AIX Operating System Commands Reference Volume 2

Programming Family

AIX Operating System Commands Reference

Volume 2

Programming Family

Second Edition (September 1988)

Portions of the code and documentation described in this book were developed at the Electrical Engineering and Computer Sciences Department at the Berkeley Campus of the University of California under the auspices of the Regents of the University of California.

The Rand MH Message Handling System was developed by the Rand Corporation and the University of California.

The Network File System was developed by Sun Microsystems, Inc.

This edition applies to Version 2.2 of the IBM AIX Operating System. Changes are made periodically to the information herein; these changes will be reported in technical newsletters or in new editions of this publication.

References in this publication to IBM products, programs, or services do not imply that IBM intends to make these available in all countries in which IBM operates. Any reference to an IBM licensed program in this publication is not intended to state or imply that only IBM's licensed program may be used. Any functionally equivalent program may be used instead.

International Business Machines Corporation provides this manual "as is," without warranty of any kind, either express or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this manual at any time.

Products are not stocked at the address given below. Requests for copies of this product and for technical information about the system should be made to your IBM authorized RT dealer, your IBM marketing representative, or your IBM authorized remarketer.

A reader's comment form is provided at the back of this publication. If the form has been removed, address comments to IBM Corporation, Department 997, 11400 Burnet Road, Austin, Texas 78758-3493. IBM may use or distribute whatever information you supply in any way it believes appropriate without incurring any obligation to you.

Trademarks

The following trademarks apply to this book:

- AIX is a trademark of International Business Machines Corporation.
- DEC and VT100 are trademarks of Digital Equipment Corporation.
- Ethernet is a trademark of XEROX CORPORATION.
- IBM is a registered trademark of International Business Machines Corporation.
- PC-NFS and NFS are trademarks of Sun Microsystems, Inc.
- Proprinter is a trademark of International Business Machines Corporation.
- Quietwriter is a registered trademark of International Business Machines Corporation.
- RT is a registered trademark of International Business Machines Corporation.
- Sun Microsystems is a registered trademark of Sun Microsystems, Inc.
- Tektronics is a trademark of Tektronix, Inc.
- UNIX was developed and licensed by AT&T. It is a registered trademark of AT&T in the United States of America and other countries.
- XEROX is a trademark of XEROX CORPORATION.

About This Book

This book contains reference information on Advanced Interactive Executive (AIX) Operating System commands. It describes the commands you can use and summarizes who can run them, how to run them, what they do, how they read input, how they write output, and how to modify their actions.

Who Should Use This Book

To use this book, you should be familiar with AIX or UNIX System V commands. If you are not already familiar with AIX or UNIX System V, see Using the AIX Operating System. If you are familiar with the commands but need to review how to use the shell and write shell procedures, see "sh" on page 913.

How To Use This Book

Most of the AIX commands described in this book are in alphabetical order by command name. Some related commands are combined in one description listed with a main or key command. The related commands have an entry with the main command in the table of contents and are listed individually in alphabetical order in the index. If you are having difficulty locating a particular command, check the "Contents" or "Index" sections of this publication.

Command Information

The "Commands" section begins on page 11. A discussion of a command may include the following information:

Purpose A single-sentence description of the major function of each

command

A syntax diagram that shows command line options (For a Syntax

discussion of how to use this syntax diagram, see "Syntax

Diagrams" on page 5.)

Description A discussion of the command that provides more details about its

function and use

Flags A list of command line flags and associated parameters with an

explanation of how the flags modify the action of the command

Subcommands A list of subcommands (for interactive commands) that explains

their use

Examples Specific examples of how you can use the command

Files A list of files used by the command

Related Information A list of related commands in this book and related discussions in

other books.

For details on other conventions used in this book, see "How to Use the Commands" on page 3.

A Task Index

"Task Index" on page TASK-1 can help you locate the commands you need to perform specific tasks. It contains lists of commands grouped by task. Next to each command is a description of what it does. To find a command that performs a specific task, locate the task in the table of contexts at the beginning of the task index, go to the indicated page and review the list of commands associated with that task, then select the desired command. For more information about the command, refer to the discussion of the command in the "Commands" section.

Other Reference Aids

A cross-reference listing of commands and program packages appears in Appendix B, "Program Cross-Reference" on page 1269. Appendix C, "Syntax Diagram Guide" on page 1277 contains a detailed description of how to read syntax diagrams. The standard system devices are described in Appendix A, "AIX Device Table" on page 1267. A "Glossary" of terms appears after the Appendixes, followed by an "Index."

In addition, a Reader's Comment Form and Book Evaluation Form are provided at the back of the second volume of this publication. Use the Reader's Comment Form at any time to give IBM information that may improve the book. After you have become familiar with the book, use the Book Evaluation Form to give IBM specific feedback about the book.

Japanese Language Support

Appendix D, "Japanese Language Support" on page 1287 contains a list of commands that have not been modified to support Japanese characters.

Special Key Sequences

You can use the AIX Operating System from any of several different display stations, each of which has a different keyboard. In some cases, you must press different keys to perform the same function from different keyboards. Throughout this publication both the function name (for example, INTERRUPT) and the necessary key sequence on the IBM RT system are identified. If you are not using an IBM RT Keyboard, look at your keyboard reference chart to find out which keys on your keyboard produce the same function.

Prerequisite Information

- IBM RT Managing the AIX Operating System provides instructions for performing such system management tasks as adding and deleting user IDs, creating and mounting file systems, repairing file system damage, and managing data communications facilities.
- IBM RT Using the AIX Operating System describes using the AIX Operating System commands, working with file systems, developing shell procedures, and using data communications facilities.

Related Information

- IBM RT AIX Operating System Programming Tools and Interfaces describes the programming environment of the AIX Operating System and includes information about using the operating system tools to develop, compile, and debug programs. In addition, this book describes the operating system services and how to take advantage of them in a program. This book also includes a diskette that includes programming examples, written in C language, to illustrate using system calls and subroutines in short, working programs. (Available optionally)
- IBM RT AIX Operating System Technical Reference is a four-volume set.

System Calls and Subroutines, describes the system calls and subroutines that a C programmer uses to write programs for the AIX Operating System.

Files and Extensions, contains information about the extensions to the kernel and base operating system, including file formats, special files, and GSL subroutines.

VRM Programming Support, describes the VRM programming environment, including the internal VRM routines. VRM floating-point support, use of the VRM debugger, and the supervisor call instructions that form the Virtual Machine Interface.

VRM Device Support, describes device IPL and configuration, minidisk management. the virtual terminal and block I/O subsystems, as well as the interfaces to VRM device driver and data link control components. This volume also describes the programming conventions for developing your own VRM code and installing it on the system. (Available optionally)

- IBM RT Using DOS Services provides step-by-step information for using AIX Operating System shell. (Available optionally; packaged with IBM RT DOS Services Reference)
- IBM RT DOS Services Reference provides reference information about the AIX Operating System shell. This book also includes information on sharing DOS files with Personal Computer AT Coprocessor Services, and on the differences between PC DOS and shell. (Available optionally; packaged with IBM RT Using DOS Services)
- IBM RT C Language Guide and Reference provides guide information for writing, compiling, and running C language programs and includes reference information about C language data structures, operators, expressions, and statements. (Available optionally)
- IBM RT Messages Reference lists messages displayed by the IBM RT and explains how to respond to the messages.
- IBM RT AIX Operating System Text Formatting Guide describes the functions and capabilities of NROFF and TROFF to perform text processing tasks. (Available optionally)
- IBM RT Bibliography and Master Index provides brief descriptive overviews of the books and tutorial program that support the IBM RT hardware and the AIX Operating System. In addition, this book contains an index to the RT and AIX Operating System library.

See IBM RT Bibliography and Master Index for order numbers of IBM RT publications and diskettes.

Ordering Additional Copies of This Book

To order additional copies of this publication (without program diskettes), use either of the following sources:

- To order from your IBM representative, use Order Number SBOF-1814.
- To order from your IBM dealer, use Part Number 27F4354.

A binder is included with the order. For information on ordering the binder and manual separately, contact your IBM representative or your IBM dealer.

VOLUME 2

m4

Purpose

Preprocesses files, expanding macro definitions.

Syntax

OL805434

Description

The m4 command is a macroprocessor used as a preprocessor for C and other languages. You can use it to process built-in macros or user-defined macros. Each file is processed in order. If you do not specify a file or if you give a minus (-) as a file name, m4 reads standard input. It writes the processed macros to standard output. Macro calls follow the form:

macroname(argument . . .)

The left parenthesis must immediately follow macroname. If the left parenthesis does not follow the name of a defined macro, m4 reads it as a macro call with no arguments. Macro names consist of ASCII alphabetic letters, digits, and the underscore character (_). Extended characters are not allowed in macro names. The first character cannot be a digit.

While collecting arguments, m4 ignores unquoted leading blanks, tabs, and new-line characters. Use single quotation marks to quote strings. The value of a quoted string is the string with the quotation marks stripped off.

When m4 recognizes a macro, it collects arguments by searching for a matching right parenthesis. If you supply fewer arguments than appear in the macro definition, m4 considers the trailing arguments in the definition to be null. Macro evaluation proceeds normally during the collection of the arguments. All commas or right parentheses within the value of a nested call are translated literally; they do not need an escape character or quotation marks. After collecting arguments, m4 pushes the value of the macro back onto the input stream and scans again.

Built-in Macros

The m4 command makes available the following built-in macros. You may redefine them, but you will lose the original meaning. The values of these macros are null unless otherwise stated:

other wise stated.				
define(name,new_name)	Replaces the macro name with the value of new_name . The new_name string can take the form $\$n$ (where n is a digit). In this case, each occurrence of n in the replacement text is replaced by the n -th argument of $name$. $\$0$ is the name of the macro. The null string replaced missing arguments. The number of arguments replaces $\$\#$. A comma-separated list of all arguments replaces $\$\#$. $\$0$ acts like $\$\#$, but each argument is quoted with the current quotation character (see changequote).			
$\mathbf{undefine}(name)$	Removes the definition of name.			
defn(name)	Returns the quoted definition of name.			
<pre>pushdef(name,new_name)</pre>	Redefines <i>name</i> with <i>new_name</i> as in <i>define</i> , but save any previous definition.			
popdef(name)	Removes the current definition of <i>name</i> and returns to the previous definition, if one existed.			
${\bf ifdef}(name, true, [false])$	Returns the value of <i>true</i> only if <i>name</i> is defined, otherwise return <i>false</i> . If you do not supply <i>false</i> , its value is null.			
	Note: The word unix is predefined.			
shift(argument)	Returns all but the first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.			
${\bf changequote}(L,R)$	Changes quote symbols to L and R . The symbols can be up to 5 bytes long. changequote without arguments restores the			

original values (' ').

changecom(Lcom,Rcom)

Changes left and right comment markers from the default # and new-line character to *Lcom* and *Rcom*. With no arguments, the comment mechanism is disabled. With one argument, the left marker becomes the parameter and the right marker becomes a new-line character. With two arguments, both markers are affected. Comment markers can be up to 5 bytes long.

divert(num)

Changes the current output stream to stream *num*. There are 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order. Initially, stream 0 is the current stream. **m4** discards output diverted to a stream other than 0-9.

undivert(num . . .)

Causes immediate output of text from the specified diversions (or all diversions if there is no argument). Text may be undiverted into another diversion. Undiverting discards the diverted text.

divnum

Returns the value of the current output stream.

dnl

Reads and discards characters up to and including the next new-line character.

ifelse([string1,string2,true,[false]] . . .)

If string1 and string2 are the same, then the value is true. If they are not and if there are more than four arguments, m4 repeats the process with the additional arguments (4, 5, 6, and 7). Otherwise, the value is either false or null if you provide no value for false.

incr(num)

Returns the value of its argument incremented by 1.

decr(num)

Returns the value of its argument decreased by 1.

eval(expr[,num1[,num2]])

Evaluates its first argument as an arithmetic expression, using 32-bit arithmetic. The operators you can use include +, -, *, /,%, $^{\circ}$ (exponentiation), bitwise &, I, $^{\circ}$, and $^{\circ}$ relationals, and parentheses. Octal and hex numbers can be specified as in C. num1 specifies the radix for the result of the expression. The default radix is 10. The optional num2 specifies the minimum number of digits in the result.

len(string)

Returns the number of bytes in string.

dlen(string)

Returns the number of displayable characters in *string*; that is, 2-byte extended characters are counted as one displayable

character.

index(s1,s2)Returns the position in the string s1 where the string s2 begins (zero origin), or -1 if the second parameter does not occur. substr(string,position,num) Returns a substring of string. The beginning of the substring is selected with position, and num indicates the length of the substring. Without num, the substring includes everything to the end of the first string. translit(string, from, to) Transliterates the characters in *string* from the set given by from to the set given by to. No abbreviations are permitted. Two-byte extended characters are correctly mapped into the corresponding replacement characters. include(file) Returns the contents of *file* or displays an error message if it cannot access the file. sinclude(file) Returns the contents of file, but it gives no error message if file is inaccessible. syscmd(command) Runs the AIX *command*. No value is returned. Returns the return code from the last call to syscmd. svsval maketemp(. . . XXXXX . . .) Replaces XXXXX in its argument with the current process ID number. m4exit(value) Exits from m4 immediately, returning the specified exit value (the default is 0). Runs lastmacro after reading the end-of-file character. For m4wrap(lastmacro) example: m4wrap('cleanup()') runs the cleanup macro at the end of m4. errprint(message) Includes *message* on the diagnostic output file. Writes to standard output the current names and definitions dumpdef([name . . .]) for the named items or for all if no arguments are provided. Turns on tracing for macro. If none is named, tracing is turned traceon(macro) on for all macros. traceoff(macro . . .) Turns off trace globally and for any macro specified. Macros specifically traced by traceon can be untraced only by specific calls to *traceoff*.

Flags

-Bnum	Makes <i>num</i> the size of the push-back and parameter collection buffers (the default is 4096).			
- е	Operates interactively. Interrupts are ignored and the output is not buffered.			
-Hnum	Makes <i>num</i> the size of the symbol table hash array (the default is 199). The size must be a prime number.			
-s	Enables the line sync output for the C preprocessor (#line).			
-Snum	Makes num the size of the call stack (the default is 800 slots). Macros take three slots, and nonmacro arguments take one.			
-Tnum	Makes num the size of the token buffer (the default is 512 bytes).			
The preceding flags must appear before any file names and before any -D or -U flags.				
$-\mathbf{D}name[=val]$	Define name as val. If val is not specified, name becomes null.			
-Uname	Undefines a name previously defined with the -D flag.			

Example

To preprocess a C language program with m4 and compile it:

```
m4 prog.m4 >prog.c
cc prog.c
```

Related Information

The following commands: "cc" on page 140 and "cpp" on page 210.

"Overview of International Character Support" in Managing the AIX Operating System.

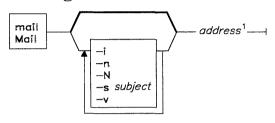

mail, Mail

Purpose

Sends and receives mail.

Syntax

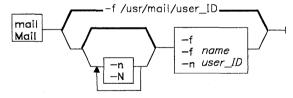

Sending Mail:

¹See **sendmail** for address formats.

AJ2FL262

Handling Mail:

AJ2FL260

Description

The mail program allows you to:

- Compose a message and send it
- Receive a message and look at it
- Store received messages in your mailbox, or in folders
- Discard messages.

To send a message to one or more persons, enter mail on the command line with arguments that are the network addresses of the people to receive the message. When mail starts, you can type the message using an editor similar to ed. When you are finished with the message, press the Enter key at the end of a line, and use a Ctrl-D (EOF) sequence at the beginning of the next line to exit the editor and send the message.

When you have messages in your mailbox, the system displays a message to tell you. The default message is:

```
[YOU HAVE NEW MAIL]
```

To look at the contents of your mailbox, enter the mail command without arguments on the command line. The program displays a listing of the messages in your mailbox and allows you to look at them, reply to them or dispose of them.

Reading Incoming Mail

To receive and read incoming mail, use mail with no arguments:

mail

The mail command then checks your system mailbox (/usr/mail/user_id) and displays a one-line entry for each message in the system mailbox similar to:

```
"/usr/mail/geo": 2 messages 2 new
>N 1 amy    Thu Sep 17 14:36 13/359 "Dept Meeting"
    N 2 amy    Thu Sep 17 16:28 13/416 "Dept Meeting Delayed"
%
```

The > symbol indicates the *current message*, or the message that commands act on if you do not specify a message number or list of message numbers. The other fields, in order, in the listing represent:

- 1. Message number
- 2. User address of the sender
- 3. Date the message was sent
- 4. Size of the message in lines/characters
- 5. The subject of the message (if one was included in the message).

From the mail command prompt &, you can enter commands to look at, reply to, save, discard, or otherwise manage the contents of the mailbox. To display a summary of some of the commands that you can use to handle mail in your mailbox, enter? at the mail command prompt. For more information on those commands and information on additional commands, refer to Figure 3 on page 611.

Many mailbox commands allow you to specify groups of messages upon which to perform the command. Commands that allow groups of messages use the parameter msg_lst in the command format. For example, the format of the **f** command (display information about messages) appears as:

```
& f msg_{-}lst
```

In this format msg_lst can be one of the following:

• One or more message numbers separated by spaces

& f 1 2 4 7

 A range of message numbers indicated by the first and last numbers in the range separated by a dash

& f 2-5

is the same as,

& f 2 3 4 5

 One or more addresses separated by spaces to apply the command to messages received from those addresses,

& f amy geo@zeus

The characters entered for an address need not match the address exactly. They must only be contained in the address field of the messages in either upper- or lower-case. Therefore, the request for address amy matches all of the following addresses (and many others):

- amy
- AmY
- amy@zeus
- hamy
- A string, preceded by a slash, to match against the Subject: field of the messages,

& f /meet

applies the command to all messages whose **Subject**: field contains the letters meet in upper- or lower-case. The characters entered for a match pattern do not need to match the **Subject**: field exactly. They must only be contained in the Subject: field of the messages in either upper- or lower-case. Therefore, the request for subject meet matches all of the following subjects (and many others):

- Meeting on Thursday
- Come to meeting tomorrow
- MEET ME IN ST. LOUIS

The special character * (asterisk) addresses all messages, ^ (caret) addresses the first message, and \$ (dollar sign) addresses the last message.

The following table lists the mail commands and describes their functions.

Command	Function
=	Echoes the number of the current message.
#	Comment character for writing comments in mail script files.
-n	Goes to the previous message and displays it. If given a number argument of n , goes to the n th previous message and displays it.
?	Displays a brief summary of commands.
$!sh_cmd$	Executes the AIX shell command specified by sh - cmd .
alias	(a) With no arguments, displays all currently defined aliases. With one argument, displays alias. With more than one argument, creates a new or changes an old alias.
${\bf alternates} alt_list$	(alt) The alternates command is useful if you have accounts on several machines. Use it to inform mail that the addresses listed in alt_list all refer to you. Then, when you reply to messages, mail does not send a copy of the message to any of the addresses given in alt_list. If you enter the alternates command with no argument, mail displays the current set of alternate names.
chdir dir	(cd) Changes your working directory to the directory dir. If no directory is given, it changes to your login directory.
copy msg_lst file	(c, co) Appends each message in msg_lst in turn to the end of file. Displays the file name in quotes, followed by the line count and character count, on the user's terminal. Does not delete any messages when you quit.
delete msg_lst	(d) Marks the messages in msg_lst to be deleted when you quit mail. Deleted messages are not saved in $mbox$, nor are they available for most other commands. However, you can restore messages that you have deleted while in the same mailbox session (see the undelete mailbox command).

Figure 3 (Part 1 of 6). Mailbox Commands

mail, Mail

Command	Function
${f discard} [fld_lst]$	(di) Identical to the ignore command.
dp	Deletes the current message and displays the next message. If there is no next message, mail displays the message at EOF.
dt	Identical to the dp command.
echo string	Displays the character string string on the command line.
edit msg	(e) Activates the editor that you define with the set EDITOR = statement and loads message msg into the editor. When you exit the editor, the saved message is replaced in the mailbox being processed.
exit	(ex or x) Exits to the shell without changing the mailbox being processed. The mailbox returns to the condition that it was when mail was started. Messages marked to be deleted are not deleted.
file [name]	(fi) Identical to the folder command.
folder [name]	(fo) Switches to a new mail file or folder. With no arguments, displays the name of the mailbox that you are currently reading. If an argument is included, it stores the current mailbox with changes (such as messages deleted) and reads in the new mailbox specified by the <i>name</i> parameter. Some special conventions are recognized for the <i>name</i> :
	 # refers to the previous file % refers to the system mailbox & refers to your personal mailbox (\$HOME/mbox) name refers to a file in your folder directory.
folders	Lists the names of the folders in your folder directory.
from msg_lst	(f) Displays the headings of messages in msg_lst.
group	(g) Identical to the alias command.
Figure 3 (Part 2 of	6). Mailbox Commands

Command	Function
headers	(h) Lists the headings in the current group of messages (each group of messages contains 20 messages by default; change this with the set screen = statement).
help	Identical to question mark (?).
hold msg_lst	(ho) Marks each message in msg_lst to be saved in your system mailbox instead of in mbox . Does not override the delete command.
if condition else endif	Construction for conditional execution of mail commands. Commands following if are executed if <i>condition</i> is true. Commands following else are executed if <i>condition</i> is not true. The else is not required. The endif ends the construction and is required. The <i>condition</i> can be receive (receiving mail) or send (sending mail).
ignore [fld_lst]	Adds the header fields in <i>fld_lst</i> to the list of fields to be ignored. Ignored fields are not displayed when you look at a message with the t or p commands. Use this command to suppress machine-generated header fields. Use the Type and Print commands to print a message in its entirety, including ignored fields. If ignore is executed with no arguments, it lists the current set of ignored fields.
list	(l) Displays a list of valid mail commands.
local	Lists other names for the local host.
$\mathbf{mail} \; addr_lst$	(m) Activates the mail editor to allow you to create and send a message to people specified in $addr_{-}lst$.
mbox msg_lst	Indicates that the messages in msg_lst be sent to your personal mailbox when you quit. This operation is the default action for messages that you have looked at if you are looking at your system mailbox and the hold option is not set.
more msg_lst	(mo) Displays the messages in msg_lst using the defined pager program to control display to the screen.
More msg_lst	(Mo) Like more but also displays ignored header fields. See more and ignore.

Figure 3 (Part 3 of 6). Mailbox Commands

Command	Function	
new msg_lst	Identical to the unread command.	
New msg_lst	Identical to the Unread command.	
next [msg]	(n) Makes the next message in the mailbox the current message and displays that message. With an argument list, it displays the next matching message.	
page msg_lst	(pa) Identical to the more command.	
Page msg_lst	(Pa) Identical to the More command.	
preserve	(pre) Identical to the hold command.	
$egin{aligned} \mathbf{print} \ msg_lst \end{aligned}$	(p) Displays the messages in msg_lst.	
Print msg_lst	(P) Like print but also displays ignored header fields. See print and ignore .	
quit	(q) Ends the session and returns to the shell. Before ending, mail saves all messages that have not been deleted or saved in your personal mailbox (\$HOME/mbox). It keeps all messages marked with hold or preserve and those messages that have not been looked at, in the system mailbox. It removes all other messages from the system mailbox. If given while editing a mailbox file with the -f flag, then the edit file is saved with changes. If the edit file cannot be saved, mail does not exit. Use the exit command to exit without saving the changes.	
reply msg	Allows you to create and send mail to the people who sent and received the message specified in <i>msg</i> .	
Reply msg	Allows you to create and send mail only to the person who sent the message specified in <i>msg</i> .	
respond msg	Identical to the reply command.	
Respond msg	Identical to the Reply command.	
Figure 3 (Part 4 of 6). Mailbox Commands		

Command	Function	
retain [fld_lst]	Adds the header fields in <i>fld_lst</i> to the list of fields to be retained. Retained fields are displayed when you look at a message with the t or p commands. Use this command to define which header fields you want displayed. Use the Type and Print commands to print a message in its entirety, including fields that are not retained. If retain is executed with no arguments, it lists the current set of retained fields.	
save msg_lst file	(s) Appends the messages specified in <i>msg_lst</i> to <i>file</i> . Displays the file name and the size of the file when the operation is complete. If you save a message to a file, that message is not returned to the system mailbox nor saved in your personal mailbox when you quit the mail program.	
set [option]	(se) With no arguments, prints all variable values. Otherwise, sets an option as specified in <i>option</i> . The <i>option</i> field can be either the name of a <i>binary</i> option (an option that is either set or not set) or a statement of the form:	
	option=value	
	That assigns a value to a valued option. Binary and valued options are described later in this command description.	
shell	(sh) Invokes an interactive version of the shell.	
size msg_lst	Displays the sizes in lines/characters of the messages in msg_lst.	
${\bf source}\ file$	(so) Reads mail commands from file.	
top msg_lst	Displays the top few lines of the messages specified by msg_lst . The number of lines displayed is determined by the valued option toplines and defaults to five.	
touch msg_lst	When operating with your system mailbox, this command marks the messages in msg_lst to be moved to your personal mailbox when you quit the mail program, even though you have not read the listed messages. The messages appear in your personal mailbox as unread messages. When you use touch , the last message in msg_lst becomes the current message.	

