 .AND. score <= 71 ) letter_grade = 'D'
WHERE( score >= 62 .AND. score <= 71 ) letter_grade = 'D'
WHERE( score >= 0 .AND. score <= 61 ) letter_grade = 'E'

```
WHERE( score >= 0 .AND. score <= 61 ) letter_grade = 'E'
```

In the next example, the arrays values, delta, and count must all be of the same shape:

```
WHERE (ABS(values) .LT. 10.0)
    values = ABS(values) + delta
    count = count + 1
ELSEWHERE
    values = 0
    count = count + 1
ENDWHERE
```

HP Fortran statements
WHERE (statement and construct)

The first two assignment statements are processed for elements corresponding to true elements of the mask. The second two assignment statements are processed for elements corresponding to false elements of the mask. Unlike the ELSE clause of an IF statement, the assignment statements in both the WHERE and ELSEWHERE parts are processed.

Note the different behavior of the calls to ABS. In evaluating the mask expression, the entire VALUES array is passed to ABS, producing an array result whose elements are then compared to 10. In the assignment statement, however, ABS is only invoked for those particular elements of VALUES corresponding to true elements of the mask. Also, note the mixed use of arrays and scalars in the assignment statement expressions.

The mask expression must have the same shape as the arrays in the assignment statements, but it might involve completely separate arrays. In the following example, A, B, and C can be independent of $D$ and $E$, as long as they are all conformable:

```
WHERE (a+b .EQ. c) d = SIN(e)
```

The following example illustrates why the order of processing is important for dependency reasons:

```
REAL a(100)
REAL b(100)
EQUIVALENCE b, a
WHERE (a(1:20:1) .GT. 0) a (20:1:-1) = -1.0
WHERE (a(61:100:2) .LT. 1) b (20:1:-1) = a(1:20:1) * 100.0
```

In the first WHERE statement, changing elements of a in the assignment might be thought to affect the mask expression. However, because the mask is evaluated before the assignment is processed, the behavior of this statement is well defined. A similar situation arises in the second wHERE statement. Assignment values to el ements of the assignment variable $b$ alter the elements of the assignment expression $a * 100.0$. Because the assignment expression is evaluated for all true elements of the mask before any transfer of values to $B$, the behavior is again well defined.

It is important to note that assignment statements in a WHERE construct are processed sequentially. In the next example, the second assignment is not processed until the first is completely finished. This means that the values of $b$ used in the second assignment have been modified by the first statement:

```
WHERE (SQRT(ABS(a)) .gt. 3.0)
    b = SIN(a)
    c = SQRT (b)
ENDWHERE
```

Related statements END (construct) and ELSEWHERE
Related concepts For related information, see the following:

- The discussion of arrays in Chapter 4, "Arrays," on page 51
- "Masked array assignment" on page 99

HP Fortran statements
WRITE

## WRITE

Outputs data to external and internal files.
Syntax WRITE (io-specifier-list) [output-list]
output-list
is a list of comma-separated data items for output. The data items can include expressions and implied-do.
io-specifier-list
is a list of the following comma-separated I/O specifiers:
[UNIT=] unit
specifies the unit connected to the output file. unit can be one of the following:

- The name of a character variable, indicating an internal file
- An integer expression that evaluates to the unit connected to an external file
- An asterisk, indicating the preconnected unit 6 (standard output)

If the optional keyword UNIT= is omitted, unit must be the first item in io-specifier-list. This is the only specifier required in io-specifier-list.
[FMT=] format
specifies the format specification for formatting the data. format can be one of the following:

- An asterisk (*), specifying list-directed I/O
- The label of a FORMAT statement containing the format specification
- An integer variable that has been assigned the label of a FORMAT statement
- An embedded format specification

If the optional keyword $\mathrm{FMT}=$ is omitted, format must be the second item in io-specifier-list.

The nML= and FMT= specifier may not both appear in the same io-specifier-list.
[NML=] name
specifies the name of a namelist group for namelistdirected output. name must have been defined in a NAMELIST statement. If the optional keyword NML= is omitted, name must be the second item in the list. The first item must be the unit specifier without the optional keyword UNIT=.
The NML= and $\operatorname{FMT}=$ specifier may not both appear in the same io-specifier-list.
ADVANCE=character-expression
specifies whether to use advancing I/O for this statement. character-expression can be one of the following arguments:

| 'YES' | Use advancing formatted <br> sequential I/O default. |
| :--- | :--- |
| ' NO ' | Use nonadvancing formatted <br> sequential I/O. |

If the ADVANCE= specifier appears in io-specifier-list, unit must be connected to an external file opened for formatted sequential I/O. Nonadvancing I/O is incompatible with list-di rected and namelist I/O.

ERR=stmt-labe
specifies the label of the executable statement to which control passes if an error occurs during statement execution.

HP Fortran statements
WRITE

## IOSTAT=integer-variable

returns the I/O status after the statement executes. If the statement executes successfully, integer-variable is set to zero. If an error occurs, it is set to a positive integer that indicates which error occurred.

REC=integer-expression
specifies the number of the record to be written to the file connected for direct access. This specifier cannot appear in io-specifier-list with the NML= and ADVANCE= specifiers, nor with FMT=* (for list-directed I/O).

Description

Examples

The WRITE statement transfers data from internal storage to an external or internal file. An external file can be opened for sequential access or direct access I/O. If it is opened for sequential access, the WRITE statement can perform the following types of I/O:

- Formatted
- Unformatted
- List-directed
- Namelist-directed

If the file is opened for direct access, the WRITE statement can perform formatted or unformatted I/O.

WRITE statements operating on internal files can perform formatted or list-directed I/O.

For detailed information about files and different types of I/O, see Chapter 8, "I/O and file handling," on page 171.

The examples in this section illustrate different uses of the WRITE statement.

## Nonadvancing I/O

```
CHARACTER(LEN=17) :: prompt = 'Enter a number: '
WRITE (6, '(A)', ADVANCE='NO') prompt
```

The WRITE statement outputs to the file connected to unit 6 , which is preconnected to standard output. The ADVANCE= ' NO' specifier indicates the following:

- The file has been opened for formatted sequential I/O.
- The statement uses nonadvancing I/O to read an integer formatted as four characters into the variable prompt.
The effect of the nonadvancing WRITE is to output the character string in prompt to standard output without a terminating newline. This means that anything subsequently entered by the user will appear on the same line.

## Internal file

```
CHARACTER(LEN=80) :: cfile
WRITE (cfile, '(I5, F10.5)') i, x
```

The statement writes a string of characters into the internal file cfile, using the embedded format specification to perform the format conversion.

## Namelist-directed I/O

In the next example, each of the four WRITE statements following the NAMELIST statement uses a different style of syntax to do exactly the same thing:

```
NAMELIST /nl/ a, b, c
WRITE (UNIT=6, NML=nl) ! 6 = standard output
WRITE (6, nl)
WRITE (*, NML=nl) ! * = standard output
WRITE nl ! assume standard output
```

## List-directed I/O

```
WRITE (6, *) int_var
```

This statement converts the value of int_var to character format and outputs the character string to standard output. The format conversion is based on the type of int_var. If you knew the format, you could substitute for the asterisk one of the following:

HP Fortran statements
WRITE

- The label of the FORMAT statement with the format specification, as in:

WRITE (6, 100) int_var
100 FORMAT(I4)

- An embedded format specification itself, as in:

```
WRITE (6, '(I4)') int_var
```

## Unformatted direct-access I/O

WRITE (31, REC=rec_num, ERR=99, IOSTAT=ios) a, b
This statement outputs to the file connected to unit 31. The REC= specifier indicates that the file has been opened for direct access and that this statement will output to the record whose number is stored in the variable rec_num. If an I/O error occurs during the execution of the statement, an error number will be stored in ios, and execution control will branch to the executable statement at label 99.

Related statements

## Related concepts

CLOSE, OPEN, PRINT, and READ
For information about I/O concepts, see Chapter 8, "I/O and file handling," on page 171, which also lists example programs that use I/O. For information about I/O formatting, see Chapter 9, "I/O formatting," on page 205.

## 11 Intrinsic procedures

I ntrinsic procedures are built-in functions and subroutines that are available by default to every Fortran 90 program and procedure. This chapter describes the intrinsic procedures provided by HP Fortran. All intrinsic procedures defined by the Fortran 90 Standard are supported in HP Fortran.

The following topics are described in this chapter:

- Basic terms and concepts
- Nonstandard intrinsic procedures
- Data representation models
- Functional categories of intrinsic procedures
- Intrinsic procedure specifications

NOTE HP Fortran intrinsic procedures are provided in the libraries /opt/fortran90/lib/libF90.a and/usr/lib/libcl.a. /usr/lib/libcl. 2 is used instead of libcl.a if using shared libraries (the default).

## Basic terms and concepts

The following sections describe the terms and concepts that are used in this chapter to describe intrinsic procedures.

## Availability of intrinsics

An intrinsic procedure is available in every Fortran 90 program unit except when an intrinsic and a user-defined procedure (or a library procedure) have the same name, and the user-defined procedure:

- Has the external attribute; see "external (statement and attribute)" on page 328 for more information. Library routines are dedared in the user program with the external attribute so that they will be called instead of intrinsics that have the same name.
- Has an explicit interface; see "Procedure interface" on page 151 for a description. A statement function has an explicit interface and therefore, if it has the same name as an intrinsic, will be recognized instead of the intrinsic.

Both a user-defined procedure and an intrinsic may have the same name when the user-defined procedure is used to extend a generic intrinsic and the argument types differ. See "Generic procedures" on page 154 for a description of this.

## Subroutine and function intrinsics

Intrinsic procedures are available as functions and subroutines. In general, they behave the same as user-defined subroutines and functions. Intrinsic subroutines are invoked by the CALL statement and can return values through arguments passed to the intrinsic. Intrinsic functions can be referenced as part of an expression or in a statement that expects a value.
All interface intrinsic subroutines and functions have an explicit interface.

## Generic and specific function names

The names of intrinsic functions can be either generic or specific. The name is generic-for example, ABS—if it permits arguments of different types. A name is specific-for example, IABS-if it permits arguments of one data type only.
A specific intrinsic function can be passed as an argument if it has the INTRINSIC attribute. A generic intrinsic function can have the INTRINSIC attribute if it is also the specific name, as in the case of the SIN intrinsic. See "Procedure dummy argument" on page 142 and the description of "INTRINSIC (statement and attribute)" on page 363.
Some compile-line options-for example, +autodbl—change the default data type sizes and can cause different or invalid intrinsic procedure references.

## Classes of intrinsics

Intrinsic procedures are classified as:

- Elemental intrinsics
- Transformational functions
- Inquiry functions

The following sections describe each class. The descriptions in "Intrinsic procedure specifications" on page 487 identify the class of each intrinsic.

## Elemental intrinsics

An intrinsic procedure is elemental if it is specified as having scalar arguments but will actual arguments that are arrays. Calling an elemental intrinsic with an array argument causes the function to perform the scalar operation on each element of the array. MVBITS is the only elemental subroutine. All other intrinsic subroutines are nonelemental.

An elemental function that is called with all scalar dummy arguments delivers a scalar result. Calling an elemental function with conformable array arguments, however, results in a conformable array result. If both array and scalar arguments are specified to an elemental function, each scalar is treated as an array in which all elements have the scalar value. The "scalar array" is conformable with the array arguments.

Intrinsic procedures

## Basic terms and concepts

## Transformational functions

Transformational intrinsic functions are nonelemental. Such functions require at least one array argument and return either a scalar or array result based on actual arguments that cannot be evaluated elementally. Often, an array result will be of a different shape than the argument(s). For example, Sum returns a scalar result that represents the sum of all the elements of the array argument.

## I nquiry functions

Inquiry intrinsic functions return information based on the properties of the principal argument-its value is irrelevant, and the argument need not be defined. For example, the SIZE inquiry function can be used to return the extent of an array along one dimension or the total number of elements in the array.

## Optimized intrinsic functions

The following intrinsics are available in millicode versions, which are optimized for performance. To get access the millicode intrinsics, you must optimize at level 2 or higher, or compile with the +Olibcalls option. See the Fortran 90 Programmer's Guide for information on this.

| $\operatorname{acos}$ | $\cos$ | pow |
| :--- | :--- | :--- |
| $\operatorname{asin}$ | $\exp$ | sin |
| $\operatorname{atan}$ | $\log$ | tan |
| $\operatorname{atan} 2$ | $\log 10$ |  |

## Nonstandard intrinsic procedures

HP Fortran 90 supports all intrinsic procedures defined by the Fortran 90 Standard. In addition, it supports the nonstandard intrinsic procedures listed in Table 53 on page 485. Like the standard intrinsics, the nonstandard intrinsics are part of the HP Fortran 90 language: their recognition is not enabled by compile-line options, and their generic nature, types, and dummy argument attributes are known to the compiler.
The nonstandard intrinsics provide:

- Additional functionality not defined in the Standard
- Compatibility with other Fortran 90 implementations
- Specific routines for data types beyond those in the Standard

Both standard and nonstandard intrinsics are described in "I ntrinsic procedure specifications" on page 487.

## Data representation models

## Data representation models

The Fortran 90 Standard specifies data representation models that suggest how data are represented in the computer and how computations are performed on the data. The computations performed by some Fortran 90 intrinsic functions are described in terms of these models.

There are three data representation models in Fortran 90:

- "The Bit Model" on page 481
- "The Integer Number System Model" on page 482
- "The Real Number System Model" on page 482

In any given implementation, the model parameters are chosen to match the implementation as closely as possible. However, an exact match is not required, and the model does not impose any particular arithmetic on the implementation.

## Data representation model intrinsics

Several intrinsic functions provide information about the three data representation models. These intrinsics are listed in Table 52.

Table 52 Intrinsic functions and data representation models

| Intrinsic function | Description |
| :--- | :--- |
| "BIT_SIZE (I)" on page 500 | Number of bits in an integer of the kind of I ( I is an <br> object, not a kind number) |
| "DIGITS $(\mathrm{X}$ )" on page 510 | Base digits of precision in integer or real model for x |
| "EPSILON $(\mathrm{X})$ " on page 515 | Small value compared to 1 in real model for x |
| "EXPONENT $(\mathrm{X})$ " on page 516 | Real model exponent value for x |
| "FRACTION $(\mathrm{X})$ " on page 517 | Real model fraction value for x |
| "HUGE $(\mathrm{X})$ " on page 519 | Largest model number in integer or real model for x |
| "MAXEXPONENT $(\mathrm{X})$ " on page 547 | Maximum exponent value in real model for x |
| "MINEXPONENT $(\mathrm{X})$ " on page 551 | Minimum exponent value in real model for x |

| Intrinsic function | Description |
| :---: | :---: |
| "NEAREST(X, S)" on page 556 | Nearest processor real value |
| "PRECISION(X)" on page 559 | Decimal precision in real model for x |
| "RADIX(X)" on page 562 | Base (radix) in integer or real model for $x$ |
| "RANGE (X)" on page 564 | Decimal exponent range in integer or real model for x |
| "RRSPACING(X)" on page 567 | $1 /($ relative spacing near x ) |
| "SCALE (X, I)" on page 568 | x with real model exponent changed by I |
| "SET_EXPONENT(X, I)" on page 571 | Set the real model exponent of x to I |
| "SPACING(X)" on page 575 | Absolute spacing near x |
| "TINY(X)" on page 581 | Smallest number in real model for x |

## The Bit Model

The bit model interprets a nonnegative scalar data object a of type integer as a sequence of binary digits (bits), based upon the model:

$$
a=\sum_{k=0}^{n-1} b_{k} \mathbf{2}^{k}
$$

where n is the number of bits, given by the intrinsic function BIT_SIZE and each $b$ has a bit value of 0 or 1 . The bits are numbered from right to left beginning with 0 .

## The Integer Number System Model

The integer number system is modeled by:

where
i
is the integer value.
S
$r \quad$ is the radix given by the intrinsic function RADIX (always 2 for HP systems).
$q \quad$ is the number of digits (integer greater than 0), given by the intrinsic function DIGITS.
d
is the eth digit and is an integer $0<=d<r$. The digits are numbered left to right, beginning with 1.

## The Real Number System Model

The real number system is modeled by:

$$
x=s b^{e} \sum_{k=1}^{p} f_{k} b^{-k}
$$

where
x

S
b
is the real value.
is the sign ( +1 or -1 ).
is the base (real radix) and is an integer greater than 1, given by the intrinsic function RADIX (always 2 for HP systems).
\(\left.$$
\begin{array}{ll}\text { e } & \begin{array}{l}\text { is an integer between some minimum value (Imin) and } \\
\text { maximum value (Imax), given by the intrinsic functions }\end{array}
$$ <br>
MINEXPONENT and MAXEXPONENT. <br>
is the number of mantissa digits and is an integer <br>

greater than 1, given by the intrinsic function DIGITS.\end{array}\right\}\)| is the kth digit and is an integer $0<=f_{k}<b$, but $f_{1}$ may |
| :--- |
| be zero only if all the $f_{k}$ are zero. The digits are |
| numbered left to right, beginning with 1. |

## Functional categories of intrinsic procedures

This section categorizes HP Fortran intrinsic procedures based on their functionality. The procedures are divided into the following categories:

- Array construction, array inquiry, array location, array manipulation, array reduction, array reshape
- Bit inquiry, bit manipulation
- Character computation, character inquiry
- Floating-point manipulation, mathematical computation, matrix multiply, numeric computation, numeric inquiry, and vector multiply
- Kind
- Logical
- Nonstandard intrinsic procedures
- Pointer inquiry
- Presence inquiry
- Pseudorandom number
- Time
- Transfer

A listing of intrinsic procedures, ordered alphabetically by category, appears in "Intrinsic procedures by category" on page 485. M ore complete information on the individual intrinsic procedures is provided in "Intrinsic procedure specifications" on page 487.

Intrinsic procedures Functional categories of intrinsic procedures

## Table 53 Intrinsic procedures by category

| Category | Intrinsic routines |
| :--- | :--- |
| Array construction | MERGE, PACK, SPREAD, UNPACK |
| Array inquiry | ALLOCATED, LBOUND, SHAPE, SIZE, UBOUND |
| Array location | MAXLOC, MINLOC |
| Array manipulation | CSHIFT, EOSHIFT, TRANSPOSE |
| Array reduction | RESHAPE |
| Array reshape | BIT_SIZE |
| Bit inquiry | BTEST, IAND, IBCLR, IBITS, IBSET, IEOR, IOR, ISHFT, <br> ISHFTC, MVBITS, NOT |
| Bit manipulation | ACHAR, ADJUSTL, ADJUSTR, CHAR, IACHAR, ICHAR, INDEX, <br> LEN_TRIM, LGE, LGT, LLE, LLT, REPEAT, SCAN, TRIM, <br> VERIFY |
| Character computation | LEN |
| Character inquiry | EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, <br> SET_EXPONENT, SPACING |
| Floating-point manipulation |  |
| Kind | KIND, SELECT_INT_KIND, SELECTED_REAL_KIND |
| Logical | LOGICAL |
| Mathematical computation | ACOS, ASIN, ATAN, ATAN2, COS, COSH, EXP, LOG, LOG10, <br> SIN, SINH, SQRT, TAN, TANH |
| Matrix multiply | MATMUL |

Intrinsic procedures
Functional categories of intrinsic procedures

| Category | Intrinsic routines |
| :--- | :--- |
| Nonstandard intrinsic <br> procedures | ABORT, ACOSD, ACOSH, AND, ASIND, ASINH, ATAN2D, ATAND, <br> ATANH, BADDRESS, COSD, DATE, DCMPLX, DFLOAT, DNUM, <br> DREAL, EXIT, FLUSH, FNUM, FREE, FSET, FSTREAM, GETARG, <br> GETENV, GRAN, HFIX, IACHAR, IADDR, IARGC, IDATE, IDIM, <br> IGETARG, IJINT, IMAG, INT1, INT2, INT4, INT8, INUM, <br> IOMSG, IQINT, IRAND, IRANP, ISIGN, ISNAN, IXOR, JNUM, <br> LOC, LSHFT, LSHIFT, MALLOC, MCLOCK, OR, QEXT, QFLOAT, <br> QNUM, QPROD, RAN, RAND, RNUM, RSHFT, RSHIFT, SECNDS, <br> SIND, SIZEOF, SRAND, SYSTEM, TAND, TIME, XOR, ZEXT |
| Numeric computation | ABS, AIMAG, AINT, ANINT, CEILING, CMPLX, CONJG, DBLE, <br> DIM, DPROD, FLOOR, INT, MAX, MIN, MOD, MODULO, NINT,, <br> REAL, SIGN |
| Numeric inquiry | DIGITS, EPSILON, HUGE, MAXEXPONENTS, MINEXPONENTS, <br> PRECISION, RADIX, RANGE, TINY |
| Pointer inquiry | ASSOCIATED |
| Optional argument inquiry | PRESENT |
| Pseudorandom number | RANDOM_NUMBER, RANDOM_SEED |
| Time | DATE_AND_TIME, SYSTEM_CLOCK |
| Transfer | TRANSFER |
| Vector multiply | DOT_PRODUCT |

## Intrinsic procedure specifications

The following sections describe the HP Fortran intrinsic procedures. The descriptions are ordered alphabetically, by intrinsic name. All of the intrinsics are generic. This means that the type, kind, and rank of the actual arguments can differ for each reference to the same intrinsic. In many cases, the kind and type of intrinsic function results are the same as that of the principal argument. For example, the SIN function may be called with any kind of real argument or any kind of complex argument, and the result has the type and kind of the argument.
Intrinsic procedure references may use keyword option. The actual argument expression is preceded by the dummy argument name-the argument keyword-and the equals sign (=). The argument keywords are shown in the descriptions.

Some intrinsic procedure's arguments are optional. Optional arguments are noted as such in the following descriptions.

Intrinsic procedures
Intrinsic procedure specifications

## ABORT()

| Description | Close all files, terminate the program, and cause an exception to create a <br> core file. |
| :--- | :--- |
| Class | Nonstandard subroutine. |

## ABS(A)

| Description | Absolute value. |
| :--- | :--- |
| Class | Elemental function. |

Argumen
Result type/ type parameters

Result value(s)

Specific forms

Description

Class

Argument
Result type/ type parameters

Result value

BABS, CABS, CDABS, DABS, HABS, QABS, ZABS.

## ACHAR (I)

Returns the character in a specified position of the ASCII collating sequence. It is the inverse of the IACHAR function.

Elemental function.
I must be of type integer.
Character of length one with kind type parameter value KIND (' $A^{\prime}$ ).