Figure 3 (Part 5 of 6). Mailbox Commands

Command	Function	
type msg_lst	(t) Identical to the print command.	
Type msg_lst	(T) Identical to the Print command.	
unalias al_lst	Removes the defined aliases specified in al_lst.	
undelete msg_lst	(u) Removes the messages in msg_lst from the list of messages to be deleted when you quit mail.	
unread msg_lst	(U) Marks each message in msg_lst as not having been read.	
Unread msg_lst	Identical to the unread command.	
${f unset}\ option_lst$	Discards the values of the options specified in option_lst. This action is the inverse of the set command.	
version	(ve) Displays the version banner for the mail program.	
visual msg	(v) Activates the editor that you define with the set VISUAL= statement and loads message msg into the editor. When you exit the editor, the saved message is replaced in the mailbox being processed.	
write msg_lst file	(w) Appends the messages specified in msg_lst to file. Displays the file name and the size of the file when the operation is complete. Does not include message headers in the file.	
xit	(x) Identical to the exit command.	
z [+] [-]	Changes the current message group (group of 20 messages) and displays the headings of the messages in that group. If a + or no argument is give, then headings in the next group are shown. If a - argument is given, the headings in the previous group are shown.	

Figure 3 (Part 6 of 6). Mailbox Commands

Handling Outgoing Mail

To compose and send a message, use mail with the following format:

mail $addr_{-}lst$

In this format $addr_{-}lst$ is a list of user addresses separated by spaces. This command activates the mail editor so that you can compose a message to be sent to the specified addresses.

By default, **mail** treats lines beginning with the character ~ (tilde) as special while you are composing a message. For instance, typing ~**m** on a line by itself places a copy of the current message into the response, shifting it to the right by one tab stop.

Other escapes set up subject fields, add and delete recipients of the message, and allow the user to escape to an editor to revise the message, or to a shell to run other commands. You can change the escape character to something other than a tilde with the **set escape** = statement. To view a summary of many useful commands, enter ~? on a line by itself while in the mail editor.

Figure 4 shows a summary of the mail editor commands. Use these commands only while in the mail editor. The editor recognizes commands only if you enter them at the beginning of a new line.

Command	Function		
\sim ! cmd	Executes the shell command, cmd and returns to the message.		
$^{\sim}\mathbf{b}\ addr_{-}lst$	Adds names in $addr_{-}lst$ to the list of people to receive blind copies of the message.		
$^{\sim}\mathbf{c}\;addr_{-}lst$	Adds names in $addr_{-}lst$ to the list of people to receive copies of the message.		
~ d	Reads the file dead.letter from your home directory into the message.		
~ e	Activates the editor that you have specified with the set EDITOR= statement using the message text in the current message. When you exit that editor, you return to the mail editor to continue appending the changed message, or to send the message by exiting the mail program.		
~ f msg_lst	Reads the named messages into the message being sent. If no messages are specified, reads the current message. This command works only if you entered the mail editor from the mailbox listing using the ${\bf m}$ or ${\bf r}$ mailbox commands.		
~ h	Allows you to edit the message header fields by typing each one in turn. Allows you to append text to the end or modify the field using the current terminal erase and kill characters.		

Figure 4 (Part 1 of 2). Mail Editor Commands

Command	Function
~ m msg_lst	Reads the named messages into the message being sent, shifted right one tab. If no messages are specified, reads the current message. This command works only if you entered the mail editor from the mailbox listing using the m or r mailbox commands.
~ p	Displays the message as it currently exists, prefaced by the message header fields.
~ q	Aborts the message being created without sending it. Saves the message in dead.letter in your home directory if the save option is set.
${^{\sim}}{f r}$ filename	Reads the named file into the message.
~s string	Changes the Subject: field to the phrase specified in string.
$^{\sim}\mathbf{t}\;addr_lst$	Adds the addresses in $addr_{-}lst$ to the To: field of the message.
~ v	Activates the editor that you have specified with the Set VISUAL= statement using the message text in the current message. When you exit that editor, you return to the mail editor to continue appending to the changed message, or to send the message by exiting the mail program.
\sim w filename	Writes the message to the named file.
~Icmd	Pipes the message through the command <i>cmd</i> as a filter. If <i>cmd</i> gives no output or terminates abnormally, it retains the original text of the message. Otherwise, the output of <i>cmd</i> replaces the current message. The command fmt is often used as <i>command</i> to rejustify the message.
~~	Allows you to use the character ~ (tilde) in a message without it being interpreted as a command prefix. The sequence ~~ results in only one ~ being sent in the message. If you have changed the escape character, double that character instead of ~ to use the new escape character as a single character.

Figure 4 (Part 2 of 2). Mail Editor Commands

You can end a mail session with the quit (q) command. Messages that you have looked at go to your personal mailbox. Messages that you have marked to be deleted are deleted. Messages that you have not looked at go back to your system mailbox.

Customizing the Mail Program

The mail command has a number of options that you can set to customize the mail system for your particular use. Use the set command to enable options, and the unset command to disable options. You can also use the set command to assign a value to an option.

The format for using the **set** command to enable options is:

set [option_list]

The option-list may be one or more options that you want to enable. To set options so that they are valid each time you use mail, put the commands in .mailrc in your \$HOME directory, in your \$HOME directory. To set options so that they are valid for all users on the system, put the commands in /usr/lib/Mail.rc. The following table, Figure 5, lists the binary options (those that need only be set or unset).

Option	Function
append	Causes messages saved in mbox to be appended (added to the end) rather than prepended (added to the beginning).
ask	Causes mail to prompt you for the subject of each message you send. If you respond with a new line (carriage return), no subject field is set.
askcc	Causes you to be prompted for the addresses of people to receive copies of the message. Responding with a new line indicates your satisfaction with the current list.
autoprint	Causes the delete command to behave like dp . Thus, after deleting a message, the next one is typed automatically.
debug	Same as specifying -d on the command line. Causes mail to display debugging information. mail does not send mail while in debug mode.
dot	Causes mail to interpret a period alone on a line as the terminator of a message you are sending.
hold	Holds messages in the system mailbox by default.
ignore	Causes interrupt signals from your terminal to be ignored and echoed as @'s.

Figure 5 (Part 1 of 2). Binary Options

mail, Mail

Option	Function
ignoreeof	Related to dot. Makes mail refuse to accept an Ctrl-D as the end of a message. ignoreeof also applies to mail command mode.
metoo	Usually, when an alias containing the sender is expanded, the sender is removed from the expansion. Setting this option causes the sender to be included in the alias expansion (and thus receives copies of messages).
nosave	Normally, when a message is terminated with two interrupt sequences (Alt-Pause), mail copies the partial letter to the file dead.letter in your home directory. Setting the binary option nosave prevents this.
Replyall	Reverses the sense of the reply and Reply mailbox commands.
quiet	Suppresses the printing of the program banner when mail starts.
verbose	Same as using the -v flag on the command line. When mail runs in verbose mode, the actual delivery of messages is displayed on the user's terminal.

Figure 5 (Part 2 of 2). Binary Options

The following table, Figure 6 lists the valued options (those that need to be assigned a value).

Option	Function
EDITOR	Path name of the text editor to use in the edit command and ~ e escape. If not defined, then a default editor (/ usr/bin/e) is used.
PAGER	Path name of the paging program to use for the more command or when the crt variable is set. If you do not specify a value for PAGER , the system uses /bin/pg.
SHELL	Path name of the shell to use in the! command and the ~! escape. A default shell is used if this option is not defined.
VISUAL	Path name of the text editor to use in the visual command and ~ v escape. The default path name is / usr/bin/vi .

Figure 6 (Part 1 of 2). Valued Options

Option	Function
$\mathbf{crt} = n$	Calls the \mathbf{pg} command to display the message when the message exceeds n lines.
escape	If defined, the first character of this option gives the character to use in the place of $^{\sim}$ to denote escapes.
folder	Defines the name of the directory to use for storing folders of messages. If this name begins with a /, mail considers it to be an absolute path name; otherwise, the folder directory is found relative to your home directory.
record	If defined, gives the path name of the file (relative to \$HOME) used to record all outgoing mail. If not defined, then outgoing mail is not saved. Do not include the home directory as part of the path name.
screen	If defined, controls the size of the window for message headers. You can set this option to show the number of lines on the screen. For example, the entry screen=22 causes the system to scroll for 22 lines and then pause.
toplines	If defined, gives the number of lines of a message to be printed out with the top command; normally, the first five lines are printed.

Figure 6 (Part 2 of 2). Valued Options

Flags

-v	Puts mail into verbose mode. Details of delivery are displayed on the user's terminal.
-i	Causes tty interrupt signals to be ignored. Useful when using mail on noisy phone lines.
-n	Inhibits the reading the /usr/lib/Mail.rc.
-N	Suppresses the initial printing of headers.
-s $subject$	Specifies a subject for a message to be created.
-f name	Causes mail to read in the contents of your mbox or the specified file for processing. When you quit, mail writes undeleted messages back to this file.
-u user_id	Short way of doing mail -f /usr/mail/user_id. Activates mail for a specified user's mailbox. You must have access permission to the specified mailbox.

mail, Mail

Files

/usr/mail/* \$HOME/mbox System mailboxes for all users.

Your personal mailbox.

\$HOME/.mailrc

File containing mail commands to customize mail to a specific

user.

/tmp/R# /usr/lib/Mail.help Temporary for editor escape. Help file for mailbox commands.

/usr/lib/Mail.tildehelp

Help file for mail editor commands.

the system.

Related Information

The following commands: "bellmail" on page 104, "sendmail" on page 897, and "uucp" on page 1144.

The chapter about sending and receiving mail in IBM RT Using the AIX Operating System.

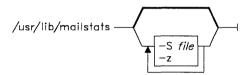

The chapters about Mail Handler (an alternative to mail) and about managing the mail system in IBM RT Managing the AIX Operating System.

mailstats

Purpose

Displays statistics regarding mail traffic.

Syntax

AJ2FL146

Description

This command reads the information in /usr/adm/sendmail/sendmail.st (or in the file specified with the -S flag), formats it, and writes it to standard output. The format of the information is shown in the following example:

Sendmail statistics from file "/usr/adm/sendmail/sendmail.st" Collection started at Thu Feb 18 17:40:41 1988

Mailer	msgs_from	bytes_from	${\sf msgs_to}$	$bytes_to$
local	1	2	1	201
prog	0	0	0	0
uucp	0	0	0	0
tcp	0	0	0	0

The fields in the report have the following meanings:

This field contains the name of the mailer program that handled the mail. Mailer

msgs_from

This field (messages from) contains the number of messages that originated from the indicated mailer.

bytes_from

This field contains the number of bytes of information in the messages sent from the indicated mailer.

mailstats

- msgs_to This field (messages to) contains the number of messages that ended locally and were received by the indicated mailer.
- bytes_to This field contains the number of bytes of information in the messages received by the indicated mailer.

The collection start time indicated on the second line of the report is the time at which the first update to the empty file was performed.

If **sendmail** transmits mail directly to a file, such as **dead.letter** or an alias target, the message and byte counts are credited to the prog mailer in addition to the normal statistics for use of the prog mailer.

Statistics Messages

When mailstats is called with no program flags, it can generate the following messages:

No statistics data in file "/usr/adm/sendmail/sendmail.st"

The **sendmail** program has not written any data into the statistics file.

mailstats: file size change; use previous mailstats version

The statistics file format is not the format expected by **mailstats**. Try using a previous version of **mailstats** to read it.

Flags

- -S file Specifies to use file as the input statistics file instead of /usr/adm/sendmail/sendmail.st
- -z Clears the contents of the statistics file. Clearing the file erases the contents and allows you to start gathering statistics again.

Files

/usr/lib/mailstats The mailstats program.
/usr/adm/sendmail/sendmail.st /usr/adm/sendmail/sendmail.cf The configuration file for sendmail program.

Related Information

The command: "sendmail" on page 897.

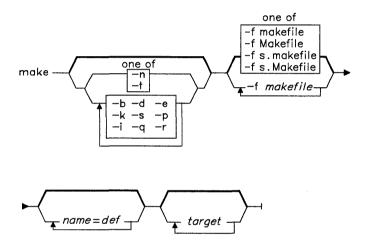

The chapter about managing the mail system in IBM RT Managing the AIX Operating System.

make

Purpose

Maintains up-to-date versions of programs.

Syntax

OL805035

Description

The **make** command reads *makefile* for information about the specified *target* files and for the commands necessary to update them. **make** does not change the *target* if you have not changed any of the source files since you last built it. It considers a missing file to be a changed file (out-of-date).

You can also include macro definitions on the command line after all of the flags. Macro definitions have the form:

macro-name = string

See "Macros" on page 628 for more information about macros and their uses.

The make command considers all entries on the command line that follow the flags and that do not contain an equal sign to be target file names.

Description File

The description file contains a sequence of entries specifying the files that the target files depend on. The general form of an entry is:

$$targ \ [targ] \ . \ . \ . \ : [:][file] \ . \ . \ . \ [; \ cmd] \ . \ . \ . \ [\#] \ [cmd] \ . \ . \ . \ [\#]$$

The first line of an entry (called the *dependency line*), contains a list of targets followed by a: (colon) and an optional list of prerequisite files or dependencies. If you put shell commands on the dependency line, they must be preceded by a; (semicolon). All commands that follow the semicolon and all following lines that begin with a tab contain shell commands that **make** uses to build the target.

To specify more than one set of commands, you must enter more than one dependency definition. In this case, each definition must have the target name followed by two colons (::), a dependency list, and a command list.

The first line that does not begin with a tab or # (pound sign) begins a new dependency or a macro definition. Command lines are performed one at time, each by its own subshell. Thus, the effect of some shell commands, such as **cd**, does not extend across new-line characters. You can, however, put a \ (backslash) at the end of a line to continue it on the next physical line. A comment begins with a # and ends with a new-line character.

The first one or two characters in a command can be one of the following special characters:

- Ignores errors returned by the command on this line.
- @: Does not display this command line.

-0

0- Does not display this command line and ignores errors.

Suffixes

The make command has default rules that govern the building of most standard files. These rules depend on the standard suffixes used by the system utility programs to identify file types. These rules define the starting and ending file types so that, for example, given a specified .o file, make can infer the existence of a corresponding .c file and knows to compile it using the CC -C command.

A rule with only one suffix (that is, .c:) defines the building of prog from all its source files. Use a ~ (tilde) in the suffix to indicate a SCCS file. For example, the .c~.0 rule governs changing an SCCS C source file into an object file. You can define rules within the description file. make recognizes as a rule any target that contains no slashes and starts with a dot.

You can also add suffixes to the list of suffixes recognized by make and add to the default dependency rules. Use the target name .SUFFIXES followed by the suffixes you want to add. Be careful of the order in which you list the suffixes. make uses the first possible name for which both a file and a rule exist. The default list is:

```
.SUFFIXES: .o .c .c~ .v
.y~ .1 .1~ .s .s~
.sh .sh~ .h .h~
```

You can clear the list of suffixes by including .SUFFIXES: with no following list.

Special Target Names

You can use some special target names in the description file to tell make to process the file in a different manner. The special target names are:

.DEFAULT	The commands that appear after this name in the description file tell make what to do if it can find no commands or default rules to tell it how to create a specific file.
.IGNORE	If this name appears on a line by itself, make does not stop when errors occur. Using a - (minus) as the first character on a line in the description file tells make to ignore errors for the command on that line.
.PRECIOUS	The files named on the same line as this special name are not removed when make is interrupted.
.SILENT	If this name appears on a line by itself, make does not display any of the commands that it performs to build a file.
.SUFFIXES	Use this name to add more suffixes to the list of file suffixes that make recognizes.

Environment

When you run make, it reads the environment and treats all variables as macro definitions. make processes the environment variables after it processes its own internal rules and before processing any description files. Therefore, macro assignments in a description file normally override duplicate environment variables. The -e flag instructs make to use the environment variables instead of the description file macro assignments.

The make command recognizes a macro MAKEFLAGS, which can be assigned any make command line flag except -f, -p, and -d. When make begins, it assigns the current flags to MAKEFLAGS. It passes this variable to any commands it invokes, including additional invocations of make itself. Thus you can perform a make -n recursively on a software system to see what would have been performed. The -n is put in MAKEFLAGS and passed to further copies of the shell that runs the next level of make commands. In this way, you can check all of the description files for a software project without actually compiling the project.

Note: Some makefile macros can conflict with csh variable substitutions. You should avoid using make with the csh shell. The sh shell does not conflict with make macros and it is the recommended shell. Otherwise, you can avoid conflicts by adding a SHELL = /bin/sh to the makefile.

Macros

Entries of the form string1 = string2 are macro definitions. string2 can consist of all characters that can occur on a line before a comment character (#) or before a new-line character that is not a continuation line. After this macro definition, make replaces each (string1) in the file with string2. You do not have to use the parentheses around the macro name if the macro name is only one character long and there is no substitute sequence (see the next paragraph). If you use the following form, you can also replace characters in the macro string with other characters for one time that you use the macro:

```
(string1[:subst1=[subst2]])
```

The optional :subst1 = subst2 + specifies a substitute sequence. If you specify a substitute sequence, **make** replaces each subst1 in the named macro with subst2 (if subst1 does not overlap with another subst1). Strings in a substitute sequence begin and end with any of the following: a blank, tab, new-line character, or beginning of line. See "Libraries" on page 629 for an example of the use of the substitute sequence.

Note: Because **make** uses the dollar sign symbol (\$) to designate a macro, do not use that symbol in file names of targets and parents, or in commands in the description file unless you are using a defined **make** macro.

Internal Macros

The **make** command has five internal macros. It assigns values to these macros under one or more of the following conditions:

- When it uses an internal rule to build a file.
- When it uses a .DEFAULT rule to build a file.
- When it uses rules in the description file to build a file.
- When the file is a library member.

They are defined as follows:

- \$* The file name (without the suffix) of the source file.
- \$0 The full target name of the current target.
- The source files of an out-of-date module. **make** evaluates this macro when applying inference rules or the .DEFAULT rule. For example:

Here, \$\leq \in \text{the equivalent of \$\dagger^*\$ and refers to the .c file of any out-of-date .o file.

- \$? The list of out-of-date files. make evaluates this macro when it evaluates explicit rules from makefile.
- \$% The name of an archive library member. make evaluates this macro only if the target is an archive library member of the form lib(file.o). In this case, \$0 evaluates to lib and \$\% evaluates to the library member. file.o.

You can add an uppercase **D** or **F** to indicate "directory part" or "file part," respectively, to all internal macros except for \$?. Thus, \$(@D) refers to the directory part of the name \$0. If there is no directory part, make uses ./.

Libraries

If a target name contains parentheses, make considers it an archive library. The string within parentheses refers to a library member. Thus, lib(file.o) and \$(LIB)(file.o) both see an archive library which contains file.o. (You must have already defined the LIB macro.) The expression (LIB) (file1.0 file2.0) is not legal.

Rules that apply to archive libraries have the form x.a, where x is the suffix of the file you want to add to an archive library. For example, .C. a indicates a rule that changes any C source file to a library file member. The following lines give the default rule for this change:

```
lib:
      lib(file1.0) lib(file2.0) lib(file3.0)
       @echo lib is now up to date
.c.a:
       $(CC) -c $(CFLAGS) $<
       ar rv $@ $*.o
       rm -f $*.o
```

.x must be different from the suffix of the archive member. Therefore, you cannot have lib(file.o) depend upon file.o.

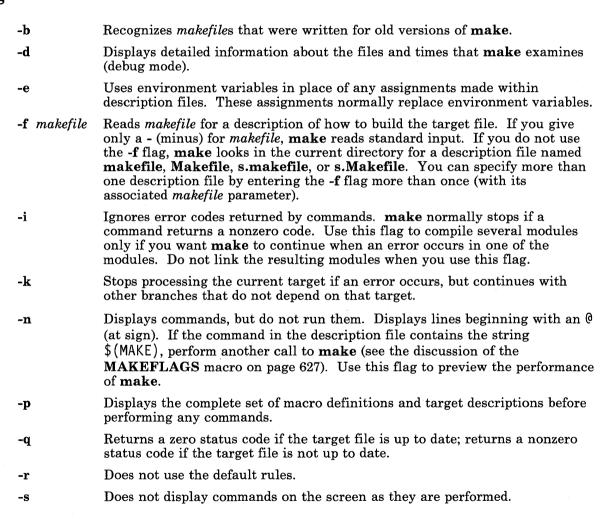

Another, but more limited, example of an archive library maintenance rule follows:

```
lib(file1.0) lib(file2.0) lib(file3.0)
lib:
       $(CC) -c $(CFLAGS) $(?:.o=.c)
       ar rv lib $?
       rm $?
                @echo lib is now up to date
.c.a:;
```

This example rule uses a substitute sequence (.0=.C) to replace with .c files all .o files generated by the \$? macro. The \$? list is the set of object file names (inside lib) with C source files that are out of date. The macro substitution translates .o to .c.

If this rule appears in your description file, it disables the default .C.a: rule, which creates each object file one by one. This type of organization speeds up archive library maintenance, but becomes hard to use if the archive library contains a mix of assembly programs and C programs.

Flags

Changes only the date of the files, rather than performing the listed -t commands. Use this flag if you have made only minor changes to a source file that do not affect anything outside of that file. This flag changes the date of all target files that appear on the command line or in the description file.

Examples

- To make the file specified by the first entry in the description file: make
- 2. To display, but not run, the commands that make would use to make a file:

```
make -n search.o
```

You may want to do this to verify that a new description file is correct before using it.

3. To save the internal rules in a file:

```
make -p -f /dev/null 2> /dev/null > defaults
```

This lists the internal rules and macros and saves them in the file defaults for viewing or editing. All exported shell environment variables are included in the list of macro definitions.

Files

Makefile makefile s.Makefile s.makefile

Related Information

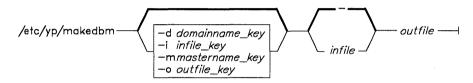

The discussion of make in AIX Operating System Programming Tools and Interfaces.

makedbm

Purpose

Makes a Yellow Pages dbm map.

Syntax

A5AC5004

Description

The makedbm command is most often invoked from /etc/yp/Makefile to generate Yellow Pages maps. The makedbm command converts infile to a pair of files in dbm format. The two files are outfile.pag and outfile.dir. Each line in the input file is converted to a single dbm record. All characters up to the first space or tab form the key while the rest of the line is the value data. If a line ends with \ (backslash), data for that record is continued on the next line. Yellow Pages clients must interpret the # symbol since makedbm does not treat it as a comment character. If infile is - (minus sign), makedbm reads standard input.

The makedbm command generates a special entry with the key YP_LAST_MODIFIED giving the date of *infile* or the current time if *infile* is specified to be standard input.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Creates a special entry with the key YP_DOMAIN_NAME.
- -i Creates a special entry with the key YP_INPUT_FILE.
- -o Creates a special entry with the key YP_OUTPUT_NAME.

- Creates a special entry with the key YP-MASTER-NAME. If no master host -m name is specified, YP-MASTER-NAME is set to the local host name.
- Displays individual entries in a dbm file, with a single space separating keys -u from values.

Example

In the following example, data from the /etc/passwd file is converted to a form that makedbm can use to create the Yellow Pages map passwd.nam:

```
awk '{FS=":"; OFS="\t"; print $1,$0}' \
  etc/passwd | makedbm - passwd.nam
```

File

/etc/yp/Makefile

Related Information

The following commands: "yppush" on page 1252 and "ypinit" on page 1243.

makekey

makekey

Purpose

Generates an encryption key.

Syntax

/usr/lib/makekey —

OL805240

Description

The **makekey** command generates an encryption key to use with programs that perform encryption. Its input and output are usually pipes.

The makekey command reads 10 characters from standard input and writes 13 characters to standard output. The first 8 of the 10 input characters can be any sequence of ASCII characters. The last two input characters (the salt), are best chosen from the set [a-zA-Z0-9.,/]. The salt characters are repeated as the first two characters of the output. The remaining 11 output characters are chosen from the same set as the salt and constitute the output key that you use as the key parameter to programs that perform encryption.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Example

To generate an encryption key:

/usr/lib/makekey 1234567890

This generates an encryption key based on the string 1234567890. The key 90y74T/NXwlU is displayed at the work station. Do not press Ctrl-D after typing the input key 1234567890 because this would end your shell session. Also, the shell prompt appears immediately after the generated key, instead of appearing on a separate line as it usually does. This is normal.

man

Purpose

Displays manual entries online.

Syntax

Description

The man command locates and displays the entries for the specified title and section of the online manual. If specified, man displays entries through editor. If an editor is not specified, man displays entries by default through the editor set by the EDITOR environment variable. If the EDITOR environment variable is not set, then the entry is displayed on standard output.

The section number may be one of the following:

- Commands and Application Programs
- System Calls
- Subroutines
- Special Files
- File Formats
- Games
- Miscellaneous Facilities.

If no section is specified, then all sections are searched for each title and all such occurrences are displayed; if a given title is not found in the specified section, then all sections are searched for that title.

Note: This command is available optionally; it is not part of the standard AIX Operating System package.