If I has a value in the range $0<=I<=127$, the result is the character in position I of the ASCII collating sequence, provided the processor is capable of representing that character; otherwise, the result is processordependent.

Intrinsic procedures
Intrinsic procedure specifications

If the processor is not capable of representing both uppercase and lowercase letters and I corresponds to a letter in a case that the processor is not capable of representing, the result is the letter in the case that the processor is capable of representing.
ACHAR (IACHAR (C)) must have the value c for any character c capable of representation in the processor.

## ACOS(X)

| Description | Arccosine (inverse cosine) function in radians. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real with a value that satisfies the inequality $\|\mathrm{x}\|<=$ <br> 1. <br> Result type/ <br> type parameters <br> Result value |
| The result has a value equal to a processor-dependent approximation to <br> arccos $(\mathrm{X})$, expressed in radians. It lies in the range $0<=$ ACOS $(\mathrm{X})<=$ Pi. |  |
| Specific forms | DCOS, QACOS. |

## ACOSD(X)

| Description | Arccosine (inverse cosine) function in degrees. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | x must be of type real with a value that satisfies the inequality $\|\mathrm{x}\|<=1$. |
| Result type/ <br> type parameters | Same as x. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> arccos $(\mathrm{X})$, expressed in degrees. It lies in the range $0<=$ ACOSD $(\mathrm{X})<=$ <br> 180. |
| Specific forms | DACOSD, QACOSD. |

Intrinsic procedures
Intrinsic procedure specifications

## ACOSH (X)

| Description | Hyperbolic arccosine of radians. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | x must be of type real with a value $\mathrm{x}>=1$. |
| Result type/  <br> type parameters Same as x. <br> Result value The result has a value equal to a processor-dependent approximation to <br> the hyperbolic arccosine of X. <br> It lies in the range $0<=$ ACOSH $(X)$.  |  |
| Specific forms | DACOSH, QACOSH. |

## ADJ USTL(STRING)

| Description | Adjust to the left, removing leading blanks and inserting trailing blanks. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | STRING must be of type character. |
| Result type | Character of the same length and kind type parameter as STRING. |
| Result value | The value of the result is the same as STRING except that any leading <br> blanks have been deleted and the same number of trailing blanks have <br> been inserted. |

## ADJ USTR(STRING)

| Description | Adjust to the right, removing trailing blanks and inserting leading <br> blanks. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | STRING must be of type character. |
| Result type | Character of the same length and kind type parameter as STRING. |

| Result value | The value of the result is the same as STRING except that any trailing blanks have been deleted and the same number of leading blanks have been inserted. |
| :---: | :---: |
|  | AlMAG(Z) |
| Description | Imaginary part of a complex number. |
| Class | Elemental function. |
| Argument | z must be of type complex. |
| Result type/ type parameters | Real with the same kind type parameter as z. |
| Result value | If $z$ has the value ( $x, y$ ), the result has value $y$. |
|  | AINT(A, KIND) |
| Optional argument | KIND |
| Description | Truncation to a whole number. |
| Class | Elemental function. |
| Arguments | A must be of type real. |
|  | KIND (optional) must be a scalar integer initialization expression. |
| Result type/ type parameters | The result is of type real. If KIND is present, the kind type parameter is that specified by KIND; otherwise, the kind type parameter is that of A. |
| Result value | If $\mid$ A $\mid<1$, AINT (A) has the value 0 ; if A $>=1$, AINT (A) has a value equal to the integer whose magnitude is the largest integer that does not exceed the magnitude of A and whose sign is the same as the sign of A. |
| Specific forms | DDINT, DINT, QINT. |

Intrinsic procedures
Intrinsic procedure specifications

## ALL(MASK, DIM)

Optional argument DIM

| Description | Determine whether all values are . TRUE. in MASK along dimension DIM. |
| :---: | :---: |
| Class | Transformational function. |
| Arguments | MASK must be of type logical. It must not be scalar. |
|  | DIM (optional) must be scalar and of type integer with value in the range $1<=$ DIM <= n where n is the rank of MASK. The corresponding actual argument must not be an optional dummy argument. |
| Result type, type parameters, and shape | The result is of type logical with the samekind type parameter as MASK. It is scalar if DIM is absent or MASK has rank one; otherwise, the result is an array of rank $n-1$ and of shape $\left(d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}, d_{\text {DIM }+1}, \ldots, d_{n}\right)$ where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of MASK. |
| Result value | Case 1 <br> The result of ALL (MASK) has the value . TRUE. if all elements of MASK are . TRUE. or if MASK has size zero, and the result has value. FALSE. if any element of MASK is .FALSE.. |
|  | Case 2 <br> If MASK has rank one, ALL (MASK, DIM) has a value equal to that of ALL (MASK). Otherwise, the value of element ( $\mathrm{s}_{1}, \mathrm{~s}_{2}, \ldots, \mathrm{~S}_{\text {DIM-1 }}, \mathrm{S}_{\text {DIM }+1}, \ldots, \mathrm{~s}_{\mathrm{n}}$ ) of ALL (MASK, DIM) is equal to ALL(MASK ( $\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\text {DIM-1 }}, i, \mathrm{~S}_{\mathrm{DIM}+1}$, ..., $\mathrm{S}_{\mathrm{n}}$ )). |

## ALLOCATED(ARRAY)

| Description | Indicate whether or not an allocatable array is currently allocated. |
| :--- | :--- |
| Class | Inquiry function. |
| Argument | ARRAY must be an allocatable array. |
| Result type, <br> type parameters, <br> and shape | Default logical scalar. |
| Result value | The result has the value . TRUE. if ARRAY is currently allocated and has <br> the value. FALSE. if ARRA is not currently allocated. The result is <br> undefined if the allocation status of the array is undefined. |

## AND (I, J)

Description Logical AND.

Class
Arguments

## type parameters

Result type/

Result value The result has the value obtained by performing a logical AND on I and $J$ bit-by-bit according to Table 54.

## Table 54

Truth table for AND intrinsic

| $\mathbf{I}$ | $J$ | $\operatorname{AND}(I, J)$ |
| :--- | :--- | :--- |
| 1 | 1 | 1 |

Intrinsic procedures Intrinsic procedure specifications

| $I$ | J | $\operatorname{AND}(I, J)$ |
| :--- | :--- | :--- |
| 1 | 0 | 0 |
| 0 | 1 | 0 |
| 0 | 0 | 1 |

The model for interpreting an integer value as a sequence of bits is described in "The Bit M odel" on page 481.

## ANINT(A, KIND)

Optional argument
Description
Class
Arguments

Result type/ type parameters

| Result value | If $A>0, \operatorname{ANINT}(A)$ has the value AINT $(A+0.5) ;$ if $A<=0, \operatorname{ANINT}$ (A) has |
| :--- | :--- |
| the value AINT (A-0.5). |  |
| Specific forms | DNINT, QNINT. |

## ANY(MASK, DIM)

| Optional argument | DIM |  |
| :---: | :---: | :---: |
| Description | Determine whether any value is . TRUE. in MASK along dimension DIM. |  |
| Class | Transformational function. |  |
| Arguments | MASK | must be of type logical. It must not be scalar. |
|  | DIM (optional) | must be scalar and of type integer with a value in the range $1<=$ DIM $<=n$, where $n$ is the rank of MASK. The corresponding actual argument must not be an optional dummy argument. |
| Result type, type parameters, and shape | The result is of type logical with the same kind type parameter as MASK. It is scalar if DIM is absent or MASK has rank one; otherwise, the result is an array of rank $n-1$ and of shape ( $d_{1}, d_{2}, \ldots, d_{\text {DIM }-1}, d_{\text {DIM }+1}, \ldots, d_{n}$ ) where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of MASK. |  |
| Result value | Case 1 | The result of ANY (MASK) has the value . TRUE. if any element of MASK is. TRUE. and has the value. FALSE. if no elements are. TRUE. or if MASK has size zero. |
|  | Case 2 | If MASK has rank one, ANY (MASK, DIM) has a value equal to that of ANY (MASK). Otherwise, the value of element ( $s_{1}, s_{2}, \ldots, S_{\text {DIM-1 }}, s_{\text {DIM }+1}, \ldots, s_{n}$ ) of ANY (MASK, DIM) is equal to $\operatorname{ANY}\left(\operatorname{MASK}\left(\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\text {DIM-1 }}, \therefore, \mathrm{S}_{\text {DIM }+1}\right.\right.$, ..., $\left.\mathrm{s}_{\mathrm{n}}\right)$ ). |

Intrinsic procedures
Intrinsic procedure specifications

## ASIN(X)

| Description | Arcsine (inverse sine) function in radians. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real. Its value must satisfy the inequality $\|\mathrm{x}\|>=1$. |
| Result type <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> arcsin $(X)$, expressed in radians. It lies in the range $-\mathrm{Pi} / 2<=\mathrm{ASIN}(\mathrm{X})<=$ <br> $\mathrm{Pi} / 2$. |

Specific forms DASIN, QASIN.

## ASIND(X)

| Description | Arcsine (inverse sine) function in degrees. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | x must be of type real. Its value must satisfy the inequality $\|x\|<=1$. |
| Result type/ <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> arcsin(X), expressed in degrees. It lies in the range <br> $-90<=A S I N(X)<=90$. |
| Specific forms | DASIND, QASIND. |

|  | ASINH(X) |
| :---: | :---: |
| Description | Hyperbolic arcsine of radians. |
| Class | Elemental nonstandard function. |
| Argument | x must be of type real. |
| Result type/ type parameters | Same as x . |
| Result value | The result has a value equal to a processor-dependent approximation to the hyperbolic arcsine of x . |
| Specific forms | DASINH, QASINH. |
|  | ASSOCIATED(POINTER, TARGET) |
| Optional argument | target |
| Description | Returns the association status of its pointer argument or indi cates the pointer is associated with the target. |
| Class | Inquiry function. |
| Arguments | POINTER must be a pointer and may be of any type. Its pointer association status must not be undefined. |
|  | TARGET <br> (optional) must be a pointer or target. If it is a pointer, its pointer association status must not be undefined. |
| Result type | The result is scalar of type default logical. |
| Result value | Case 1 <br> If TARGET is absent, the result is . TRUE. if POINTER is currently associated with a target and .FALSE. if it is not. |
|  | Case 2 <br> If TARGET is present and is a target, the result is . TRUE. if POINTER is currently associated with target and. FALSE. if it is not. |

Intrinsic procedures
Intrinsic procedure specifications

```
Case 3 If TARGET is present and is a pointer, the result is
    .TRUE. if both POINTER and TARGET are currently
    associated with the same target, and is .FALSE.
    otherwise.If either POINTER or TARGET is
    disassociated, the result is .FALSE..
```

## ATAN (X)

| Description | Arctangent (inverse tangent) function in radians. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | X must be of type real. |
| Result type <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> arctan $(X)$, expressed in radians, that lies in the range -Pi/2 $<=$ ATAN (X) <br> $<=P \mathrm{Pi} / 2$. |
| Specific forms | DATAN, QATAN. |

## ATAN2(Y, X)

Description

Class

Arguments

Result type/ type parameters

Result value

Arctangent (inverse tangent) function in radians. The result is the principal value of the argument of the nonzero complex number ( $\mathrm{X}, \mathrm{Y}$ ).

Elemental function.
Y must be of type real.
X
must be of the same type and kind type parameter as Y. If $y$ has the value zero, $x$ must not have the value zero.

Same as x .

The result has a value equal to a processor-dependent approximation to the principal value of the argument of the complex number ( $\mathrm{X}, \mathrm{Y}$ ), expressed in radians.

The result lies in the range $-\mathrm{Pi}<=\operatorname{ATAN} 2(\mathrm{Y}, \mathrm{X})<=\mathrm{Pi}$ and is equal to a processor-dependent approximation to a value of $\arctan (Y / X)$ if $x$ is not 0 .
If $Y>0$, the result is positive. If $Y=0$, the result is zero if $X>0$ and the result is Pi if $\mathrm{X}<0$. If $\mathrm{Y}<0$, the result is negative. If $\mathrm{X}=0$, the absol ute value of the result is $\mathrm{Pi} / 2$.

Specific forms DATAN2, QATAN2.

## ATAN2D(Y, X)

| Description | Arctangent (inverse tangent) function in degrees. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Arguments | Y |

Result type/ type parameters

Result value

Specific forms
DATAN2D, QATAN2D.

## ATAND(X)

Description Arctangent (inverse tangent) function in degrees.
Class Elemental nonstandard function.
Argument $\quad \mathrm{x}$ must be of type real.
Result type/ Same as x.
type parameters
Same as x .

The result has a value equal to a processor-dependent approximation to the principal value of the argument of the complex number ( $\mathrm{X}, \mathrm{Y}$ ), expressed in degrees, that lies in the range $-90<A T A N 2 D(Y, X)<90$.

Intrinsic procedures
Intrinsic procedure specifications

| Result value | The result has a value equal to a processor-dependent approximation to <br> $\arctan (X)$, expressed in degrees, that lies in the range <br> $-90<A T A N D ~$ |
| :--- | :--- |
| Specific forms | DATAND, QATAND. |

| Description | Hyperbolic arctangent of radians. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | X must be of type real. |
| Result type/ <br> type parameters <br> Result value | Same as X. <br> The result has a value equal to a processor-dependent approximation to <br> the hyperbolic arctangent of X. |
| Specific forms | DATANH, QATANH. |

## BADDRESS(X)

| Description | Return the address of x. |
| :--- | :--- |
| Class | Inquiry nonstandard function. |
| Argument | x may be of any type. |
| Result type | The result is of type default integer. |
| Description | Returns the number of bits n, defined by the model described in "The Bit <br> Model" on page 481, for integers with the kind parameter of the <br> argument. |
| Class | Inquiry function. |

| Argument | I must be of type integer. |
| :---: | :---: |
| Result type, type parameters, and shape | Scalar integer with the same kind type parameter as I. |
| Result value | The result has the value of the number of bits n in the model integer, defined for bit manipulation contexts in "The Bit M odel" on page 481, for integers with the kind parameter of the argument. |
|  | BTEST(I, POS) |
| Description | Tests a bit of an integer value. |
| Class | Elemental function. |
| Arguments | I must be of type integer. |
|  | POS must be of type integer. It must be nonnegative and be |
| Result type | The result is of type default logical. |
| Result value | The result has the value. TRUE. if bit POS of I has the value 1 and has the value.FALSE. if bit POS of $I$ has the value 0 . The model for the interpretation of an integer value as a sequence of bits is described in "The Bit M odel" on page 481. |
| Specific forms | Bbtest, bitest, butest, bktest, htest. |
|  | CEILING(A) |
| Description | Returns the least integer greater than or equal to its argument. |
| Class | Elemental function. |
| Argument | A must be of type real. |
| Result type/ type parameters | Default integer. |

## Intrinsic procedures

Intrinsic procedure specifications

| Result value | The result has a value equal to the least integer greater than or equal to |
| :--- | :--- |
|  | A. The result is undefined if the processor cannot represent this value in |

## CHAR(I, KIND)

Optional argument
Description

## Class

Arguments
Result type/
type parameters

Result value

KIND

Returns the character in a given position of the processor collating sequence associated with the specified kind type parameter. It is the inverse of the function ICHAR.

Elemental function.

I
must be of type integer with a value in the range $0<=I$ $<=n-1$, where n is the number of characters in the collating sequence associated with the specified kind type parameter.
KIND (optional) must be a scalar integer initialization expression.
Character of length one. If KIND is present, the kind type parameter is that specified by KIND; otherwise, the kind type parameter is that of default character type.

The result is the character in position I of the collating sequence associated with the specified kind type parameter.

ICHAR (CHAR (I, KIND (C) )) must have the value I for $0<=1<=n-1$ and CHAR (ICHAR (C), KIND (C)) must have the value C for any character c capable of representation in the processor.

## CMPLX(X, Y, KIND)

Optional arguments
Y, KIND
Convert to complex type.
Elemental function.
$X \quad$ must be of type integer, real, or complex.

|  | Y (optional) must be of type integer or real. It must not be present if $x$ is of type complex. |
| :---: | :---: |
|  | KIND (optional) must be a scalar integer initialization expression. |
| Result type/ type parameters | The result is of type complex. If KIND is present, the kind type parameter is that specified by KIND; otherwise, the kind type parameter is that of default real type. |
| Result value | - If Y is absent and X is not complex, it is as if Y were present with the value zero. |
|  | - If Y is absent and x is complex, it is as if y were present with the value Aimag ( X ). |
|  | CMPLX ( $\mathrm{X}, \mathrm{Y}, \mathrm{KIND}$ ) has the complex value whose real part is REAL ( $\mathrm{X}, \mathrm{KIND}$ ) and whose imaginary part is REAL (Y, KIND). |

## CONJ G(Z)

| Description | Conjugate of a complex number. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | $z$ must be of type complex. |
| Result type/ <br> type parameters | Same as $z$. |
| Result value | If $z$ has the value $(x, y)$, the result has the value $(x,-y)$. |
| Specific forms | DCONJG. |

## $\cos (\mathrm{X})$

Description
Cosine function in radians.
Class

Argument
Elemental function.
x must be of type real or complex.

Intrinsic procedures
Intrinsic procedure specifications

Result type/
type parameter
Result value

Specific forms
CCOS, CDCOS, DCOS, QCOS, ZCOS.

## COSD(X)

Cosine function in degrees.
Elemental nonstandard function.
x must be of type real.
Same as x .

The result has a value equal to a processor-dependent approximation to $\cos (\mathrm{X})$.

DCOSD, QCOSD.

## COSH (X)

| Description | Hyperbolic cosine function. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real. |
| Result type/ <br> type parameters | Same as x. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> cosh(X). |
| Specific forms | DCOSH, QCOSH. |

## COUNT(MASK, DIM)

| Optional argument | DIM |
| :---: | :---: |
| Description | Count the number of . TRUE. elements of MASK along dimension DIM. |
| Class | Transformational function. |
| Arguments | MASK must be of type logical. It must not be scalar. |
|  | DIM (optional) must be scalar and of type integer with a value in the range |
|  | $1<=$ DIM $<=n$, where $n$ is the rank of MASK. The corresponding actual argument must not be an optional dummy argument. |
| Result type, type parameters, and shape | The result is of type default integer. It is scalar if DIM is absent or MASK has rank one; otherwise, the result is an array of rank $\mathrm{n}-1$ and of shape $\left(d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}, d_{\text {DIM }+1}, \ldots, d_{n}\right)$ where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of MASK. |
| Result value | Case 1 The result of COUNT (MASK) has a value equal to the number of . TRUE. elements of MASK or has the value zero if MASK has size zero. |
|  | Case 2 <br> If MASK has rank one, COUNT (MASK, DIM) has a value equal to that of COUNT (MASK). Otherwise, the value of element ( $\mathrm{s}_{1}, \mathrm{~s}_{2}, \ldots, \mathrm{~S}_{\text {DIM-1 }}, \mathrm{s}_{\text {DIM }+1}, \ldots, \mathrm{~s}_{\mathrm{n}}$ ) of COUNT (MASK, DIM) is equal to COUNT (MASK ( $\mathrm{S}_{1}, \mathrm{~S}_{2}$, $\left.\ldots, S_{\text {DIM }-1},:, S_{\text {DIM }+1}, \ldots, S_{n}\right)$ ). |

Specific forms KCOUNT.

Intrinsic procedures
Intrinsic procedure specifications

## CSHIFT(ARRAY, SHIFT, DIM)

Optional argument DIM

| Description | Perform a circular shift on an array expression of rank one, or perform <br> circular shifts on all the complete rank one sections along a given <br> dimension of an array expression of rank two or greater. |
| :--- | :--- |
| Elements shifted out at one end of a section are shifted in at the other |  |
| end. Different sections may be shifted by different amounts and in |  |
| different directions (positive for left shifts, negative for right shifts). |  |
| Class |  |
| Transformational function. |  |

Result type, The result is of the type and type parameters of ARRAY, and has the type parameters, and shape

Result value

| Case 1 | If ARRAY has rank one, element i of the result is |
| :--- | :--- |
|  | ARRAY $(1+\operatorname{MODULO}(\mathrm{i}+\operatorname{SHIFT}-1$, |
|  | $\operatorname{SIZE}(\operatorname{ARRAY})))$. |

KCSHIFT.

## DATE (DATE STR)

| Description | Return current system date. |
| :---: | :---: |
| Class | Nonstandard subroutine. |
| Argument | DATESTR must be of type character. It must be a character string of length 9 or more. |
|  | DATE_AND_TIME (DATE, TIME, ZONE, VALUES) |
| Optional arguments | DATE, TIME, ZONE, VALUES |
| Description | Returns data on the real-time clock and date in a form compatible with the representations defined in ISO 8601:1988 ("Data elements and interchange formats - Information interchange - Representation of dates and times"). |
| Class | Subroutine. |
| Arguments | DATE (optional) must be scalar and of type default character, and must be of length at least 8 in order to contain the complete value. It is an Intent (OUT) argument. Its leftmost 8 characters are set to a value of the form CCYYMMDD, where CC is the century, YY the year within the century, MM the month within the year, and DD the day within the month. If there is no date available, they are set to blank. |
|  | TIME (optional) must be scalar and of type default character, and must be of length at least 10 in order to contain the complete value. It is an intent (out) argument. Its leftmost 10 characters are set to a value of the form hhmmss.sss, where hh is the hour of the day, mm is the minutes of the hour, and ss.sss is the seconds and milliseconds of the minute. If there is no clock available, they are set to blank. |
|  | ZONE (optional) must be scalar and of type default character, and must be of length at least 5 in order to contain the complete value. It is an INTENT (OUT) argument. Its leftmost 5 |

Intrinsic procedures
Intrinsic procedure specifications
characters are set to a value of the form (+/-)hhmm, where hh and mm are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively. If there is no clock available, they are set to blank.

VALUES
(optional) must be of type default integer and of rank one. It is an INTENT (OUT) argument. Its size must be at least 8. The values returned in VALUES are as follows:

| VALUES (1) | the year (for example, 1990), or - |
| :--- | :--- |
|  | HUGE (0) if there is no date available; |

VALUES (2) the month of the year, or - $\operatorname{HUGE}(0)$ if there is no date available;

VALUES (3) the day of the month, or - $\operatorname{HUGE}(0)$ if there is no date available;

VALUES (4) the time difference with respect to Coordinated U niversal Time (UTC) in minutes, or -HUGE (0) if this information is not available;

VALUES (5) the hour of the day, in the range of 0 to 23, or - HUGE (0) if there is no clock;

VALUES (6) the minutes of the hour, in the range 0 to 59, or -HUGE (0) if there is no clock;

VALUES (7) the seconds of the minute, in the range 0 to 60, or - HUGE ( 0 ) if there is no clock;

VALUES (8) the milliseconds of the second, in the range 0 to 999, or - HUGE (0) if there is no clock.