Flag

```
-e editor Displays entries with the specified editor.
-e - Does not display entries with the editor.
-n Displays entries without pagination.
```

Files

```
/usr/bin/man
/usr/man/cat[1-7]/*
/usr/bin/man[i l n o p]
```

Examples

- 1. To display the man entry on standard output when the **EDITOR** variable is not set: man man
- 2. To view section 1 of this entry in the ${\bf vi}$ editor:

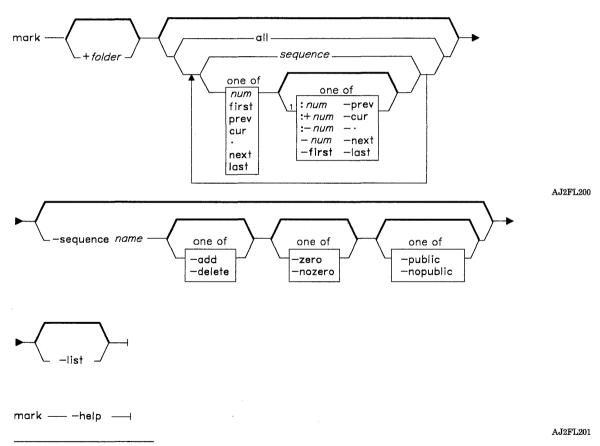

```
man -e vi 1 man
```

mark

Purpose

Creates, modifies, and displays message sequences.

Syntax

¹ Do not put a blank between these items.

OL805308

Description

The mark command is used to create a sequence, delete a sequence, add messages to a sequence, and delete messages from a sequence. The mark command is also used to list messages in a sequence and list sequences in a folder. The mark command is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The mark command specified with only a folder name lists the sequences defined for that folder and the messages that comprise each of the sequences. If you specify a new sequence name with the **-sequence** flag, **mark** creates a new sequence. You can use the -add flag to add messages to a sequence and the -delete flag to remove messages from a sequence. When all messages are deleted from a sequence, mark removes the sequence name from the folder.

Flags

-add

-public

Adds messages to the specified sequence. If messages are specified, -add is the default. -delete Deletes messages from the specified sequence. +folder msgs Specifies messages that you want mark to select from. msgs can be several messages, a range of messages, or a single message. You can use the following message references when specifying msgs: numfirst prev next cur all last seauence If the **-list** flag is used, the default for msgs is all. Otherwise, the default is the current message. The default folder is the current folder. If you specify a folder, that folder becomes the current folder. -help Displays help information for the command. -list Displays the messages in the specified sequence. If you do not specify a sequence, -list displays all sequence names defined for the folder and the messages in each sequence. -nopublic Restricts the specified sequence to your usage. -nopublic does not restrict the messages in the sequence, only the sequence. This option is the default if the folder is write-protected from other users. Modifies the sequence by adding or deleting only the specified messages -nozero

(see the **-zero** flag). This flag is the default.

Makes the specified sequence available to other users. -public does not make protected messages available, only the sequence. This flag is the

default if the folder is not write-protected from other users.

-sequence name

Specifies a sequence for the -list, -add, and -delete operations. You

must specify this flag for the -add and -delete operations.

-zero

Clears the specified sequence of all messages before adding any other messages. When the **-delete** flag is also specified, **-zero** places all of the messages from the folder into the sequence before deleting any messages.

Profile Entries

Current-Folder: Path:

Sets your default current folder. Specifies your *user_mh_directory*.

Files

\$HOME/.mh_profile

The MH user profile.

Related Information

"Overview of the Message Handling Package" in Managing the AIX Operating System.

mdrc

Purpose

Allows you to reinstall a user-created minidisk after you have reinstalled AIX.

Syntax

OL805440

Description

The mdrc command provides access to user-created minidisks. You should run this command if you have reinstalled the AIX Operating System or if you have had to replace the /etc/system, /etc/filesystems, or /etc/ddi/cpmgr files with copies that do not contain stanzas describing any user-installed minidisks. The system uses the information in these stanzas to configure the minidisks at system startup, and mdrc recreates the necessary stanzas. Normally, mdrc uses the backup copy of /etc/filesystems produced by the minidisks command when you use it to create a new minidisk. This backup copy is named /u/filesystems.

If mdrc cannot recreate the original /etc/filesystems stanza for AIX Operating System minidisks, it assigns attributes of Auto Mount = no, Read/Write Status = R/W, and Mount Directory = /tmp/directory/hdn to the minidisk. In this case, you should then run the minidisk command to change the attributes to the values you want. You might also need to run the mkdir command to create the mount directory, if you reinstalled the entire AIX Operating System.

If a minidisk has been created for use by the Personal Computer AT Coprocessor®4, mdrc will update the /etc/ddi/cpmgr file. If you have not installed Personal Computer AT Coprocessor Services before running mdrc, it creates an entry in /etc/system, but displays a warning message because the /etc/ddi/cpmgr does not exist. You must run mdrc again after you install the Coprocessor to be able to use the coprocessor minidisks.

⁴ Personal Computer AT Coprocessor is a registered trademark of International Business Machines Corporation.

The mdrc command does not recognize external disks, or any minidisks on them, if the disks are not configured. To configure an external disk and its minidisks, see "varyon" on page 1180.

You must have superuser authority or be a member of the system group to run the mdrc command. When auditing is on, an audit record of the type mdrc is created.

Flag

-h hdisknum[, hdisknum] . . .

Specifies any disks that have been removed or damaged and tells mdrc to remove the minidisk configuration entries for these disks. If you do not specify this flag and an external disk is not configured, mdrc ignores entries in the configuration files for the external disk's minidisks.

Note: If you do not have any external disks, you do not need to specify this flag.

Files

/etc/filesystems /etc/system /etc/ddi/cpmgr

Related Information

The following commands: "watch" on page 1209, "mkdir" on page 657, and "varyon" on page 1180.

The filesystems and system files in AIX Operating System Technical Reference.

mesg

Purpose

Permits or refuses write messages.

Syntax

OL805036

Description

The **mesg** command controls whether other users on the system can send messages to you with the **write** command. Called without arguments, **mesg** displays the current work station message-permission setting. The shell startup process permits messages by default. You can override this default action by including the line: Mesg n in your **\$HOME/.profile** file. A user with superuser authority can send **write** messages to any work station, regardless of its message permission setting. Message permission has no effect on messages delivered through the electronic mail system (**sendmail**).

Flags

- n Disables incoming write messages. Use this form of the command to avoid having others clutter your display with incoming messages.
- y Permits write messages.

Files

/dev/tty*

Related Information

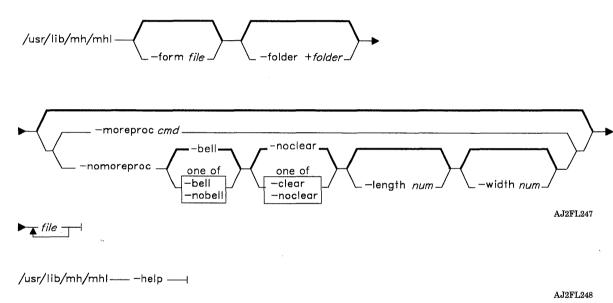

The following commands: "write" on page 1225 and "sendmail" on page 897.

mhl

Purpose

Produces formatted listings of messages.

Syntax

Description

The **mhl** command is used to create formatted lists of messages. The **mhl** command is part of the MH (Message Handling) package and can be used with other MH and AIX commands. **mhl** is usually invoked through the profile entry **showproc**: or through the **-showproc** flag in other MH commands.

The mhl command uses the formatting directions listed in the format file to display the message information about each of the specified messages. If you specify more than one message, mhl provides a prompt before displaying each screen of messages or with -nomoreproc, before displaying each message. If you specify -nomoreproc, press Enter or END OF FILE to see the next message. Press INTERRUPT to stop the current message output and to receive a prompt for the next message. Press QUIT to stop the command output.

Flags

-bell Produces an audible indicator at the end of each page. This flag affects

mhl only if the output device is a display and the moreproc: entry is

defined and empty. This flag is the default.

-clear Clears the screen at the end of each page when the output device is a

display. When the output device is not a display, -clear inserts a form feed character at the end of each message. If the output device is a display, mhl uses the \$TERM and \$TERMCAP environment variables to determine the type of display. This flag affects mhl only if the

moreproc: entry is defined and is empty.

-folder + folder Specifies the folder to be used for the mhl.format messagename entry.

The default is the value of the **\$mhfolder** environment variable.

-form file Uses the format contained in the specified file. If you do not specify this

flag, **mhl** uses the format described in *user_mh_directory*/**mhl.format**. If this file does not exist, **mhl** uses the system default format described

in /usr/lib/mh/mhl.format.

-help Displays help information for the command.

-length num Sets the length of the output. The default value is the value indicated

by **\$TERMCAP**. If that value is not appropriate, the default value is 40.

-moreproc cmd Uses cmd instead of the value of the moreproc: entry specified in

\$HOME/.mh_profile.

-nobell Does not produce an audible indicator at the end of each page. This flag

affects mhl only if the output device is a display and the moreproc:

entry is defined and is empty.

-noclear Does not clears the screen at the end of each page when the output

device is a display. When the output device is not a display, -clear does not insert a form feed character at the end of each message. This flag affects mhl only if the moreproc: entry is defined and is empty. This

flag is the default.

-nomoreproc Sets moreproc: as an empty value.

-width num Sets the width of the output. The default value is the value indicated by

\$TERMCAP. If that value is not appropriate, the default value is 80.

Profile Entry

moreproc:

Specifies the interactive program for communicating with user.

Files

/usr/lib/mh/mhl.format user_mh_directory/mhl.format The default MH message template.

The user's default message template. (If it exists, it

overrides the default MH message template.)

\$HOME/.mh_profile

The MH user profile.

The mh-format and mh-profile files in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

mhmail

Purpose

Sends or receives mail.

Syntax

mhmail -----

mhmail — -help —

AJ2FL236

Description

The **mhmail** command is used to incorporate messages and compose messages. The **mhmail** command is part of the MH (Message Handling) package and can be used with MH and AIX commands.

The **mhmail** command entered by itself incorporates messages from your mailbox. If you specify user addresses, **mhmail** accepts text from your terminal and composes a message. You can end the message text by pressing **END OF FILE**. **mhmail** sends a copy of the message to each specified address.

Flags

Sends a message with *string* as the body. When you specify **-body**, -body string

mhmail does not accept text from the terminal.

Sends a copy of the message to the specified users. mhmail puts the -cc users

addresses in the cc: field.

Places the specified user address in the From: field of the message. -from user

-help Displays help information for the command.

-subject string Places the specified text string in the **Subject**: field of the message.

Files

/usr/mail/\$USER

The location of the mail drop.

The mh-alias, mh-mail, and mh-profile files in AIX Operating System Technical Reference.

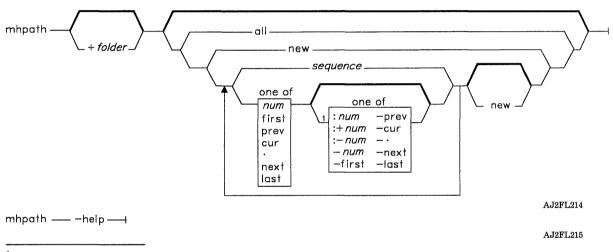

"Overview of the Message Handling Package" in Managing the AIX Operating System.

mhpath

Purpose

Prints full path names of messages and folders.

Syntax

¹ Do not put a blank between these items.

OL805308

Description

The **mhpath** command is used to list the path names of folders and messages. **mhpath** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The **mhpath** command lists the path names of all specified messages. If you do not specify any messages, **mhpath** lists the path name of the folder. If you do not specify messages or a folder, **mhpath** lists the path name of the current folder.

Flags

+folder msgs

Specifies the folder or the messages for which you want to list path names. msgs can be several messages, a range of messages, or a single message. You can use the following message references when specifying msgs:

first numprev cur next last new

all sequence

You cannot use **new** in a message range.

If you do not specify a message, mhpath lists the path name of the specified folder. The default folder is the current folder.

-help

Displays help information for the command.

Profile Entries

Current-Folder:

Sets your default current folder.

Path:

Specifies your *user_mh_directory*.

Files

\$HOME/.mh_profile

The MH user profile.

minidisks

minidisks

Purpose

Adds, deletes, changes, and displays minidisks.

Syntax

minidisks ----

OL805307

Description

The minidisks command lets you add, delete, show, or change characteristics of a minidisk. To use the minidisks command, you must be a member of the system group or have superuser authority. When a minidisk is added or deleted, an audit record of the type minidisk - add or minidisk - del is created. When a minidisk is changed, an audit record of the type stanza - add and stanza - del is created.

The minidisks command is menu-driven. For information on how to use it, see Installing and Customizing the AIX Operating System.

The discussion of minidisks in Installing and Customizing the AIX Operating System.

mkcatdefs

Purpose

Preprocesses a message source file.

Syntax

OL805486

Description

The mkcatdefs message facility program preprocesses a message source file containing symbolic identifiers, allowing gencat to create the symbname message catalog. The format for mkcatdefs is:

\$ mkcatdefs symbname sourcefile

The sourcefile message source file contains symbolic identifiers.

The **mkcatdefs** program produces the symbname_msg.h file containing definition statements equating your symbolic identifiers with set numbers and message ID numbers assigned by mkcatdefs. The symbname_msg.h file is required in your application program if you use symbolic identifiers.

The mkcatdefs program sends message source data, with numbers instead of symbolic identifiers, to standard output. This output is suitable as input to the gencat program. You can use the > (redirection symbol) to write the message source to a file, then use the file as input to gencat, or use the runcat shell script described in "runcat" on page 852. You can create a message text source file, using any text editor to enter the messages.

Assign message set numbers and message ID numbers to each message by using the commands described in this section.

Symbolic references are not defined by X/Open, but are an AIX extension.

mkctdefs

Use the **\$set** command in a source file to give a group of messages a set number. The format of the **\$set** command is:

\$set n [comment]

The message number is specified by n. Instead of a number, you can specify a symbolic identifier, which must contain only letters, digits, or the $_$ (underscore character). The maximum length of an identifier is 65 characters. The **mkcatdefs** program assigns a set number to the identifier. The assigned set number is one higher than the preceding set number, or 1 if it is the first \$set.

Note that mkcatdefs inserts a \$delset before the \$set in the output message source file.

You can mix numbers and symbolic identifiers.

You can include a comment in the **\$set** command, but it is not required. The following example includes a comment:

\$set CEM Communication Error Messages

Use the **\$delset** command to remove all of the messages belonging to the specified set from a catalog. The format of the **\$delset** command is:

\$delset n [comment]

The message set is specified by n. The **\$delset** command must be placed in the proper set number order with respect to any **\$set** commands in the same source file. You can include a comment in the **\$delset** command also.

You can include a comment line anywhere in the source file, except within message text. Indicate comments as shown below:

\$ [comment]

You must leave at least one space after the \$.

Enter the message text and symbolic message identifier as follows:

ID message-text

ID can be either a number or a symbolic identifier and can contain only letters, digits, or the _ (underscore character). The maximum length of an identifier is 65 characters. The **mkcatdefs** program assigns a message number to the identifier. The assigned number is one higher than the preceding message number, or 1 if it is the first message after the \$set command.

Note that **mkcatdefs** inserts a \$delset before the \$set, which means you cannot add, delete, or replace single messages in the catalog if you are using symbolic message identifiers. You must enter all messages in the set.

You can mix numbers and symbolic identifiers.

You must leave at least one space after the message identifier or number.⁶ All text following the first nonblank character is included in the message text, to the end of the line. If the source contains a \$quote command preceding the message, all text between the two quotation marks is included. Use the \ (escape character) to continue message text on the following line. The \ must be the last character on the line, as in the following example:

```
FIVE
         Text associated with \
message FIVE.
```

These two lines define the single-line message:

```
FIVE
         Text associated with message FIVE.
```

The \ can be used to include special characters in the message text. These special characters are defined as follows:

- \n Performs a new-line function when the message is displayed.
- ١t Inserts a horizontal tab character when the message is displayed.
- Inserts a vertical tab when the message is displayed. ١v
- Performs a backspace function when the message is displayed. **b**
- \mathbf{r} Inserts a carriage-return character when the message is displayed.
- **f** Inserts a form feed character when the message is displayed.
- 11 Displays the \ (backslash) character in the message.
- \d Displays the single-byte character associated with the octal value represented by the valid octal digits ddd. One, two, or three octal digits can be specified: however, you must include leading zeros if the characters following the octal digits are also valid octal digits. For example, the octal value for \$ is 44. To display \$5.00 use \0445.00, not \445.00, or the 5 will be parsed as part of the octal value.
- $\mathbf{x} dddd^7$ Displays the single-byte or double-byte character associated with the hexadecimal value represented by the four valid hexadecimal digits dddd. You can specify one, two, three, or four digits, but you must include leading zeros to avoid parsing errors (see $\backslash ddd$).

AIX allows any amount of white space after the message ID number; however X/Open specifies that you leave only one space between the message number and the message text.

⁷ This escape sequence is an AIX extension to X/Open.

You can also include **printf** conversion specifications in messages that are displayed by applications using **printf** or **NLprintf** (see **printf** in AIX Operating System Technical Reference). If you display a message from a shell script with **dspmsg**, the message can contain the %s or %n\$s conversion specifications (see "**dspmsg**" on page 359).

You can use the **\$quote** command in a message source file to define a character for delimiting message text. The format for this command is:

```
$quote [char] [comment]
```

Use the specified character before and after the message text as shown in the following example source file:

\$quote " Use a double quotation mark to delimit message text

\$set MSFAC

Message Facility - symbolic identifiers

SYM_FORM "Symbolic identifiers can only contain alphanumeric \ characters or the _ (underscore character)\n"

SYM_LEN "Symbolic identifiers cannot be more than 65 \ characters longn \"

5

"You can mix symbolic identifiers and numbers \n"

\$quote

 MSG_H

Remember to include the " msg_h " file in your program\n

In this example, the **\$quote** command sets the quote character to " then disables it before the last message, which contains quotation marks.

When you process this file with **mkcatdefs**, the modified source is written to standard output. Standard output can either be redirected to a file using the > (redirection symbol) or piped to **gencat** see "**gencat**" on page 470.

The following source is created:

```
Use double quotation marks to delimit message text
$auote "
$delset 1
$set 1
      "Symbolic identifiers can only contain alphanumeric \
characters or the _ (underscore character)\n"
      "Symbolic identifiers cannot be more than 65 \
characters long\n"
5
      "You can mix symbolic identifiers and numbers\n"
$quote
6
      remember to include the "msq_h" file in your program
```

Note that the assigned message numbers are noncontiguous because the source contained a specific number. The mkcatdefs program always assigns the previous number plus 1 to a symbolic identifier.

The **mkcatdefs** program also produces a definition file for inclusion in your program. The name of the file is symbname, entered as the first parameter to the mkcatdefs command. (If you specify the -h flag instead of the symbname, no definition file is produced.)

If the symbolic source defined above were in a file called Symb.src, you could use the mkcatdefs command as follows:

```
$ mkcatdefs symb symb.src >symb.msq
```

The generated Symb_msq.h file would look as follows:

```
#include <limits.h>
#include <nl_types.h>
#define MF_SYMB "symb.cat"
/* The following was generated from symb.src. */
/* definitions for set MSFAC */
#define MSFAC 1
#define SYM_FORM 1
#define SYM_LEN 2
#define MSG_H 6
```

mkctdefs

Note that **mkcatdefs** also created a symbol MF_SYMB by adding **MF**_ to the *symbname*, in uppercase letters. The **mkcatdefs** program assumes that the name of the generated catalog should be *symbname*.cat, and generates this symbol for your use with **catopen** or **NLcatopen**.

Since this file includes **limits.h** and **nl_types.h**, you do not need to include them in your application program. (**nl_types** defines special data types required by the message facility routines.)

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-h Supresses the generation of a ...msg.h file.

Related Information

mkdir

Purpose

Makes a directory.

Syntax

OL805037

Description

The mkdir command makes a new directory in either the local or a remote node. mkdir creates the new directories with read, write, and execute permissions enabled for all users. You can change the permissions it sets by default with the umask command (see page 1110). mkdir also creates by default the standard entries . (dot), for the directory itself, and .. (dot dot), for its parent.

Note: To make a new directory you must have write permission in the parent directory.

Related Information

The following commands: "sh" on page 913, "rm" on page 833, and "umask" on page 1110.

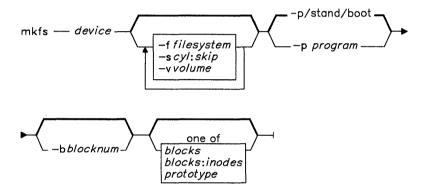

The mkdir system call in AIX Operating System Technical Reference.

mkfs

Purpose

Makes a file system.

Syntax

OL805364

Description

The **mkfs** command makes new file systems. **mkfs** initializes the volume label and file system label, start-up block, bad-block list, and interleaves the free list in accordance with the flags or with defaults found in the **/etc/filesystems** file.

The **mkfs** command creates the new file system on the *device* specified on the command line. *device* can be a block device name, raw device name, or file system name. If it is a file system name, **mkfs** uses this name as the *file system* and uses the following parameters from the applicable stanza in /etc/filesystems:

dev	Device name.
cyl	See the following -s flag.
skip	See the following -s flag.
vol	Volume ID.
bad	List of bad blocks separated by commas.
size	File system size.
hoot	Program to be installed in startup block

File System Size

You can specify the size of a new file system in the following way:

- On the command line
- In the prototype file
- In the /etc/filesystems entry for the given file system.

If the size is not specified in any of these places, mkfs takes it from the devinfo structure for the block device associated with the file system being generated. (See the ioctl system call and the **devinfo** file in AIX Operating System Technical Reference.) The size provided in the **devinfo** structure is the maximum size of the file system in any case. A size specification on the command line overrides any defaults found in the devinfo structure or in /etc/filesystems.

Prototype Files

To initialize the contents of a new file system in accordance with a prototype, specify the name of a prototype file on the command line. The proto command can be used to construct prototype files from existing file systems.

The prototype file contains tokens separated by spaces or new-line characters. The first token is the name of a file to be copied onto block 0 as the bootstrap program. The second token is a number specifying the size of the created file system. Typically it is the number of blocks on the device, perhaps diminished by space for paging. The next token is the number of i-nodes in the i-list. (mkfs rounds this to fill out the appropriate number of blocks.) The next set of tokens contains the specifications for the root file. File specifications consist of tokens giving the mode, the user name, the group name, and the initial contents of the file. The syntax of the contents field depends on the mode.

The mode token for a file is a six-character string. The first character specifies the type of the file. (The characters -, b, c, and d specify regular, block special, character special, and directory files, respectively.) The second character must be either u or -. If u is used, the set-user-ID mode is specified; if - is used, the set-user-ID mode is not specified. The third character must be either g or - for specifying the set-group-ID mode. The rest of the mode is a three-digit octal number giving the owner, group, and other read, write, execute permissions (see "chmod" on page 160).

Two decimal number tokens come after the mode. They specify the user and group names of the owner of the file.

If the file is a regular file, the next token is a path name from which the contents and size are copied.

If the file is a block or character special file, two decimal number tokens follow, which give the major and minor device numbers.

If the file is a directory, **mkfs** makes the entries. (dot) and .. (dot dot) and then recursively reads a list of names and file specifications for the entries in the directory. The scan is ended with the token \$ (dollar sign).

Flags

-bblocknum When present, specifies the number of blocks allocated to file i-node1 which is automatically created. Specifies the file system label for the new file system. This can be up to 6 **-f**filesystem bytes. -pprogram Specifies the name of a program to be installed in block 0 of the new file system. The default bootstrap program is /stand/boot. Specifies an interleaving of the free list. (Interleaving the free list can -scyl:skip improve the speed of disk I/O.) cyl is the number of blocks per cylinder, and *skip* is the number of blocks to skip. -vvolume Specifies the volume label for the new file system. This can be up to 6 bytes. blocks[:inodes] A size specification where blocks is the number of 512-byte blocks in the file system. When *inodes* is specified, it determines the number of i-nodes on the system. If *inodes* is not specified, a number suitable for the size of the file system is used. The number of i-nodes is rounded up so that the i-node area occupies an integral number of blocks.

Examples

1. To create an empty file system on a diskette:

mkfs /dev/fd0

2. To specify volume and file system names for a new file system:

mkfs /dev/fd0 -fWORKFS -vVOL001

This creates an empty file system on the diskette, giving it the volume serial VOL001 and file system name WORKFS.

Related Information

The following command: "fsck, dfsck" on page 445.

The ioctl system call and the devinfo, dir, filesystems, and fs files in AIX Operating System Technical Reference.

mknod

Purpose

Creates a special file.

Syntax

OL805146

Description

The **mknod** command makes a directory entry and corresponding i-node for a special file. The first parameter is the name of the entry device. Select a name that is descriptive of the device.

The mknod command has two forms. In the first case, the second argument is b or c. The b argument indicates that the special file is a block-oriented device (disk, diskette, tape). The c argument indicates that it is a character-oriented device (other devices). The last two parameters are numbers specifying the major device, which helps the operating system find the device driver code, and the minor device, that is, the unit drive, or line number, which may be either decimal or octal.

The assignment of major device numbers is specific to each system. Device numbers are determined by examining the system source file conf.c.

Note: If you change the contents of **conf.c** to add a device driver, you must rebuild the operating system. See the discussion of device drivers in AIX Operating System Programming Tools and Interfaces and in AIX Operating System Technical Reference.