The HUGE intrinsic function is described in "HUGE (X)" on page 519.

## DBLE(A)

| Description | Convert to double precision real type. |
| :---: | :---: |
| Class | Elemental function. |
| Argument | A must be of type integer, real, or complex. |
| Result type/ type parameters | Double precision real. |
| Result value | Case 1 If A is of type double precision real, $\operatorname{DBLE}(\mathrm{A})=\mathrm{A}$. |
|  | Case 2 If A is of type integer or real, the result is as much precision of the significant part of A as a double precision real datum can contain. |
|  | Case 3 <br> If $A$ is of type complex, the result is as much precision of the significant part of the real part of A as a double precision real datum can contain. |
| Specific forms | DBLEQ. |
|  | DCMPLX(X,Y) |
| Optional argument | Y |
| Description | Convert to double precision complex type. |
| Class | Elemental nonstandard function. |
| Arguments | x must be of type integer, real, or complex. |
|  | $Y \quad$ must not be supplied if X is of type complex; otherwise is optional and must be of the same type and kind type parameter as x . |
| Result type/ type parameters | Double precision complex. |

Intrinsic procedures
Intrinsic procedure specifications

## DF LOAT(A)

| Description | Convert to double precision type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer. |
| Result type/ <br> type parameters | Double precision. |
| Specific forms | DFLOTI, DFLOTJ, DFLOTK. |

## DIGITS(X)

| Description | Returns the number of significant di gits in the model representing <br> numbers of the same type and kind type parameter as the argument. |
| :--- | :--- |
| Class | Inquiry function. |
| Argument | $x$ must be of type integer or real. It may be scalar or array valued. |
| Result type, <br> type parameters, <br> and shape | Default integer scalar. |
| Result value | The result has the value $q$ if $x$ is of type integer and $p$ if $x$ is of type real, <br> where $q$ and $p$ are as defined in "Data representation models" on <br> page 480 for the model representing numbers of the same type and kind <br> type parameter as $x$. |

|  | DIM(X, Y) |
| :---: | :---: |
| Description | The difference $\mathrm{X}-\mathrm{Y}$ if it is positive; otherwise zero. |
| Class | Elemental function. |
| Arguments | $\mathrm{X} \quad$ must be of type integer or real. |
|  | Y must be of the sametype and kind type parameter as x . |
| Result type/ type parameters | Same as x . |
| Result value | The value of the result is $\mathrm{X}-\mathrm{Y}$ if $\mathrm{X}>\mathrm{Y}$ and zero otherwise. |
| Specific forms | BDIM, DDIM, HDIM, QDIM. |
|  | DNUM(I) |
| Description | Convert to double precision. |
| Class | Elemental nonstandard function. |
| Argument | I must be of type character. |
| Result type | Double precision. |
|  | DOT_PRODUCT(VECTOR_A, VECTOR_B ) |
| Description | Performs dot-product multiplication of numeric or logical vectors. |
| Class | Transformational function. |
| Arguments | VECTOR_A must be of numeric type (integer, real, or complex) or of logical type. It must be array valued and of rank one. |
|  | VECTOR_B must be of numerictype if VECTOR_A is of numeric type or of type logical if VECTOR_A is of type logical. It must be array valued and of rank one. It must be of the same size as VECTOR_A. |

Intrinsic procedures
Intrinsic procedure specifications
Result type,
type parameters,
and shape

| Result value | Case 1 |
| :--- | :--- |
| Case 2 | If VECTOR_A is of type integer or real, the result has <br> the value SUM (VECTOR_A*VECTOR_B). If the vectors <br> havesize zero, the result has the value zero. <br> If VECTOR_A is of type complex, the result has the <br> value SUM (CONJG (VECTOR_A)*VECTOR_B). If the <br> vectors have size zero, the result has the value zero. |
| Case 3 | If VECTOR_A is of type logical, the result has the value <br> ANY (VECTOR_A . AND. VECTOR_B). If the vectors |

## DPROD(X, Y)

Double precision real product.

Elemental function.

| $X$ | must be of type default real. |
| :--- | :--- |
| $Y$ | must be of type default real. |

Double precision real.

The result has a value equal to a processor-dependent approximation to the product of $X$ and $Y$.

## DREAL(A)

| Description | Convert to double precision. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, or complex. |
| Result | Double precision. |

## EOSHIFT(ARRAY, SHIFT, BOUNDARY, DIM)

| Optional arguments | BOUNDARY, DIM |
| :--- | :--- |
| Description | Perform an end-off shift on an array expression of rank one or perform <br> end-off shifts on all the complete rank-one sections al ong a given <br> dimension of an array expression of rank two or greater. |
| Elements are shifted off at one end of a section and copies of a boundary <br> value are shifted in at the other end. |  |
| Different sections may have different boundary values and may be <br> shifted by different amounts and in different directions (positive for left <br> shifts, negative for right shifts). |  |
| Arguments | Transformational function. |

Intrinsic procedures
Intrinsic procedure specifications

Table 55 Default values for the BOUNDARY argument

| Data type of ARRAY | Default value of boundary |
| :--- | :--- |
| Integer | 0 |
| Real | 0.0 |
| Complex | $(0.0,0.0)$ |
| Logical | .FALSE. |
| Character (len) | Ien blanks |

DIM (optional) must be scalar and of type integer with a value in the range $1<=D I M<=n$, where $n$ is the rank of ARRAY. If DIM is omitted, it is as if it were present with the value 1.

Result type, type parameters, and shape

|  | EPSILON(X) |
| :---: | :---: |
| Description | Returns a positive model number that is almost negligible compared to unity in the model representing numbers of the same type and kind type parameter as the argument. |
| Class | Inquiry function. |
| Argument | x must be of type real. It may be scalar or array valued. |
| Result type, type parameters, and shape | Scalar of the same type and kind type parameter as x . |
| Result value | The result has the value $b^{1-p}$ where $b$ and $p$ are as defined in "The Real Number System M odel" on page 482 for the model representing numbers of the same type and kind type parameter as x . |
|  | EXIT(STATUS) |
| Optional argument | Status |
| Description | Close all files and terminate the program. |
| Class | Nonstandard subroutine. |
| Argument | STATUS must be of type integer. |
|  | If STATUS is supplied, the calling program exits with a return code status of STATUS. Otherwise the return code status is indeterminate. |
|  | In csh the \$status environment variable holds the return code for the last executed command. In ksh, the $\$$ ? environment variable holds the return code. |

Intrinsic procedures
Intrinsic procedure specifications

## EXP(X)

| Description | Exponential. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real or complex. |
| Result type/ <br> type parameters | Same as x. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> $e^{x}$. If x is of type complex, its imaginary part is regarded as a value in <br> radians. |
| Specific forms | CEXP, CDEXP, DEXP, QEXP, ZEXP. |

## EXPONENT(X)

| Description | Returns the exponent part of the argument when represented as a model <br> number. |
| :--- | :--- |
| Class | Elemental function. |
| Resument type | x must be of type real. |
| Result value | Default integer. |
| The result has a value equal to the exponent e of the model <br> representation (see "The Real Number System M odel" on page 482) for <br> the value of x , provided x is nonzero and e is within the range for default <br> integers. The result is undefined if the processor cannot represent e in <br> the default integer type. EXPONENT ( X ) has the value zero if x is zero. |  |

## FLOOR(A)

| Description | Returns the greatest integer less than or equal to its argument. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | A must be of type real. |
| Result type/ <br> type parameters | Default integer. |
| Result value | The result has a value equal to the greatest integer less than or equal to <br> A. The result is undefined if the processor cannot represent this value in <br> the default integer type. |

## FLUSH(LUNIT)

Description
Class
Flush pending I/O on a logical unit.
Nonstandard subroutine.

## FNUM(UNIT)

| Description | Get an operating system file descriptor. |
| :--- | :--- |
| Class | Inquiry nonstandard function. |
| Description | Returns the fractional part of the model representation of the argument <br> value. |
| Class | Elemental function. |
| Argument | x must be of type real. |
| Result type/ <br> type parameters | Same as x. |

Intrinsic procedures
Intrinsic procedure specifications
$\begin{array}{ll}\text { Result value } & \text { The result has the value } \mathrm{x} * \mathrm{~b}^{-\mathrm{e}} \text {, where } \mathrm{b} \text { and e are as defined in "The } \\ \text { Real Number System } \mathrm{M} \text { odel" on page 482. If } \mathrm{x} \text { has the value zero, the }\end{array}$ result has the value zero.

## FREE(P)

| Description | Free a block of memory. |
| :--- | :--- |
| Class | Nonstandard subroutine. |
|  | FSET(UNIT, NEWFD, OLDFD) |

Description Attach a system file descriptor to a logical unit.
Class $\quad$ Nonstandard subroutine.

## FSTREAM(UNIT)

| Description | Retrieve a C language FILE stream pointer. |
| :--- | :--- |
| Class | Inquiry nonstandard function. |

## GETARG(N, STRING)

Description Get the arguments passed to the program.

Class

Arguments

Nonstandard subroutine.

N

STRING
must be of type integer. n specifies which commandline argument is requested. When $\mathrm{N}=1$, it returns the program name. When $\mathrm{N}=0$, it returns all blanks.
must be a character variable. It is assigned the requested command-line argument, padded with blanks on the end. If the requested argument is longer than STRING, a truncated version is assigned to STRING.

## GETE NV(VAR, VALUE)

| Description | Return the value of a system environment variable. |
| :---: | :---: |
| Class | Nonstandard subroutine. |
| Arguments | VAR and VALUE are of type character. VAR specifies the environment variable name. The character variable vALUE is assigned the environment variable's value. VALUE must be declared large enough to hold the value. If the environment variable is not defined VALUE is set to all blanks. |
|  | GRAN() |
| Description | Generate Gaussian normal random numbers. |
| Class | Elemental nonstandard function. |
| Result | REAL (4). The numbers generated by GRAN have a mean of 0.0 , a standard deviation of 1.0, and a range of approximately -5.0 through +5.0 . |
|  | HFIX(A) |
| Description | Convert to Integer (2) type. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, double precision, or complex. |
| Result | Integer (2) type. |
|  | HUGE(X) |
| Description | Returns the largest number in the model representing numbers of the same type and kind type parameter as the argument. |
| Class | Inquiry function. |
| Argument | x must be of type integer or real. It may be scalar or array valued. |

Intrinsic procedures
Intrinsic procedure specifications

Result type, Scalar of the same type and kind type parameter as x . type parameters, and shape

Result value
The result has the value $r^{q}-1$ if $x$ is of type integer and $\left(1-b^{-p}\right) b^{* *} e_{\max }$
if $x$ is of type real, where $r, q, b, p$, and $e_{\max }$ are as defined in "The Real Number System M odel" on page 482.

## IACHAR (C)

| Description | Returns the position of a character in the ASCII collating sequence. |
| :---: | :---: |
| Class | Elemental function. |
| Argument | c must be of type default character and of length one. |
| Result type/ type parameters | Default integer. |
| Result value | If C is in the collating sequence defined by the codes specified in ISO 646:1983 ("Information technol ogy - ISO 7-bit coded character set for information interchange"), the result is the position of c in that sequence and satisfies the inequality ( $0<=$ IACHAR ( $C$ ) $<=127$ ). |
|  | A processor-dependent value is returned if C is not in the ASCII collating sequence. The results are consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE (C, D) is .TRUE., IACHAR (C) . LE. IACHAR (D) is . TRUE. where C and D are any two characters representable by the processor. |

## IADDR(X)

| Description | Return the address of x. |
| :--- | :--- |
| Class | I nquiry nonstandard function. |
| Argument | x may be of any type. |
| Result type | The result is of type default integer. |

See "BADDRESS(X)" on page 500 for examples.

## IAND(I, J)

| Description | Performs a bitwise logical AND. |
| :--- | :--- |
| Class | Elemental function. |

Arguments I must be of type integer.

J must be of type integer with the same kind type parameter as I.

Result type/
type parameters
Result value

Table 56

Specific forms
BIAND, HIAND, IIAND, JIAND, KIAND.

Intrinsic procedures
Intrinsic procedure specifications

## IARGC()

| Description | Get the number of arguments passed to the program. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Result type | Integer. |
| Result value | If no arguments are passed to the program, IARGC returns zero. <br> Otherwise IARGC returns a count of the arguments that follow the <br> program name on the command line. |

## IBCLR(I, POS)

Description
Class

Arguments

Result type/ type parameters

Result value

Specific forms BBCLR, HBCLR, IIBCLR, JIBCLR, KIBCLR.

## IBITS(I, POS, LEN)

| Description | Extracts a sequence of bits. |
| :---: | :---: |
| Class | Elemental function. |
| Arguments | I must be of type integer. |
|  | ```POS must be of type integer. It must be nonnegative and POS + LEN must be less than or equal to BIT_SIZE(I).``` |
|  | LEN must be of type integer and nonnegative. |
| Result type/ type parameters | Same as I. |
| Result value | The result has the value of the sequence of LEN bits in I beginning at bit pos, right-adjusted and with all other bits zero. The model for the interpretation of an integer value as a sequence of bits is in "The Bit Model" on page 481. |
| Specific forms | BBITS, HBITS, IIBITS, JIBITS, KIBITS. |
|  | IBSET(I, POS) |
| Description | Sets a bit to one. |
| Class | Elemental function. |
| Arguments | I must be of type integer. |
|  | $\begin{array}{ll} \text { POS } & \text { must be of type integer. It must be nonnegative and } \\ \text { less than BIT_SIZE (I). } \end{array}$ |
| Result type/ type parameters | Same as I. |
| Result value | The result has the value of the sequence of bits of $I$, except that bit POS of $I$ is set to one. The model for the interpretation of an integer value as a sequence of bits is in "The Bit M odel" on page 481. |
| Specific forms | HBSET, IIBSET, JIBSET, KIBSET. |

Intrinsic procedures
Intrinsic procedure specifications

## ICHAR (C)

| Description | Returns the position of a character in the processor collating sequence associated with the kind type parameter of the character. |
| :---: | :---: |
| Class | Elemental function. |
| Argument | c must be of type character and of length one. Its value must be that of a character capable of representation in the processor. |
| Result type/ type parameters | Default integer. |
| Result value | The result is the position of c in the processor collating sequence associated with the kind type parameter of c and is in the range $0<=$ IACHAR ( $C$ ) $<n-1$, where $n$ is the number of characters in the collating sequence. <br> For any characters C and D capable of representation in the processor, C.LE.D is.TRUE. if and only if ICHAR (C) .LE. ICHAR (D) is .TRUE., and C.EQ.D is . TRUE. if and only if ICHAR (C).EQ. ICHAR (D) is .tRUE. . |

## IDATE (MONTH, DAY, YEAR)

Description Return the month, day, and year of current system.
Class Nonstandard subroutine.
Arguments MONTH, DAY, and YEAR must be of type integer.

## IDIM(X, Y)

| Description | Integer positive difference. |
| :---: | :---: |
| Class | Nonstandard function. |
| Arguments | X ( must be of type integer. |
|  | Y must be of type integer with the same kind parameter as x . |
| Result type/ type parameters | Integer of same kind type parameter as X . |
| Result value | If $\mathrm{X}>\mathrm{Y}, \operatorname{IDIM}(\mathrm{X}, \mathrm{Y})$ is $\mathrm{X}-\mathrm{Y} . \operatorname{lf~} \mathrm{X}<=\mathrm{Y}, \operatorname{IDIM}(\mathrm{X}, \mathrm{Y})$ is zero. |
| Specific forms | IIDIM, JIDIM. KIDIM. |

## IEOR (I, J)

Description
Class
Arguments

Performs a bitwise exclusive or.
Elemental function.
I must be of type integer.
J must be of type integer with the same kind type parameter as I.

Result type/
Same as I.
type parameters
Result value The result has the value obtained by combining I and J bit-by-bit according to Table 57.

Intrinsic procedures
Intrinsic procedure specifications

Table 57 Truth table for IEOR intrinsic

| I | J | IEOR (I, J) |
| :--- | :--- | :--- |
| 1 | 1 | 0 |
| 1 | 0 | 1 |
| 0 | 1 | 1 |
| 0 | 0 | 0 |

The model for the interpretation of an integer value as a sequence of bits is in "The Bit M odel" on page 481.

Specific forms BIEOR, HIEOR, IIEOR, JIEOR, KIEOR.

## IGETARG(N, STR, STRLEN)

Description Get command-line argument.
Class Inquiry nonstandard function.
Arguments
N must be of type integer. n specifies which commandline argument is requested. When $\mathrm{N}=0$, it returns the program name.
STR must be a character variable. It is assigned first STRLEN characters of the requested command-line argument, padded with blanks on the end. If the requested argument is longer than STR, a truncated version is assigned to STR.

STRLEN must be of type integer. STRLEN specifies the number of characters of argument N to assign to STR.

Result value IGETARG returns an integer value, either - 1 if the requested argument was not found, or a positive integer that indicates the number of characters copied from the command line to STR.

## IJ INT(A)

| Description | Convert to INTEGER (2) type. |
| :---: | :---: |
| Class | Elemental nonstandard function. |
| Argument | A must be of type Integer (4). |
| Result | INTEGER (2) type. |
|  | IMAG (A) |
| Description | Imaginary part of complex number. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type complex or double complex. |
| Result | Real if $A^{\prime}$ is complex. Double precision if A is double complex. |
|  | INDEX(STRING, SUBSTRING, BACK) |
| Optional argument | BACK |
| Description | Returns the starting position of a substring within a string. |
| Class | Elemental function. |
| Arguments | STRING must be of type character. |
|  | SUBSTRING must be of type character with the same kind type parameter as STRING. |
|  | BACK (optional) must be of type logical. |
| Result type/ type parameters | Default integer. |
| Result value | Case 1 If BACK is absent or present with the value .FALSE., the result is the minimum positive value of I such that STRING(I : I + LEN(SUBSTRING) - 1) = SUBSTRING or zero if there is no such value. |
|  | Chapter 11527 |

Intrinsic procedures
Intrinsic procedure specifications

Zero is returned if LEN (STRING) <LEN (SUBSTRING) and one is returned if LEN (SUBSTRING) $=0$.
Case 2 If BACK is present with the value.TRUE., the result is the maximum value of I less than or equal to LEN (STRING) - LEN (SUBSTRING) +1 such that STRING(I : I + LEN(SUBSTRING) - 1) = SUBSTRING or zero if there is no such value.

Zero is returned if LEN (STRING) <LEN (SUBSTRING) and LEN (STRING) +1 is returned if LEN (SUBSTRING) $=0$.

## Specific forms KINDEX.

## INT(A, KIND)

Optional argument
Description

Class
Arguments

Result type/
type parameters
Result value

Specific forms

KIND
Convert to integer type.
Elemental function.
A
must be of type integer, real, or complex. KIND (optional) must be a scalar integer initialization expression.

Integer. If KIND is present, the kind type parameter is that specified by KIND; otherwise, the kind type parameter is that of default integer type.

Case 1 If A is of type integer, $\operatorname{INT}(A)=A$.
Case 2 If A is of type real, there are two cases: if $|A|<1$, INT (A) has the value 0; if $|A|>=1$, INT (A) is the integer whose magnitude is the largest integer that does not exceed the magnitude of $A$ and whose sign is the same as the sign of A.

Case 3 If A is of type complex, INT (A) is the value obtained by applying the above rules (for reals) to the real part of A. The result is undefined if the processor cannot represent the result in the specified integer type.

IFIX, IIFIX, IINT, JIFIX, JINT, KIFIX, KINT.

|  | INT1(A) |
| :---: | :---: |
| Description | Convert to INTEGER (1) type. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, or complex. |
| Result | INTEGER (1) type. If A is complex, INT1 (A) is equal to the truncated real portion of $A$. |
|  | I NT2(A) |
| Description | Convert to Integer (2) type. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, or complex. |
| Result | INTEGER (2) type. If A is complex, INT2 (A) is equal to the truncated real portion of A. |
|  | I NT4(A) |
| Description | Convert to Integer (4) type. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, or complex. |
| Result | INTEGER (4) type. If A is complex, INT 4 (A) is equal to the truncated real portion of $A$. | real portion of $A$.

Intrinsic procedures
Intrinsic procedure specifications

## INT8(A)

| Description | Convert to INTEGER (8) type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, or complex. |
| Result | INTEGER (8) type. If A is complex, INT8 (A) is equal to the truncated <br> real portion of A. |
| Specific forms | IDINT. |
| Description | Convert character to INTEGER (2) type. |
| Class | Elemental nonstandard function. |
| Argument | I must be of type character. |
| Result | INTEGER (2) type. |

## IOMSG(N, MSG)

| Description | Print the text for an I/O message. |
| :--- | :--- |
| Class | Nonstandard subroutine. |

## IOR(I, J)

Description Performs a bitwise inclusive or.
Class Elemental function.
Arguments I must be of type integer.
J must be of type integer with the same kind type parameter as I.

Result type/ type parameters

Result value

Table 58

Specific forms
BIOR, HIOR, IIOR, JIOR, KIOR

## IQINT(A)

| Description | Convert to integer type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | A must be of type REAL (16). |
| Result | Integer type. |
| Specific forms | IIQINT, JIQINT, KIQINT. |

Intrinsic procedures
Intrinsic procedure specifications

## IRAND()

| Description | Generate pseudorandom numbers. |
| :---: | :---: |
| Class | Elemental nonstandard function. |
| Result type/ type parameters | INTEGER (4) type. |
| Result value | RAND generates numbers in the range 0 through $2^{15}-1$. |
| NOTE | For details about restarting the pseudorandom number generator used by IRAND and RAND, see "SRAND(ISEED)" on page 577. |
|  | IRANP(X) |
| Description | Generate Poisson-distributed random numbers. |
| Class | Elemental nonstandard function. |
| Argument | $x$ must be of REAL (4) type and must be in the range 0.0 through 87.33. For better performance, it is recommended that x be less than 50.0 (see "Result value" below). |
| Result type/ type parameters | INTEGER (4) type. |
| Result value | IRANP returns an error code of -1 if $X<=0.0$. |
|  | IRANP returns an error code of -2 if $X>87.33$. |
|  | IRANP calculates exponentially distributed random numbers until the product is less than exp ( -x ). The random number returned by IRANP is the number of exponentials needed, minus 1. IRANP makes an average of $\mathrm{x}+1$ calls to RAND, so it is recommended that x be less than 50 . |

## ISHFT(I,SHIFT)

| Description | Performs a logical shift. <br> Class <br> Arguments <br> Elemental function. |
| :--- | :--- |
| I <br> Result type/ <br> type parameters | Sust be of type integer. <br> must be of type integer. The absolute value of SHIFT <br> must be less than or equal to BIT_SIZE (I). |
| Result value | The result has the value obtained by shifting the bits of I by SHIFT <br> positions. <br> If SHIFT is positive, the shift is to the left; if SHIFT is negative, the shift <br> is to the right; and if SHIFT is zero, no shift is performed. Bits shifted out <br> from the left or from the right, as appropriate, are lost. Zeros are shifted <br> in from the opposite end. |
| Specific forms | The model for the interpretation of an integer value as a sequence of bits <br> is described in "The Bit M odel" on page 481. |
| BSHFT, HSHFT, IISHFT, JISHFT, KISHFT. |  |

## ISHFTC(I, SHIFT, SIZE)

Optional argument
Description
Class

Arguments

SIZE

Performs a circular shift of the rightmost bits.
Elemental function.
I must be of type integer.
SHIFT must be of type integer. The absolute value of SHIFT must be less than or equal to SIZE.
SIZE (optional) must be of type integer. The value of SIZE must be positive and must not exceed BIT_SIZE (I). If SIZE is absent, it is as if it were present with the value of BIT_SIZE (I).