The second form of mknod is used to create FIFOs (named pipes). The p flag after device indicates that you are creating a named pipe. See the AIX Operating System Technical Reference for an explanation of FIFOs and named pipes.

Example

To create the special file for a new diskette drive:

mknod /dev/fd2 b 1 2

This creates the special file /dev/fd2, which is a block special file with major device number 1 and minor device number 2.

The **mknod** file and device driver description in AIX Operating System Technical Reference.

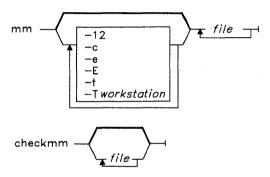

The discussion of device drivers in AIX Operating System Programming Tools and Interfaces.

mm, checkmm

Purpose

Displays or checks documents formatted with Memorandum Macros.

Syntax

OL805039

Description

Using the **nroff** command and the Memorandum Macro text-formatting package (MM), the mm command writes files to standard output. If you specify a - (minus) instead of any files, mm reads standard input. Do not specify both file names and standard input on the command line.

The mm command has flags to specify preprocessing by the tbl and/or eqn commands and postprocessing by various work station oriented-output filters. It generates the proper pipelines, and the required arguments for nroff and MM, depending on the flags selected, creates the required pipelines.

The **checkmm** command is a program for checking the contents of the named *files* for errors in the use of MM and some eqn and negn constructions. The program skips all directories, and if you do not specify a file, checkmm reads standard input.

Notes:

- 1. Use the **-o**list argument of **nroff** to specify ranges of pages to be output. Note, however, that invoking **mm** with one or more of the **-e**, **-t**, and **-** minus arguments together with **nroff -o**list may cause a harmless broken pipe diagnostic if the last page of the document is not specified in list.
- 2. The **mm** command calls **nroff** with the **-h** flag. With this flag, **nroff** assumes that the work station has tabs set every eight character positions.
- 3. If you use the -s flag of nroff (to stop between pages of output), use a line feed (rather than Enter or a new-line character) to restart the output. The -s flag of nroff does not work with the -c flag of mm or if mm automatically calls the col command.
- 4. If you provide inaccurate information to **mm** about the kind of work station its output is to be printed on, you will get unsatisfactory results; however, if you are redirecting output to a file, use the -T37 flag and then use the appropriate work station filter when you actually print the file.

Flags

Any flags on the command line not listed below are passed to **nroff** or to MM, as appropriate. The flags can occur in any order, but they must come before *file*. To obtain a list of **mm** flags, enter the command name with no arguments.

- -c Invokes the **col** command. Note that **col** is invoked automatically by **mm** unless *workstation* (the -T flag parameter) is one of the following:
 - 300
 - 300s
 - 450
 - 37
 - 4000a
 - 382
 - 4014
 - tek
 - 1620
 - X
- **-e** Invokes the **negn** command.
- -E Invokes the -e flag of nroff.
- -t Invokes the **tbl** command.
- -Tworkstation Uses work station specification workstation. For a list of recognized values for workstation, enter:

help term1

By default, mm uses the value of the shell variable \$TERM from the environment as the value of workstation. If **\$TERM** is not set **mm** uses **lp**. If several work station types are specified, the last one listed takes effect.

-12

Uses 12-pitch font. This may be used when **\$TERM** is set to one of **300**. 300s, 450, or 1620. (The pitch switch on the DASI 300 and 300s work stations must be manually set to 12 if this flag is used.)

Related Information

The discussion of mm in Text Formatting Guide.

mmt, checkmm

Purpose

Typesets documents, manual pages, view graphs, and slides.

Syntax

¹ If no files are given, these commands will display their flags.

OL805092

Description

These commands are similar to the mm command, except they typeset their input via troff as opposed to formatting it via nroff. The mvt, mt, and mant commands are links to mmt. mmt uses the MM Macro Package (see mm in AIX Operating System Technical Reference), mvt uses the macro package for view graphs and slides (see mv in AIX Operating System Technical Reference), mant uses the manual page macros, and mt does not use a macro package.

These commands have flags to specify preprocessing by **tbl**, **cw**, or **eqn**. **mmt** generates the proper pipelines and the required arguments for **troff** and for the macro package used, depending on the flags selected. These commands read standard input if you specify a (minus) instead of any file names.

The checkmm command can be used to check the input to mmt.

If the input contains a troff comment line consisting solely of the string '\" x (single quotation mark, backslash, double quotation mark x), where x is any combination of the three letters c, e, and t and where there is exactly one blank between the double quotation mark and x, then the input will be processed through the appropriate combination of cw. eqn, and tbl, respectively, regardless of the command-line arguments.

Note: Use the -olist argument of troff to specify ranges of pages to be output. Note, however, that calling these commands with one or more of the -c, -e, -t, and - arguments together with troff -olist may cause a harmless broken pipe diagnostic if the last page of the document is not specified in list.

Flags

Flags other than the ones listed below are passed to troff or to the macro package, as appropriate. All flags must appear before the file names. If you do not provide any arguments, these commands print a list of their flags.

- Invokes the -a flag of troff. -a
- Preprocesses the input files with cw. -c
- Preprocesses the input files with eqn. -e
- -t Preprocesses the input files with tbl.
- -T4014
- -Ttek Directs the output to a Tektronix 4014 work station via the tc command.

Related Information

The profile file and the environ, mm, and my miscellaneous facilities in AIX Operating System Technical Reference.

	_	_	_
п		()	()

moo

Purpose

Plays a number-guessing game.

Syntax

/usr/games/moo ---

OL805231

Description

The **moo** command picks a random four-digit decimal number with nonrepeating digits. You guess four digits and score a "cow" with a correct digit in an incorrect position and a "bull" with a correct digit in a correct position. The game continues until you guess the number.

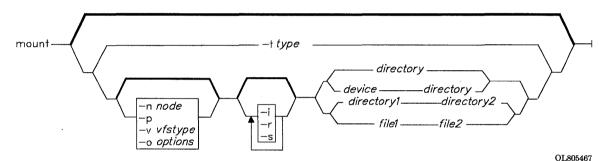

To quit the game, press INTERRUPT (Alt-Pause) or END OF FILE (Ctrl-D).

mount

Purpose

Makes a file system available for use.

Syntax

Description

The mount command instructs the operating system to make a file system available for use. In addition, you can use **mount** to build other file trees made up of directory and file mounts. In the case of file system mounts, the mount command mounts the specified device on the specified directory. After mount has finished, directory becomes the root of the newly mounted file system.

Any user can issue a mount directory1 directory2 or mount file1 file2 command if that user has search or write permission to the directory or file to be mounted over (directory2 or file2). Members of the system group can also do any mount described in the /etc/filesystems file (mount directory). Users operating as superusers can issue any mount command.

If you enter the **mount** command without arguments, it writes to standard output the mounted file systems, their locations, and their mount options.

If you specify only a directory name, mount takes it to be the name of the directory or file on which a file system, directory, or file is usually mounted (as defined in the /etc/filesystems file). mount looks up the associated device, directory, or file and mounts it. This is the most convenient way of using the mount command, as it does not require you to remember what is normally mounted on a directory or file.

The /etc/filesystems file should include a stanza for each mountable file system, directory, or file. This stanza should specify at least the name of the file system and either the device on which it resides or the directory name. If the stanza includes a mount attribute, the mount command uses the associated values. It recognizes five values in the mount attribute: true, false, removable, inherit and read-only (see the filesystems file in AIX Operating System Technical Reference for a description of these mount attributes.) The command mount all causes all file systems with the attribute mount = true to be mounted in their normal places. This command is typically used during system initialization.

If you are operating with superuser authority, you can mount a file system arbitrarily by naming both a *device* and a *directory* on the command line. **mount** takes *device* to be the name of the block device special file and *directory* to be the directory on which it should mount the file system.

Flags

-i	Services mo	Requests an inherited mount. This option is only valid for Distributed Services mounts. (For information on inherited mounts, see <i>Managing the AIX Operating System.</i>)		
-n node	Specifies the node that holds the directory to be mounted. If you specify this option without specifying the directory to be mounted, mount displays a list of all mounts issued at <i>node</i> , if the nodes are connected with Distributed Services.			
-0	Sets options for a hard or soft mount in the Network File System environment. The following options can be used:			
	bg	Mount is attempted in background if first attempt fails.		
	fg	Mount is attempted in foreground if first attempt fails.		
	retry = n	Mount is attempted n times.		
	rsize = n	Sets read buffer size to n bytes.		
	$\mathbf{wsize} = n$	Sets write buffer size to n bytes.		
	timeo = n	Sets NFS timeout period to n tenths of a second.		
retrans = n		Sets the number of NFS transmissions to n .		
	port = n	Sets server IP port number to n .		
	soft	Error is returned if server does not respond.		
	hard	Request is retried until server responds.		
	intr	Allows keyboard interrupts on hard mounts.		
	rw	Mounted file is read/write accessible.		

	ro	Mounted file is read-only.		
	The default options and their values (if any) are as follows: fg, retry = 10000, rsize = 8192, wsize = 8192, timeo = 7, retrans = 3, port = NFS_PORT (a system-specified constant), hard, and rw.			
		ons you enter on the command line should be separated only by t a comma and a space.		
-p	on it, a remo mounted file process has a disk buffers the structure media such a	e system as a removable file system. While there are open files vably mounted file system behaves the same as a normally system. However, when there are no open files (and no a current directory on the file system), all of the file system's are written to the medium, and the operating system "forgets" to of the file system. This allows you to remove and reinsert as diskettes without issuing a mount or umount command Use this flag only for diskette mounts.		
-r		e system as a read-only file system, regardless of the in /etc/filesystems.		
-s	This flag is f	or backwards compatibility only.		
-t type	Mounts all stanzas in /etc/filesystems that contain type = type and are not mounted. (type is a string value, such as remote.)			
-v vfstype		Tile system using the specified file system type, such as aix, If no <i>vfstype</i> is specified, the defaults set in the /etc/vfs file are		

Examples

1. To list the file systems that are mounted:

mount

nodename	mounted	mounted over	vfs	date	options
				5 17 00 04	
-	/dev/hd0	/	aix	Dec 17 08:04	rw
-	/dev/hd6	/vrm	aix	Dec 17 08:05	ro
-	/dev/hd1	/u		Dec 17 08:06	rw
-	/dev/hd2	/usr		Dec 17 08:06	rw
_	/dev/hd3	/tmp		Dec 17 08:06	rw
darlene	/usr	/usr	ds	Dec 17 10:44	rw

For each file system, **mount** lists the node name, the device name, the name under which it is mounted, the access permitted (read only or read/write), and the date and time it was mounted.

2. To mount a diskette:

mount /dev/fd0 /diskette0

This mounts a diskette (/dev/fd0) onto the directory /diskette0. A file system must already exist on the diskette, and the directory /diskette0 must already exist. To access a file on the diskette, use a path name that begins with /diskette0. For example, to access prog.c use /diskette0/prog.c.

Warning: Be sure that the current directory is not still on the diskette when you remove it from the drive, or you may lose some of your data.

3. To mount a write-protected diskette:

mount -r /dev/fd0 /diskette0

This mounts the diskette on /diskette0 as a read-only file system. This tells the operating system not to update file access times, which would cause errors with a write-protected diskette.

4. To mount a default file system:

mount /diskette0

This mounts the device that is usually mounted on /diskette0, which is determined by information in the file /etc/filesystems.

5. To mount all default file systems:

mount all

This mounts all standard file systems in /etc/filesystems marked mount = true.

6. To mount a remote directory:

mount -n nodeA /u/tom /u/tom

This mounts the remote **nodeA** directory /u/tom onto the local node directory /u/tom. It assumes the default remote **vfs_type** (which must be defined in /etc/vfs).

7. To mount a file or directory from the /etc/filesystem file with a specific type:

mount -t remote

This mounts all files or directories in the /etc/filesystems file that have a stanza that contains the attribute type = remote.

Files

/etc/filesystems /etc/vfs Descriptions of mountable file systems. Descriptions of file system types.

mountd

mountd

Purpose

Answers NFS mount requests.

Syntax

/usr/etc/rpc.mountd ____

OL805506

Description

The mountd daemon answers file system mount requests. It reads the file /etc/exports to determine which file systems are available to which machines and users in the network.

This daemon also identifies clients that have file systems mounted. Use the **showmount** command to display this information.

The inetd daemon invokes the mountd daemon.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

/etc/exports /etc/inetd.conf

Related Information

The following command: "showmount" on page 945.

The inetd daemon in IBM RT Interface Program for use with TCP/IP.

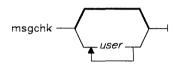

The NFS chapter in Managing the AIX Operating System.

msgchk

Purpose

Checks for messages.

Syntax

AJ2FL231

Description

The msgchk command is used to check mail drops for messages waiting to be received. msgchk is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The msgchk command checks all mail drops belonging to the specified user IDs and reports which mail drops contain messages that have not been received. msgchk also indicates whether it appears you have already seen these messages. If you do not specify a user argument, msgchk checks the current user's mail drops.

Flag

Displays help information for the command. -help

Files

\$HOME/.mh_profile /usr/lib/mh/mtstailor /usr/mail/\$USER

The MH user profile. The MH tailor file.

The location of the mail drop.

Related Information

The MH command "inc" on page 518.

The mh-mail and and mh-profile files in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

msh

Purpose

Creates an MH shell.

Syntax

AJ2FL232

Description

The msh command is used to work with messages stored in a packed format. msh is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The msh command performs a modified subset of MH commands on messages stored in packed format. msh prompts you to enter one of the following MH commands, and continues to prompt you for commands until you press END OF FILE or enter quit:

ali	burst	comp	dist
folder	\mathbf{forw}	inc	mark
mhmail	msgchk	\mathbf{next}	packf
pick	prev	refile	repl
rmm	scan	\mathbf{send}	show
sortm	whatnow	whom	

You can also enter help to display a brief overview.

Flags

-help

Displays help information for the command.

-noscan

Does not scan unseen items.

-notopcur

Makes the current message track the center line of the **vmh** scan window when **msh** is invoked from **vmh**. This flag is the default.

-prompt string

Prompts for msh commands with the specified string.

-scan

Scans unseen items.

-topcur

Makes the current message track the top line of the vmh scan window

when **msh** is invoked from **vmh**.

Profile Entries

fileproc:

Specifies the program used to refile messages.

Msg-Protect:

Sets the protection level for your new message files.

Path:

Specifies your *user_mh_directory*.

showproc:

Specifies the program used to show messages.

Files

\$HOME/.mh_profile /usr/lib/mh/mtstailor

The MH user profile.
The MH tailor file.

Related Information

The mh-alias, mh-format, mh-mail, and mh-profile files in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

mv

Purpose

Moves files

Syntax

OL805010

Description

Warning: The my command may overwrite many files if you do not ensure that the file path names you are specifying do not already exist.

The my (move) command moves files from one directory to another, or it renames a file or directory. If you move a file to a new directory, it retains the base file name. When you move a file, all links to other files remain intact, except when you move it to a different file system.

You can only rename a *directory* with **mv**; you cannot move it. Both *directory* and newname must have the same parent. All files in directory are moved to a newly-created directory newname under the same file names.

When you use **mv** to rename a *file*, then *newname* can specify either a new file name or a new directory path name. If moving the file would overwrite an existing write-protected file and if standard input is a work station, my displays the permission code of the file to be overwritten and reads one line from standard input. If the line begins with y, the move takes place and the file is overwritten. If not, mv does nothing with the file.

Japanese Language Support Information

An affirmative response in Japanese Language Support matches one of the elements in the environment variable YESSTR.

Note: If the file is on different file system than directory, mv must copy the file to the new file system and delete the original. In this case, the owner name becomes that of the user, and all links to other files are lost.

Flags

-f Does not prompt before removing a write-protected file.

Examples

1. To rename a file:

```
mv appendix apndx.a
```

This renames appendix to apndx.a. If a file named apndx.a already exists, its old contents are replaced with those of appendix.

2. To rename a directory:

```
mv book manual
```

This renames book to manual. If a directory named manual already exists, then an error message is displayed.

3. To move a file to another directory and give it a new name:

```
mv intro manual/chap1
```

This moves intro to manual/chap1. The name intro is removed from the current directory, and the same file appears as Chap1 in the directory manual.

4. To move a file to another directory, keeping the same name:

```
mv chap3 manual
```

This moves chap3 to manual/chap3.

Note the difference: Examples 1 and 3 name two files, Example 2 names two existing directories, and Example 4 names a file and a directory.

5. To move several files into another directory:

```
mv chap4 jim/chap5 /u/manua1
```

This moves chap4 to /u/manual/chap4 and jim/chap5 to /u/manual/chap5.

6. To use mv with pattern-matching characters:

```
mv manual/* .
```

This moves all files in the directory manual into the current directory (.), giving them the same names they had in manual. This also empties manual. Note that you must type a space between the star and the period.

The rename system call in AIX Operating System Technical Reference.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

mydir

Purpose

Moves (renames) a directory.

Syntax

```
mvdir — directory1 — directory2 —
```

OL805137

Description

The mvdir command renames directories within a file system. To use mvdir, you must have write permission to directory1 and directory2 and to the parent directories of directory1 and directory2. The directory1 parameter must name an existing directory. If directory2 does not exist, directory1 is moved to directory2. If directory2 exists, directory1 becomes a subdirectory of directory2. Neither directory can be a subset of the other.

Note: directory1 and directory2 may be the names of files. If directory2 is a file name, it is replaced with directory1.

Example

To rename or move a directory to another location:

```
mvdir appendixes manual
```

If manual does not exist, then this renames the directory appendixes to manual. You can also rename a directory with the **mv** command.

If a directory named manual already exists, this moves appendixes and its contents to manual/appendixes. In other words, appendixes becomes a subdirectory of manual.

Related Information

The following commands: "mkdir" on page 657 and "mv" on page 679.

The **rename** system call in AIX Operating System Technical Reference.

ncheck

Purpose

Generates path names from i-numbers.

Syntax

OL805196

Description

The **ncheck** command without any flags writes to standard output the path name and i-number list for all files in *filesystem*.

If you specify an invalid file system, the ?? in the name stands for the parent of a file system that does not have a parent. Path names beginning with . . . (dot dot dot) indicate a loop.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

-a Lists includes the file names. (dot) and .. (dot dot).

-i inumber . . . Lists only the file specified by inumber.

-s Lists only special files and files with set-user-ID mode.

Examples

1. To list the i-number and path name of each file in the default file systems: ncheck

ncheck

2. To list all the files in a specified file system:

```
ncheck -a /
```

This lists the i-number and path name of each file in the root file system (/), including the . (dot) and .. (dot-dot) entries in each directory (-a).

3. To list the name of a file when you know its i-number:

```
ncheck -i 690 357 280 /diskette0
```

This lists the i-number and path name for every file in the file system /diskette0 with i-numbers of 690, 357, or 280. If a file has more than one link, all of its path names are listed.

4. To list special and set-user-ID files:

```
ncheck -s /
```

This lists the i-number and path name for every file in the root file system that is a special file (also called a *device file*) or that has set-user-ID mode enabled.

Related Information

The following commands: "fsck, dfsck" on page 445 and "sort" on page 958.

ndtable

Purpose

Accesses the Distributed Services Node Table.

Syntax

ndtable —

OL805470

Description

The ndtable command lets you build, examine, or change the Distributed Services Network Node Table. Only members of the system group or users operating with superuser authority can use **ndtable** to change the state of the table (see "su" on page 1026). Other users can use ndtable to browse through the table.

Note: If your system crashes when a user is running ndtable to view or update a remote machine's table, you will get system error message 000-002 the next time you try to access the table. If this happens, remove the contents of the /etc/profsycs/NID directory (where NID is the numeric node ID of the remote machine), and retry the **ndtable** command.

Related Information

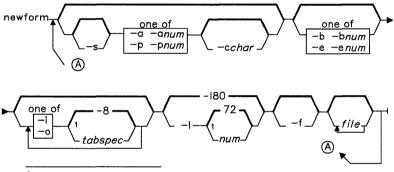

"Getting Started With Distributed Services Configuration Menus" in Managing the AIX Operating System.

newform

Purpose

Changes the format of a text file.

Syntax

¹Do not put a blank between these items.

OL805197

Description

The **newform** command takes lines from *file* (standard input by default), and writes the formatted lines to standard output. Lines are reformatted in accordance with the command line flags in effect.

Except for -s, command line flags can appear in any order, can be repeated, and can be mixed with the *file* parameter. Command line flags are processed in the order specified. In other words, flag sequences like -e15 -160 yield results different from -160 -e15. Flags are applied to all *files* on the command line.

An exit value of 0 indicates normal execution, a 1 indicates an error.

Notes:

- The **newform** command normally only keeps track of physical characters; however, for the -i and -o flags, newform keeps track of backspaces in order to line up tabs in the appropriate logical columns.
- 2. The **newform** command does not prompt you if a tabspec is to be read from the standard input (by use of -i-- or -o --).
- If the -f flag is used and the last -o flag specified was -o-- and was preceded by either a -o-- or a -i--, the tab specification format line will be incorrect.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

$-\mathbf{a}[num]$	Adds num characters to the end of the line when the line length is less than
	the effective line length (see the -c and -p flags in this section).

-b[*num*] Truncates num characters from the beginning of the line when the line length is greater than the effective line length (see -lnum). The default action truncates the number of characters necessary to obtain the effective line length. If you specify -b with no num, the default takes effect. This flag can be used to delete the sequence numbers from a COBOL program as follows:

newform -11-b7 file-name

The -11 must be used to set the effective line length shorter than any existing line in the file so that the **-b** flag is activated.

 $-\mathbf{c}[char]$ Changes the prefix/add character to char. Default character for char is a space.

-e[num]Same as -bnum except that characters are truncated from the end of the line.

-f Writes the tab specification format line to standard output before any other lines are written. The tab specification format line displayed corresponds to the format specified in the last -o flag. If no -o flag is specified, the line displayed contains the default specification of -8.

-i[tabspec] Replaces all tabs in the input with the number of spaces specified by tabspec. tabspec recognizes all tab specification forms described in "tabs" on page 1041. If you specify a -- (minus minus) for the value of tabspec, newform assumes that the tab specification can be found in the first line read from standard input (see fspec in AIX Operating System Technical Reference). The default tabspec is -8. A tabspec of -0 expects no tabs; if any are found, they are treated as -1.

newform

-1[num]

Sets the effective line length to *num* characters. If *num* is not entered, -l defaults to 72. The default line length without the -l flag is 80 characters. Note that tabs and backspaces are considered to be one character (use -i to expand tabs to spaces).

-o[tabspec]

Replaces spaces in the input with a tab in the output, according to the tab specifications given. The default *tabspec* is -8. A *tabspec* of -0 means that no spaces are converted to tabs on output.

 $-\mathbf{p}[num]$

Prefixes *num* characters (see -cchar) to the beginning of a line when the line length is less than the effective line length. The default action is to prefix the number of characters that are necessary to obtain the effective line length.

-s

Removes leading characters on each line up to the first tab and places up to eight of the removed characters at the end of the line. If more than eight characters (not counting the first tab) are removed, the eighth character is replaced by an * (asterisk) and any characters to the right of it are discarded. The first tab is always discarded.

The removed characters are saved internally until all other flags specified are applied to that line. The characters are then added at the end of the processed line.

For example, to convert a file with leading digits, one or more tabs, and text on each line, to a file beginning with the text, all tabs after the first expanded to spaces, padded with spaces out to column 72 (or truncated to column 72), and the leading digits placed starting at column 73, the command would be as follows:

newform -s -i -l -a -e file-name

The **newform** command displays an error message and stops if this flag is used on a file without a tab on each line.

Related Information

The following commands: "tabs" on page 1041 and "csplit" on page 252.

The fspec file in AIX Operating System Technical Reference.

newgrp

Purpose

Changes your primary group identification.

Syntax

OL805198

Description

The newgrp command changes your primary group identification to group. newgrp recognizes only group names, not group ID numbers. Without an argument, it changes your primary group to the one specified in the /etc/passwd file.

If the group has a password and you do not or if the group has a password and you are not listed in the /etc/group file as a member, then newgrp asks you for the group password. (The use of group passwords is not encouraged because, by their very nature, they encourage poor security practices.)

Note: Any active user-generated shell will be terminated when newgrp is used.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flag

Changes the environment to the login environment of the new group.

Examples

- 1. To change the primary group ID of the current shell session to admin: newgrp admin
- 2. To change the primary group ID back to your original login group: newgrp

Files

/etc/group Group file; contains group IDs. Password file; contains user IDs.

Related Information

The following commands: "login" on page 584 and "users, adduser" on page 1129.

The group and passwd files in Installing and Customizing the AIX Operating System.

news

Purpose

Writes system news items to standard output.

Syntax

OL805199

Description

The **news** command keeps you informed of news concerning the system. Each news item is contained in a separate file in directory /usr/news. Anyone having read/write permission to this directory can create a news file.

If you run the **news** command without any flags, it displays every current file in /usr/news, showing the most recent first. Or you can specify the items you want displayed.

Each file is preceded by an appropriate header. To avoid reporting old news, news stores a currency time. news considers your currency time to be the modification time of the file named \$HOME/.news_time. Each time you read the news, the modification time of this file changes to that of the reading. Only news item files posted after this time are considered current.

Pressing INTERRUPT (Alt-Pause) during the display of a news item stops the display of that item and starts the next. Pressing INTERRUPT (Alt-Pause) again ends news.