Intrinsic procedures
Intrinsic procedure specifications

Result type/ type parameters

Result value

Specific forms HSHFTC, ISHFTC, JISHFTC, KISHFTC.

## ISIGN(A, B )

Description
Class

Arguments

Result type/ type parameters

Result value

## ISNAN(X)

| Description | Determine if a value is NaN (not a number). |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | X must be of type real. |
| Result type | Logical. |

## IXOR (I, J )

Description Exclusive OR.

Class
Arguments

Result type/
type parameters
Result value

Table 59
Truth table for IXOR intrinsic

| I | J | $\operatorname{IXOR}(\mathrm{I}, \mathrm{J})$ |  |
| :--- | :--- | :--- | :--- |
| 1 |  | 1 | 0 |
| 1 |  | 0 | 1 |
| 0 | 1 | 1 |  |
| 0 |  | 0 | 0 |

The model for interpreting an integer value as a sequence of bits is described in "The Bit M odel" on page 481.

Specific forms
BIXOR, HIXOR, IIXOR, JIXOR.

Intrinsic procedures
Intrinsic procedure specifications

## IZEXT(A)

| Description | Zero extend. |
| :---: | :---: |
| Class | Generic elemental nonstandard function. |
| Argument | A must be of type $\operatorname{INTEGER}$ (1), INTEGER (2), LOGICAL (1), or LOGICAL (2). |
| Result type/ type parameters | The result is of type INTEGER (2). |
| Result | IZEXT converts A to INTEGER (2) by sign-extending zeroes instead of the actual sign bit. |

## J NUM(I)

| Description | Convert character to integer type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | I must be of type character. |
| Result | Integer type. |

## J ZEXT(A)

| Description | Zero extend. |
| :---: | :---: |
| Class | Generic elemental nonstandard function. |
| Argument | A must be of type InTEGER (1), INTEGER (2), INTEGER (4), LOGICAL (1), LOGICAL (2), or LOGICAL (4). |
| Result type/ type parameters | The result is of type INTEGER (4). |
| Result | JZEXT converts A to INTEGER (4) by sign-extending zeroes instead of the actual sign bit. |

KIND(X)

| Description | Returns the value of the kind type parameter of X. |
| :--- | :--- |
| Class | I nquiry function. |
| Argument | x may be of any intrinsic type. |
| Result type, <br> type parameters, <br> and shape | Default integer scalar. |
| Result value | The result has a value equal to the kind type parameter value of X. |
|  | KZEXT(A) |

| Description | Zero extend. |
| :---: | :---: |
| Class | Generic elemental nonstandard function. |
| Argument | A must be of type Integer (1), INTEGER (2), INTEGER (4), INTEGER (8), LOGICAL (1), LOGICAL (2), LOGICAL (4), or LOGICAL (8). |
| Result type/ type parameters | The result is of type INTEGER (8). |
| Result | KZEXT Converts A to INTEGER (8) by sign-extending zeroes instead of the actual sign bit. |

Intrinsic procedures
Intrinsic procedure specifications

## LBOUND(ARRAY, DIM)

| Optional argument | DIM |
| :--- | :--- |
| Description | Returns all the lower bounds or a specified lower bound of an array. |
| Class | Inquiry function. |

Arguments ARRAY may be of any type. It must not be scalar. It must not

DIM (optional) must be scalar and of type integer with a value in the range $1<=$ DIM $<=n$, where $n$ is the rank of ARRAY. The corresponding actual argument must not be an optional dummy argument.

Result type,
type parameters,
and shape

Result value

Specific forms KLBOUND.

For an array section or for an array expression other than a whole array or array structure component, LBOUND (ARRAY, DIM) has the value 1. For a whole array or array structure component, LBOUND (ARRAY, DIM) has the value:

- equal to the lower bound for subscript DIM of ARRAY if dimension DIM of ARRAY does not have extent zero or if ARRAY is an assumed-size array of rank DIM
or
- one (1), otherwise.

Case 2 LBOUND (ARRAY) has a value whose ith component is equal to LBOUND (ARRAY, i), for $\mathrm{i}=1,2, \ldots, \mathrm{n}$, where n is the rank of ARRAY.

| Case 1 | For an array section or for an array expression other |
| :--- | :--- |
| than a whole array or array structure component, |  |
| LBOUND (ARRAY, DIM) has the value 1. For a whole |  |
| array or array structure component, LBOUND (ARRAY, |  |

The result is of type default integer. It is scalar if DIM is present; otherwise, the result is an array of rank one and size $n$, where $n$ is the rank of ARRAY.

|  | LEN(STRING) |
| :---: | :---: |
| Description | Returns the length of a character entity. |
| Class | Inquiry function. |
| Argument | STRING must be of type character. It may be scalar or array valued. |
| Result type, type parameters, and shape | Default integer scalar. |
| Result value | The result has a value equal to the number of characters in STRING if it is scalar or in an element of STRING if it is array valued. |
| Specific forms | KLEN. |
|  | LEN_TRIM(STRING) |
| Description | Returns the length of the character argument without counting trailing blank characters. |
| Class | Elemental function. |
| Argument | STRING must be of type character. |
| Result type) type parameter | Default integer. |
| Result value | The result has a value equal to the number of characters remaining after any trailing blanks in STRING are removed. If the argument contains no nonblank characters, the result is zero. |
| Specific forms | KLEN_TRIM. |

Intrinsic procedures
Intrinsic procedure specifications

## LGE(STRING_A, STRING_B)

| Description | Tests whether a string is lexically greater than or equal to another <br> string, based on the ASCII collating sequence. |
| :--- | :--- |
| Class | Elemental function. |
| Arguments | STRING_A must be of type default character. <br> STRING_B $\quad$ must be of type default character. |
| Desult type/ <br> type parameters | If the strings are of unequal length, the comparison is made as if the <br> shorter string were extended on the right with blanks to the length of the <br> longer string. |
| Result value |  |
| If either string contains a character not in the ASCII character set, the |  |
| result is processor dependent. |  |

If either string contains a character not in the ASCII character set, the result is processor-dependent.
The result is . TRUE. if STRING_A follows STRING_B in the ASCII collating sequence; otherwise, the result is .FALSE . . N ote that the result is .FALSE. if both STRING_A and STRING_B are of zero length.

## LLE(STRING_A, STRING_B)

| Description | Tests whether a string is lexically less than or equal to another string, <br> based on the ASCII collating sequence. |
| :--- | :--- |
| Class | Elemental function. |
| Arguments | STRING_A must be of type default character. <br> Result type/ <br> type parameters |
| Defring_B must be of type default character. |  |

Intrinsic procedures
Intrinsic procedure specifications

## LLT(STRING_A, STRING_B)

| Description | Tests whether a string is lexically less than another string, based on the ASCII collating sequence. |
| :---: | :---: |
| Class | Elemental function. |
| Arguments | STRING_A must be of type default character. |
|  | STRING_B must be of type default character. |
| Result type/ type parameters | Default logical. |
| Result value | If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks to the length of the longer string. |
|  | If either string contains a character not in the ASCII character set, the result is processor-dependent. |
|  | The result is .TRUE. if STRING_A precedes STRING_B in the ASCII collating sequence; otherwise, the result is .FALSE . . N ote that the result is .FALSE. if both STRING_A and STRING_B are of zero length. |
|  | LOC(X) |
| Description | Return the address of the argument. |
| Class | Inquiry nonstandard function. |

## LOG(X)

| Description | Natural logarithm. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real or complex. If x is real, its value must be greater <br> than zero. If x is complex, its value must not be zero. |
| Result type/ <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> log $_{e} \mathrm{X}$. A result of type complex is the principal value with imaginary part <br> w in the range -Pi < $<=$ Pi. The imaginary part of the result is Pi only <br> when the real part of the argument is less than zero and the imaginary <br> part of the argument is zero. |
| Specific forms | ALOG, CDLOG, CLOG, DLOG, QLOG, ZLOG. |

## LOG10(X)

| Description | Common logarithm. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | x must be of type real. The value of x must be greater than zero. |
| Result type/ <br> type parameters | Same as x. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> $\log _{10} \mathrm{X}$. |
| Specific forms | ALOG10, DLOG10, QLOG10. |

Intrinsic procedures
Intrinsic procedure specifications

## LOGICAL(L, KIND)

Optional argument KIND
Description Converts between kinds of Iogical.

Class Elemental function.

| Arguments | L $\quad$ must be of type logical. |
| :--- | :--- |
|  | KIND (optional) must be a scalar integer initialization expression. |
| Result type/ <br> type parameters | Logical. If KIND is present, the kind type parameter is that specified by <br> KIND; otherwise, the kind type parameter is that of default logical. |
| Result value | The value is that of L. |

## LSHFT(I,SHIFT)

| Description | Left shift. |
| :--- | :--- |
| Class | Elemental nonstandard func |
|  | LSHIFT(I, SHIFT) |

| Description | Left shift. |
| :--- | :--- |
| Class | Elemental nonstandard function. |

## MALLOC(SIZE)

| Description | Allocate a block of memory. |
| :--- | :--- |
| Class | Transformational nonstandard function. |

## MATMUL(MATRIX_A, MATRIX_B)

| Description | Performs matrix multiplication of numeric or logical matrices. |  |
| :---: | :---: | :---: |
| Class | Transformational function. |  |
| Arguments | MATRIX_A | must be of numeric type (integer, real, or complex) or of logical type. It must be array valued and of rank one or two. |
|  | MATRIX_B | must be of numeric type if MATRIX_A is of numeric type and of logical type if MATRIX_A is of logical type. It must be array valued and of rank one or two. |
|  |  | If MATRIX_A has rank one, MATRIX_B must have rank two. If MATRIX_B has rank one, MATRIX_A must have rank two. The size of the first (or only) dimension of MATRIX_B must equal the size of the last (or only) dimension of MATRIX_A. |
| Result type, type parameters, | If the arguments are of numeric type, the type and kind type parameter of the result are determined by the types of MATRIX_A and MATRIX_B. |  |
|  | If the arguments are of type logical, the result is of type logical with the kind type parameter of the arguments. |  |
|  | The shape of the result depends on the shapes of the arguments as follows: |  |
|  | Case 1 | If MATRIX_A has shape [ $n, m$ ] and MATRIX_B has shape [ $m, k]$, the result has shape [ $n, k]$. |
|  | Case 2 | If MATRIX_A has shape [m] and MATRIX_B has shape [ $m, k]$, the result has shape [k]. |
|  | Case 3 | If MATRIX_A has shape [n, m] and MATRIX_B has shape [ m ], the result has shape [ n ]. |
| Result value | Case 1 | Element ( $\mathrm{i}, \mathrm{j}$ ) of the result has the value |
|  |  | SUM (MATRIX_A(i,:) * MATRIX_B(:, j)) if the arguments are of numeric type and has the value |
|  |  | ANY (MATRIX_A(i, :) .AND. MATRIX_B(:, j)) if the arguments are of logical type. |

Intrinsic procedures
Intrinsic procedure specifications

| Case 2 | Element (j) of the result has the value |
| :---: | :---: |
|  | SUM (MATRIX_A(:) * MATRIX_B(:, j)) if the arguments are of numeric type and has the value |
|  | ANY (MATRIX_A(:) .AND. MATRIX_B(:, j)) if the arguments are of logical type. |
| Case 3 | Element (i) of the result has the value |
|  | SUM (MATRIX_A(i, :) * MATRIX_B(:)) if the arguments are of numeric type and has the value |
|  | ANY (MATRIX_A (i, :) .AND. MATRIX_B(:)) if the arguments are of logical type. |

## MAX(A1, A2, A3, ...)

Optional arguments A3, ...

| Description | Maximum value. |
| :--- | :--- |
| Class | Elemental function. |

Arguments The arguments must all have the same type which must be integer or real, and they must all have the same kind type parameter.

Same as the arguments.

The value of the result is that of the largest argument.

AIMAX0, AJMAX0, AKMAX0, AMAX0, AMAX1, DMAX1, IMAX0, IMAX1, JMAX0, JMAX1, KMAX0, KMAX1, MAX0, MAX1, QMAX1.

|  | MAXE XPONE NT(X) |
| :---: | :---: |
| Description | Returns the maximum exponent in the model representing numbers of the same type and kind type parameter as the argument. |
| Class | Inquiry function. |
| Argument | x must be of type real. It may be scalar or array valued. |
| Result type, type parameters, and shape | Default integer scalar. |
| Result value | The result has the value $\mathrm{e}_{\text {max }}$, as defined in "The Real Number System Model" on page 482. |
| Specific forms | KMAXLOC. |
|  | MAXLOC(ARRAY, MASK) |
| Optional argument | MASK |
| Description | Returns the location of the first element of ARRAY having the maximum value of the elements identified by MASK. |
| Class | Transformational function. |
| Arguments | ARRAY must be of type integer or real. It must not be scalar. |
|  | MASK (optional) must be of type logical and must be conformable with ARRAY. |
| Result type, type parameters, and shape | The result is of type default integer; it is an array of rank one and of size equal to the rank of ARRAY. |
| Result value | Case 1 If MASK is absent, the result is a rank-one array whose element values are the values of the subscripts of an element of ARRAY whose value equals the maximum value of all of the elements of ARRAY. |
|  | The ith subscript returned lies in the range 1 to e , where $e_{\text {, }}$ is the extent of the ith dimension of ARRAY. |
|  | Chapter 11 547 |

Intrinsic procedures
Intrinsic procedure specifications

If more than one element has the maximum value, the element whose subscripts are returned is the first such element, taken in array element order. If ARRAY has size zero, the value of the result is processordependent.

Case 2 If MASK is present, the result is a rank-one array whose element values are the values of the subscripts of an element of ARRAY, corresponding to a . TRUE . element of MASK, whose value equals the maximum value of all such elements of ARRAY.

The ith subscript returned lies in the range 1 to e, where $e_{i}$ is the extent of the ith dimension of ARRAY.
If more than one such element has the maximum value, the element whose subscripts are returned is the first such element taken in array element order.
If there are no such elements (that is, if ARRAY has size zero or every element of MASK has the value.FALSE.), the value of the result is processor-dependent.

In both cases, an element of the result is undefined if the processor cannot represent the value as a default integer.

## MAXVAL (ARRAY, DIM, MASK)

Optional arguments DIM, MASK
Description Maximum value of the elements of ARRAY along dimension DIM that correspond to the. TRUE. elements of MASK.

Class Transformational function.
Arguments ARRAY must be of type integer or real. It must not be scalar.
DIM (optional) must be scalar and of type integer with a value in the range $1<=D I M<=n$ where $n$ is the rank of ARRAY. The corresponding actual argument must not be an optional dummy argument.

MASK (optional) must be of type logical and must be conformable with ARRAY.

| Result type, type parameters, and shape | The result is of the same type and kind type parameter as ARRAY. <br> It is scalar if DIM is absent or ARRAY has rank one; otherwise, the result is an array of rank $n-1$ and of shape ( $\left.d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}, d_{\text {DIM }+1}, \ldots, d_{n}\right)$ where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of ARRAY. |  |
| :---: | :---: | :---: |
| Result value | Case 1 | The result of MAXVAL (ARRAY) has a value equal to the maximum value of all the elements of ARRAY or has the value of the negative number of the largest magnitude supported by the processor for numbers of the type and kind type parameter of ARRAY if ARRAY has size zero. |
|  | Case 2 | The result of MAXVAL (ARRAY, MASK = MASK) has a value equal to the maximum value of the elements of ARRAY Corresponding to .TRUE. elements of MASK or has the value of the negative number of the largest magnitude supported by the processor for numbers of the same type and kind type parameter as ARRAY if there are no . TRUE. elements. |
|  | Case 3 | If ARRAY has rank one, MAXVAL (ARRAY, DIM [, MASK]) has a value equal to that of MAXVAL (ARRAY [, MASK = MASK]). Otherwise, the value of element $\left(s_{1}, s_{2}, \ldots, S_{\text {DIM }-1}, S_{D I M+1}, \ldots, s_{n}\right)$ of MAXVAL (ARRAY, DIM [, MASK]) is equal to the following: |
|  |  | MAXVAL (ARRAY ( $S_{1}, S_{2}, \ldots, S_{D I M-1},:, S_{D I M+1}$, $\left.\ldots, S_{n}\right)$ [, MASK $=\operatorname{MASK}\left(S_{1}, S_{2}, \ldots, S_{D I M-1}\right.$, :, $S_{D I M+1}, \ldots, S_{n}$ ] ) |

## MCLOCK()

Description Return time accounting for a program.
Class Inquiry nonstandard function.
Result type I nteger.
Result value The value returned, in units of microseconds, is the sum of the current process's user time and the user and system time of all its child processes.

Intrinsic procedures
Intrinsic procedure specifications

## ME R GE (TSOURCE , FSOURCE , MASK)

| Description | Choose alternative value according to the value of a mask. |
| :---: | :---: |
| Class | Elemental function. |
| Arguments | TSOURCE may be of any type. |
|  | FSOURCE must be of the same type and type parameters as TSOURCE. |
|  | MASK must be of type logical. |
| Result type/ type parameters | Same as TSOURCE. |
| Result value | The result is TSOURCE if MASK is . TRUE. and FSOURCE otherwise. |

## MIN(A1, A2, A3, ...)

Optional arguments
Description
Class
Arguments

Result type/
type parameters
Result value

Specific forms AIMIN0, AJMIN0, AKMIN0, AMIN0, AMIN1, DMIN1, IMIN0, IMIN1, JMIN0, JMIN1, KMIN0, KMIN1, MIN0, MIN1, QMIN1.

|  | MI NEXPONE NT(X) |
| :---: | :---: |
| Description | Returns the minimum exponent in the model representing numbers of the same type and kind type parameter as the argument. |
| Class | Inquiry function. |
| Argument | x must be of type real. It may be scalar or array valued. |
| Result type, type parameters, and shape | Default integer scalar. |
| Result value | The result has the value $\mathrm{e}_{\text {min }}$, as defined in "The Real Number System M odel" on page 482. |

## MI NLOC(ARRAY, MASK)

Optional argument MASK

| Description | Returns the location of the first element of ARRAY having the minimum <br> value of the elements identified by MASK. |
| :--- | :--- |
| Class | Transformational function. |

Result type, type parameters, and shape

Result value

The result is of type default integer; it is an array of rank one and of size equal to the rank of ARRAY.

Case 1 If MASK is absent, the result is a rank-one array whose element values are the values of the subscripts of an element of ARRAY whose value equals the minimum value of all the elements of ARRAY.

The ith subscript returned lies in the range 1 to e , where $e_{1}$ is the extent of the ith dimension of ARRAY.

Intrinsic procedures
Intrinsic procedure specifications

If more than one element has the minimum value, the element whose subscripts are returned is the first such element, taken in array element order. If ARRAY has size zero, the value of the result is processordependent.

Case 2 If MASK is present, the result is a rank-one array whose element values are the values of the subscripts of an element of ARRAY, corresponding to a . TRUE. element of MASK, whose value equals the minimum value of all such elements of ARRAY.

The ith subscript returned lies in the range 1 to e, where $e_{1}$ is the extent of the ith dimension of ARRAY. If more than one such element has the minimum value, the element whose subscripts are returned is the first such element taken in array element order.
If ARRAY has size zero or every element of MASK has the value . FALSE. , the value of the result is processordependent.

In both cases, an element of the result is undefined if the processor cannot represent the value as a default integer.

Specific forms KMINLOC.

## MI NVAL(ARRAY, DIM, MASK)

| Optional argument | DIM, MASK |  |
| :---: | :---: | :---: |
| Description | Minimum value of all the elements of ARRAY along dimension DIM corresponding to .TRUE. elements of MASK. |  |
| Class | Transformational function. |  |
| Arguments | ARRAY | must be of type integer or real. It must not be scalar. |
|  | DIM (optional) | must be scalar and of type integer with a value in the range $1<=D I M<=n$, where $n$ is the rank of ARRAY. The corresponding actual argument must not be an optional dummy argument. |
|  | MASK (optional) | must be of type logical and must be conformable with ARRAY. |
| Result type, type parameters, and shape | The result is of the same type and kind type parameter as ARRAY. It is scalar if DIM is absent or ARRAY has rank one; otherwise, the result is an array of rank $n-1$ and of shape ( $d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}, d_{\text {DIM }+1}, \ldots, d_{n}$ ) where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of ARRAY. |  |
| Result value | Case 1 | The result of MINVAL (ARRAY) has a value equal to the minimum value of all the elements of ARRAY or has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind type parameter of ARRAY if ARRAY has size zero. |
|  | Case 2 | The result of MINVAL (ARRAY, MASK = MASK) has a value equal to the minimum value of the elements of ARRAY corresponding to . TRUE. elements of MASK or has the value of the positive number of the largest magnitude supported by the processor for numbers of the same type and kind type parameter as ARRAY if there are no . TRUE. elements. |
|  | Case 3 | If ARRAY has rank one, MINVAL (ARRAY, DIM [, MASK]) has a value equal to that of MINVAL (ARRAY [,MASK = MASK]). Otherwise, the value of element $\left(s_{1}, s_{2}, \ldots, S_{D I M-1}, S_{D I M+1}, \ldots, s_{n}\right)$ of MINVAL (ARRAY, DIM [, MASK]) is equal to the following: |

Intrinsic procedures

```
MINVAL (ARRAY (S1, S2, ..., S SIM-1, :, SDIM+1,
..., Sn) [, MASK= MASK(S S , S2, ..., SDIM-1, :,
SDIM+1, ..., Sn) ] )
```

## MOD(A, P)

| Description | Remainder function. |
| :---: | :---: |
| Class | Elemental function. |
| Arguments | A must be of type integer or real. |
|  | P must be of the same type and kind type parameter as A. |
| Result type/ type parameters | Same as A. |
| Result value | If $P$ is not 0 , the value of the result is $A-\operatorname{INT}(A / P)$ * $P$. If $P=0$, the result is processor-dependent. |
| Specific forms | AMOD, BMOD, DMOD, HMOD, IMOD, JMOD, KMOD, QMOD. |

## MODULO(A, P)

Description Modulo function.
Class Elemental function.