Most users run news each time they log in by including the line:

news -n

in their \$HOME/.profile file or in the system's /etc/profile.

Flags

-a Displays all news items, regardless of the currency time. The currency time does not change.

- -n Reports the names of current news items without displaying their contents. The currency time does not change.
- -s Reports the number of current news items without displaying their names or contents. The currency time does not change.

Examples

1. To display the items that have been posted since you last read the news:

news

2. To display all the news items:

news -a | pg

This displays all the news items a page at a time (I pg) whether or not you have read them yet.

3. To list the names of the news items that you have not read yet:

news -n

Each name is a file in the directory /usr/news.

4. To display specific news items:

news newusers services

This displays news about newusers and services, which are names listed by news -n.

5. To display the number of news items that you have not read yet:

news -s

6. To post news for everyone to read:

cp schedule /usr/news

This copies the file schedule into the system news directory, /usr/news, to create the file /usr/news/schedule. To do this you must have write permission for /usr/news.

Files

/etc/profile /usr/news/* \$HOME/.news_time

Related Information

The following command: "pg" on page 744.

The profile file and environ special facility in AIX Operating System Technical Reference.

next

Purpose

Shows the next message.

Syntax

next ---- -help -----

AJ2FL159

Description

The **next** command is used to display the next message in a folder. **next** is equivalent to the **show** command with **next** specified as the message. **next** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The next command links to the show program and passes show its flags and attributes.

Note: If you link to **next** and call that link something other than **next**, your link will function like the **show** command, rather than like the **next** command.

The show command invokes a program to perform the listing. The system default is /bin/pg. You can define your own default with the showproc: entry in \$HOME/.mh-profile. If you set showproc: entry to mhl, show calls an internal mhl routine instead of the mhl command. You can also specify the program to perform a listing in the *cmdstring* of the -showproc flag.

The **show** command passes any flags that it does not recognize to the program performing the listing. Thus, you can specify flags for the listing program, as well as the flags described in this command section.

Flags

+folder Specifies the folder that contains the message you want to show.

-header Displays a one-line description of the message being shown. The

description includes the folder name and the message number.

-help Displays help information for the command.

-noheader Does not display a one-line description of each message being

shown.

-noshowproc Uses /bin/cat to perform the listing.

-showproc *cmdstring* Uses the specified command string to perform the listing.

Profile Entries

Current-Folder: Sets your default current folder.

Path: Specifies your *user_mh_directory*.

showproc: Specifies the program used to show messages.

Files

\$HOME/.mh_profile The MH user profile.

Related Information

Other MH commands: "prev" on page 765, "show" on page 942.

The mh-format, mh-mail, and mh-profile files in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

nfsd

Purpose

Starts the daemons that handle client Network File System requests.

Syntax

nfsd ____ nservers____

OL805488

Description

The nfsd command starts the daemons that handle client file system requests.

The nservers parameter specifies the number of file system request daemons to start. Assign the number based on the load expected on a server. Four is an average load number.

When a file opened by a client is unlinked, a new file is created by the client. The new file is in the form .nfsxxx. When the open file is closed, the .nfsxxx file is removed.

Note: If the client crashes before the file can be closed, the .nfsxxx file is not removed.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

.nfsxxx Client machine's pointer to an open file that has been unlinked. /etc/rc.nfs

Related Information

The following command, "biod" on page 114.

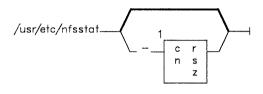

The IBM AIX/RT Network File System section in Managing the AIX Operating System.

nfsstat

Purpose

Displays Network File System statistics.

Syntax

¹ Do not put a blank between these items.

OL805489

OL805308

Description

The **nfsstat** command displays statistical information about NFS (Network File System) and RPC (Remote Procedure Call).

If you have superuser authority, you can also use nfsstat to reinitialize the NFS and RPC statistical information.

The default for nfsstat is nfsstat -csnr. If you use it without flags, information for NFS and RPC is displayed and reinitialization does not occur.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

Use the following flags for displaying and reinitializing the statistics for specific areas:

- Displays NFS and RPC client information.
- -cn Displays NFS client information only.
- Displays RPC client information only.

nfsstat

- -n Displays NFS client and server information.
- -r Displays RPC client and server information.
- -s Displays NFS and RPC server information.
- -sn Displays NFS server information only.
- -sr Displays RPC server information only.
- -z Reinitializes statistics to zero. Only users with superuser authority can reinitialize statistics.

After displaying certain sets of the statistics, you can reinitialize them by using the flag that identifies the area followed by the -z flag. For example, you would use the flag combination -cnz to reinitialize NFS client statistics.

Files

/unix System name list /dev/kmem Kernel memory

Related Information

The following command: "rstatd" on page 847.

nice

Purpose

Runs a command at a different priority.

Syntax

nice
$$-10 \frac{1}{1}$$
 cmdstring $-$

¹ Maximum increment is 19.

OL805200

Description

The nice command lets you run the specified *command* at a lower priority. The value of *number* can range from 1 to 19, with 19 being the lowest priority. The default value of *number* is 10.

If you have superuser authority, you can run commands at a higher priority by specifying *number* as a negative number, such as --10.

Examples

1. To run a command at low priority:

This runs the command CC -C *.C at low priority. Note that this does not run the command in the background. Your work station is not available for doing other things.

2. To run a low priority command in the background:

This runs the command CC -C \star .C at low priority in the background. Your work station is free so that you can run other commands while cc is running. See page 914 for details about starting background processes with &.

3. To specify a very low priority:

```
nice -15 cc -c *.c &
```

This runs **cc** in the background at a priority that is even lower than the default priority set by **nice**.

4. To specify a very high priority:

```
nice --10 wall <<end
System shutdown in 2 minutes!
end
```

This runs wall at a higher priority than all user processes. Doing this slows down everything else running on the system. If you do not have superuser authority when you run this command, then the wall command runs at the normal priority.

The <<end and end define a "Here Document," which uses the text entered before the end line as standard input for the command. For more details, see "Inline Input Documents" on page 928.

Related Information

The following commands: "csh" on page 225 and "nohup" on page 707.

Note: The **csh** command contains a built-in subcommand named **nice**. The command and subcommand do not necessarily work the same way. For information on the subcommand, see the **csh** command.

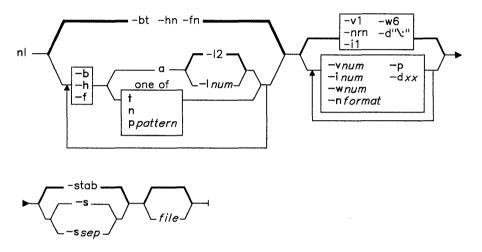

The nice system call in AIX Operating System Technical Reference.

nl

Purpose

Numbers lines in a file.

Syntax

OL805386

Description

The **nl** command reads *files* (standard input by default), numbers the lines in the input, and writes the numbered lines to standard output. In the output, **nl** numbers the lines on the left according to the flags you specify on the command line.

The input test must be written in logical pages. Each logical page has a header, a body, and a footer section (you can have empty sections). Unless you use the -p flag, nl resets the line numbers at the start of each logical page. You can set line numbering flags independently for the header, body, and footer sections (for example, no numbering of header and footer lines while numbering text lines only in the body).

Signal the start of logical page sections with lines in *file* that contain nothing but the following delimiter characters:

 Line contents
 Start of

 \:\:\:
 Header

 \:\:
 Body

 \:
 Footer

You can name only one file on the command line. You can list the flags and the file name in any order.

Flags

All the parameters are set by default. Use the following flags to change these default settings. Except for the -s flag, enter a flag without a parameter to see its default value.

-btype Chooses which body section lines to number. The recognized types are:

a Numbers all lines.

t Does not number blank lines (default).

n Does not number any lines.

ppattern Numbers only those lines containing the specified pattern.

Uses xx as the delimiters for the start of a logical page section. The default characters are \: (backslash followed by a colon). You may specify two ASCII characters, two 1-byte extended characters, or one extended character. If you enter only one 1-byte character after -d, the second character remains the default (colon). If you want to use a backslash as a delimiter, enter two backslashes (\\).

-ftype Chooses which logical page footer lines to number. The types recognized are the same as in -btype. The default type is n (no lines numbered).

-htype Chooses which logical page header lines to number. The types recognized are the same as in -btype. The default type is n (no lines numbered).

-inum Increments logical page line numbers by num. The default value of num is 1.

-lnum Uses num as the number of blank lines to count as one. For example, -13 will only number the third adjacent blank. The default value of num is 2. This flag can only be used in documents where the -ba flag is used.

-nformat Uses format as the line numbering format. Recognized formats are:

In Left justified, leading zeros suppressed.

rn Right justified, leading zeros suppressed (default).

rz Right justified, leading zeros kept.

-p Does not restart numbering at logical page delimiters.

-s[sep]Separates the text from its line number by the sep character. The default value of sep is a tab character. If you enter -s without a parameter, there is no separation between the line number and its text.

Sets the initial logical page line number to num, (1 by default). -vnum

Uses num as the number of characters in the line number. The default value of -wnumnum is 6.

Examples

1. To number only the nonblank lines:

nl chap1

This displays a numbered listing of Chapl, numbering only the nonblank lines in the body sections. If chap1 contains no \:\:\+:, \:\+:, or \: delimiters, then the entire file is considered the body.

2. To number all lines:

nl -ba chap1

This numbers all the lines in the body sections, including blank lines. This form of the nl command is adequate for most uses.

3. To specify a different line number format:

```
-i10 -nrz -s:: -v10 -w4 chap1
```

This numbers the lines of chap1 starting with ten (-v10) and counting by tens (-i10). It displays four digits for each number (-w4), including leading zeros (-nrz). The line numbers are separated from the text by two colons (-S::).

For example, if chap1 contains the text:

A not-so-important note to remember:

You can't kill time without injuring eternity.

then the numbered listing is:

0010::A not-so-important 0020::note to remember:

0030::You can't kill time

0040::without injuring eternity.

Note that the blank line was not numbered. To do this, use the -ba flag as shown in Example 2.

Related Information

The following command: "pr" on page 761.

"Overview of International Character Support" in Managing the AIX Operating System.

nm

Purpose

Displays the symbol table of an object file.

Syntax

OL805202

Description

Size

The **nm** command writes the symbol table of each specified object *file* to standard output. file can be a single relocatable or absolute common object file or an archive library of relocatable or absolute common object files. nm displays the following information for each symbol:

Name The name of the symbol.

Value Its value expressed as an offset or an address depending on its storage class.

Class Its storage class.

Type Its type and derived type. If the symbol refers to a structure or a union, the structure or union tag follows the type declaration. If the symbol is an array, the array dimensions follow the type. Note that you must have compiled the object file with cc -g for this information to appear.

Its size in bytes, if available. Note that you must have compiled the object file with cc -g for this information to appear.

Line The source line number at which it is defined, if available. Note that you must have compiled the object file with cc -g for this information to appear.

Section For static and external storage classes, the object file section containing the symbol.

Flag

- -e Displays only static and external symbols.
- -h Does not display output header data.
- -n Sorts external symbols by name before displaying them. Use this flag only in conjunction with the -e flag.
- -o Displays a symbol's value and size as an octal rather than a decimal number.
- Truncates every name that would otherwise overflow its column, making the last character displayed in the name an asterisk. By default, **nm** displays the entire name of the symbols listed, and a name that is longer than the width of the column set aside for it causes every column after the name to be misaligned.
- -u Displays only undefined symbols.
- -v Sorts external symbols by value before displaying them. Use this flag only in conjunction with the -e flag.
- -x Displays a symbol's value and size as a hexadecimal rather than a decimal number.

Files

a.out Default input file.

Related Information

The following commands: "ar" on page 55, "as" on page 61, "backup" on page 88, "cc" on page 140, "ld" on page 557, "size" on page 949, and "strip" on page 1017.

The a.out and ar files in AIX Operating System Technical Reference.

nohup

Purpose

Runs a command without hangups and quits.

Syntax

```
nohup --- command ---
```

OL805203

Description

The nohup command runs command, ignoring all hangups and QUIT signals. You can use this command to run programs in the background after you log off of the system. To run a nohup command in the background, add an & to the end of the command.

If **nohup** output is redirected to a terminal or is not redirected at all, the output goes to the file **nohup.out**. If **nohup.out** is not writable in the current directory, the output is redirected to \$HOME/nohup.out.

The syntax of this command ignores quits and hangups for only one command. If you want to apply nohup to a pipeline or list of commands, you can put the pipeline or list in a shell script file. Then you can run sh as the command using the format: nohup sh file. You can also assign the shell file execute permission and run it as the command in the form: nohup file.

Examples

1. To leave a command running after you log off:

```
nohup find / -print &
Shortly after you enter this, the following is displayed:
670
$ Sending output to nohup.out
```

The number will probably be different when you use this command. It is the ID of the background process started by & (ampersand). (See page 914 about starting background processes with &.) The \$ (dollar sign) is your shell prompt. Sending output . . . is a message from **nohup** telling you that it is storing the output from the .find command in the file nohup.out. You can log off after you see these messages, even if the find command has not finished yet.

2. To do the same, but redirect the standard output to a different file:

```
nohup find / -print >filenames &
```

This runs the find command and stores its output in a file named filenames. Now only the process ID and your prompt are displayed:

```
677
$
```

Wait for a second or two before logging off, because the **nohup** command takes a moment to start the *command* you specified. If you log off too quickly, your *command* may not run at all. Once your *command* has started, logging off will not affect it.

3. To run more than one command, use a shell procedure. For example, if you write the shell procedure:

```
negn math1 ] nroff > fmath1
```

and name it nnfmath1, you can run **nohup** for all of the commands in nnfmath1 with the command:

```
nohup sh nnmath1
```

If you assign nnfmath1 execute permission, you can obtain the same results by issuing the command:

```
nohup nnmath1
```

To run this command in the background, enter the command:

```
nohup nnmath1 &
```

Related Information

The following commands: "csh" on page 225, "nice" on page 699, and "sh" on page 913.

Note: The **csh** command contains a built-in subcommand named **nohup**. The command and subcommand do not necessarily work the same way. For information on the subcommand, see the **csh** command.

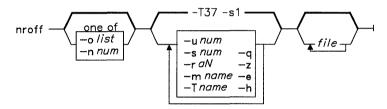

The signal system call in AIX Operating System Technical Reference.

nroff, troff

Purpose

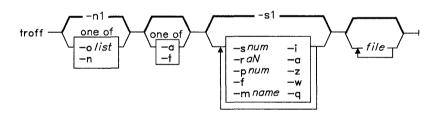

Formats text for printing devices.

Syntax

OL805204

troff --- -b ---

OL805368

Description

A complete list of nroff and troff requests, escape sequences and number registers begins on page 712. See Text Formatting Guide for a complete list of the naming conventions for the non-ASCII special characters and for information on writing text suitable for processing by troff or nroff.

nroff, troff

The **nroff** command reads *files* (standard input by default), formats the text in its input for printing, and writes to standard output. **nroff** formats text for line printers and other **printing devices**, excluding phototypesetters. An input file name of - (minus) indicates standard input.

troff

The **troff** command formats text in the input *files* (or standard input by default) for a phototypesetter, and writes its output to standard output. It is similar to the **nroff** command. An input file name of - (minus) indicates standard input.

nroff and troff Flags:

- -i Reads standard input after the input files.
- -mname Adds /usr/lib/tmac/tmac.name to the beginning of the list of input file names.
- -nnum Numbers the first printed page num. Do not use this flag with -olist.
- Prints only pages with page numbers appearing in *list* which consist of a comma-separated list of page numbers and ranges. A range of A-B means print pages A through B; an initial -A means print from the beginning to page A; and a final A- means print from page A to the end.

Note: When this flag is used in a pipeline (for example, with **cw**, **eqn**, or **tbl**) it may cause a broken pipe diagnostic if the last page in the document is not specified in *list*.

- -q Invokes the simultaneous input/output mode of the .rd request. nroff echoes the .rd prompt, but does not echo your input. When you enter two consecutive new-line characters, normal output is resumed.
- -raN Sets register a to N. a must have a one-character name. This is useful for automatic numbering of sections, paragraphs, lines, and so forth.
- -snum Stops every num pages (the default is 1). **nroff** or **troff** will halt every num pages to allow paper loading or changing and will resume upon receipt of a line-feed or new-line character. This flag does not work in pipelines. When **nroff** halts between pages, an ASCII BEL character is sent to the printing device.
- -z Suppresses the formatted output. Prints only messages generated by .tm (work station message) requests.

nroff Flags:

- -e Produces equally spaced words in adjusted lines, using the full resolution of the printing device.
- -h Uses tab characters during horizontal spacing. Tab settings are assumed to be every eight spaces.
- -Tname Prepares the output for the specified printing device. Known names are:
 - 37 TELETYPE Model 37 work station (default)
 - tn300 GE TermiNet 300 or any work station without half-line capability
 - 300s DASI 300s 300 DASI 300
 - 450 DASI 450
 - lp Any ASCII line printer
 - 382 DCT-382
 - 4000A Trendata 4000A
 - 832 Anderson Jacobson 832X any EBCDIC printer
 - 2631 Hewlett Packard 2631 line printer. Use a name of 2631-c to get compressed print. Use 2631-e to get expanded print.
- -u[num] Sets the number of character overstrikes for boldface to num or to zero if num is not specified.

troff Flags:

- -a Sends a printable ASCII approximation of the output to standard output.
- -b Reports whether the phototypesetter is busy or available. No text processing is done.
- -f Does not feed out paper and stop the phototypesetter at the end of the run.
- -pnum Prints all characters in the point size specified by num. Smaller point sizes may reduce the printing time.
- -t Directs output without modification to standard output instead of the phototypesetter.
- -w Waits until phototypesetter is available if it is currently busy.

nroff and troff Requests

Request Form	Function Font and Character Size Control
.ps $\pm N$	Change point size by N points. Also, for troff only, $\$ $\pm N$.
.ss N	Space-character size set to $N/36$ em (troff) only.
.cs FNM	Constant character space (width) mode (font F) (troff only).
.bd F N	Embolden font F by N units (troff only).
.bd SFN	Embolden Special Font when current font is F (troff only).
.ft F	Change to font F.
.fp NF	Mount font F on position N (1-4).

Request Form	Function Page Control
$.pl \pm N$	Change page length by N .
$\mathbf{.bp} \pm N$	Eject current page; next page number is N .
.pn N	Next page number is N .
.po $\pm N$	Page offset = N .
.ne N	Need N vertical space.
.mk R	Mark current vertical place in register R.
$\mathbf{.rt} \pm N$	Return (upward only) to marked vertical place.

Request Form	Function Text Filling, Adjusting, and Centering
.br	Break.
.fi	Fill subsequent output lines.
.nf	No filling or adjusting of output lines.
.ad [c]	Adjust output lines with mode c .
.na	Do not adjust output lines.
.ce N	Center the following N lines.

Request Form	Function Vertical Spacing
.vs N	Set vertical base-line spacing to N .
.ls N	Output N-1 base-line spaces after each text output line.
.sp N	Space vertical distance N in either direction.
.sv N	Save vertical distance N.
.os	Output saved vertical space.
.ns	Turn no-space mode on.
.rs	Restore spacing; turn no-space mode off.

Request Form	Function Line Length and Indenting
.li $\pm N$	Change line length by N .
$.$ in $\pm N$	Change indenting by N.
.ti $\pm N$	Change the indent on the next line by N.

Request Form	Function Macros, Strings, Diversion, and Position Traps
.de xx yy	Define or redefine macro xx; end at call of yy.
.am xx yy	Append to a macro.
.ds xx string	Define a string xx containing string.
.as xx string	Append string to string xx.
.rm xx	Remove request, macro, or string named xx.
.rn xx yy	Rename request, macro, or string xx to yy.
.di xx	Divert output to macro xx.
.da xx	Divert and append to xx.
.wh $N xx$	Set location trap; negative is with respect to the end of the page.
$.\mathbf{ch} xx N$	Change trap location.
$\mathbf{.dt} \ N \ xx$	Set a diversion trap.
.it N xx	Set an input line trap.
.em xx	End macro is xx.

Request Form	Function Number Registers
.nr $R \pm N M$	Define and set number register R ; auto-increment by M .
.af R c	Assign format to register R ($c=1$, i, I, a, A).
.rr R	Remove register R .

Request Form	Function Tabs, Leaders, and Fields
.ta Nt	Tab settings; left type, unless $t=R$ (right) or C (centered).
.tc c	Tab repetition character.
.1c c	Leader repetition character.
.fc a b	Set field delimiter a and pad character b .

Request Form	Function Input/Output Conventions and Character Translations
.ec c	Set escape character.
.eo	Turn off escape character mechanism.
.lg N	Ligature on if $N > 0$.
.ul N	Underline in nroff or italicize in troff the next N input lines.
.cu N	Continuous underline in nroff. Acts like .ul in troff.
.uf F	Underline font set to F (to be switched to by $.ul$).
.cc c	Set control character to c .
.c2 c	Set no-break control character to c.
.tr $abcd$	Translates a to b, and so on, on output.

Request Form	Function Hyphenation
.nh	No hyphenation.
.hy H	Hyphenate; $N = \text{mode}$.
.hc c	Hyphenation indicator character c .
.wc word	Exception words.

Request Form	Function Three Part Titles
.tl 'left'center'right'	Three part title.
.pc <i>c</i>	Page number character.
.lt $\pm N$	Length of title.

Request Form	Function Output Line Numbering
.nm $\pm N M S I$	Number mode on or off, set parameters.
.nm N	Do not number next N lines.

Request Form	Function Conditional Acceptance of Input
.if c.anything	If condition c is true, accept anything as input. For multiple lines, use $\{anything\}$.
.if !c anything	If condition c is false, accept anything as input.
.if N anything	If expression $N>0$, accept anything as input.
.if! N anything	If expression $N \le 0$, accept anything as input.
.if 'string1'string2' anything	If string1 is identical to string2, accept anything as input.
.if !'string1'string2.' anything	If string1 is not identical to string2, accept anything as input.
.ie c anything	If part of if-else; can take all forms of if above.
.el anything	Else part of if-else.

Request Form	Function Environment Switching
.ev N	Environment switched (push down).

Request Form	Function Insertions from Standard Input
.rd prompt	Read insertion.
.ex	Exit from nroff or troff .

Request Form	Function Input/Output File Switching	
.so file	Switch source file (push down).	
.nx file	Next file.	
.pi program	Pipe output to program (nroff only).	

Request Form	Function Miscellaneous
.mc c N	Set margin character c and separation N .
.tm string	Print string on standard error output.
.ig yy	Ignore until call of yy.
.pm t	Print macro names and sizes; if t is present, print only the total of sizes.
.fl	Flush output buffer.
.ab [text]	Prints text on standard error output and stops output. User abort is printed if no text is included.
! cmd parms	Runs the AIX command <i>cmd</i> and interpolates at that point. The standard input for <i>cmd</i> is closed.

Escape Sequences for Characters, Indicators, and Functions

Escape Sequence	Meaning
\\	Prevents or delays interpretation of \.
\e	Printable version of the current escape character.
٧٠.	Acute accent; equivalent to \((aa.
\'.	Grave accent; equivalent to \(ga.
\-	Minus sign in the current font.
١.	Dot.
\(space)	Unpaddable space-size character.
\0	Digit width space.
\I	1/6 em narrow space character (zero width in nroff).

Escape Sequence	Meaning
\^	1/12 em half-narrow space character (zero width in nroff).
\&	Non-printing, zero-width character.
\!	Transparent line indicator.
\\$ <i>N</i>	Interpolate argument $1 \le N \le 9$.
\%	Default optional hyphenation character.
\(xx	Character named xx.
*x, *(xx	Interpolate string x or xx .
∖a	Non-interpreted leader character.
\ b 'abc '	Bracket building function.
\ c	Interrupt text processing (continue word across input line break).
\d	Forward (down) 1/2 em vertical motion (1/2 line in nroff).
$\footnote{1}{\footnote{1}}\footnote{1}}\footnote{1}}\footnote{1}}\footnote{1}}\footnote{1}}\footnote{1}}}}}}}}}}}}}}}}}}}} }} \footnote{1}} \f$	Change to font N named x or xx , or font position N .
$\gx, \g(xx)$	Return the format of register x or xx . Return nothing if the register has not yet been referenced.
\h'N'	Local horizontal motion; move right N (negative left).
$\forall jx, \forall jxx$	Mark in register x or xx the current horizontal position on the output line.
\ k x	Mark horizontal input place in register x.
\1'N[c]'	Horizontal line drawing function.
$\backslash \mathbf{L'}N[c]'$	Vertical line drawing function.
$\n x, \(xx$	Interpolate number register x or xx .
\o'abc '	Overstrike characters a, b, c, \ldots
\ p	Break and spread output line.
\ r	Reverse 1 em vertical motion (reverse line in nroff).
\slash s N , \slash s $\pm N$	Point-size change function.
\t	Non-interpreted horizontal tab.
\u	Reverse (up) 1/2 em vertical motion (1/2 line in nroff).
\ v' N'	Local vertical motion; move down N (negative up).
\w'string'	Interpolate width of string.

Escape Sequence	Meaning
\ x' N'	Extra line-space function (negative before; positive after).
\ z c	Print c with zero width without spacing.
\{	Begin conditional input.
\}	End conditional input.
\(new line)	Concealed new line.
$\setminus X$	X, any character not listed above.