Arguments
A
P

Same as A.

## Case 1

 value $R$ such that $A=Q * P+R$, where $Q$ is an integer, the inequalities $0<=R<P$ hold if $P>0$, and $P<R$ $<=0$ hold if $\mathrm{P}<0$. If $\mathrm{P}=0$, the result is processordependent.Intrinsic procedures
Intrinsic procedure specifications

## Case 2

 $A$ is of type real. If $P$ is not 0 , the value of the result is $A$ $-F L O O R$ (A / P) * P.If $P=0$, the result is processordependent.
## MVBITS(FROM, FROMPOS, LEN, TO, TOPOS)

| Description | Copies a sequence of bits from one data object to another. |  |
| :---: | :---: | :---: |
| Class | Elemental subroutine. |  |
| Arguments | FROM | must argu |
|  | FROMPOS | must <br> INTE <br> than <br> inter <br> is de |
|  | LEN | must <br> INTE |
|  | TO | must <br> type <br> varia |
|  |  | To is start of TO LEN that entry |
|  |  | The a seq page |
|  | TOPOS | must <br> INTE <br> than |
| Specific forms | BMVBITS | TS. |

Intrinsic procedures
Intrinsic procedure specifications

## NEAREST(X, S)

| Description | Returns the nearest different machine representable number in a given <br> direction. |
| :--- | :--- |
| Class | Elemental function. |
| Arguments | S must be of type real. |
| Result type/ <br> type parameters | Same as x. |
| Result value of type real and not equal to zero. |  |$\quad$| The result has a value equal to the machine representable number |
| :--- |
| distinct from x and nearest to it in the direction of the infinity with the |
| same sign as S. |

## NINT(A, KIND)

| Optional argument | KIND |
| :---: | :---: |
| Description | Nearest integer. |
| Class | Elemental function. |
| Arguments | A must be of type real. |
|  | KIND (optional) must be a scalar integer initialization expression. |
| Result type/ type parameters | Integer. If KIND is present, the kind type parameter is that specified by KIND; otherwise, the kind type parameter is that of default integer type |
| Result value | If $A>0, \operatorname{NINT}(A)$ has the value INT ( $A+0.5$ ) ; if $A<=0, N \operatorname{NiNT}(A)$ has the value INT ( $A-0.5$ ). The result is undefined if the processor cannot represent the result in the specified integer type. |
| Specific forms | IDNINT, IIDNNT, IIQNNT, ININT, IQNINT, JIDNNT, JIQNNT, JNINT, KIDNNT, KIQNNT, KNINT. |

|  | NOT(I) |  |
| :---: | :---: | :---: |
| Description | Performs a bitwise logical complement. |  |
| Class | Elemental function. |  |
| Argument | I must be of type integer. |  |
| Result type/ type parameters | Same as I. |  |
| Result value | The result has the value obtained by complementing I bit-by-bit according to the following truth table: |  |
| Table 60 | Truth table for NOT intrinsic |  |
|  | I | NOT( 1 ) |
|  | 1 | 0 |
|  | 0 | 1 |
|  | The model for the interpretation of an integer value as a sequence of bits is described in "The Bit M odel" on page 481. |  |
| Specific forms | BNOT, HNOT, INOT, JNOT, KNOT. |  |
|  | OR(1, J ) |  |
| Description | Bitwise logical OR. |  |
| Class | Elemental nonstandard function. |  |
| Arguments | I | must be |
|  |  | must be paramet |
| Result type/ type parameters | Same as I. |  |

Intrinsic procedures

The model for interpreting an integer value as a sequence of bits is described in "The Bit M odel" on page 481.

## PACK(ARRAY, MASK, VE CTOR)

Optional argument
Description
Class

Arguments

Result type, type parameters, and shape

VECTOR
Pack an array into an array of rank one under the control of a mask.
Transformational function.

ARRAY<br>MASK<br>VECTOR

(optional)
may be of any type. It must not be scalar.
must be of type logical and must be conformable with ARRAY.
must be of the same type and type parameters as

ARRAY and must have rank one. VECTOR must have at least as many elements as there are . TRUE. elements in MASK. If MASK is scalar with the value . TRUE., VECTOR must have at least as many elements as there are in ARRAY.

The result is an array of rank one with the same type and type parameters as ARRAY. If VECTOR is present, the result size is that of VECTOR; otherwise, the result size is the number $t$ of . TRUE. elements in MASK unless MASK is scalar with the value. TRUE., in which case the result size is the size of ARRAY.

| Result value | Element i of the result is the element of ARRAY that corresponds to the ith . TRUE. element of MASK, taking elements in array element order, for $\mathrm{i}=1,2, \ldots, \mathrm{t}$. If VECTOR is present and has size $\mathrm{n}>\mathrm{t}$, element i of the result has the value vector (i), for $i=t+1, \ldots, n$. |
| :---: | :---: |
| Specific forms | KPACK. |
|  | PRECISION(X) |
| Description | Returns the decimal precision in the model representing real numbers with the same kind type parameter as the argument. |
| Class | Inquiry function. |
| Argument | x must be of type real or complex. It may be scalar or array valued. |
| Result type, type parameters, and shape | Default integer scalar. |
| Result value | The result has the value INT ( (p-1) * LOG10 (b) ) +k. The values of $b$ and $p$ are as defined in "The Real Number System Model" on page 482 for the model representing real numbers with the same kind type parameter as x . The value of k is 1 if b is an integral power of 10 and 0 otherwise. |
|  | PRESENT(A) |
| Description | Determine whether an optional argument is present. |
| Class | Inquiry function. |
| Argument | A must be the name of an optional dummy argument that is accessible in the procedure in which the PRESENT function reference appears. |
| Result type/ type parameters | Default logical scalar. |
| Result value | The result has the value. TRUE. if A is present and otherwise has the value . FALSE. |

Intrinsic procedures
Intrinsic procedure specifications

## PRODUCT(ARRAY, DIM, MASK)

| Optional arguments | DIM, MASK |
| :---: | :---: |
| Description | Product of all the elements of ARRAY along dimension DIM corresponding to the . TRUE. elements of MASK. |
| Class | Transformational function. |
| Arguments | ARRAY must be of type integer, real, or complex. It must not be <br> scalar.  |
|  | DIM (optional) must be scalar and of type integer with a value in the range $1<=$ DIM $<=n$, where $n$ is the rank of ARRAY. The corresponding actual argument must not be an optional dummy argument. |
|  | MASK (optional) must be of type logical and must be conformable with ARRAY. |
| Result type, type parameters, and shape | The result is of the same type and kind type parameter as ARRAY. It is scalar if DIM is absent or ARRAY has rank one; otherwise, the result is an array of rank $n-1$ and of shape ( $d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}, d_{\text {DIM }+1}, \ldots, d_{n}$ ) where $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$ is the shape of ARRAY. |
| Result value | Case 1 <br> The result of PRODUCT (ARRAY) has a value equal to a processor-dependent approximation to the product of all the elements of ARRAY or has the value one if ARRAY has size zero. |
|  | Case 2 <br> The result of PRODUCT (ARRAY, MASK = msk) has a value equal to a processor-dependent approximation to the product of the elements of ARRAY corresponding to the. TRUE. elements of msk or has the value one if there are no. TRUE. elements. |
|  | Case 3 If ARRAY has rank one, PRODUCT (ARRAY, DIM [,msk]) has a value equal to that of PRODUCT (ARRAY [, MASK $=\mathrm{msk}$ ]). Otherwise, the value of element ( $\mathrm{s}_{1}$, $\mathrm{S}_{2}, \ldots, \mathrm{~S}_{\text {DIM }-1}, \mathrm{~S}_{\text {DIM }+1}, \ldots, \mathrm{~S}_{\mathrm{n}}$ ) of PRODUCT (ARRAY, DIM | $[, \mathrm{msk}]$ ) is equal to the following:

Intrinsic procedures Intrinsic procedure specifications

```
PRODUCT (ARRAY (S1, S2, ..., SDIM-1, :, SDIM +1,
..., Sn) &
    [, MASK = msk(S1, S2, ..., SDIM-1, :,
SDIM+1, ..., Sn)])
```

## QEXT(A)

| Description | Convert to REAL (16) type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer, real, double precision, or complex. |
| Result | REAL (16). |
| Specific forms | QEXTD. |

## QFLOAT(A)

Description Convert to REAL (16) type.
Class Elemental nonstandard function.
Argument A must be of type integer or REAL (4).

Result REAL (16).
Specific forms QFLOATI, QFLOTI, QFLOTJ, QFLOTK.

## QNUM(I)

| Description | Convert character to REAL (16) type. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | I must be of type character. |
| Result | REAL (16) type. |

Intrinsic procedures
Intrinsic procedure specifications

## QPROD(X, Y)

| Description | Double precision product. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Arguments | X and Y must be of type double precision. |
| Result | REAL (16) type. |

## RADIX(X)

Class

Result type,
type parameters, and shape

Result value

Description

Class

Argument

Result type/ type parameters

Description Returns the base of the model representing numbers of the same type

Argument $\quad X$ must be of type integer or real. It may be scalar or array valued.
Returns the base of the model representing numbers of the same type and kind type parameter as the argument.

Inquiry function.

Default integer scalar.

The result has the value $r$ if $x$ is of type integer and the value $b$ if $x$ is of type real, where r and b are as defined in "The Real N umber System Model" on page 482.

## RAN(ISEED)

Multiplicative congruent random number generator.
Elemental nonstandard function.

ISEED must be an INTEGER (4) variable or array element. RAN stores a number in ISEED to be used by the next call to RAN.

ISEED should initially be set to an odd number, preferably very large; see the following example.

REAL (4) type.

| NOTE | To ensure different random values for each run of a program, ISEED should be set to a different value each time the program is run. One way to implement this would be to have the user enter the seed at the start of the program. Another way would be to compute a value from the current year, day, and month (returned by IDATE) and the number of seconds since midnight (returned by SECNDS). |
| :---: | :---: |
|  | RAND() |
| Description | Generate successive pseudorandom numbers uniformly distributed in the range of 0.0 to 1.0. |
| Class | Elemental nonstandard function. |
| Result type/ type parameters | REAL (4) type. |
| NOTE | For details about restarting the pseudorandom number generator used by IRAND and RAND, see "SRAND(ISEED)" on page 577 section. |
|  | RANDOM_NUMBER(HARVEST) |
| Description | Returns one pseudorandom number or an array of pseudorandom numbers from the uniform distribution over the range $0<=x<1$. |
| Class | Subroutine. |
| Argument | HARVEST must be of type real. It is an INTENT (OUT) argument. It may be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution in the interval $0<=x<1$. |
|  | RANDOM_SEED(SIZE, PUT, GET) |
| Optional arguments | SIZE, PUT, GET |
| Description | Restarts or queries the pseudorandom number generator used by RANDOM_NUMBER. |
| Class | Subroutine. |
| Arguments | There must either be exactly one or no arguments present. |

Intrinsic procedures
Intrinsic procedure specifications

| SIZE (optional) | must be scalar and of type default integer. It is an <br> INTENT (OUT) argument. It is set to the number $N$ of <br> integers that the processor uses to hold the value of the <br> seed. |
| :--- | :--- |
| PUT (optional) | must be a default integer array of rank one and size >= <br> N.It is an INTENT (IN) argument. It is used by the |
| processor to set the seed value. |  |

## RANGE(X)

Description

Class
Argument

Result type, type parameters, and shape

Result value Case $1 \quad$ For an integer argument, the result has the value INT (LOG10 (huge)), where huge is the largest positive integer in the model representing integer numbers with same kind type parameter as X. See "The Integer Number System M odel" on page 482 for more information.

Case $2 \quad$ For a real or complex argument, the result has the value INT (MIN (LOG10 (huge), -LOG10 (tiny))), where huge and tiny are the largest and smallest positive numbers in the model representing real numbers with the same value for the kind type parameter as x. See "The Real Number System M odel" on page 482 for more information.

Intrinsic procedures
Intrinsic procedure specifications

| Example | RANGE (X) has the value 38 for real X , whose model is described in "The Real Number System M odel" on page 482, because in this case huge=(1-$\left.2^{-24}\right) * 2^{127}$ and tiny $=2^{-127}$. |
| :---: | :---: |
| Specific forms | SNGL, SNGLQ. |
|  | REAL(A, KIND) |
| Optional argument | KIND |
| Description | Convert to real type. |
| Class | Elemental function. |
| Arguments | A must be of type integer, real, or complex. |
|  | KIND (optional) must be a scalar integer initialization expression. |
| Result type/ type parameters | Real. |
|  | $\begin{array}{ll}\text { Case } 1 & \text { If A is of type integer or real and KIND is present, the } \\ & \text { kind type parameter is that specified by KIND. }\end{array}$ |
|  | If A is of type integer or real and KIND is not present, the kind type parameter is the processor-dependent kind type parameter for the default real type. |
|  | Case 2 If A is of type complex and KIND is present, the kind type parameter is that specified by KInD. |
|  | If $A$ is of type complex and KIND is not present, the kind type parameter is the kind type parameter of A. |
| Result value | Case 1 If A is of type integer or real, the result is equal to a processor-dependent approximation to A. |
|  | Case 2 If A is of type complex, the result is equal to a processor-dependent approximation to the real part of A. |
| Specific forms | FLOAT, FLOATI, FLOATJ, FLOATK. |

Intrinsic procedures
Intrinsic procedure specifications

## REPEAT(STRING, NCOPIES)

| Description | Concatenate several copies of a string. |
| :--- | :--- |
| Class | Transformational function. |
| Arguments | STRING <br> NCOPIES |
| must be scalar and of type character. <br> must be scalar and of type integer. Its value must not <br> be negative. |  |
| Result type, <br> type parameters, <br> and shape | Character scalar of length NCOP IES times that of STRING, with the same <br> kind type parameter as STRING. |
| Result value | The value of the result is the concatenation of NCOP IES copies of STRING. |
| Specific forms | KREPEAT. |

## RESHAPE(SOURCE , SHAPE, PAD, ORDER)

## Optional arguments

PAD, ORDER
Description Constructs an array of a specified shape from the elements of a given array.

Class Transformational function.
Arguments

| SOURCE | may be of any type. It must be array valued. If PAD is <br> absent or of size zero, the size of SOURCE must be <br> greater than or equal to PRODUCT (SHAPE). The size of <br> the result is the product of the values of the elements of |
| :--- | :--- |
| SHAPE. |  |
| SHAPE | must be of type integer, rank one, and constant size. Its <br> size must be positive and less than 8. It must not have <br> an element whose value is negative. |
| PAD (optional)must be of the same type and type parameters as <br> SOURCE. PAD must be array valued. |  |

Result type,
type parameters,
and shape

Result value

## Specific forms

Description
Class
Argument

Result

Class

Argument
Result type/
type parameters
Result value

ORDER (optional) must be of type integer, must have the same shape as SHAPE, and its value must be a permutation of $[1,2, \ldots$, n ], where n is the size of SHAPE. If absent, it is as if it were present with value $[1,2, \ldots, n]$.

The result is an array of shape SHAPE (that is, SHAPE (RESHAPE (SOURCE, SHAPE, PAD, ORDER)) is equal to SHAPE) with the same type and type parameters as SOURCE.

The elements of the result, taken in permuted subscript order $\operatorname{ORDER}(1), \ldots, \operatorname{ORDER}(\mathrm{n})$, are those of SOURCE in normal array element order followed if necessary by those of PAD in array element order, followed if necessary by additional copies of PAD in array element order.

```
KRESHAPE.
```

## RNUM(I)

Convert character to real type.
Elemental nonstandard function.
I must be of type character.
Default real type.

## RRSPACING(X)

Returns the reciprocal of the relative spacing of model numbers near the argument value.

Elemental function.
X must be of type real.
Same as X .

The result has the value $\left|x * b^{-e}\right| * b^{p}$, where $b, e$, and $p$ are as defined in "The Real Number System M odel" on page 482.

Intrinsic procedures
Intrinsic procedure specifications

## RSHFT(I,SHIFT)

| Description | Bitwise right shift. |
| :--- | :--- |
| Class | Elemental nonstandard function. |

## RSHIFT(I, SHIFT)

| Description | Bitwise right shift. |
| :---: | :---: |
| Class | Elemental nonstandard function. |
|  | SCALE (X, I) |
| Description | Returns $x$ * $b^{1}$ where $b$ is the base in the model representation of $x$. See "The Real Number System M odel" on page 482 for a description of this. |
| Class | Elemental function. |
| Arguments | $\mathrm{X} \quad$ must be of type real. |
|  | I must be of type integer. |
| Result type/ type parameters | Same as X . |
| Result value | The result has the value $x * b^{l}$, where $b$ is defined in "The Real Number System Model" on page 482, provided this result is within range; if not, the result is processor dependent. |

## SCAN(STRING, SET, BACK)

Optional argument
BACK

Description

Class

Arguments
must be of type character.
Result type/
type parameters
Result value

Description

Class
Argument
Result type/
type parameters
NOTE
must be of type character with the same kind type parameter as STRING.
BACK (optional) must be of type logical.

Case 1 If BACK is absent or is present with the value . FALSE. and if STRING contains at least one character that is in SET, the value of the result is the position of the leftmost character of STRINg that is in SET.
Case 2 If BACK is present with the value. TRUE. and if STRING contains at least one character that is in SET, the value of the result is the position of the rightmost character of STRING that is in SET.

Case 3 The value of the result is zero if no character of STRING is in SET or if the length of STRING or SET is zero.

## SE CNDS(X)

Default integer.

Return the number of seconds that have elapsed since midnight, less the value of the argument.

Elemental nonstandard function.
$x$ must be of type REAL (4).
REAL (4).

SECNDS is accurate to one one-hundredth of a second ( 0.01 second). The SECNDS routine is useful for computing elapsed time for a code's execution.

Intrinsic procedures
Intrinsic procedure specifications

## SELECTED_INT_KIND(R)

| Description | Returns a value of the kind type parameter of an integer data type that represents all integer values $n$ with $-10^{R}<n<10^{R}$. |
| :---: | :---: |
| Class | Transformational function. |
| Argument | R must be scalar and of type integer. |
| Result type, type parameters, and shape | Default integer scalar. |
| Result value | The result has a value equal to the value of the kind type parameter of an integer data type that represents all values $n$ in the range of values $n$ with $-10^{\mathrm{R}}<\mathrm{n}<10^{\mathrm{R}}$, or if no such kind type parameter is available on the processor, the result is -1 . |
|  | If more than one kind type parameter meets the criteria, the value returned is the one with the smallest decimal exponent range, unless there are several such values, in which case the smallest of these kind values is returned. |
|  | SELECTED_REAL_KIND(P, R ) |
| Optional arguments | P, R |
| Description | Returns a value of the kind type parameter of a real data type with decimal precision of at least $P$ digits and a decimal exponent range of at least R . |
| Class | Transformational function. |
| Arguments | At least one argument must be present. |
|  | P (optional) must be scalar and of type integer. |
|  | $R$ (optional) must be scalar and of type integer. |
| Result type, type parameters, and shape | Default integer scalar. |

\section*{Result value <br> Description <br> Class <br> Arguments <br> Result type/ type parameters <br> The result has a value equal to a value of the kind type parameter of a real data type with decimal precision, as returned by the function PRECISION, of at least $P$ digits and a decimal exponent range, as returned by the function RANGE, of at least $R$. <br> If no such kind type parameter is available on the processor, the result is -1 if the precision is not available, -2 if the exponent range is not available, and -3 if neither is available. <br> If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision, unless there are several such values, in which case the smallest of these kind values is returned. <br> SET_EXPONENT(X,I) <br> Returns the model number whose exponent is I and whose fractional part is the fractional part of $X$. <br> Elemental function. <br> | $X$ | must be of type real. |
| :--- | :--- |
| $I$ | must be of type integer. | <br> Same as X . <br> The result has the value $x * b^{l-e}$, where $b$ and e are as defined in "The Real Number System M odel" on page 482, provided this result is within range; if not, the result is processor-dependent.}

If $x$ has value zero, the result has value zero.

Intrinsic procedures
Intrinsic procedure specifications

## SHAPE (SOURCE)

| Description | Returns the shape of an array or a scalar. |
| :--- | :--- |
| Class | Inquiry function. <br> Argument |
| SOURCE may be of any type. It may be array valued or scalar. It must not <br> be a pointer that is disassociated or an allocatable array that is not <br> allocated. It must not be an assumed-size array. |  |
| Result type, <br> type parameters, <br> and shape | The result is a default integer array of rank one whose size is equal to <br> the rank of SOURCE. |
| Result value | The value of the result is the shape of SOURCE. |
| Specific forms | KSHAPE. |

## SIGN(A, B)

| Description | Absolute value of A times the sign of B. |
| :---: | :---: |
| Class | Elemental function. |
| Arguments | A must be of type integer or real. |
|  | B must be of the same type and kind type parameter as A. |
| Result type/ type parameters | Same as A. |
| Result value | The value of the result is $\|A\|$ if $B>=0$ and $-\|A\|$ if $B<0$. |
| Specific forms | BSIGN, DSIGN, HSIGN, IISIGN, JSIGN, QSIGN, KISIGN. |

## SIN(X)

| Description | Sine function in radians. |
| :---: | :---: |
| Class | Elemental function. |
| Argument | x must be of type real or complex. |
| Result type/ type parameters | Same as x . |
| Result value | The result has a value equal to a processor-dependent approximation to $\sin (X)$. <br> - If $x$ is of type real, it is regarded as a value in radians. <br> - If $x$ is of type complex, its real part is regarded as a value in radians. |
| Specific forms | CDSIN, CSIN, DSIN, QSIN, ZSIN. <br> SIND(X) |
| Description | Sine function in degrees. |
| Class | Elemental nonstandard function. |
| Argument | x must be of type real. |
| Result type/ type parameters | Same as x . |
| Result value | The result has a value equal to a processor-dependent approximation to $\sin (X)$. |
| Specific forms | QSIND. |

Intrinsic procedures
Intrinsic procedure specifications

## SINH (X)

| Description | Hyperbolic sine function. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | X must be of type real. |
| Result type <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> sinh(X). |
| Specific forms | QSINH. |

## SIZE (ARRAY, DIM)

## Optional argument DIM

| Description | Returns the extent of an array along a specified dimension or the total number of elements in the array. |
| :---: | :---: |
| Class | Inquiry function. |
| Arguments | may be of any type. It must not be scalar. It must not be a pointer that is disassociated or an allocatable array that is not allocated. If ARRAY is an assumed-size array, DIM must be present with a value less than the rank of ARRAY. |
|  | DIM (optional) must be scalar and of type integer with a value in the range $1<=$ DIM $<=n$, where n is the rank of ARRAY. |
| Result type, type parameters, and shape | Default integer scalar. |

| Result value | The result has a value equal to the extent of dimension DIM of ARRAY or, <br> if DIM is absent, the total number of elements of ARRAY. |
| :--- | :--- |
| Specific forms | KSIZE. |

## SIZE OF (A)

| Description | Return the number of bytes of storage used by the argument. |
| :--- | :--- |
| Class | Inquiry nonstandard function. |
| Argument | A may be of any type (except assumed-size arrays or passed-length <br> character arguments). |
| Result type | Integer. |

## SPACING(X)

Description Returns the absolute spacing of model numbers near the argument value.

Class
Elemental function.

Argument
x must be of type real.
Result type/
Same as X.
type parameters
Result value
If $x$ is not zero, the result has the value $b^{e-p}$, where $b, e$, and $p$ are as defined in "The Real Number System Model" on page 482, provided this result is within range; otherwise, the result is the same as that of TINY (X).

## SPREAD(SOURCE, DIM, NCOPIES)

Description Replicates an array by adding a dimension. Broadcasts several copies of SOURCE al ong a specified dimension (as in forming a book from copies of a single page) and thus forms an array of rank one greater.

Class

Arguments
Transformational function.

SOURCE may be of any type. It may be scalar or array valued. The rank of sOURCE must be less than 7.

|  | Intrinsic procedures |  |
| :---: | :---: | :---: |
|  | Intrinsic procedure specifications |  |
|  | DIM | must be scalar and of type integer with value in the range $1<=$ DIM $<=n+1$, where $n$ is the rank of SOURCE. |
|  | NCOPIES | must be scalar and of type integer. |
| Result type, type parameters, | The result is an array of the same type and type parameters as SOURCE and of rank $n+1$, where $n$ is the rank of SOURCE. |  |
| and shape | Case 1 | If SOURCE is scalar, the shape of the result is (MAX (NCOPIES, 0)). |
|  | Case 2 | If SOURCE is array valued with shape ( $d_{1}, d_{2}, \ldots, d_{n}$ ), the shape of the result is $\left(d_{1}, d_{2}, \ldots, d_{\text {DIM-1 }}\right.$, MAX (NCOPIES, 0), $d_{D I M}, \ldots, d_{n}$ ). |
| Result value | Case 1 | If SOURCE is scalar, each element of the result has a value equal to SOURCE. |
|  | Case 2 | If SOURCE is array valued, the element of the result with subscripts $\left(r_{1}, r_{2}, \ldots, r_{n+1}\right)$ has the value $\operatorname{SOURCE}\left(r_{1}, r_{2}, \ldots, r_{\text {DIM-1 }}, r_{\text {DIM }+1}, \ldots, r_{n+1}\right)$. |
|  | SQRT(X) |  |
| Description | Square root. |  |
| Class | Elemental function. |  |
| Argument | x must be of type real or complex. If x is real, its value must be greater than or equal to zero. |  |
| Result type) type parameters | Same as x . |  |
| Result value | The result has a value equal to a processor-dependent approximation to the square root of x . |  |
|  | A result of type complex is the principal value with the real part greater than or equal to zero. When the real part of the result is zero, the imaginary part is greater than or equal to zero. |  |
| Specific forms | CDSQRT, | DSQRT, QSQRT, ZSQRT. |

    CDSQRT, CSQRT, DSQRT, QSQRT, ZSQRT.
    Intrinsic procedures
Intrinsic procedure specifications

## SRAND(ISEED)

| Description | Restart the pseudorandom number generator used by IRAND and RAND. |
| :--- | :--- |
| Class | Elemental nonstandard subroutine. |
| Argument | ISEED must be of INTEGER ( 4 ) type. <br> The same value for ISEED generates the same sequence of random <br> numbers. To vary the sequence, call SRAND with a different ISEED value <br> each time the program is executed. The default for ISEED is 1. |
|  | SUM (AR RAY, DIM, MASK) |

Intrinsic procedures
Intrinsic procedure specifications

```
Case2 Theresult of SUM(ARRAY, MASK = msk) has a value equal to a processor-dependent approximation to the sum of the elements of ARRAY corresponding to the . TRUE. elements of msk or has the value zero if there are no. TRUE. elements.
Case 3 If ARRAY has rank one, SUM (ARRAY, DIM [,msk]) has a value equal to that of SUM (ARRAY [, MASK = msk ]). Otherwise, the value of element ( \(\mathrm{s}_{1}, \mathrm{~s}_{2}, \ldots, \mathrm{~S}_{\text {DIM }}\) \({ }_{1}, S_{\text {DIM }+1}, \ldots, S_{n}\) ) of SUM (ARRAY, DIM [,msk]) is equal to the following:
SUM (ARRAY \(\left(S_{1}, S_{2}, \ldots, S_{D I M-1},:, S_{D I M+1}, \ldots\right.\), \(\left.S_{n}\right) \quad \&\)
[, MASK=msk (S \({ }_{1}, S_{2}, \ldots, S_{D I M-1},:\),
SDIM+1, ..., \(S_{n}\) )])
```

## SYSTEM(STR)

## Description

Class

Argument

Issue a shell command from a Fortran 90 program.
Nonstandard subroutine.

STR must be of type character. SYSTEM gives STR to the default shell (/ bin/sh) as input, as if the string were entered at a terminal. When the shell has completed, the process continues.

# SYSTEM_CLOCK(COUNT, COUNT_RATE, COUNT_MAX) 

| Optional arguments | COUNT, COUNT_RATE, COUNT_MAX |
| :---: | :---: |
| Description | Returns integer data from a real-time clock. |
| Class | Subroutine. |
| Arguments | Count (optional) must be scalar and of type default integer. It is an intent (OUT) argument. It is set to a processordependent value based on the current value of the processor clock or to - HUGE (0) if there is no clock. The processor-dependent value is incremented by one for each clock count until the value count_max is reached and is reset to zero at the next count. It lies in the range 0 to COUNT_MAX if there is a clock. |
|  | COUNT_RATE <br> (optional) must be scalar and of type default integer. It is an INTENT (OUT) argument. It is set to the number of processor clock counts per second, or to zero if there is no clock. |
|  | COUNT_MAX <br> (optional) <br> must be scalar and of type default integer. It is an INTENT (OUT) argument. It is set to the maximum value that count can have, or to zero if there is no clock. |
|  | TAN(X) |
| Description | Tangent function in radians. |
| Class | Elemental function. |
| Argument | x must be of type real. |
| Result type/ type parameters | Same as x . |

Intrinsic procedures
Intrinsic procedure specifications

| Result value | The result has a value equal to a processor-dependent approximation to <br> tan $(X)$, with $X$ regarded as a value in radians. |
| :--- | :--- |
| Specific forms | CTAN,DTAN,QTAN,ZTAN. |

| Description | Tangent function in degrees. |
| :--- | :--- |
| Class | Elemental nonstandard function. |
| Argument | X must be of type real. |
| Result type/ <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> tan $(X)$. |
| Specific forms | DTAND, QTAND. |

## TANH (X)

| Description | Hyperbolic tangent function. |
| :--- | :--- |
| Class | Elemental function. |
| Argument | X must be of type real. |
| Result type/ <br> type parameters | Same as X. |
| Result value | The result has a value equal to a processor-dependent approximation to <br> tanh $(X)$. |
| Specific forms | DTANH, QTANH. |

## TIME (TIME STR)

| Description | Return the current system time. |
| :--- | :--- |
| Class | Nonstandard subroutine. |
| Argument | TIMESTR must be of type character and must provide at least 8 bytes of <br> storage. |
| Result value | TIME fills TIMESTR with an 8-byte character string of the form <br> hh: mm: ss (hh is the current hour, mm the current minute, ss the <br> number of seconds past the minute). |
|  | TINY(X) |

Description Returns the smallest positive number in the model representing numbers of the same type and kind type parameter as the argument.

Class
Argument
Result type, type parameters, and shape

Result value

Inquiry function.
x must be of type real. It may be scalar or array valued.
Scalar with the same type and kind type parameter as x.

The result has the value ${ }_{b}{ }^{e}$ min-1
where $b$ and $\mathrm{e}_{\text {min }}$ are as defined in "The Real Number System Model" on page 482.

Intrinsic procedures
Intrinsic procedure specifications

## TRANSFER(SOURCE , MOLD, SIZE )

Optional argument SIZE

| Description | Returns a result with a physical representation identical to that of <br> SOURCE but interpreted with the type and type parameters of MOLD. |
| :--- | :--- |
| Class | Transformational function. |

Arguments SOURCE may be of any type and may be scalar or array valued.
MOLD may be of any type and may be scalar or array valued.

SIZE (optional) must be scalar and of type integer. The corresponding actual argument must not be an optional dummy argument.

The result is of the same type and type parameters as MOLD.
Case 1 If MOLD is a scalar and SIZE is absent, the result is a scalar.

Case 2 If MOLD is array valued and SIZE is absent, the result is array valued and of rank one. Its size is as small as possible such that its physical representation is not shorter than that of SOURCE.
Case 3 If SIZE is present, the result is array valued of rank one and size SIZE.

If the physical representation of the result has the same length as that of SOURCE, the physical representation of the result is that of SOURCE.

- If the physical representation of the result is longer than that of SOURCE, the physical representation of the leading part is that of SOURCE and the remainder is undefined.
- If the physical representation of the result is shorter than that of SOURCE, the physical representation of the result is the leading part of SOURCE. If D and E are scalar variables such that the physical representation of $D$ is as long as or longer than that of $E$, the value of TRANSFER (TRANSFER (E, D), E) must be the value of E.
- If $D$ is an array and $E$ is an array of rank one, the value of TRANSFER (TRANSFER (E, D), E, SIZE (E)) must bethe value of E.

## TRANSPOSE (MATRIX)

| Description | Transpose an array of rank two. |
| :--- | :--- |
| Class | Transformational function. |
| Result type, <br> type parameters, <br> and shape | MATRIX may be of any type and must have rank two. <br> The result is an array of the same type and type parameters as MATRIX <br> and with rank two and shape $(n, m)$ where $(m, n)$ is the shape of MATRIX. |
| Result value | Element $(i, j)$ of the result has the value MATRIX $(j, i), i=1,2, \ldots, n ; j=1,2$, |

## TRIM(STRING)

Description
Class
Argument
Result type/
type parameters

Result value
Returns the argument with trailing blank characters removed.
Transformational function.
STRING must be of type character and must be a scalar.
Character with the same kind type parameter value as STRING and with a length that is the length of String less the number of trailing blanks in STRING.

The value of the result is the same as STRING except any trailing blanks are removed. If STRING contains no nonblank characters, the result has zero length.

## UBOUND(ARRAY, DIM)

Optional argument DIM
Description
Returns all the upper bounds of an array or a specified upper bound.
Class
Inquiry function.

Intrinsic procedures
Intrinsic procedure specifications

## UNPACK(VECTOR, MASK, FIELD)

Description Unpack an array of rank one into an array under the control of a mask.
Class Transformational function.

| Arguments | VECTOR |
| :--- | :--- |
| MASK | may be of any type. It must have rank one. Its size <br> must be at least t where t is the number of . TRUE <br> elements in MASK. |
| FIELD | must be array valued and of type logical. |
|  | must be of the same type and type parameters as <br> VECTOR and must be conformable with MASK. |

| Result type, |
| :--- |
| type parameters, |
| and shape |

Result value

| The result is an array of the same type and type parameters as VECTOR |
| :--- |
| and the same shape as MASK. |

| The element of the result that corresponds to the ith . TRUE. element of |
| :--- |
| MASK, in array element order, has the value VECTOR (i) for $\mathrm{i}=1,2, \ldots, \mathrm{t}$, |

where is the number of . TRUE. values in MASK. Each other element has
a value equal to FIELD if FIELD is scalar or to the corresponding element
of FIELD if it is an array.

## VERIFY(STRING, SET, BACK)

| Optional argument | BACK |
| :--- | :--- |
| Description | Verify that a set of characters contains all the characters in a string by <br> identifying the position of the first character in a string of characters <br> that does not appear in a given set of characters. |
| Class | Elemental function. |
| Arguments | STRING <br> SET |
| must be of type character. <br> must be of type character with the same kind type <br> parameter as STRING. |  |
| type parameters | Default integer. |

Intrinsic procedures
Intrinsic procedure specifications

## XOR(I, J)

| Description | Bitwise exclusive OR. |
| :---: | :---: |
| Class | Elemental nonstandard function. |
| Arguments | I must be of type integer. |
|  | $J \quad$ must be of type integer with the same kind type parameter as I. |
| Result type/ type parameters | Same as I. |
| Result value | The result has the value obtained by performing an exclusive or on I and $J$ bit-by-bit according to Table 59. |
|  | The model for interpreting an integer value as a sequence of bits is described in "The Bit M odel" on page 481. |
|  | ZEXT(A) |
| Description | Zero extend. |
| Class | Elemental nonstandard function. |
| Argument | A must be of type integer or logical. |
| Result | zext converts a 1-, 2-, or 4-byte logical or integer to a 2- or 4-byte integer by sign-extending zeroes instead of the actual sign bit. |

## 12 <br> BLAS and libU77 Iibraries

This chapter describes the Basic Linear Algebra Subroutines (BLAS) and the BSD $3 f$ (libu77) libraries that are shipped with HP Fortran.
The libu77 library provides routines that have a Fortran 90 interface for system routines in the libc library. The libu77 routines make it easier to call HP-UX system-level routines from Fortran 90 programs because they use Fortran 90 argument-passing conventions. The libu77 routines are also compatible with other Fortran implementations that supply these routines by default.

NOTE
Even though system routines use different argument-passing rules from HP Fortran programs, you can call these routines from HP Fortran programs by using the \%VAL and \%REF built-in functions to change how arguments are passed. For more information about \%VAL and \%REF, see "\%VAL and \%REF built-in functions" on page 148.
The Basic Linear Algebra Subroutine (BLAS) library consists of a set of routines that perform low-level vector and matrix operations. These routines have been tuned for maximum performance and are callable from HP Fortran programs. For information about the background and significance of the BLAS library, refer to the LAPACK User's Guide, by E. Anderson et al (SIAM Press, 1992).
The following sections considerations to keep in mind when writing and compiling a program that calls routines from the BLAS or libu77 library, and briefly describes the routines in the libraries. For information about other libraries that are shipped with HP Fortran, including how to create and link libraries with your programs-refer to the HP Fortran Programmer's Guide.

## Calling libU77 and BLAS routines

This section discusses considerations pertinent to writing and compiling programs that call libu77 and BLAS routines, including:

- The compile-line options that make libu77 and BLAS routines available to your programs
- Declaring the type of return type of library functions
- Declaring library functions with the external attribute
- BLAS and libu77 man pages

## Compile-line options

The following sections describe the compile-line options to use to access routines from the libu77 and BLAS libraries.

## +U77 option

To access libu77 routines, compile with the +U77 option. The entrypoint name of each libu77 routine has an appended underscore, which must also be added to the external name of any libu 77 routine that your program calls. The +U77 option does this. For example, if your program contains the following call:

```
CALL FLUSH(unit_no)
```

compiling with +U 77 causes the compiler to generate the external name access_. The +ppu and +uppercase options have no effect on libu77 external names.

## -lblas option

To access BLAS routines, compile with the -lblas option. Unlike most compile-line options, the -1 option must appear at the end of the command line, following any source files that call BLAS routines; see "General Compiler Syntax" on page 572. Here is an example command line for compiling do_math. f 90 to access BLAS routines:

```
$ f90 do_math.f90 -lblas
```

## Year-2000 compatibility

Two new libU 77 routines (DATEY2K and IDATEY2K, both described in this chapter) are provided in the Fortran 90 compiler to handle Year-2000 (Y2K) daterelated issues on HP-UX 10.x and HP-UX 11.x. The +U77 flag must be used with both of these routines.

Although both are provided for Y 2 K compliance, it is recommended that the standard DATE_AND_TIME intrinsic be used instead of these functions, when possible.
The guidelines for changing code which uses the date or idate libU 77 routines are as follows:

- In code where date is referenced, replace DATE with DATEY2K. Also, make sure that DATEY2K's argument is at least 11 characters in length.
- In code where the idate intrinsic (not the libu77 idate routine) is used, replace IDATE with IDATEY2K.

## Declaring library functions

Unlike intrinsics, library routines do not have an explicit interface within your program. This means (among other things) that, if the routine is a function, the compiler applies the implicit typing rules to the return value. When these rules are in effect, the return value is likely to be meaningless if the type implied by the function name does not agree with the type of the returned value or if the return type is not explicitly declared within the program unit that calls the routine.

Consider the following program, call_ttynam.f90. The program consists of two subroutines, both of which call the libu77 function tTYnAm. This function returns a character value-the path name of a terminal device associated. But the return type is declared in only one of the subroutines; in the other subroutine, the type is undeclared, and the compiler therefore assumes-applying the rules of implicit typing-that the return value is of type real. The consequences of this assumption are illustrated in the output, below.

## BLAS and libU77 libraries

## Calling libU77 and BLAS routines

## call_ttynam.f90

```
PROGRAM main
! illustrates the consequences of failure to declare
! the return type of a library function. Both
! subroutines do the same thing--invoke the libU77
! function TTYNAM. But only the second subroutine
! declares the return type of the function.
! This program must be compiled with the +U77 option.
    CALL without_decl
    CALL with_decl
END PROGRAM main
SUBROUTINE without_decl
    PRINT *, TTYNAM(6) ! implicit typing is in effect
END SUBROUTINE without_decl
SUBROUTINE with_decl
    ! declare the return type of TTYNAM
    CHARACTER(LEN=80), EXTERNAL :: TTYNAM
    PRINT *, TTYNAM(6)
END SUBROUTINE with_decl
```

Here are the command lines to compile and execute the program, along with the output from a sample run:

```
f90 +U77 call_ttynam.f90
$ a.out
0.0
/dev/pts/0
```

For information about explicit interface, see "Procedure interface" on page 151. See "I mplicit typing" on page 28 for the rules of implicit typing.

## Declaring library routines as EXTE R NAL

There are two cases when you should declare a library routine with the EXTERNAL attribute:

- The routine name is passed to a procedure as an actual argument
- The routine name is the same as an intrinsic name

The first case applies to both libu77 and BLAS routines. The second applies only to libu77 routines; as shown in Table 62, several of the names of libu77 routines are also those of intrinsics. Unless you declare these routines with the EXTERNAL attribute, the compiler will map the call to the intrinsic library.

## Table 62 libu77 naming conflicts

| FLUSH | FREE | GETARG |
| :--- | :--- | :--- |
| GETENV | IARGC | IDATE |
| LOC | MALLOC | SYSTEM |
| TIME |  |  |

For example, if a program unit makes a call to flush, the compiler will make a call to the intrinsic, unless the program unit includes the fol lowing statement:

```
EXTERNAL FLUSH
```

See "external (statement and attribute)" on page 328 for a description of the external statement and attribute. As noted in the description, the attribute form of External cannot be used with subroutines, which must therefore be specified in the statement form.

## Man pages

You can get detailed, online information for any libu77 or BLAS routine by using the man command to display an online reference page for that routine. The command-line syntax for the man command is:
man section_number routine_name
where section_number is either 3 f (for libu77) man pages or 3 x (for BLAS); and routine_name is the name of the libu77 or BLAS routine. For example, to display the man page for the libu77 routine FLUSH, give the command:
$\$$ man $3 f$ flush
To display the man page for the BLAS routine SAXPY, give the command:

## \$ man 3x saxpy

Two of the BLAS man pages provide general information about the BLAS routines: blas1(3x) describes basic vector operations, and blas2(3x) describes basic matrix operations.

BLAS and libU77 libraries
libU77 routines

## libU77 routines

Table 63 lists the libu77 routines by category, and Table 64 briefly describes each routine, including signature and argument information. The sizes of the data types listed in Table 64 are the default sizes, unless indicated otherwise. See Table 5 for the sizes of the default data types.