Predefined General Number Registers

Register Name	Description
%	Current page number.
ct	Character width type (set by width function).
dl	Maximum width of last completed diversion.
dn	Height (vertical size) of last completed diversion.
dw	Current day of the week (1=Sunday 7=Saturday).
dy	Current day of the month (1-31).
hp	Current horizontal place on the input line.
ln	Output line number.
mo	Current month (1-12).
nl	Vertical position of last printed text baseline.
sb	Depth of string below base line (generated by width function).
st	Height of string above base line (generated by width function).
yr	Last two digits of current year.

Predefined Read-Only Number Registers

Register Name	Meaning
\$	Number of arguments available at the current macro level.
.A	Set to 1 in troff if the -a flag is used; always 1 in nroff .
.F	The name of the current input file.
.Н	Available horizontal resolution in basic units.
.L	Contains the current line spacing parameter.
.Р	Contains the value 1 if the current page is being printed, 0 otherwise.
.R	The number of columns available.
т.	Set to 1 in nroff , it the -T flag is used; always 0 in troff .
.V	Available vertical resolution in basic units.
.a	Post-line extra line-space most recently utilized using \s'N'.
.b	Emboldening factor of the current font.
.c	Number of lines read from current input file, including .so files.
.d	Current vertical place in current diversion; equal to nl if no diversion.
.f	Current font as physical quadrant.
.h	Text base-line high-water mark on current page or diversion.
.i	Current indent.
·j	Current adjustment mode and type.
.k	Contains the horizontal size of the text portion of the current, partially-collected output line, if any, in the current environment.
.1	Current line length.
.n	Length of text portion on previous output line.
.0	Current page offset.
.p	Current page length.
.s	Current point size.
.t	Distance to the next trap.
.u	Equal to 1 in fill mode; equal to 0 in no-fill mode.

Register Name	Meaning
.v	Current vertical line spacing.
.w	Width of previous character.
·x	Reserved version-dependent register.
у	Reserved version-dependent register.
.z	Name of current diversion.

Files

/usr/lib/suftab	Suffix hyphenation tables.
/tmp/ta\$#	Temporary file.
/usr/lib/tmac/tmac.*	Standard macro files.
/usr/lib/macros/*	Standard macro files.
/usr/lib/font/*	Font width tables for troff.
/usr/lib/term/*	Work station driving tables for nroff .

Related Information

The following commands: "col" on page 179, "cw, checkcw" on page 275, "eqn, neqn, checkeq" on page 395, "mm, checkmm" on page 663, "mmt, checkmm" on page 666, "greek" on page 499, "tbl" on page 1053, and "tc" on page 1056.

The mm miscellaneous facility in AIX Operating System Technical Reference.

The discussion of nroff and troff in Text Formatting Guide.

number

Purpose

Displays the written form of a number.

Syntax

```
/usr/games/number —
```

OL805229

Description

The number game displays the written form of a number that it reads from standard input. The largest number it can translate accurately contains 66 digits.

The number game does not prompt you for a number. Once loaded, it simply waits for input. To exit the program, press INTERRUPT (Alt-Pause) or END OF FILE (Ctrl-D).

Example

To display the written form of several numbers:

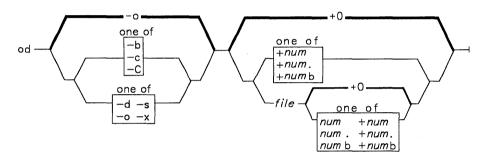

```
You: /usr/games/number
      eight hundred twenty nine.
System:
 You: 12345678
System: twelve million.
      three hundred forty five thousand.
      six hundred seventy eight.
 You: Ctrl-D
```

od

Purpose

Writes the contents of storage to the standard output.

Syntax

OL805205

OL805308

Description

The od command reads file (standard input by default), and it writes to standard output the information stored in file using the format specified by the first flag. If you do not specify the first flag, -o is the default.

When **od** reads standard input, num must be preceded by a + (plus sign).

Flags

- Displays bytes as octal values. -b
- Displays bytes as ASCII characters. The following nongraphic characters appear as C -c escape sequences:
 - \0 Null
 - Backspace **b**
 - Form feed
 - New-line character

¹ Do not put a blank between these items.

\r Return

\t Tab

\s1

\s2

\s3

\s4 Extended character shifts. (When Japanese Language Support is installed on your system, extended character shifts are not supported.)

Others appear as three-digit octal numbers.

-C Displays any extended characters as standard printable ASCII characters, using the appropriate character escape string.

Japanese Language Support Information

- -C Displays any SJIS characters in hexadecimal form.
- -d Displays 16-bit words as unsigned decimal values.
- -o Displays 16-bit words as octal values.
- -s Displays 16-bit words as signed decimal values.
- -x Displays 16-bit words as hexadecimal values.

The num parameter specifies the point in the file where the storage output starts. The num parameter is interpreted as octal bytes. If a . (dot) is added to num, it is interpreted in decimal. If b is added to num, it is interpreted in blocks of 512 bytes.

The storage output continues until the end of the file.

Examples

1. To display a file in octal a page at a time:

This displays a.out in octal (base 8) word format a page at a time.

2. To translate a file into several formats at once:

This writes a .out in hexadecimal (base 16) format (-x) into the file a .xcd, giving also the ASCII character equivalent, if any, of each byte (-c).

3. To start in the middle of a file:

od -bcx a.out +100.

This displays a.out in octal-byte, character, and hexadecimal formats, starting from the 100th byte. The . (dot) after the offset makes it a decimal number. Without the dot, the dump would start from the 64th (100 octal) byte.

Related Information

The following commands: "sdb" on page 875 and "pg" on page 744.

"Overview of International Character Support" in Managing the AIX Operating System.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

on

Purpose

Executes a command remotely when NFS is installed on your system.

Syntax

OL805490

Description

The **on** program executes commands on another system. All environment variables are passed. The current working directory is preserved if the working file is mounted on the host or exported to it. Relative path names work only if they are within the current file system. Because commands are issued at one machine and executed on another, absolute path names can cause problems.

The **on** command's standard input passes as standard input to the remote program, unless you use the **-n** flag. The **on** command's files receive standard output and standard error from the remote command.

Note: The on command cannot be used to execute commands requiring superuser authority.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Displays status messages as work progresses.
- -i Uses remote echoing and special character processing. This flag should be used when remotely executing interactive programs, such as vi. Terminal modes are active when this flag is used.

-n Does not pass standard input to the remote standard input. This causes the remote program to get an end-of-file message when it reads standard input. The on -n program is used to run commands in the background with job control.

File

/etc/exports

Related Information

The following command, "rexd" on page 832.

open

Purpose

Opens a virtual terminal.

Syntax

open —
$$cmd$$
 — arg —

OL805337

Description

The **open** command opens a virtual terminal and runs the specified *file* on that terminal. If *file* does not reside in one of the directories specified in the shell **PATH** variable, you must give a full path name. Any arguments that follow *file* on the command line are passed to *file*. To move from one virtual terminal to another, press Next Window (Alt-Action). To close a virtual terminal, press **END OF FILE** (Ctrl-D) or end the application that is running on it.

Notes:

1. Be sure to use **Alt-Action** to check for open virtual terminals and **Ctrl-D** to close them before you log off.

2. You can run the **actman** command before opening any virtual terminals to help you keep track of virtual terminals so you can close all of them before you log off.

3. If you are in a trusted shell and issue the command **opensh**, then the new virtual terminal is opened, but not activated. You must use **Alt-Action** to activate the new virtual terminal.

Usability Services Commands

The following additional commands are available to you from within the Usability Services Activity Manager (/usr/bin/actmngr):

hide Removes an activity window from the window ring.

activate Activates an activity window.

cancel Cancels an activity window.

For details about using these commands, see *Usability Services Reference* or *Usability Services Guide*.

Example

To run another shell on a new virtual terminal:

open sh

To move back and forth between this new virtual terminal and any others that you have opened, press Next Window (Alt-Action). To close this terminal and log off the new shell, press END OF FILE (Ctrl-D).

Related Information

The following command: "actman" on page 32.

"Using Display Station Features" in Using the AIX Operating System.

pack

Purpose

Compresses files.

Syntax

OL805061

Description

pack

The **pack** command stores the specified *file* in a compressed form. The input file is replaced by a packed file with a name derived from the original file name (*file.z*), with the same access modes, access and modification dates, and owner as the original file. Directories cannot be compressed.

The input file name can contain no more than 12 bytes to allow space for the added z extension.

If pack cannot create a smaller file, it stops processing and reports that it is unable to save space. (A failure to save space, generally happens with small files or files with uniform character distribution.) The amount of space saved depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each .z file, you will generally not be able to save space with files smaller than three blocks. Typically, text files are reduced 25 to 40 percent.

The exit value of the **pack** command is the number of files that it could not pack. Packing is not done under any one of the following conditions:

- The file is already packed.
- The input file name has more than 12 bytes.
- The file has links.
- The file is a directory.
- The file cannot be opened.

- No storage blocks are saved by packing.
- A file called *file*.z already exists.
- The **.z** file cannot be created.
- An I/O error occurs during processing.

Note: Both pcat and unpack operate only on files ending in .z. As a result, when you specify a file name that does not end in .z. pcat and unpack add the suffix and search the directory for a file name with that suffix.

pcat

The pcat command reads the specified files, unpacks them, and writes them to standard output. (Japanese Language Support does not support the pcat command.)

unpack

The unpack is the reverse of the pack command. It reads the input files, expands them, and writes them to their original file name-that is, the name without the z suffix.

The exit value of pcat is the number of files it was unable to unpack. A file cannot be unpacked if any one of the following occurs:

- The file name (exclusive of the .z) has more than 12 bytes.
- The file cannot be opened.
- The file is not a packed file.

The unpack command expands files created by pack. For each file specified, unpack searches for a file called file.z. If this file is a packed file, unpack replaces it by its expanded version. The unpack command names the new file name by removing the .z suffix from file. The new file has the same access modes, access and modification dates, and owner as the original packed file.

The exit value is the number of files the **unpack** command was unable to unpack. A file cannot be unpacked if any one of the following occurs:

- The file cannot be opened.
- The file is not a packed file.
- A file with the unpacked file name already exists.
- The unpacked file cannot be created.

Note: The unpack command writes a warning to standard output if the file it is unpacking has links. The new unpacked file has a different i-node than the packed file from which it was created. However, any other files linked to the packed file's original i-node still exist and are still packed.

Flag

- Displays statistics about the input *files*. The statistics are calculated from a Huffman minimum redundancy code tree built on a byte-by-byte basis. Repeating - (minus) on the command line toggles this function.

Examples

1. To compress files:

```
pack chap1 chap2
```

This compresses chap1 and chap2, replacing them with files named chap1.z and chap2.z. pack displays the percent decrease in size for each file.

2. To display statistics about the amount of compression done:

```
pack - chap1 - chap2
```

This compresses chap1 and chap2 and displays statistics about chap1, but not about chap2. The first - (minus) turns on the statistic display, and the second turns it off.

3. To display compressed files:

```
pcat chap1.z chap2 | pg
```

This displays the compressed files Chap1.z and Chap2.z on the screen in expanded form, a page at a time (I pg). Note that **pcat** added the .z to the end of Chap2, even though we did not enter it.

4. To use a compressed file without expanding the copy stored on disk:

```
pcat chap1.z ! grep 'Greece'
```

This pipes the contents of chapl.z in its expanded form to the **grep** command. See page 914 for a discussion of piping.

5. To expand compressed files:

```
unpack chap1.z chap2
```

This expands the compressed files chap1.z and chap2.z, replacing them with files named chap1 and chap2. Note that you can give unpack file names either with or without the .z suffix.

Related Information

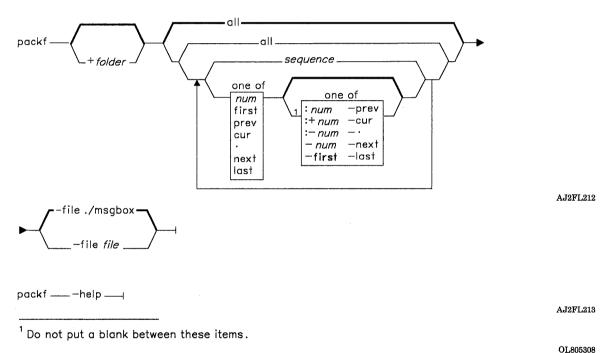

The following command: "cat" on page 137.

packf

Purpose

Compresses the contents of a folder into a file.

Syntax

Description

The packf command is used to move messages from a folder and compress those messages into a single file. You can unpack packed messages by using the inc command. packf is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

packf

The **packf** command takes the specified messages from the specified folder and appends them to the specified file. If the file does not exist, **packf** displays a prompt that asks if you want to create the file. If you want to create the file, **packf** creates the file and places the messages in the file. **packf** separates each message with four **Ctrl-A** characters and a **New line** character.

Flags

-file file

Places the messages at the end of the specified file. If *file* does not exist, **packf** asks you if you want to create the file. If you want to create the file, **packf** creates *file*. The default file is ./msgbox.

+folder msgs

Specifies the messages that you want to pack. msgs can be several messages, a range of messages, or a single message. You can use the following message references when specifying msgs:

numfirstprevcur.nextlastallsequence

The default is all of the messages in the current folder. If several messages are specified, the first message packed becomes the current message.

-help

Displays help information for the command.

Profile Entries

Current-Folder:

Sets your default current folder.

Msg-Protect:

Sets the protection level for your new message files.

Path:

Specifies your user_mh_directory.

Files

\$HOME/.mh_profile

The MH user profile.

Related Information

The MH command "inc" on page 518.

The mh-profile file in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

passwd

Purpose

Changes login password.

Syntax

passwd --- user ----

OT-805206

Description

The passwd command establishes or changes the password for your login user name. When you enter this command, you get a prompt for the old password if one exists, and two successive prompts for the new password. You must enter the same password twice for it to take effect. Passwords can be up to eight ASCII characters long. Only the password owner or the superuser can change a password. To change a password, the owner must know the old password. Passwords are subject to restrictions established by the person who administers the system.

Note: The password files must be on the same node.

Files

/etc/passwd /etc/opasswd /etc/security/passwd /etc/security/opasswd /etc/security/config

Password file: contains user IDs. Previous version of the password file. Password field; contains encrypted passwords. Previous version of the security password file. Defines password restrictions.

Related Information

The following commands: "login" on page 584 and "users, adduser" on page 1129.

The getpwent subroutine and the passwd file in AIX Operating System Technical Reference.

The discussion of password security in Managing the AIX Operating System.

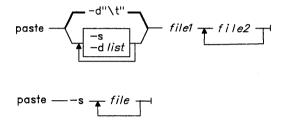

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

paste

Purpose

Merges the lines of several files or subsequent lines in one file.

Syntax

OL805366

OL805207

Description

The **paste** command reads input *files* (standard input if you specify a - as a file name), concatenates the corresponding lines of the given input files, and writes the resulting lines to standard output. Output lines are restricted to 511 characters.

Without a flag, or with the **-d** flag, **paste** treats each file as a column and joins them horizontally with a tab character by default (parallel merging). You can think of **paste** as the counterpart of the **cat** command (see page 137), which concatenates files vertically, that is, one file after another.

With the -s flag, paste combines subsequent lines of an input file (serial merging). These lines are joined with the tab character by default.

Note: The action of **pr -t -m** is similar to that of **paste**, but creates extra blanks, tabs and lines for a nice page layout.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

-dlist Changes the delimiter that separates corresponding lines in the output with one or more characters in list (the default is a tab). If more than one character is in list, then they are repeated in order until the end of the output. In parallel merging, the lines from the last file always end with a new-line character, instead of one from list.

The following special characters can also be used in *list*:

New-line character \n Tab \t // Backslash

\0 Empty string (not a null character).

An extended character.

You must quote characters that have special meaning to the shell.

Merges subsequent lines from the first file horizontally. With this flag, paste -s works through one entire file before starting on the next. When it finishes merging the lines in one file, it forces a new line and then merges the lines in the next input file, continuing in the same way through the remaining input files, one at a time. A tab separates the lines unless you use the -d flag. Regardless of the list, the last character of the file is forced to be a new-line character.

Examples

1. To paste several columns of data together:

paste names places dates > npd

This creates a file named npd that contains the data from names in one column, places in another, and dates in a third. If names, places, and dates look like:

names	places	dates
rachel	New York	February 5
jerry	Austin	March 13
mark	Chicago	June 21
marsha	Boca Raton	July 16
scott	Seattle	November 4

then npd contains:

rachel New York February 5
jerry Austin March 13
mark Chicago June 21
marsha Boca Raton July 16
scott Seattle November 4

A tab character separates the name, place, and date on each line. As in this example, the columns do not always line up because the tab stops are set at every eighth column.

2. To separate the columns with a character other than a tab:

```
paste -d"!0" names places dates > npd
```

This alternates ! and 0 as the column separators. If names, places, and dates are the same as in Example 1, then npd contains:

```
rachel!New York@February 5
jerry!Austin@March 13
mark!Chicago@June 21
marsha!Boca Raton@July 16
scott!Seattle@November 4
```

3. To display the standard input in multiple columns:

```
ls | paste - - - -
```

This lists the current directory in four columns. Each - tells **paste** to create a column containing data read from the standard input. The first line is put in the first column, the second line in the second column, . . . , the fifth line in the first column, and so on.

This is equivalent to:

```
ls | paste -d'' \cdot t \cdot t \cdot n'' - s -
```

which fills the columns across the page with subsequent lines from the standard input. The $-d'' \t \t \n''$ defines the character to insert after each column: a tab character (\t) after the first three columns, and a new-line character (\n) after the fourth. Without the -d flag, paste -s - would display all of the input as one line with a tab between each column.

Related Information

The following commands: "grep" on page 501, "cut" on page 269, and "pr" on page 761. "Overview of International Character Support" in Managing the AIX Operating System.

pcnfs

Purpose

Serves PC-NFS client requests.

Syntax

OL805499

Description

The pcnfsd daemon handles PC-NFS client requests for services, such as authentication and print spooling, on remote machines. PC-NFS is a program that allows machines running the Personal Computer Disk Operating System (PC-DOS) to be networked with machines running NFS. See Managing the AIX Operating System for information on PC-NFS.

The pcnfsd daemon starts when the inetd server starts if the appropriate entry is placed in the **inetd.conf** file. Print spooling requests are then sent to the default print default print spooling directory, which is usually requests is If you plan to use a directory other than the default print spooling directory (/usr/tmp), you cannot start penfsd from inetd.conf. Instead, you must specify the directory (using the -2 flag) and start pcnfsd from the command line.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-s spooldir Specifies the name of the directory designated to receive print spooling requests for PC-NFS clients. When this flag is used, the pcnfsd command must be issued from the command line. If the spooldir name is not specified, the default print spooling directory is used.

penfsd

File

/etc/inetd.conf TCP/IP configuration file.

Related Information

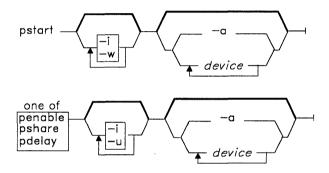

The section on configuring penfsd in Managing the AIX Operating System.

pdisable, phold

Purpose

Disables or reports the availability of login ports.

Syntax

OL805208

Description

The pdisable and phold commands each disable a set of login ports. No one can log in on a disabled port. The system disables a port by updating an entry in the /etc/portstatus file and then sending a signal to init. When init receives the signal and reads the updated status entry, it takes the appropriate action.

Use the device parameter to specify the ports to be enabled. Permitted values for device include:

- A full device name, such as /dev/tty1.
- A simple device name, such as tty1.
- A general class of devices in the form attribute = value, which is equivalent to naming each port with a stanza in /etc/ports that includes the specified attribute).

If you do not specify a device to disable, each command report the names of currently disabled ports in its set.

pdisable

The **pdisable** command disables the specified port. Even if a user is logged in at that port, subsequent log in is not permitted. To disable the port, the system ends **logger**. If you do not specify any arguments, **pdisable** reports the names of all disabled ports.

phold

The **phold** command allows logged-in users to continue, but does not allow any more users to log in. If you do not specify any arguments, **phold** reports the names of all ports on hold.

Flags

- -a With **pdisable**, disables all ports that are currently enabled in the /etc/portstatus file. With **phold**, holds all ports that are currently enabled in the /etc/portstatus file.
- -i Reinitializes an existing /etc/portstatus file instead of updating the existing one. You typically use this flag in the /etc/rc command file to re-establish default port enabling before starting up the system with multiple users.
- -w Makes the command return immediately rather than wait for init to confirm the changes in port status.

Examples

1. To display the names of all ports currently disabled:

```
pdisable
```

2. To disable all ports that are enabled in /etc/portstatus, even if users are logged in:

```
pdisable -a
```

3. To disable the work station attached to the /dev/tty8 port:

```
pdisable tty8
```

4. To disable the work station attached to the /dev/tty2 and make the command return immediately rather than wait for init to confirm port status:

```
pdisable -w /dev/tty2
```

5. To list the ports that are currently on hold:

```
phold
```

6. To put all 9600 baud ports on hold:

```
phold speed=9600
```

Files

/etc/locks

Contains lock files for pshare and pdelay.

/etc/ports

Contains descriptions of known normal, shared, and delayed login

/etc/portstatus

Contains current status of each known login port.

Related Information

The ports and portstatus files in AIX Operating System Technical Reference.

pg

Purpose

Formats files to the work station.

Syntax

OL805245

Description

The **pg** command reads *files* and writes them to standard output one screen at a time. If you specify *file* as - (minus) or run **pg** without arguments, **pg** reads standard input. Each screen is followed by a prompt. If you press the **Enter** key, another page is displayed. The **pg** command lets you back up to review something that has already passed.

To determine work station attributes, **pg** scans the file **terminfo** for the work station type specified by the environment variable **TERM**. The default type is **dumb**. See AIX Operating System Technical Reference for information on **terminfo**.

Subcommands

When **pg** pauses and issues its prompt, you can issue a subcommand. Some of these subcommands change the display to a particular place in the file, some search for specific patterns in the text, and others change the environment in which **pg** works.

The following commands display a selected place in the file:

page	Displays the specified page.
+num	Displays the page num pages after the current page.
-num	Displays the page num pages before the current page.
1	Scrolls the display one line forward.

Displays a screen with the specified line *num*ber at the top. numl

+num1Scrolls the display num lines forward. Scrolls the display num lines backward. -numl

Scrolls half a screen forward. Pressing Ctrl-D also does this. d -d Scrolls half a screen backward. Pressing -Ctrl-D also does this.

Ctrl-L Displays the current page again. A single period also does this.

Displays the last page in the file. Do not use this when the input is from a pipeline.

The following commands search for text patterns in the text. You can use the patterns described in "ed" on page 371. They must always end with a new-line character, even if the -n flag is used. In an expression such as [a-z], the minus means "through" according to the current collating sequence. A collating sequence may define equivalence classes for use in character ranges. See "Overview of International Character Support" in Managing the AIX Operating System for more information on collating sequences and equivalence classes.

Search for the *num*th occurrence of *pattern*. The search begins [num]/pattern/ immediately after the current page and continues to the end of the current file, without wraparound. The default for num is 1.

num?pattern? num^pattern^

Search backward for the *num*th occurrence of *pattern*. The searching begins immediately before the current page and continues to the beginning of the current file, without wraparound. The ^ (circumflex) is useful for the Adds 100 work station, which cannot handle the?. The default for *num* is 1.

After searching, pg normally displays the line found at the top of the screen. You can change this by adding m or b to the search command to leave the line found in the middle or at the bottom of the window with all succeeding subcommands. Use the suffix t to return to displaying the line with the pattern to the top of the screen.

You can change the **pg** environment with the following subcommands:

 $[num]\mathbf{n}$ Begins examining the *num*th next file in the command line. The default

num is 1.

 $[num]\mathbf{p}$ Begins examining the *num*th previous file on the command line. The

default *num* is 1.

 $[num]\mathbf{w}$ Displays another window of text. If num is present, sets the window size

to num.

s file Saves the input in file. Only the current file being examined is saved.

This command must always end with a new-line character, even if you

specify the -n flag.

h Displays an abbreviated summary of available subcommands.

q or Q Quits pg.

!AIX-cmd Sends the specified AIX command to the shell named in the SHELL

environment variable. If this is not available, the default shell is used. This command must always end with a new-line character, even if the -n

flag is used.

At any time when output is being sent to the work station, you can press QUIT WITH DUMP (Ctrl-V) or INTERRUPT (Alt-Pause). This causes pg to stop sending output and displays the prompt. Then you can enter one of the preceding commands in the normal manner.

Note: Some output is lost when when you press QUIT WITH DUMP (Ctrl-V) or INTERRUPT (Alt-Pause) because any characters waiting in the output queue are purged when the dQUIT signal is received.

If standard output is not a work station, pg acts like the cat command, except that a header is displayed before each file.

While waiting for work station input, **pg** stops running when you press INTERRUPT (Alt-Pause). Between prompts these signals interrupt the current task and place you in the prompt mode.

Note: If work station tabs are not set every eight positions, unpredictable results can occur.

Flags

-c	Moves the cursor to the home position and clears the screen before each
	page. This flag is ignored if clear_screen is not defined for your work
	station type in the terminfo file.

-e Does not pause at the end of each file.