Table 63
Categories of libu77 routines

| Category | libu77 routines |
| :--- | :--- |
| Date and time | CTIME, DATEY2K, DTIME, ETIME, FDATE, <br> GMTIME, IDATE, IDATEY2K, ITIME, LTIME, <br> TIME |
| Error handling | GERROR, IERRNO, PERROR |
| File system functions | ACCESS, CHDIR, CHMOD, FSTAT, ISATTY, <br> LINK, LSTAT, RENAME, STAT, SYMLNK, <br> TTYNAM, UNLINK |
| Information retrieval | GETARG, GETCWD, GETENV, GETGID, GETLOG, <br> GETPID, GETUID, HOSTNM, IARGC |
| Input/Output | FGETC, FPUTC, FSEEK, FTELL, GETC, PUTC |
| Memory allocation | FALLOC, FREE, MALLOC |
| Miscellaneous | LOC, QSORT, SYSTEM |
| Process control | ALARM, FORK, KILL, SIGNAL, SLEEP, WAIT |
| Tape input/output | TCLOSE, TOPEN, TREAD, TREWIN, TSKIPF, <br> TSTATE, TWRITE |

## Table 64

libu77 routines

| Name | Description and signature |
| :---: | :---: |
| ACCESS | Determines the accessibility of a file. INTEGER FUNCTION ACCESS (name, mode) CHARACTER (LEN=*) :: name, mode |
| ALARM | Executes a subroutine after a specified time. INTEGER FUNCTION ALARM (time, proc) <br> INTEGER : : time <br> external proc |
| CHDIR | Changes the default directory. INTEGER FUNCTION CHDIR (dir_name) CHARACTER (LEN=*) :: dir_name |
| CHMOD | Changes the mode of a file. INTEGER FUNCTION CHMOD (name, mode) CHARACTER (LEN=*) :: name, mode |
| CTIME | Converts a system time to a 24-character ASCII string. CHARACTER (LEN=*) FUNCTION CTIME (stime) INTEGER :: stime |
| DATEY2K | Designed to replace the 990 DATE instrinsic. Its function and arguments are the same as the date intrinsic's ecept that the returned string contains a four-digit year in mm-dd-yyyy format instead of a two-digit year in mm-dd--yy format. <br> SUBROUTINE DATEY2K (DATE) <br> CHARACTER*11 DATE <br> The +U77 flag (described in "+U77 option" on page 588) must be used with DATEY2K. |
| DTIME | Returns elapsed execution time since the last call to dtime or since the start of execution on the first call. <br> REAL FUNCTION DTIME (tarray) <br> REAL : : tarray (2) |
| ETIME | Returns the el apsed execution time, in seconds, for the calling process. <br> Real function etime (tarray) <br> REAL :: tarray (2) |

BLAS and libU77 libraries
libU77 routines

| Name | Description and signature |
| :---: | :---: |
| FALLOC | Allocates array space in memory. <br> SUbroutine falloc (nelem, elsize, clean, basevec, addr, offset) <br> INTEGER :: nelem, elsize, clean, addr, offset <br> basevec must be declared as an array whose elements are elsize bytes in size. FALLOC allocates space for basevec to contain nelem elements. |
| FDATE | Returns the date and time as an ASCII string; available as a subroutine: <br> SUBROUTINE FDATE (string) <br> CHARACTER (LEN=*) : : string <br> And as a function: <br> CHARACTER (LEN=*) :: FUNCTION FDATE () |
| FGEtc | Retrieves a character from a file specified by an HP Fortran logical unit. <br> INTEGER FUNCTION FGETC (lunit, char) <br> INTEGER : : lunit <br> ChARACTER char |
| FLUSH | Flushes file for specified unit number. <br> SUBROUTINE FLUSH (unit) <br> integer :: unit |
| FORK | Creates a copy of the calling process. integer function Fork () |
| FPUTC | Writes a character to the file specified by an HP Fortran logical unit, bypassing normal HP Fortran I/O. <br> integer function fputc (lunit, char) <br> INTEGER : : lunit <br> CHARACTER :: char |
| FREE | Releases memory previously allocated with MALLOC or FALLOC. SUbroutine free (addr) INTEGER :: addr |
| FSEEK | Repositions a file specified by an HP Fortran logical unit. integer function fseek (lunit, offset, from) integer :: lunit, offset, from |
| FSTAT | Returns detailed information about a file by logical unit number. <br> integer function fstat (lunit, statb) <br> Integer :: lunit, statb (12) |

| Name | Description and signature |
| :---: | :---: |
| FTELL | Returns the current position of the file associated with the specified logical unit. <br> Integer function fiell (lunit) <br> INTEGER : : lunit |
| GERROR | Returns the system error message to string; available as a subroutine: CHARACTER (LEN=*) : : string SUBROUTINE GERROR (string) <br> And as a function: <br> CHARACTER (LEN=*) FUNCTION GERROR() |
| GEtARG | Returns command-line arguments. <br> SUBROUTINE GETARG (k, arg) <br> INTEGER : : k <br> CHARACTER (LEN=*) : : arg |
| GETC | Retrieves a character from HP Fortran logical unit 5. INTEGER FUNCTION GETC (char) Character char |
| GETCWD | Retrieves the pathname of the current working directory. integer function getcwd (dir_name) CHARACTER (LEN=*) : : dir_name |
| Getenv | Retrieves the value of an environment variable. SUBROUTINE GETENV (ename, evalue) CHARACTER (LEN=*) :: ename, evalue |
| GETGID | Retrieves the group ID of the user of the process. integer function getgid () |
| GEtLog | Retrieves the user's login name; available as a subroutine: <br> SUBROUTINE GETLog (name) <br> CHARACTER (LEN=*) :: name <br> And as a function: <br> CHARACTER (LEN=*) FUNCTION GETLOG() |
| GETPID | Returns the process ID of the current process. INTEGER FUNCTION GETPID() |
| GETUID | Returns the user ID of the user of the process. <br> INTEGER FUNCTION GETUID() |

BLAS and libU77 libraries
libU77 routines

| Name | Description and signature |
| :---: | :---: |
| GMTIME | Returns the Greenwich mean time in HP-UX format within an array of time elements. <br> SUBROUTINE GMTIME (stime, tarray) <br> INTEGER : : stime, tarray (9) |
| HOSTNM | Retrieves the name of the current host. integer function hostnm (name) CHARACTER (LEN=*) :: name |
| IARGC | Returns the index of the last command-line argument. INTEGER FUNCTION IARGC() |
| IDATE | Returns the date in numerical form. SUBROUTINE IDATE (iarray) INTEGER :: iarray (3) |
| IDATEY2K | Designed to replace the HP 990 IDATE intrinsic. This returns the true year in its third argument, as opposed to the idate intrinsic, which returns the number of years since 1900 in its third argument. <br> SUBROUTEIN IDATEY2K (MONTH, DATE, YEAR) <br> integer month, DAy, year <br> The +U77 flag (described in "+U77 option" on page 588) must be used with IDATEY2K. |
| IERRNO | Returns the error number of the last detected system error. integer function ierrno () |
| ISATTY | Checks whether a logical unit is associated with a terminal device. <br> logical function isatty (lunit) <br> integer :: lunit |
| ITIME | Returns the time in numerical form. SUBROUTINE ITIME (iarray) INTEGER :: iarray (3) |
| KILL | Sends a signal number to a user's process. <br> INTEGER FUNCTION KILL (pid, signum) INTEGER :: pid, signum |
| LINK | Creates a link to an existing file. Integer function link (namel, name2) CHARACTER (LEN=*) :: namel, name2 |
| LOC | Returns the address of an object. <br> INTEGER FUNCTION LOC (arg) |

| Name | Description and signature |
| :---: | :---: |
| LSTAT | Returns detailed information about the symbolic link to a specified file. (Use STAT to obtain information about the file to which the link points.) integer function listat (name, statb) CHARACTER (LEN=*) :: name <br> INTEGER :: statb (12) |
| LTIME | Returns the local time in HP-UX format within an array of time elements. SUBROUTINE LTIME (stime, tarray) INTEGER :: stime, tarray (9) |
| MALLOC | Allocates memory. <br> SUBROUTINE MALLOC (size, addr) INTEGER :: size, addr |
| NUM_PROCS | Returns the total number of processors on which the process has initiated threads. <br> INTEGER FUNCTION NUM_PROCS () |
| NUM <br> THREADS | Returns the total number of threads that the process creates at initiation, regardless of how many are idle or active. <br> INTEGER FUNCTION NUM_THREADS() |
| PERROR | Retrieves system error messages. PERROR writes a message to HP Fortran logical unit 7 for the last detected system error. <br> SUBROUTINE PERROR (string) <br> CHARACTER (LEN=*) : : string |
| PUTC | Writes a character to the file specified by HP Fortran logical unit number 6, bypassing normal HP Fortran I/O. <br> integer function putc (char) <br> Character char |
| QSORT | Uses the quick-sort algorithm to sort the elements in a one-dimensional array. <br> SUBROUTINE QSORT (array, len, isize, compar) <br> INTEGER :: len, isize <br> EXTERNAL compar <br> INTEGER (2) compar |
| RENAME | Renames a file to the specified new name. INTEGER FUNCTION RENAME (from, to) ChARACTER (LEN=*) : : from, to |

BLAS and libU77 libraries
libU77 routines

| Name | Description and si gnature |
| :--- | :--- |
| SIGNAL | Allows you to change the action for a signal. <br> INTEGER FUNCTION SIGNAL (signum, proc, flag) <br> INTEGER : signum, flag <br> EXTERNAL |
| proc |  |$\quad$| Suspends the execution of a process for a specified interval. |
| :--- |
| SUBROUTINE SLEEP (itime) |
| INTEGER : : itime |

| Name | Description and signature |
| :---: | :---: |
| TSKIPF | Allows the user to skip over files and records. integer function tskipf (tlu, nfiles, nrecs) integer :: tlu, nfiles, nrecs |
| tState | Allows the user to determine the logical state of the tapel/O channel and to see the tape drive control status register. <br> integer function tstate (tlu, fileno, recno, erff, eoff, eoff, tcsr) <br> integer :: tlu, fileno, recho, tcsr <br> LOGICAL :: erff, eoff, eoff |
| TTYNAM | Returns a blank padded path name of the terminal device associated with a specified logical unit number. <br> Character (Len=*) function ttynam (lunit) <br> INTEGER :: lunit |
| TWRITE | Writes a physical record to tape from the specified buffer. integer function twrite (tlu, buffer) integer :: tlu <br> CHARACTER (LEN=*) :: buffer |
| UNLINK | Removes a specified directory entry. integer function unlink (name) CHARACTER (LEN=*) :: name |
| WAIT | Waits for a process to terminate. INTEGER FUNCTION WAIT (status) INTEGER :: status |

## BLAS and libU77 libraries

## BLAS routines

## BLAS routines

Table 65 lists the routines in the BLAS library and briefly summarizes the calculations they perform.

Table 65
BLAS routines

| Routine name | Calculation performed |
| :--- | :--- |
| ISAMAX, IDAMAX, ICAMAX, <br> IZAMAX | Return index of largest element in vector. |
| SASUM, DASUM, SCASUM, <br> DZASUM | Sum absolute values. |
| SAXPY, DAXPY, <br> CAXPY,ZAXPY | Add scalar multiple of vector to vector. |
| SCOPY, DCOPY, CCOPY, <br> ZCOPY | Copy a vector. |
| SDOT, DDOT, CDOTC,CDOTU, <br> ZDOTC, ZDOTU | Compute dot product of two vectors. |
| SGBMV, DGBMV, CGBMV, <br> ZGBMV | Multiply band matrix times vector. |
| SGEMM, DGEMM, CGEMM, <br> ZGEMM | Multiply two general matrices. |
| SGEMV, DGEMV, CGEMV, <br> ZGEMV | Multiply general matrix times vector. |
| SGER, DGER, CGERC, CGERU, <br> ZGERC, ZGERU | Compute dyadic product of two vectors. |
| SNRM2, DNRM2, SCNRM2, <br> DZNRM2 | Compute Euclidean norm of vector. |
| SROT, DROT, CROT, ZROT | Apply Givens plane rotation. |
| SROTM, DROTM | Apply a modified Givens rotation. |
| SROTG, DROTG, CROTG, <br> ZROTG | Construct Givens plane rotation. |
| $\mathbf{6 0 0}$ | Chapter 12 |

| R outine name | Calculation performed |
| :--- | :--- |
| SROTMG, DROTMG | Construct modified Givens plane rotation. |
| SSBMV, DSBMV, CHBMV, <br> ZHBMV | Multiply symmetric/Hermitian band matrix times vector. |
| SSCAL, DSCAL, CSCAL, <br> CSSCAL, ZSCAL, ZDSCAL | Scale vector. |
| SSPMV, DSPMV, CHPMV, <br> ZHPMV | Multiply symmetric/Hermitian packed matrix times vector. |
| SSPR, DSPR, CHPR, ZHPR | Compute symmetric/Hermitian dyadic product of vector <br> with itself, leaving result in packed form. |
| SSPR2, DSPR2, CHPR2, <br> ZHPR2 | Compute symmetric/Hermitian dyadic product of two <br> vectors, leaving result in packed form. |
| SSWAP, DSWAP, CSWAP, <br> ZSWAP | Swap two vectors. |
| SSYMM, DSYMM, CHEMM, <br> CSYMM, ZHEMM, ZSYMM | Multiply two symmetric matrices. |
| SSYMV, DSYMV, CHEMV, <br> ZHEMV | Multiply symmetric/Hermitian matrix times vector. |
| SSYR, DSYR, CHER, ZHER | Compute symmetric/Hermitian dyadic product of vector <br> with itself. |
| SSYR2, DSYR2, CHER2, <br> ZHER2 | Compute symmetric/Hermitian dyadic product of two <br> Zectors. |
| SSYR2K, DSYR2K, CHER2K, <br> CSYR2K, ZHER2K, ZSYR2K | Compute symmetric product of matrix and transpose or <br> adjoint of second matrix. |
| SSYRK, DSYRK, CHERK, <br> CSYRK, ZHERK, ZSYRK | Compute product of matrix and its transpose or adjoint. |
| STBMV, DTBMV, CTBMV, | Multiply triangular band matrix times vector. |
| Multiply inverse of triangular band matrix times vector. |  |

BLAS and libU77 libraries
BLAS routines

| Routine name | Calculation performed |
| :--- | :--- |
| STPMV, DTPMV, CTPMV, <br> ZTPMV | Multiply triangular packed matrix times vector. |
| STPSV, DTPSV, CTPSV, <br> ZTPSV | Multiply inverse of packed triangular matrix times vector. |
| STRMM, DTRMM, CTRMM, <br> ZTRMM | Multiply triangular matrix by general matrix. |
| STRMV, DTRMV, CTRMV, <br> ZTRMV | Multiply triangular matrix times vector. |
| STRSM, DTRSM, CTRSM, <br> ZTRSM | Multiply inverse of triangular matrix by general matrix. |
| STRSV, DSTRSV,CTRSV, <br> ZTRSV | Multiply inverse of triangular matrix times vector. |
| XERBLA | Handle errors for BLAS matrix operations (Level 2 and <br> Level 3 routines). |

## A <br> I/O runtime error messages

This appendix lists and describes the I/O runtime error messages that can be returned by the IOSTAT=integer-variable specifier. If an I/O error occurs during the execution of an I/O statement, and the statement includes the IOSTAT= integer-variable specifier, the status code for the error will be returned in integer-variable. Consider the following example:

INTEGER ios
.
.
OPEN (10, FILE='data_file', ERR=99, IOSTAT=ios)
If data_file is successfully opened, ios will return 0; if for any reason the file cannot be opened, a nonzero status code will be returned in ios. By referring to this appendix, you can get information about the error and how to correct it.

## Runtime I/O errors

The error information listed in this section includes the codes returned by IOSTAT=, plus the following:

- The message that the runtime system would send to standard error if you did not include the IOSTAT = specifier.
- A diagnosis of the conditions that might have resulted in the error.
- Actions that the programmer can take to correct the error.

Table 66 Runtime I/O errors

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 900 | ERROR IN FORMAT | FORMAT statement <br> syntax contains an error. | See the "I/O and file <br> handling" chapter for the <br> syntax of the format <br> specification and edit <br> descriptors. |
| 901 | NEGATIVE UNIT <br> NUMBER SPECIFIED | Unit number was not <br> greater than or equal to <br> zero. | Use a nonnegative unit <br> number. |
| 902 | FORMATTED I/O <br> ATTEMPTED ON <br> UNFORMATTED FILE | Formatted I/O was <br> attempted on a file <br> opened for unformatted <br> I/O. | Open the file for <br> formatted I/O or perform <br> unformatted I/O on this <br> file. |
| 903 | UNFORMATTED I/O <br> ATTEMPTED ON <br> FORMATTED FILE | Unformatted I/O was <br> attempted on a file <br> opened for formatted I/O. | Open the file for <br> unformatted I/O or <br> perform formatted I/O on <br> this file. |
| 904 | DIRECT I/O <br> ATTEMPTED ON <br> SEQUENTIAL FILE | Direct operation <br> attempted on sequential <br> file, direct operation <br> attempted on opened file <br> connected to a terminal. | Use sequential <br> operations on this file, <br> open file for direct access, <br> or do not do direct I/O on <br> a file connected to a <br> terminal. |

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 905 | ERROR IN LIST- <br> DIRECTED READ OF <br> LOGICAL DATA | Found repeat value, but <br> no asterisk. First <br> character after optional <br> decimal point was not T <br> or F. | Change input data to <br> correspond to syntax <br> expected by list-directed <br> input of Iogicals, or use <br> input statement that <br> corresponds to syntax of <br> input data. |
| 907 | ERROR IN LIST- <br> DIRECTED READ OF <br> CHARACTER DATA | Found repeat value, but <br> no asterisk. Characters <br> not delimited by <br> quotation marks. | Change input data to <br> correspond to syntax <br> expected by list-directed <br> input of characters, or <br> use input statement that <br> corresponds to syntax of <br> input data. |
| 908 | COULD NOT OPEN <br> FILE SPECIFIED | Tried to open a file that <br> the system would not <br> allow for one of the <br> following reasons: access <br> tothe file was denied by <br> the file system dueto <br> access restriction; the <br> named file does not exist; <br> or the type of access <br> request is impossible. | Correct the pathname to <br> open the intended file. |
| 909 | SEQUENTIAL I/O <br> ATTEMPTED ON <br> DIRECT ACCESS FILE | Attempted a <br> BACKSPACE, REWIND, <br> or ENDFILE on a <br> terminal or other device <br> for which these <br> operations are not <br> defined. | Do not use the <br> BACK SPACE, REWIND, <br> and ENDFILE <br> statements. |
| 910 | ACCESS PASTEND OF <br> RECORD ATTEMPTED | Tried to do I/O on record <br> of a file past beginning or <br> end of record. | Perform I/O operation <br> within bounds of the <br> record, or increase record <br> length. |

I/O runtime error messages
Runtime I/O errors

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 912 | ERROR IN LIST I/O <br> READ OF COMPLEX <br> DATA | While reading complex <br> data, one of the fol lowing <br> problems has occurred: <br> no left parenthesis and <br> no repeat value; repeat <br> value was found but no <br> asterisk; or no cl osing <br> right parenthesis. | Change input data to <br> correspond to syntax <br> expected by list-directed <br> input of complex <br> numbers, or use input <br> statement corresponding <br> to syntax of input data. |
| 913 | OUT OF FREE SPACE | Library cannot allocate <br> an I/O block (from an <br> OPEN statement), parse <br> array (for formats <br> assembled at run-time), <br> file name string (from <br> OPEN) characters from <br> list-directed read, or file <br> buffer. The program may <br> be trying to overwrite a <br> shared memory segment <br> defined by another <br> process. | Allocate more free space <br> in the heap area, open <br> fewer files, use FORMAT <br> statements in place of <br> assembling formats at <br> run time in character <br> arrays, or reduce the <br> maximum size of file <br> records. |
| 914 | ACCESS OF <br> UNCONNECTED UNIT <br> ATTEMPTED | Unit specified in I/O <br> statement has not <br> previously been <br> connected to anything. | Connect unit using the <br> OPEN statement before <br> attempting I/O on it, or <br> perform I/O on another, <br> already connected, unit. |
| 915 | READ UNEXPECTED <br> CHARACTER | Read a character that is <br> not admissible for the <br> type of conversion being <br> performed. Input value <br> was too large for the type <br> of the variable. | Remove from input data <br> any characters that are <br> illegal in integers or real <br> numbers. |

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 916 | ERROR IN READ OF <br> LOGICAL DATA | An illegal character was <br> read when logical data <br> was expected. | Change input data to <br> correspond to syntax <br> expected when reading <br> logical data or use input <br> statement corresponding <br> to syntax of input data. |
| 917 | OPEN WITH NAMED <br> SCRATCH FILE <br> ATTEMPTED | Executed OPEN <br> statement with <br> STATUS='SCRATCH', <br> but also named the file. <br> Scratch files must not be <br> named. | Either removethe FILE $=$ <br> specifier, or open the file <br> with a status other than <br> STATUS='SCRATCH'. |
| 918 | OPEN OF EXISTING <br> FILE WITH <br> STATUS='NEW' <br> ATTEM PTED | Executed OPEN <br> statement with <br> STATUS='NEW', but file <br> already exists. | Either remove the <br> STATUS= specifier from <br> the OPEN statement, or <br> use the STATUS=OLD'; <br> STATUS='UNKNOWN'; <br> or STATUS='REPLACE' <br> specifier. |
| 920 | OPEN OF FILE <br> CONNECTED TO <br> DIFFERENT UNIT <br> ATTEMPTED | You attempted to open a <br> file that is already open <br> with a different unit <br> number. | Close the file with the <br> current unit number <br> before attempting toopen <br> it with a different unit <br> number. |
| 921 | UNFORMATTED <br> OPEN WITH BLANK <br> SPECIFIER <br> ATTEMPTED | OPEN statement <br> specified <br> FORM=UNFORMATTE <br> D' and BLANK=xx. | Either use <br> FORM ='FORMATTED' <br> or remove BLANK =xx. |
| 922 | READ ON ILLEGAL <br> RECORD ATTEMPTED | Attempted to read a <br> record of a formatted or <br> unformatted direct file <br> that is beyond the <br> current end-of-file. | Read records that are <br> within the bounds of the <br> file. |

I/O runtime error messages
Runtime I/O errors

| Error no. | Error message | Description | Action |
| :---: | :---: | :---: | :---: |
| 923 | OPEN WITH ILLEGAL FORM SPECIFIER ATTEMPTED | FORM = specified string other than 'FORMATTED' or 'UNFORMATTED'. | Use either 'FORMATTED' or 'UNF ORMATTED' for the FORM = specifier in an OPEN statement. |
| 924 | CLOSE OF SCRATCH <br> FILE WITH <br> STATUS='KEEP' <br> ATTEMPTED | The file specified in the CLOSE statement was previously opened with 'SCRATCH ' specified in the STATUS=specifier. | Open the file with a STATUS $=$, specifying a string other than 'SCRATCH' or do not specify STATUS $=$ KEEP ${ }^{\prime}$ in the CLOSE statement for this scratch file. |
| 925 | OPEN WITH ILLEGAL STATUS SPECIFIER ATTEMPTED | STATUS= specified string other than 'OLD' 'NEW' 'UNK NOWN' 'REPLACE' or 'SCRATCH'. | Use 'OLD', 'NEW', 'UNKNOWN', 'REPLACE' or 'SCRATCH' for the STATUS=specifier in OPEN statement. |
| 926 | CLOSE WITH <br> ILLEGAL STATUS <br> SPECIFIER <br> ATTEMPTED | STATUS=specified string other than 'KEEP' or 'DELETE'. | Use 'KEEP' or 'DELETE' for the STATUS= specifier in a CLOSE statement. |
| 927 | OPEN WITH ILLEGAL ACCESS SPECIFIER ATTEMPTED | ACCESS=specified string other than 'SEQUENTIAL' or 'DIRECT'. | Use 'SEQUENTIAL' or 'DIRECT' for the ACCESS=specifier in an OPEN statement. |
| 929 | OPEN OF DIRECT <br> FILE WITH NO RECL SPECIFIER <br> ATTEMPTED | OPEN statement has ACCESS $=$ 'DIRECT', but no RECL = specifier. | Add RECL=specifier to OPEN statement, or specify ACCESS= 'SEQUENTIAL'. |
| 930 | OPEN WITH RECL LESS THAN 1 ATTEMPTED | RECL = specifier in OPEN statement was less than or equal to zero. | Specify a positive number for RECL=specifier in OPEN statement. |

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 931 | OPEN WITH ILLE GAL <br> BLANK SPECIFIER <br> ATTEM PTED | BLANK=specified string <br> other than 'NULL' or <br> 'ZERO' | Use 'NULL' or 'ZE RO' for <br> BLANK =specifier in <br> OPEN statement. |
| 933 | END (OR BEGIN) OF <br> FILE WITH NO END $=x$ <br> SPECIFIER | End-of-file mark read by <br> a READ statement with <br> no END=specifier to <br> indicate label to which to <br> jump. | Use the END=specifier <br> to handle EOF, or check <br> logic. |
| 937 | ILLEGAL RECORD <br> NUMBER SPECIFIED | A record number less <br> than one was specified <br> for direct I/O. | Use record numbers <br> greater than zero. |
| 942 | ERROR IN LIST- <br> DIRECTED READ - <br> CHARACTER DATA <br> READ FOR <br> ASSIGNMENT TO <br> NONCHARACTER <br> VARIABLE | A character string was <br> read for a numerical or <br> logical variable. | Check input data and <br> input variable type. |
| 944 | RECORD TOO LONG <br> IN DIRECT <br> UNF ORMATTED I/O | Output requested is too <br> long for specified (or pre <br> existing) record length. | Make the number of <br> bytes output by WRITE <br> less than or equal to the <br> file record size. |
| 945 | ERROR IN <br> FORMATTED I/O | More bytes of I/O were <br> requested than exist in <br> the current record. | Match the format to the <br> data record. |
| 953 | NO REPEATABLE <br> EDIT DESCRIPTOR IN <br> FORMAT STRING | No format descriptor was <br> found to match I/O list <br> items. | Add at least one <br> repeatableedit descriptor <br> to the format statement. |
| 956 | FILE SYSTEM ERROR | The file system returned <br> an error status duringan an <br> I/O operation. | See the associated file <br> system error message. |
| 9 |  |  |  |

I/O runtime error messages
Runtime I/O errors

| Error no. | Error message | Description | Action |
| :---: | :---: | :---: | :---: |
| 957 | FORMAT <br> DESCRIPTOR <br> incompatible with <br> NUMERICITEM IN I/O <br> LIST | A numericitem in thel/O list was matched with a nonnumeric edit descriptor. | Match format descriptors to I/O list. |
| 958 | FORMAT <br> DESCRIPTOR <br> INCOMPATIBLE WITH <br> CHARACTER ITEM IN I/O LIST | A character item in the I/ O list was matched with an edit descriptor other than $A$ or $R$. | Match format descriptors to I/O list. |
| 959 | FORMAT <br> DESCRIPTOR <br> incompatible with <br> LOGICAL ITEM IN I/O LIST | A logical item in the I/O list was matched with a edit descriptor other than L. | Match format descriptors to I/O list. |
| 973 | RECORD LENGTH DIFFERENTIN SUBSEQUENT OPEN | Record length specified in second OPEN conflicted with the value as opened. | Only BLANK =, DELIM =, and PAD=specifiers may be changed by a redundant OPEN. |
| 974 | RECORD ACCESSED <br> PAST END OF <br> INTERNAL FILE <br> RECORD (VARIABLE) | An attempt was made to transfer more characters than internal file length. | Match READ or WRITE statement with internal file size. |
| 975 | ILLEGAL NEW FILE NUMBER <br> REQUESTED IN FSET FUNCTION | The file number requested to be set was not a legal file system file number. | Check that the OPEN succeeded and the file number is correct. |
| 976 | UNEXPECTED CHARACTERIN "NAMELIST"READ | An illegal character was found in namelistdirected input. | Be sure input data conforms to the syntax rules for namelistdirected input, or remove illegal character from data. |

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 977 | ILLEGAL SUBSCRIPT <br> OR SUBSTRING IN <br> "NAMELIST" READ | An invalid subscript or <br> substring specifier was <br> found in namelist- <br> directed input. Possible <br> causes include bad <br> syntax, subscript/ <br> substring component out- <br> of-bounds, wrong number <br> of subscripts and <br> substring on non- <br> character variable. | Check input data for <br> syntax errors. Be sure <br> subscript/substring <br> specifiers are correct for <br> data type. Specify only <br> array elements within <br> the bounds of the array <br> being read. |
| 978 | TOO MANY VALUES <br> IN "NAMELIST" READ | Too many input values <br> were found during a <br> namelist-directed READ. <br> This message will be <br> generated by attempts to <br> fill variables beyond their <br> memory limits. | Supply only as many <br> values as the length of <br> the array. |
| 979 | VARIABLE NOT IN <br> NAMELIST GROUP | A variable name was <br> encountered in the input <br> stream that was not <br> declared as part of the <br> current namelist group. | Read only the variables <br> in this namelist. |
| 980 | NAMELIST I/O <br> ATTEMPTED ON <br> UNFORMATTED FILE | An illegal namelist- <br> directed I/O operation <br> was attempted on an <br> unformatted (binary) file. | Specify <br> FORM='F ORMATTED' <br> in OPEN statement, or <br> use namelist-directed <br> I/O only on formatted <br> files. |
| 1010 | OPEN WITH ILLE GAL <br> PAD SPECIFIER <br> ATTEM PTED | An attempt was made to <br> open a file with an illegal <br> value specified for the <br> PAD=specifier. | Specify either PAD='YES' <br> or PAD='NO'. |

I/O runtime error messages
Runtime I/O errors

| Error <br> no. | Error message | Description | Action |
| :--- | :--- | :--- | :--- |
| 1011 | OPEN WITH ILLEGAL <br> POSITION SPECIFIER <br> ATTEMPTED | An attempt was made to <br> open a file with an illegal <br> value specified for the <br> POSITION=specifier. | Specify <br> POSITION='ASIS', <br> POSITION='REWIND' or <br> POSITION='APPEND'. |
| 1012 | OPEN WITH ILLEGAL <br> DELIM SPECIFIER <br> ATTEMPTED | An attempt was made to <br> open a file with an illegal <br> value specified for the <br> DELIM= specifier. | Specify DELIM= <br> 'APOSTROPHE', <br> DELIM='QUOTE' or <br> DELIM='NONE'. |
| 1013 | OPEN WITH ILLEGAL <br> ACTION SPECIFIER <br> ATTEMPTED | An attempt was made to <br> open a file with an illegal <br> value specified for the <br> ACTION=specifier. | Specify <br> ACTION='READ', <br> ACTION='WRITE' or <br> ACTION='READWRITE'. |

## Glossary

## A

actual argument A value, variable, or procedure that is passed by a call to a procedure (function or subroutine). The actual argument appears in the source of the calling procedure. See also dummy argument.
adjustable array A dummy argument that is an array having at least one nonconstant dimension.
allocatable array A named array with the ALLOCATABLE attribute whose rank is specified at compile time, but whose bounds are determined at run time. Storage for the array must be explicitly allocated before the array may be referenced.
archive library A library of routines that can be linked to an executable program at link-time. See al so shared library.
argument (1) A variable, declared in the argument list of a procedure or ENTRY statement, that receives a value when the procedure is called (a dummy argument). (2) The variable, expression, or procedure that is passed by a call to a procedure (an actual argument).
argument association The correspondence between an actual argument and a dummy argument during execution of a procedure reference.
argument keyword A dummy argument name. Argument keywords can be used to pass actual arguments to a procedure in any order if the procedure has an explicit interface.
array A rectangular pattern of elements of the same data type. The properties of an array include its rank, shape, extent, and data type. See al so bounds and dimension.
array constructor A rank-one array represented as a sequence of scalar or array values that may be constant or variable.
array element An individual, scalar component of an array that is specified by the array name and, in parenthesis, one or more subscripts that identify the element's position in the array.
array element order The order in arrays are laid out in memory. The array element order for HP Fortran 90 arrays is columnmajor order. Array element order can also be used to determine sequence association.
array pointer An array that has the POINTER attri bute and may therefore be used to point to a target object.
array section A subset of an array specified by a subscript triplet or vector subscript in one or more dimensions. For an array a (4, 4) , a (2:4:2,2:4:2) is an array section containing only the evenly indexed elements $a(2,2), a(4,2), a(2,4)$, and a $(4,4)$.
array-valued Having the property of being an array. For example, an array-valued
function has a return value that is an array.
association The mechanism by which two or more names may refer to the same entity. See also argument association, host association, pointer association, sequence association, storage association, and use association.
assumed-shape array An array that is a dummy argument to a procedure and whose shape is assumed (taken) from that of the associated actual argument. An assumed-shape array's upper bound in each dimension is represented by a colon (:). See also assumed-size array.
assumed-size array An older FORTRAN 77 feature. An array that is a dummy argument to a procedure and whose size (but not necessarily its shape) is
assumed (taken) from that of the associated actual argument. The upper bound of an assumed-size array's last dimension is specified by an asterisk (*). See also assumed-shape array.
attribute A property of a constant or variable that may be specified in a type declaration statement. M ost attributes may alternately be specified in a separate statement. For instance, the ALLOCATABLE statement has the same meaning as the ALLOCATABLE attribute, which appears in a type declaration statement.
automatic array An explicitshape array that is local to a procedure and is not a dummy argument. One or more of an automatic array's bounds is determined upon entry to the procedure, allowing automatic arrays to have a different size and shape each time the procedure is invoked.
automatic data object A data object declared in a subprogram whosestoragespace is dynamically allocated when the subprogram is invoked; its storage is released on return from the subprogram.
Fortran 90 supports automatic arrays and automatic character string variables.

## B

bit A binary digit, either 1 or 0 . See also byte.
blank common A common block that is not associated with a name.
block A series of consecutive statements that are treated as a complete unit and are within a SELECT CASE, DO, If, or where construct.
block data program unit A procedure that establishes initial values for variables in named common blocks and contains no executable statements. A block data program unit begins with a BLOCK DATA statement.
bounds Theminimum and maximum values permitted as a subscript of an array for each dimension. For each dimension, there are two bounds-the upper and lower bounds-that define the range of values for subscripts.
BOZ constants A literal constant that can be formatted as binary, octal, or hexadecimal. See also typeless constant.
built-in functions \%REF and \%VAL-HP extensions that can be used to change argument-passing rules in procedure references.
byte A group of contiguous bits starting on an addressable boundary. In HP machines, a byte is 8 bits in length.

## C

character A digit, letter, or other symbol in the character set. See Appendix B, "Character set".
character string A sequence of zero or more consecutive characters.
column-major order The default storage method for arrays in HP Fortran 90. Memory representation of an array is such that the columns are stored contiguously. For example, given the array a $(2,3)$, element a $(1,1)$ would be stored in the first location, element a $(2,1)$ in the second location, element a (1,2) in the third location, and so on. See also row-major order.
common block A block of memory for storing variables. A common block is a global entity that may be referenced by one or more program units.
compile-line option A flag that can be specified with the $f 90$ command line to override the default actions of the HP Fortran compiler.
compiler directive A speciallyformatted comment within a source program that affects how the program is compiled. Compiler directives are not part of the Fortran 90 Standard. In HP Fortran 90, compiler directives provide control over source listing, optimization, and other features.
component A constituent that is part of a derived type. A derived type may consist of one or more components. For example, time\%hour refers to the hour component of time (and time is a
variable whose data type is a derived type defined in the program).
conformable Two arrays are conformable if both arrays have the same rank (number of dimensions) and the same extent (number of elements for each dimension). A scalar is conformable with any array.
connected (1) A unit is connected if it refers to an external file. (2) An external file is connected if a unit refers to it. In both cases, connection is established either by the OPEN statement or by preconnection. See also preconnected.
constant A data object that retains the same value during a program's execution. A constant's value is established when a program is compiled. A constant is either a literal constant or a named constant.
constant expression An expression whose value does not vary during the program's execution. A constant expression's operands are all constants.
construct A series of statements that begins with a SELECT CASE, DO, IF, or WHERE statement and ends with a corresponding END SELECT, END DO, END IF, or ENDWHERE statement.

## D

data type A named category of data that has a set of values, a way to denote its values, and a set of operations for interpreting and manipulating the values. Fortran 90 intrinsic data types include character, complex, double precision, integer, logical, and real. HP Fortran 90 also provides the byte and double complex data types as extensions. See also derived type.
deferred-shape array An allocatable array or a pointer array (an array with the ALLOCATABLE Or POINTER attribute).
defined assignment A nonintrinsic assignment statement that is defined by an ASSIGNMENT (=) interface block and a subroutine.
defined operator An operator that is present in an INTERFACE statement and has its operation implemented by one or more userdefined functions.
demand-loadable A process is demand-loadable if its pages are brought into physical memory only when they are accessed.
derived type A user-defined (non-intrinsic) data type that consists of one or more components. Each component of a derived type is either an intrinsic data type or another derived type.
dimension Each subscript of an array corresponds to a dimension of the array; arrays may have from one to seven dimensions. The number of dimensions is an array's rank. See also extent.
directive See compiler directive.
disassociated A pointer that is disassociated points to no target. A pointer becomes disassociated following a DEALLOCATE or NULLIFY statement involving the pointer or by the pointer being associated with (pointing to) a disassociated pointer.
dummy argument An entity whose name appears in the argument list of a procedure or ENTRY statement. It is associated with an actual argument when the procedure is called. The dummy argument appears in the source of the called procedure.
dummy array A dummy argument that is an explicitshape array.
dusty deck program An older, pre-FORTRAN 77 program. Presumably called a "dusty deck" program because it was stored on punched cards and has not been changed since. Such programs generally rely on nonstructured programming techniques such as the GOTO statement.

## E <br> element See array element.

elemental To be elemental, an intrinsic operation, procedure, or assignment must apply independently to every element of an array or apply independently to the corresponding elements of a set of conformable arrays and scalars
equivalencing The process of sharing storage units among two or more data objects by means of the EQUIVALENCE statement.
executable statement An instruction that causes the program to perform one or more computational or branching actions.
explicitinterface A procedure interface whose properties (including the name and attributes of the procedure and the order and attributes of its arguments) are known by the calling program unit. A procedure may have an explicit interface in a scoping unit if it is any of the following:

- Described by an interface block
- An internal procedure
- A module procedure
- A statement function
explicit-shape array An array with explicitly-declared bounds for each dimension.
expression A series of operands and (optionally) operators and parentheses that forms either a data reference or a computation. See also constant
expression, initialization expression, and specification expression.
extended operator See defined operator.
extent The number of elements in one dimension of an array.
external file A filethat is stored on a medium external to the executing program.
external name The name of an object referenced by a program unit, as it appears to the linker. Case is not significant in the names that appear in Fortran source files; but it is significant in external names.
external procedure A procedure that is not contained in a main program, module, or another subprogram.

## F-H

file A sequence of records
(characters or values processed as a unit).

See also external file and internal file.
function A procedure that returns a value (the function result) and that can be referenced in an expression.
function result The data object returned from a call to a function.
generic procedure A
procedure in which at least one actual argument may have more
than one data type. Generic procedures may be intrinsic or user-defined.
global entity A program unit, common block, or external procedure whose scope is the entire executable program.
High Performance Fortran
(HPF) An extension to the Fortran 90 Standard that provides user-directed data distribution and alignment. HPF is not a standard, but rather a set of features desirable for parallel programming.
host A program unit or subprogram that contains an internal procedure or module.
host association Theprocess by which an internal procedure, module procedure, or derived type definition accesses the entities of its host.

I-K
initialization expression A more restricted form of constant expression that is used to initialize data.
inquiry function An intrinsic function whose return value provides information based on the principal arguments' properties and not the arguments' values.
intent An attribute of a dummy argument that indicates whether the argument is used for transferring data into the procedure, out of the procedure, or both.
internal file A variable that is used as a file storage medium for formatted I/O. Internal files are stored in memory and typically are used to convert data from a machine representation to a character representation by use of edit descriptors.
internal procedure A procedure contained in a main program or another subprogram.
intrinsic Assignment statements, data types,
operations, and procedures are intrinsic if they are defined in the Fortran 90 Standard and may be used, without being defined, in any scoping unit.
keyword option A Fortran 90 feature that allows an actual argument to appear anywhere in the argument list to a procedure reference.
kind type parameter An integer parameter whose value determines the range for an intrinsic data type; for example INTEGER (KIND=2). The kind type parameter also determines the precision for complex and real data types.

## L-M

label An integer, one to five digits long, that precedes a statement and identifies it with a unique number. A statement's label provides a way to transfer control to the statement or to reference it as a FORMAT statement.
library A file that contains object code for subroutines and data that can be used by programs written in Fortran 90, among other languages. See also linker.
linker The ld utility. The linker resolves references in a program's source to routines that are not in the source file being compiled. The linker matches each reference, if possible, to the corresponding library routine.
literal constant A constant that does not have a name. A literal constant's value is written directly into a program. See also named constant.
lower bounds See bounds.
main program Thefirst program unit that starts executing when a program is run. The first statement of a main program usually is the PROGRAM statement.
module A program unit that contains definitions of derived types, procedures, namelists, and variables that are made accessible to other program units. A module begins with the MODULE statement and its public definitions are made available to other program units by means of the USE statement.
module procedure A procedure that is contained in a module and is not an internal procedure.

N-O
name A letter followed by up to 254 alphanumeric characters (letters, digits, underscores, and \$) that identifies an entity in an HP Fortran 90 program unit, such as a common block, dummy argument, procedure, program unit, or variable.
named constant A constant that has a name. See also literal constant.
numerictype A complex, double precision, integer, or real data type.
obsolescent feature A feature defined in the FORTRAN 77 Standard that still is in common use but is considered to be redundant, such as the arithmetic IF statement.

The use of obsolescent features is discouraged. The Fortran 90 Standard summarizes the obsolescent features.
operand An expression that precedes or follows an operator. For example, in a + b, both a and b are operands.
operator A sequence of one or more characters in an expression that specifies an operation. For example, in a + b, + is an operator.
option See compile-line option.
optional argument A dummy argument that does not require a corresponding actual argument to be supplied when its procedure is invoked.

P-R
pointer A variable that has the POINTER attribute, which enables it to reference (point to) variables of a specified data type (rather than storing the data itself).
pointer association The process by which a pointer becomes associated with the storage space of its target. Pointer association occurs during pointer assignment or a valid ALLOCATE statement.
preconnected Three input/ output units are preconnected to files by the operating system and need not be connected by the OPEN statement. The preconnected units are:

- Unit 5 (standard input)
- Unit 6 (standard output)
- Unit 7 (standard error)
procedure A unit of program code that may be invoked. A procedure can be either a function or a subroutine.
program A sequence of instructions for execution by a computer to perform a specific task. A program is executable after successful compilation and linking.
program unit A main program, a module, an external procedure, or a block data subprogram.
rank The number of dimensions of an array. Scalars have a rank of zero.
record A sequence of values treated as a whole within a file.
renaming feature A feature of the USE statement that allows module entities to be renamed within the program unit having access to the entities by use association.
return value See function result.
row-major order The default storage method for arrays in C. Memory representation is such that the rows of an array are stored contiguously. For example, given the array a [3] [2], the element a[0][0] would be stored in the first location, element a [0] [1] in the second location, element a[1] [0] in the third location, and so on. See also column-major order.

## S

scalar A data item that has a rank of zero and therefore is not an array.
scope The part of a program in which a name or declaration has a single interpretation.
scoping unit A derived-type definition, an interface body (excluding derived-type definitions
or interface bodies it contains), or a program unit or subprogram (excluding any derived-type definitions, interface bodies, or subprograms it contains).
sequence association The association between dummy argument and actual argument that occurs when the two differ in rank or character length. Dummy and actual arguments are matched element by element or character by character, starting with the first and proceeding in order. See also array element order and column-major order.
sequence derived type $A$ derived type whose definition includes the SEQUENCE statement. The components of a sequence derived type are in the storage sequence as specified in the definition of the derived type.
shape An array's extent (number of elements) in each dimension and rank (number of dimensions).
shared library A library of routines that can be linked to an executable program at runtime, allowing the shared library to be used by several programs simultaneously. See also archive library.
size The total number of elements in an array; the product of all its extents.
specific procedure A procedure for which each actual argument must be of a specific data type. See also generic procedure.
specification expression A limited form of an expression that can appear in a specification statement-for example, a type declaration statement-and can be evaluated on entry to a procedure.
statement A sequence of characters that represents an instruction or step in a program. A single statement usually, but not always, occupies one line of a program.
statement function A
function that returns a scalar value and is defined by a single scalar expression.
statement label See label.
storage association The association of different Fortran objects with the same storage. Storage association is achieved by means of common blocks and equivalencing.
storage sequence The order in which Fortran objects are laid out in memory. Programmers can control storage sequence by means of common blocks and equivalencing, and by defining sequence derived types. The storage sequence of arrays is determined by array element order.
stride Theincrement that may optionally be specified in a subscript triplet. If it is not specified, the stride has a value of one.
structure A data object that is scalar and is of derived type.
structure component See component.
subprogram See procedure.
subroutine A procedure that is referenced by a CALL statement; values returned by a subroutine are usually provided through the subroutine's arguments.
subscript A scalar value within the bounds of one dimension of an array. To specify a single array element, a subscript must be specified for each of the array's dimensions.
subscript triplet An array section specification that consists of a starting element, an ending element, and (optionally) a stride separated by colons (: ).
substring A contiguous segment of a scalar character string. Note that a substring is not an array section.

T-Z
target A named data object that may be associated with a pointer. A target is specified in a TARGET statement or in a type declaration statement that has the TARGET attribute.
type See data type.
type declaration statement A statement that specifies the data type and, optionally, attributes for one or more constants, functions, or variables.
typeless constants A literal constant that is formatted to represent a bit pattern and
therefore does not imply the type of the constant. BOZ constants and Hollerith constants are both typeless.
unit number A logical number that can be connected to a file to provide a means for referring to the file in input/output statements.
upper bounds See bounds.
use association Theassociation of names among different scoping units as specified by a USE statement. See also module.
user-defined operator See defined operator.
user-defined assignment See defined assignment.
variable A data object whose value may be defined and redefined during a program's execution. For example, array elements or array sections, named data objects, structure components, and substrings all can be variables.
vector subscript A method of referencing multiple, possibly discontinuous elements of an array by using a rank-one array of integer values as a subscript.
whole array An array
reference-for example, in a type declaration statement-that consists of the array name alone, without the subscript notation. Whole array operations affect every element in the array, not just a single, subscripted element.
zero-sized array An array with at least one dimension that has at least one extent of zero. A zerosized array has a size of zero and contains no elements.