-f Does not split lines. Normally, pg splits lines longer than the screen width.

-n Stops processing when a **pg** command letter is entered. Normally, commands must end with a new-line character.

-p string Uses string as the prompt. If the string contains a %d, the %d is replaced by the current page number in the prompt. The default prompt is: (colon). If string contains spaces, you must quote it.

Highlights all messages and prompts.

+ linenum Starts at linenum.

-num Specifies the number of lines in the window. On work stations that contain 24 lines, the default is 23.

+/pattern/ Starts at the first line that contains pattern.

-S

Files

/usr/lib/terminfo/* /tmp/pg*

The following commands: "ed" on page 371 and "grep" on page 501.

The terminfo file in AIX Operating System Technical Reference.

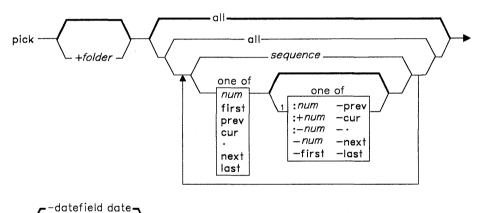

"Overview of International Character Support" in Managing the AIX Operating System.

pick

Purpose

Selects messages by content, and creates and modifies sequences.

Syntax

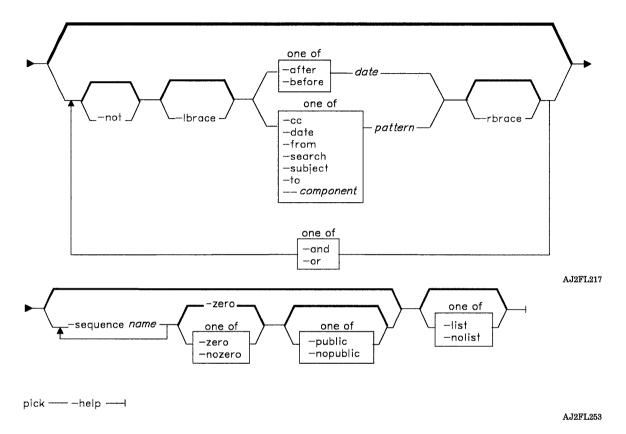

-datefield date

AJ2FL161

AJ2FL216

OL805308

¹ Do not put a blank between these items.

Description

The **pick** command is used to select messages and put them into sequences. The **pick** command is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The **pick** command allows you to select messages that contain particular character patterns or that have particular dates. You can use the **-and**, **-or**, **-not**, **-lbrace**, and **-rbrace** flags to construct compound conditions for selecting messages.

Flags

-after date

Selects messages with dates later than the specified date. You can use the following date specifications for *date*:

yesterday	today	tomorrov
sunday	monday	tuesday
wednesday	thursday	friday
saturday	-dd	sysdate

The **pick** command treats the days of the week as days in the past. For example, **monday** means last Monday, not today or next Monday. You can use the -dd argument to specify a number of days in the past. For example, -31 means 31 days ago. For sysdate you can specify any valid format defined for your system. See "date" on page 281 for more information about date formats.

-and

Forms a logical AND operation between two message selecting flags (for example, pick -after Sunday -and -from mark). -and has precedence over -or, but -not has precedence over -and. Use the -lbrace and -rbrace flags to override this precedence.

-before date

Selects messages with dates earlier than the specified date. See the -after flag for how to specify date.

-cc pattern

Selects messages that contain the character string pattern in the

Cc: field.

-date pattern

Selects messages that contain the character string pattern in the **Date**: field.

-datefield field

Specifies which dated field is parsed when the -after and -before flags are given. By default, pick uses the Date: field.

+folder msgs

Specifies the messages that you want to search. *msgs* can be several messages, a range of messages, or a single message. You can use the following message references when specifying *msgs*:

num	first	prev
cur	•	next
last	all	sequence

The default for msgs is all. The default folder is the current folder. If you specify a folder, that folder becomes the current folder.

-from *pattern*

Selects messages that contain the character string pattern in the **From:** field.

-help

Displays help information for the command.

-lbrace Groups -and. -or, and -not operations. Operations between the -lbrace and -rbrace flags are evaluated as one operation. You can nest the **-lbrace** and **-rbrace** flags. -list Sends a list of selected message numbers to standard output. This allows you to use the **pick** command to generate message numbers to use as input for other commands. For example, scan 'pick -after tuesday -list' scans all messages in the current folder that were sent after last Tuesday. -list is the default if no sequence is specified. -nolist Keeps the **pick** command from generating a list of the selected message numbers (see the -list flag). If a sequence is specified. **-nolist** is the default. -nopublic Restricts the specified sequence to your usage. -nopublic does not restrict the messages in the sequence, only the sequence. This option is the default if the folder is write-protected from other users. -not Forms a logical NOT operation on a message selecting flag (for example, pick -not -from george). This construction evaluates to all messages not chosen by the message selecting flag. -not has precedence over -and, and -and has precedence over -or. Use the **-lbrace** and **-rbrace** flags to override this precedence. Appends the selected messages to the specified sequence (see the -nozero -zero flag). Forms a logical OR operation on two message-selecting flags (for -or example, pick -from amy -or -from mark). -not has precedence over -and, and -and has precedence over -or. Use the **-lbrace** and **-rbrace** flags to override this precedence. -public Makes the specified sequence available to other users. -public does not make protected messages available, only the sequence. This option is the default if the folder is not write-protected from other users. -rbrace Groups -and, -or, and -not operations. Operations between the -lbrace and -rbrace flags are evaluated as one operation. You can nest the -lbrace and -rbrace flags. -search pattern Selects messages that contain the character string pattern anywhere in the message. Stores the messages selected by the pick command in the sequence -sequence name Selects messages that contain the character string pattern in the -to pattern To: field.

pick

-zero

Clears the specified sequence before placing the selected messages into the sequence. This flag is the default (see the **-nozero** flag).

--component pattern

Selects messages that contain the character string pattern in the heading field component (for example, pick --reply-to amy).

Profile Entries

Current-Folder: Path:

Sets your default current folder.

Specifies your user_mh_directory.

Files

\$HOME/.mh_profile

The MH user profile.

Related Information

The MH command "mark" on page 637.

The mh-profile file in AIX Operating System Technical Reference.

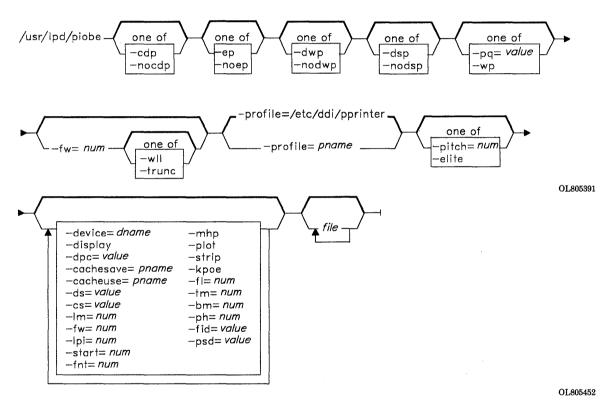

"Overview of the Message Handling Package" in Managing the AIX Operating System.

piobe

Purpose

Writes a file to standard output in a format suitable for sending to a line printer.

Syntax

Description

The **piobe** command writes *file* to its standard output in a form that is suitable for a line printer. If you do not specify a *file*, **piobe** reads standard input. **piobe** is normally called by the **qdaemon** command after you have enqueued a file with the **print** command (see "**print**" on page 767). The **qdaemon** directs the output from **piobe** to the appropriate device.

Flags

You can specify the following flags on the **print** command line or in the /etc/qconfig file (see AIX Operating System Technical Reference).

-bm = num Sets the bottom margin to num lines from the top of the page.

-cachesave = pname Specifies the path name of the file where the font Personal

PagePrinter adapter is to be saved after the input data stream

prints.

cacheuse = pname Specifies the path nname of the font cache file loaded in the

IBM Personal PagePrinter adapter before the input data stream

is printed.

-cdp

-nocdp Turns the condensed printing mode on (-cdp) or off (-nocdp).

-cs = value Uses PC code set 1 or 2.

-device = dname Specifies the name of a printer stanza in the printer

configuration file (see "Files" on page 756).

-display Specifies that the input data stream has KSR code page

controls.

-dpc = value Prints in the specified color. Valid color values are red, blue,

yellow, and black.

-ds = value Specifies how the input data stream is to be printed on the IBM

4216 Personal PagePrinter. Valid values are the following:

ps ps

ppxl Proprinter XL emulation any This is the default.

ps is assumed if the first character of the data stream is %.

Otherwise, Proprinter XL emulation is assumed.

-dsp

-nodsp Turns the double strike mode on (**-dsp**) or off (**-nodsp**).

-dwp

-nodwp Turns the double wide printing mode on (-dwp) or off (-nodwp).

-elite Sets the character pitch to 12, the same as specifying

-pitch = 12.

-ep

-noep Turns the emphasized printing mode on (-ep) or off (-noep).

-fid = value Specifies the font identifier for an IBM 5202 Quietwriter® III

Printer font. Valid values for embedded fonts are 11 (Courier

10), 85 (Courier 12), 254 (Courier 17), and 159 (Boldface).

Values for fonts in the pluggable cartridges precede the font name on the cartridge label. -fl = numSets the form length to *num*. Allows font change. Valid values for num are 1 through 8. -fnt = num $-\mathbf{fw} = num$ Sets the right margin at num characters from the left edge of the carriage. Forgives keving mistakes and ignores invalid flags. If you -kpoe specify this flag, piobe processes the job and sends you no message. If you do not specify this flag, piobe does not forgive invalid flags and does not print the job. In this case, it sends you a message detailing the error. -lm = numSets the left margin at num characters from the left edge of the carriage. -lpi = numSets the number of lines per inch to num. Valid settings are 6 and 8. Allows the horizontal position on the print line to be -mhp maintained for line feed and vertical tab controls, if desired. $-\mathbf{ph} = num$ Allows you to use single-sheet paper in the Quietwriter printer. The printer stops at the end of each page, beeps three times, and waits for you to push the start button. num can have the following values: Manual operation. Sheetfeed operation. 1 2 Continuous operation. -pitch = numSets the character pitch to num. -plot Specifies that the input data is to be passed through without modification. This allows arbitrary files to be printed on arbitrary printers. -=valueSpecifies the printer name. Messages that report a printer is out of paper or needs attention include the name of the printer. The default name of the printer is specified in the /etc/qconfig -pq = valuePrints in specified print quality. Valid quality values are dp, text. and letter. -profile = pname Specifies the name of a printer configuration file. The default name is /etc/ddi/pprinter.

piobe

-psd = value Specifies a paper source drawer for the optional IBM 5202

Quietwriter III Printer two-drawer sheetfeeder. Valid values

are 1 (top drawer), 2 (bottom drawer), and 3 (envelopes).

-start = num Sets the starting page number to num.

-strip Strips all multibyte controls from the data stream. This flag is

useful in filter mode in order to send data that has imbedded

printer controls to a nonprinter device.

-tm = num Sets the top margin to num lines.

-trunc Specifies that lines exceeding the value set by -fw should be

truncated.

-wll Specifies that lines exceeding the value set with the -fw flag

should overflow to the next line. This is the reverse of the

-trunc flag.

-wp Selects word processing mode, the same as specifying

-pq = letter.

Files

/etc/ddi/pprinter /etc/ddi/sprinter Parallel configuration information. Serial configuration information.

The following commands: "print" on page 767 and "qdaemon" on page 802.

The qconfig file in AIX Operating System Technical Reference.

portmap

Purpose

Maps RPC programs to the servicing ports on RPC servers

Syntax

portmap ——

A5AC5022

Description

The portmap program, also known as the portmapper, maps RPC program number to the port numbers on RPC servers in order for NFS clients to make RPC service calls. When an RPC server starts, it contacts the portmap program to register the RPC programs it is prepared to serve and the port on which it is listening for calls. When NFS clients call an RPC procedure for a given program number, the clients contact the portmap program to determine the port number to which they should send the packets.

The portmap program is usually started from an entry in the **inetd.conf** file.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

/etc/portmap /etc/rc.tcpip

Related Information

The following command: "rpcinfo" on page 845.

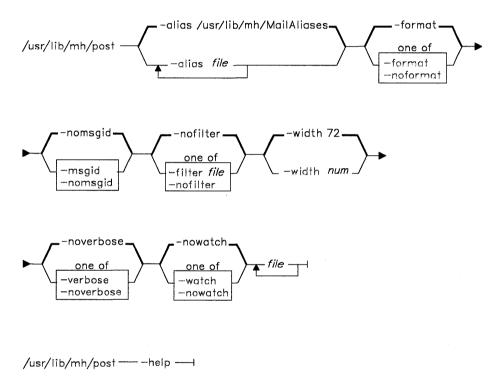

The section on NFS in Managing the AIX Operating System.

post

Purpose

Delivers a message.

Syntax

AJ2FL233

Description

The **post** command is used to route messages to the proper destinations. **post** is not designed to be run directly by the user; it is designed to be called by other programs. The **post** command is part of the MH (Message Handling) package.

The **post** command searches all components of a message that specify a recipient's address and parses each address to check for proper format. **post** puts proper addresses in the

standard format and calls the sendmail command. post also performs header operations, such as appending the Date: and From: components and processing the Bcc: component.

The post command may report errors when parsing complex addresses (for example, @A:harold@B.UUCP). If the sendmail program is installed on your system and you use complex addresses, use the spost command instead of the post command.

Flags

-alias file	Searches the specified mail alias file for addresses. You can use this flag repetitively to specify multiple mail alias files. post automatically searches the file /usr/lib/mh/MailAliases.
-filter file	Uses the header components in the specified file for copies of the message sent to Bcc : recipients.
-format	Puts all recipient addresses in a standard format for the delivery transport system. This flag is the default.
-help	Displays help information for the command.
-msgid	Adds a message-identification component (such as Message-ID :) to the message.
-nofilter	Strips the Bcc : header from the message for the To : and cc : recipients. Sends the message with minimal headers to the Bcc : recipients. This flag is the default.
-noformat	Does not alter the format of the recipient addresses.
-nomsgid	Does not add a message-identification component to the message. This flag is the default.
-noverbose	Does not display information during the delivery of the message to the sendmail command. This flag is the default.
-nowatch	Does not display information during delivery by the sendmail command. This flag is the default.
-verbose	Displays information during the delivery of the message to the sendmail command. This information allows you to monitor the steps involved.
-watch	Displays information during the delivery of the message by the sendmail command. This information allows you to monitor the steps involved.
-width num	Sets the width of components that contain addresses. The default is 72 columns.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

pr

Purpose

Writes a file to standard output.

Syntax

¹ Do not put a blank between these items.

OL805437

Description

The **pr** command writes *file* to the standard output. If you do not specify *file* or if *file* is a (minus), **pr** reads standard input. A heading that contains the page number, date, time, and the name of the file separates the output into pages.

Unless specified, columns are of equal width and separated by at least one space. Lines that are too long for the page width are cut off. If the standard output is a work station, **pr** does not display any error messages until it has ended.

Flags

- -a Displays multicolumn output across the page.
- -d Double-spaces the output.

761

-e[char][num]	Expands tabs to character positions $num+1$, $2*num+1$, $3*num+1$, and so on. The default value of num is 8. Tab characters in the input expand to the appropriate number of spaces to line up with the next tab setting. If you specify $char$ (any character other than a digit) that character becomes the input tab character. The default value of $char$ is the ASCII TAB character.
-f	Uses a form feed character to advance to a new page. (Otherwise pr issues a sequence of line feed characters.) Pauses before beginning the first page if the standard output is a work station.
-h "string"	Displays <i>string</i> as the page header instead of the file name. The flag and string should be separated by a blank.
-i[char][num]	In the <i>output</i> , replaces white space wherever possible by inserting tabs to character positions $num+1$, $2*num+1$, $3*num+1$, and so on. The default value of num is 8. If you specify $char$ (any character other than a digit), that character becomes the output tab character. (The default value of $char$ is the ASCII TAB character).
-lnum	Sets the length of a page to num lines (the default is 66).
-m	Combines and writes all files at the same time, with each file in a separate column. (This overrides the -num and -a flags).
-n[char][num]	Provides num -digit line numbering (the default value of num is 5). The number occupies the first $num+1$ character positions of each column of normal output or each line of -m output. If you specify $char$ (any character other than a digit), that character is added to the line number to separate it from whatever follows (the default value of $char$ is an ASCII TAB character).
-onum	Indents each line by <i>num</i> character positions (the default is 0). The number of character positions per line is the sum of the width and offset.
- p	Pauses before beginning each page if the output is directed to a work station. (pr sounds the alarm at the work station and waits for you to press the Enter key.)
-r ·	Does not display diagnostic messages if the system cannot open files.
-schar	Separates columns by the single character <i>char</i> instead of by the appropriate number of spaces (the default for <i>char</i> is an ASCII TAB character).
-t	Does not display the five-line identifying header and the five-line footer. Stops after the last line of each file without spacing to the end of the page.
-wnum	Sets the width of a line to <i>num</i> character positions (the default value is 72 for equal-width multicolumn output, no limit otherwise).

-num

Produce num-column output (the default is 1). The -e and -i flags are assumed for multicolumn output.

+num

Begin the display with page num (the default value is 1).

Examples

1. To print a file with headings and page numbers on the printer:

This adds page headings to proq. c and sends it to the **print** command. The heading consists of the date the file was last modified, the file name, and the page number.

2. To specify a title:

```
pr -h "MAIN PROGRAM" prog.c | print
```

This prints proq. C with the title MAIN PROGRAM in place of the file name. The modification date and page number are still printed.

3. To print a file in multiple columns:

```
pr -3 word.lst | print
```

This prints the file word. 1st in three vertical columns.

4. To print several files side by side on the paper:

```
pr -m -h "Members and Visitors" member.lst visitor.lst | print
```

This prints member.lst and visitor.lst side by side with the title Members and Visitors.

5. To modify a file for later use:

```
pr -t -e prog.c > prog.notab.c
```

This replaces tab characters in proq. c with blanks and puts the result in proq.notab.c. Tab positions are at columns 9, 17, 25, 33, The -e tells pr to replace the tab characters; the -t suppresses the page headings.

Files

/dev/tty* To suspend messages.

Related Information

The following command: "cat" on page 137.

prev

Purpose

Shows the previous message.

Syntax

prev --- -help----

AJ2FL162

Description

The **prev** command is used to display the previous message in a folder. **prev** is equivalent to the show command with prev specified as the message. prev is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The prev command links to the show program and passes show its flags and attributes.

Note: If you link to prev and call that link something other than prev, your link will function like the **show** command, rather than like the **prev** command.

The **show** command invokes a program to perform the listing. The system default is /bin/pg. You can define your own default with the showproc: entry in **\$HOME/.mh_profile.** If you set **showproc:** entry to **mhl**, **show** calls an internal **mhl** routine instead of the mhl command. You can also specify the program to perform a listing in the *cmdstring* of the **-showproc** flag.

The **show** command passes any flags that it does not recognize to the program performing the listing. Thus, you can specify flags for the listing program, as well as the flags described in this command section.

Flags

+folder

Specifies the folder that contains the message you want to show.

-header

Displays a one-line description of the message being shown. The description includes the folder name and the message number.

-help

Displays help information for the command.

-noheader

Does not display a one-line description of each message being

shown.

-noshowproc

Uses /bin/cat to perform the listing.

-showproc cmdstring

Uses the specified command string to perform the listing.

Profile Entries

Current-Folder:

Sets your default current folder.

Path:

Specifies your user_mh_directory.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

print

Purpose

Enqueues a file.

Syntax

OL805354

OL805147

OL805348

print
$$Queue$$
 $Queue$ $Queue$

OL805328

Description

The **print** command is a general purpose utility for enqueuing requests to a shared resource, typically a printer device. With the **print** command you can do the following:

- Enqueue print requests
- Cancel print requests
- Alter the priority of print requests
- Display the status of print queues and devices
- Specify the printing of security labels on hard copy.

For complete information about security labels, see the discussion of printer security labels in *Managing the AIX Operating System*.

To enqueue files on a specific queue, specify -queue. If more than one device services a queue, you can also request a particular device by specifying :device after the name of the queue. If you do not specify a device, the job is sent to the first available device. If you do not specify a file, print copies standard input into a file and enqueues it for printing.

Print requests can have operator messages associated with them. This feature is useful in a distributed services environment. You can use messages to tell the user operating the printer to load a special form into the printer before allowing this job to print. These messages are specified with the **-of** and **-ot** flags. When **qdaemon**, the daemon that processes print requests, is ready to begin a request that has an associated message, the system displays the message on the console of the machine where **qdaemon** is running. The text of the message is accompanied by a prompt that tells the printer operator how to signal the request to continue or cancel the request.

¹ Do not put a blank between these items.

²Only members of the system group can use these flags.

³Only specify -fi once.

Notes:

- 1. Before you can print a file, you must have read access to it. To remove a file, you must also have write access to the directory that contains the file.
- 2. If you want to continue changing the *file* after you issue the **print** command but before it is printed, you must use the -cp flag.
- 3. The operator must respond to messages sent with the **-of** and **-ot** flags. Print requests with these flags stop processing until the operator responds.
- 4. When enqueuing files on a printer, flags and file names can be interspersed in any order.
- 5. Blanks between flags and their arguments are not permitted.

Flags

If you give **print** a list of *file* names, it enqueues them all for printing on the default printer.

-ap = num

Changes to *num* the priority of the named file. The file must have been submitted for printing prior to entering the **print** command with this flag. See "-pr" on page 770 for a description of priorities.

 $-\mathbf{bp} = num$

-bp

-nb

Controls the printing of burst pages according to the value of num as follows:

- 0 Does not print headers or trailers.
- 1 Prints one header page before each file. No trailer appears.
- 2 Prints a header page at the beginning and a trailer page at the end of each *file*.

The **header** stanza in the **qconfig** file defines the default treatment of burst pages.

Specifying only -bp is the same as specifying -bp = 2. Specifying -nb is the same as specifying -bp = 0.

-ca

Cancels the printing of the named files.

-ctl[=filename]

Specifies security labels and access codes for a file located on a remote system. You must be a superuser to use this flag.

-cp

Copies the file. Ordinarily, to save disk space, **print** remembers the name of the file, but does not actually copy the file itself. Use the **-cp** flag if you want to continue changing the file while you are waiting for the current copy to be printed.

-fi		Causes print to act as a filter. The print command automatically reads standard input if you do not specify <i>files</i> as arguments. However, if you specify <i>file</i> arguments, you can use the -fi flag to force print to read standard input at the appropriate time.
$-\mathbf{nc} = n$	um	Prints num copies of the file. Normally a file prints only once.
-nl		Supresses top-of-page and bottom-of-page output labeling.
-no		Notifies you when your job is finished. If the -to flag is also used, print notifies the user for whom the request is intended (see the -to flag on page 770).
- of =fil	le	Submits an operator message with a print request. The specified <i>file</i> contains the text of the message.
$-\mathbf{ot} = te$	xt	Submits an operator message with a print request. The specified <i>text</i> contains the text of the message.
- pr = n	um	Sets the priority of the named <i>file</i> to <i>num</i> . Higher numbers assign higher priority. The default priority is 15. The maximum priority is 20 for most users and 30 for the users with superuser authority and members of the system group (group 0).
-q		Displays the status of the queues and printers. You can specify an argname to view a single queue. The environment variable NLTIME controls the appearance of the time field.
-rm	è	Removes the file after it prints.
$-\mathbf{tl} = tit$	le	Puts <i>title</i> on the header page and displays it when the -q flag is specified. Normally the job title is the name of the file. If print reads from standard input, the job title is STDIN. # where # is the process ID of the print command.
-to = no	ате	Labels the output for delivery to <i>name</i> . Normally the output is labeled for delivery to the person issuing the print request.
In addition to the previous flags that are available to all users, the print command accepts the following flags when they are entered by users who have superuser authority or users who are members of the system group:		
-dd		Turns off the device associated with queue. The qdaemon no longer sends jobs to the device, and entering print -q shows its status as OFF. Any job currently running on the device is allowed to finish.
-dg[=1	node]	Kills the qdaemon after all currently running jobs are finished. Use of this flag is the only clean way to bring the qdaemon down. Use of the kill command may cause problems, such as jobs hanging up in the queue. If the qdaemon is on a remote node, specify the node. You can specify it as either a node ID or nickname. If no node is specified, the local node is assumed.

-dk

Acts the same as -dd, except current jobs are killed. They remain in the queue, and are run again when the device is turned on.

-du

Turns on the device associated with queue. The **qdaemon** sends jobs to it again and entering print -q shows its status as READY.

Note: If more than one device is associated with a queue, you must specify the device as well as the queue when you use the -dd, -dk, and -du flags. Devices are numbered, starting at zero, in the order that they appear in the **qconfig** file. For example, -1p:0 designates the first device on the lp queue. - lp designates the same device only if there is no other device on that queue.

-from = name

Labels the output as though name had submitted it. You can only use this flag with superuser authority.

 $-\mathbf{rr}[=node]$

Forces the **qdaemon** to reread the **qconfig** file after all currently running jobs are finished. With this flag, a user with superuser authority can change the **qconfig** file without having to kill and restart the **gdaemon**. If the gdaemon is on a remote node, specify the node either a node ID or nickname. If no node is specified, the local node is assumed.

 $-\mathbf{su} = user$

Cancels or changes the priority on another user's job when used with the -ca or the -ap flags. For example, a job report submitted by user ann can be cancelled as follows:

print -su=ann -ca report

The **print** command passes flags it does not recognize to the backend that does the printing. Thus, for each queue there are flags not described above that can be included on the print command line. See "piobe" on page 753 for a list of these flags.

Examples

1. To print a file on the default printer:

print memo

2. To print a file with page numbers:

pr prog.c | print

The pr command puts a heading at the top of each page that includes the date the file was last modified, the name of the file, and the page number. The **print** command then prints the file.

3. To see if a file is still waiting to be printed:

print -q

This command displays the status of the queues and printers. If a file has not yet printed, then it appears in the queue status listing. If you piped data to **print**, as in Example 2, then it is listed as PRIMARY.OUTPUT.

4. To stop printing a file:

```
print -ca chapter1
```

This command cancels the request you made earlier to print the file chapter1. If the file is currently being printed, then the printer stops immediately. If the file has not yet printed, then it is removed from the queue so that it will not be printed. If the file is not in the queue, **print** displays the message:

no such request from you -- perhaps it's done?

5. To disconnect a printer from the queueing system:

```
print -a:2 -dd
```

This command stops print requests from being sent to the third printer that serves the -a queue. If a file is currently being printed, it is allowed to finish. You must be a member of the **system** group (group 0) to run this command.

Note: The printers serving a given queue are numbered starting with zero in the order that they appear in the /etc/qconfig file.

Files

/etc/qdaemon /usr/lpd/qdir/* /usr/lpd/stat/* /usr/spool/qdaemon/* /etc/qconfig /etc/security/config

Queueing daemon. Queue requests. Information on the status of the devices. Temporary copies of enqueued files.

Queue configuration file.

Specifies output labelling information.

The discussion of the printer subsystem in Managing the AIX Operating System.

"Overview of International Character Support" in Managing the AIX Operating System.

prof

Purpose

Displays program profile data.

Syntax

OL805438

Description

The **prof** command interprets profile data collected by the **monitor** subroutine for the object file **prog** (a.out by default). It reads the symbol table in the object file *prog* and correlates it with the profile file (**mon.out** by default). **prof** displays, for each external text symbol, the percentage of execution time spent between the address of that symbol and the address of the next, the number of times that function was called, and the average number of milliseconds per call.

For the number of calls to a function to be tallied, you must have compiled the file using the -p flag of the cc command. This flag also arranges for the object file to include a special profiling startup function that calls the monitor subroutine at the beginning and end of execution. It is the call to monitor at the end of execution that writes mon.out. Thus, only programs that explicitly exit or return from main cause the mon.out file to be produced.

Note: No more than 600 functions can have call counters established during program execution. If you exceed this limit, **prof** overwrites other data and damages the **mon.out** file. **prof** automatically reports the number of call counters used whenever the number exceeds 500.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

The mutually exclusive flags a, c, n, and t determine how prof sorts the output lines:

- -a Sorts by increasing symbol address.
- -c Sorts by decreasing number of calls.
- -n Sorts lexically by symbol name.
- -t Sorts by decreasing percentage of total time (default).

The mutually exclusive flags o and x specify how to display the address of each symbol monitored.

- -o Displays each address in octal, along with the symbol name.
- -x Displays each address in hexadecimal, along with the symbol name.

Use the following flags in any combination:

- -g Includes nonglobal symbols (static functions). This option requires object code that was compiled with the -g flag.
- -h Suppresses the heading normally displayed on the report. (This is useful if the report is to be processed further.)
- -m mdata Takes profiling data from mdata instead of mon.out.
- -s Displays a summary of monitoring parameters and statistics on standard error.
- -z Includes all symbols in the profile range, even if associated with zero calls and zero time.

Files

mon.out

Default profile.

a.out

Default object file.

Related Information

The following commands: "cc" on page 140 and "nm" on page 705.

The exit and profil system calls and the monitor subroutine in AIX Operating System Technical Reference.

profiler

Purpose

Profiles the operating system.

Syntax

prfld
$$-\sqrt{\text{kernel-image}}$$

prfstat $-\sqrt{\text{on}}$

prfdc $-\sqrt{\text{file}}$

prfsnap $-\sqrt{\text{file}}$

prfpr $-\sqrt{\text{file}}$
 $-\sqrt{\text{cutoff}}$
 $-\sqrt{\text{kernel-image}}$

OL805006

Description

With the prfld, prfstat, prfdc, prfsnap, and prfpr commands, you can examine the activity of the AIX Operating System.

prfld

Use **prfld** to initialize the recording mechanism in the system. It produces a table containing the starting address of each system subroutine as extracted from *kernel-image*.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

prfstat

Use **prfstat** to enable or disable the sampling mechanism. **prfstat** also reveals the number of text addresses being measured.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

prfdc, prfsnap

Use **prfdc** and **prfsnap** to collect profiler data by copying the current value of all the text address counters to a file where the data can be analyzed. **prfdc** stores the counters into *file* every specified *minutes* and turns off at *hour* (0-24). **prfsnap** collects data at the time of invocation only, adding the counter values to *file*.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

prfpr

Use **prfpr** to format the data collected by **prfdc** or **prfsnap**. It converts each text address to the nearest text symbol (as found in *kernel-image*) and displays it if the percent activity for that range is greater than *cutoff*.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Files

/dev/prf /unix

Interface to profile data and text addresses. System kernel image file.

Related Information

The prf file in AIX Operating System Technical Reference.

prompter

Purpose

Invokes a prompting editor.

Syntax

prompter -- help---

AJ2FL250

Description

The prompter command is used to invoke the prompter editor for message entry. prompter is not designed to be run directly by the user; it is designed to be called by other programs. The prompter command is part of the MH (Message Handling) package.

The prompter command opens the specified file and scans it for empty components such as **To:** and prompts you to fill in those fields. If you press **Enter** without adding text, **prompter** later deletes the component.

After the first blank line or line of dashes in the file, **prompter** accepts text for the body of the message. If the body already contains text and the flag **-noprepend** is specified, **prompter** displays the text followed by the message:

-----Enter additional text

prompter appends any text that is entered to the message body. If you specify the **-prepend** flag, **prompter** displays the following message instead:

-----Enter initial text

When you press END OF FILE, prompter ends text entry and returns control to the calling program.

Flags

Sets the character to be used as the erase character. You -erase char

can specify the octal representation of the character in the

form $\nn n$, or you can specify the character itself.

-help Displays help information for the command.

-kill char Sets the character to be used as the kill character. You can

specify the octal representation of the character in the form

 \normalfont{nnn} , or you can specify the character itself.

Places additional text below any text already in the message -noprepend

body.

-norapid Displays any text already in the message body. This is the

default.

-prepend Places additional text before any text already in the message

body. This is the default.

Does not display text already in the message body. -rapid

Profile Entries

Msg-Protect: prompter-next: Sets the protection level for your new message files. Specifies the editor used after exiting prompter.

Files

\$HOME/.mh_profile

The MH user profile.

/tmp/prompter*

A temporary copy of a message.

Related Information

Other MH commands: "comp" on page 185, "dist" on page 336, "forw" on page 438, "repl" on page 821, "whatnow" on page 1215.

The **mh-profile** file in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

proto

Purpose

Constructs a prototype file for a file system.

Syntax

OL805007

Description

The **proto** command makes a prototype file for a file system or part of a file system. Use the prototype file as input to the **mkfs** command to construct a file system according to a predefined template. The prototype file consists of a recursive directory listing of every file on the file system, with its owner, group, and protection. It also contains the file from which the prototype file is to be initialized, formatted as described in the **mkfs** command.

Specify the base directory from which the prototype file is made with *directory*. The prototype file includes the complete subtree below *directory* that is contained on the same file system as *directory*.

The prefix parameter is added to the names of all the initialization files, forcing the initialization files to be taken from a place other than the prototype. Before the output from **proto** can be used with **mkfs**, **mkfs** needs a start up program, a file system size, and an i-list size. Link information is not preserved with the **proto** command.

The collating sequence is determined by the ct_collate array in the NLctab subroutine.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Related Information

The following command: "mkfs" on page 658.

"Overview of International Character Support" in Managing the AIX Operating System.

prs

Purpose

Displays a Source Code Control System (SCCS) file.

Syntax

OL805248

Description

The prs command reads files, and writes to standard output a part or all of a Source Code Control System (SCCS) file. If you specify a directory in place of file, prs performs the requested actions on all SCCS files (those with a name that has the s. prefix). If you specify a - (minus) in place of file, prs reads standard input and interprets each line as the name of an SCCS file. prs continues to take input until it reads an end-of-file character.

Data Keywords

Data keywords specify which parts of an SCCS file are to be retrieved and written to standard output. All parts of an SCCS file have an associated data keyword. There is no limit to the number of times a data keyword can appear in a string. The information that prs displays consists of user-supplied text and appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in string. The format of a data keyword value is either simple, in which the keyword substitution is direct, or multiline, in which the substitution is followed by a carriage return. Text is any characters other than recognized data keywords. Specify a tab character with \t and a carriage return/new-line character with a \n. Remember to quote the \t and \n with an extra \ to prevent shell from interpreting the \ and just passing a t or n to prs as text.

The following table lists the keywords associated with information in the delta table in the SCCS file (see the sccsfile file in AIX Operating System Technical Reference for the structure of an SCCS file).

Keyword	Data Represented	Value	Format
:R:	Release number	num	Simple

The following table lists the keywords associated with other parts of the SCCS file.

Keyword	Data Represented	Value	Format
:UN:	User names	text	Multiline
:FD:	Descriptive text	text	Multiline
:BD:	Body of text	text	Multiline
:GB:	Text in a g-file	text	Multiline
:W:	A what string	:Z::M: \tab :I:	Simple
:A:	A what string	:Z::Y::M::I::Z:	Simple
:Z:	A what string delimiter	0(#)	Simple
:F:	SCCS file name	text	Simple
:PN:	SCCS file path name	text	Simple

Figure 9. Other Keywords

Flags

Each flag or group of flags applies independently to each named file.

- -a Writes information for the specified deltas, whether or not they have been removed (see "rmdel" on page 837). If you do not specify the -a flag, prs supplies information only for the specified deltas that have not been removed.
- -ccutoff Specifies a cutoff date and time for the -e and -l flags. Specify cutoff in the following form:

YY[MM[DD[HH[MM[SS]]]]]

All omitted items default to their maximum values, so specifying -c8402 is the same as specifying -c840229235959. You can separate the fields with any non-numeric characters. For example, you can specify -c84/2/20,9:22:25 or -c"84/2/20 9:22:25" or "-c84/2/20 9:22:25".

- -d"string" Specifies the data items to be displayed. string is a string consisting of optional text and SCCS file data keywords. You must enclose all text and spaces in string in quotation marks.
- -e Requests information for all deltas created *earlier* than and including the delta specified by the -r flag.

- -1 Requests information for all deltas created later than and including the delta specified by the -r flag.
- -rSIDSpecifies the SID of a delta for which prs will retrieve information. If no SID is specified, prs retrieves the information for the SID of the highest numbered delta.

ps

Purpose

Reports process status.

Syntax

OL805439

Description

The **ps** command writes certain information about active processes to standard output. Without flags, **ps** displays information about the current work station.

The column headings in a **ps** listing have the following meaning. The letters **f** and **l** following the column heads indicate which flags cause the corresponding heading to appear. If **all** follows the column head, that heading always appears. Note that the **-f** and **-l** flags determine only what information is provided about a process; they do not determine which processes are listed.

F (1)

Flags (octal and additive) associated with the process:

- 01 In core
- 02 System process
- 04 Locked in core (for example, for physical I/O);
- 10 Waiting for a page default, or forking
- 20 Being traced by another process
- 40 Another tracing flag
- 100 Process has shared text.

S (1)

The state of the process:

- 0 Nonexistent
- S Sleeping
- W Waiting
- R Running

- T Intermediate
- 7. Canceled
- \mathbf{T} Stopped
- K Available kernel process
- X Growing.

UID (f.1)

The user ID of the process owner; the login name is displayed with the -f flag.

PID (all)

The process ID of the process.

PPID (f,1)

The process ID of the parent process.

C (f.1)

Processor utilization for scheduling.

STIME (f)

Starting time of the process. The NLLDATE and NLTIME environment variables control the appearance of this field.

PRI (1)

The priority of the process: higher numbers mean lower priority.

NI (1)

Nice value; used in calculating priority.

ADDR (1)

The segment number of the process stack, if normal; if a kernel process, the address of the preprocess data area.

SZ(1)

The size in blocks of the core image of the process.

WCHAN (1)

The event for which the process is waiting or sleeping; if blank, the process is running.

The controlling work station for the process.

TIME (all)

The total execution time for the process.

CMD (all)

The command name; the full command name and its parameters are displayed with

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked < defunct >.

With the -f flag, ps determines what the command name and parameters were when the process was created by examining memory or the paging area. If it cannot find this information, the command name, as it would appear without the -f flag, displays in square brackets.

Notes:

- 1. The process can change while ps is running.
- 2. Some data displayed for defunct processes are irrelevant.
- 3. The current work station is defined as the one associated with standard error. Thus redirecting standard error, for example:

ps 2> /dev/null does not work as expected.

Flags

-a	Writes to standard output information about all processes except the process group leaders and processes not associated with a terminal.
-c corefile	Uses corefile instead of the default /dev/mem. corefile is a core image file that has been created by the Ctrl-(left)Alt-End key sequence.
-d	Writes information to standard output about all processes except the process group leaders.
-е	Writes information to standard output about all processes except kernel processes.
- f	Generates a full listing. The meaning of columns in a full listing is described on page 786.
-g glist	Writes information to standard output only about processes that are in the process groups listed in <i>glist</i> . The <i>glist</i> is either a comma-separated list of process-group identifiers or a list of process-group identifiers enclosed in double quotation marks (" ") and separated from one another by a comma and/or one or more spaces.
-k	Writes information to standard output about kernel processes. Otherwise, it does not list kernel processes.
-1	Generates a long listing. The meaning of a long listing is described on page 786.
-n kernel-image	Takes kernel-image as the name of an alternate kernel-image file (/unix is the default).

-p plist Displays only information about processes with the process numbers specified in plist. plist is either a comma-separated list of process-ID numbers or a list of process-ID numbers enclosed in double quotation marks (" ") and separated from one another by a comma and/or one or more spaces.

-t tlist Displays only information about processes associated with the work stations listed in *tlist*. *tlist* is either a list of comma-separated work-station identifiers or a list of work-station identifiers enclosed in double quotation marks (" ") and separated from one another by a comma and/or one or more spaces.

-u ulist Displays only information about processes with the user ID numbers or login names specified in *ulist*. *ulist* is either a comma-separated list of user ID's or a list of user ID's enclosed in double quotation marks (" ") and separated from one another by a comma and/or one or more spaces. In the listing, ps displays the numerical user ID unless the -f flag is used; then it displays the login name.

Examples

1. To list the processes that you have started:

ps

This command displays a summary of information about the processes associated with your work station.

2. To display all process information available:

This command displays all of the information (-1 -f) about all processes (-e).

3. To list processes owned by specific users:

This command displays all the information available (-1 -f) about the processes being run by the users jim, jane, and su.

4. To list processes associated with specific work stations:

This command displays information about processes not connected to any work station (-t-), and processes associated with the work station /dev/console.

Files

/unixSystem kernel image./dev/memMemory./etc/passwdSupplies UID information./etc/ps_dataInternal data structure./devSearched to find work station (tty) names.

Related Information

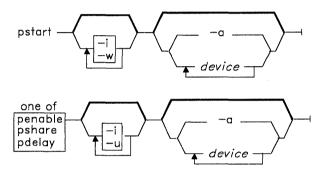

The following commands: "kill" on page 552 and "nice" on page 699.

pstart, penable, pshare, pdelay

Purpose

Enables or reports the availability of login ports.

Syntax

OL805208

Description

The **pstart**, **penable**, **pshare**, and **pdelay** commands each enable a set of login ports in the **/etc/ports** file. Enabling a port makes the port available to log in. The system enables a port by updating an entry in the **/etc/portstatus** file and then sending a signal to **init**. When **init** receives the signal and reads the updated status entry, it takes the appropriate action.

Use the *device* parameter to specify the ports to be enabled. Permitted values for *device* include:

- A full device name, such as /dev/tty1.
- A simple device name, such as tty1.
- A general class of devices in the form attribute = value, which is equivalent to naming each port with a stanza in /etc/ports that includes the specified attribute).

If you do not specify a *device* to enable, each command reports the names of currently enabled ports in its set.

pstart

The **pstart** command enables all ports (normal, shared, and delayed) that are enabled in the **/etc/ports** file. If you do not specify a *device* to enable, **pstart** reports the names of all enabled ports and tells whether they are currently enabled as normal, shared, or delayed. Usually the command is run in the form **pstart -a -i -w** from **/etc/rc** to enable all ports on a multiuser system.

penable

The **penable** command enables normal ports that are enabled in the /etc/ports file. Normal ports are ports that are asynchronous and only allow users to login to those ports. No outgoing use of the port is allowed while it is enabled. This command is equivalent to the statement **penable enabled = true**. If you do not specify a device, **penable** reports the names of the currently enabled normal ports.

pshare

The pshare command enables shared ports that are enabled in the /etc/ports file. Shared ports are bidirectional. This command is equivalent to the statement pshare enabled = share. If you do not specify a device, pshare reports the names of the currently enabled shared ports. To enable shared ports, getty attempts to create a lock file in /etc/locks which contains the ASCII process ID of the getty process. If the port is already in use by some other process, getty waits until the port is available and tries again.

pdelay

The **pdelay** command enables delayed ports that are enabled in the /etc/ports file. Delayed ports are ports that are enabled like shared ports except that the login herald is not displayed until the user types one or more characters (usually carriage returns). If the port is directly connected to a remote system or connected to an intelligent modem, the port is usually enabled as a delayed port to prevent the **getty** from talking to a **getty** on the remote side or to the modem on a local connection, thereby consuming system resources. This statement is equivalent to **pdelay enabled = delay**. If you do not specify a device, **pdelay** reports the names of the currently enabled delayed ports.

Flags

- -a With pstart, this flag enables all ports enabled in the /etc/ports file (normal, shared, and delayed ports). With penable, this flag enables all normal ports that are enabled in the /etc/ports file. With pshare, this flag enables all shared ports that are enabled in the /etc/ports file. With pdelay, this flag enables all delayed ports that are enabled in the /etc/ports file.
- -i Reinitializes an existing /etc/portstatus file instead of updating the existing one. You typically use this flag in the /etc/rc command file to re-establish default port enabling before starting up the system with multiple users.

Makes the command return immediately rather than wait for init to confirm the changes in port status. You must use this flag when running pstart, penable, pshare, or pdelay either in maintenance mode or from /etc/rc because init does not initiate loggers until the system is in normal mode.

Examples

1. To display the names of all ports (normal, shared, and delayed) currently enabled and how they are enabled:

pstart

2. To enable all normal, shared, and delayed ports that are enabled in /etc/ports, reinitialize the existing /etc/ports, and make the command return immediately rather than wait for **init** to confirm port status:

3. To enable the work station attached to the /dev/ttv2 port as a shared port:

4. To display the names of the delayed ports that are currently enabled:

pdelay

5. To enable the work station attached to the /dev/tty8 port as a shared port and return immediately without waiting to confirm the changes in the port status:

6. To enable all 9600 baud ports as delayed:

Files

/etc/locks /etc/ports

Contains lock files for pshare and pdelay.

Contains descriptions of known normal, shared, and delayed ports.

Contains current status of each known login port. /etc/portstatus

The following commands: "init" on page 521 and "pdisable, phold" on page 741.

The ports and portstatus files in AIX Operating System Technical Reference.

ptx

Purpose

Generates a permuted index.

Syntax

OL805250

Description

The **ptx** command reads *infile* (standard input by default), creates a permuted index from its input, and writes to *outfile* (standard output by default).

The ptx command searches *infile* for keywords, sorts the lines, and generates the file *outfile*. *outfile* can then be processed with **nroff** or **troff** to produce a permuted index from the file *infile*.

The ptx command follows three steps:

- 1. In the permutation, generates one line for each keyword in an input line, and rotates the keyword to the front.
- 2. Sorts the permuted file.
- 3. Rotates the sorted lines so that the keyword comes at the middle of each line.

The resulting lines in output are in the form:

.xx, "tail" "before keyword" "keyword and after" "head"

where .XX is an **nroff** or **troff** macro provided by the user, or provided by the **mptx** macro package (see the AIX Operating System Technical Reference for information on this macro package). The before keyword and keyword and after fields incorporate as much of the line as will fit around the keyword when it is printed. tail or head, at least one of which is always the empty string, are wrapped-around pieces small enough to fit in the unused space at the opposite end of the line.

Notes:

- 1. Line length counts do not account for overstriking or proportional spacing.
- 2. Lines that contain tildes (~) do not work because **ptx** uses that character internally.

Flags

- -b break Uses the characters in the break file to separate words. Tab characters, new-line characters, and spaces are always used as break characters.
- Does not distinguish between uppercase and lowercase characters while sorting -f (see "sort" on page 958).
- Uses num as the number of spaces displayed between the four parts of the line. -g num The default num is 3.
- Does not use any words in the *ignore* file as keywords. If the -i and -o flags are -i ignore not used, /usr/lib/eign is the default ignore file.
- -o only Uses only the words in the only file as keywords.
- Takes any leading nonblank characters of each input line to be a reference -r identifier separate from the text of the line. Attaches that identifier as a fifth field on each output line.
- -t Prepares the output for the phototypesetter.
- Uses num as the length of the output line. The default line length is 72 -w num characters for **nroff** and 100 for **troff**.

Files

/bin/sort /usr/lib/eign /usr/lib/tmac/tmac.ptx

The mm and mptx miscellaneous facilities in AIX Operating System Technical Reference.

"Overview of International Character Support" in Managing the AIX Operating System.

puttext

Purpose

Updates an output file that contains message/insert/help descriptions.

Syntax

OL805209

Description

The **puttext** command uses the message/insert/help descriptions in *infile* to change, delete and add message/insert/help text to *outfile* for a component. (For information about the format and contents of *infile*, see AIX Operating System Programming Tools and Interfaces.)

The *infile* parameter specifies the name of the file where the message/insert/help descriptions reside. See *AIX Operating System Programming Tools and Interfaces* for a discussion of the **gettext** output file parameters that describes the format and contents of this file.

The *outfile* parameter specifies the name of the output file. If you specify an *outfile* that does not exist, a new component file is created. If you specify an existing *outfile*, a copy of that file is renamed as a backup file. In this case, an old backup file will be deleted.

Note: In order for the new file to be accessed by the message support run-time services, the output file name must be in the format $xxxccc_EN.m$. If you do not specify *outfile*, the component ID is prefixed to $_EN.m$ to form the output file name.

Flag

-n Causes **puttext** to assign available index numbers to the input descriptions. If you specify this flag, all the index number fields of the input file must be underscore characters or blanks.

Related Information

The following commands: "gettext" on page 488.

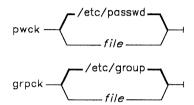

The discussion of puttext in AIX Operating System Programming Tools and Interfaces.

pwck

Purpose

Checks the password and group files for inconsistencies.

Syntax

OL805008

OL805558

Description

The **pwck** command scans the named *file* or the default file /**etc/passwd** and writes to standard output any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and existence of the login directory and optional program name.

The grpck command scans the named *file* or the default file /etc/group and writes to standard output any inconsistencies. The checks include validation of the number of fields, group name, group ID, and whether all login names appear in the password file. The grpck command writes to standard output any group entries that do not have login names.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Files

/etc/passwd /etc/group Password file; contains user IDs. Group file; contains group IDs.

Related Information

The discussion of passwords in Managing the AIX Operating System.

pwd

Purpose

Displays the path name of the working directory.

Syntax

⊢ bwa

OL805210

Description

The **pwd** command writes to standard output the full path name of your current directory (from the root directory). All directories are separated by a / (slash). The root directory is represented by the first /, and the last directory named is your current directory.

Related Information

The following command: "cd" on page 150.

The fullstat and ffullstat system calls in AIX Operating System Technical Reference.

pwtable

Purpose

Accesses the Distributed Services Node Security Table.

Syntax

pwtable ____

AJ2FL144

Description

The pwtable command lets you build, examine, or change the Distributed Services Network Node Security Table. Only members of the system group or users operating with superuser authority can use pwtable to change the state of the table (see "su" on page 1026). Other users can use pwtable to browse through the table.

Related Information

Information on the status of the devices. Temporary copies of files to be printed.

Related Information

The following commands: "lp" on page 593, "piobe" on page 753, and "print" on page 767.

The qconfig file in AIX Operating System Technical Reference.

¹ This command is not usually entered on the command line.

quiz

Purpose

Tests vour knowledge.

Syntax

OL805230

Description

The quiz game gives associative knowledge tests on various selectable subjects. It asks about items chosen from *category1* and expects answers from *category2*. If you do not specify the categories, quiz gives instructions and lists the available categories.

The quiz game gives the correct answer whenever you press the **Enter** key by itself. The game ends when questions run out or when you press INTERRUPT (Alt-Pause); quiz reports a score and exits.

Flags

-ifile Substitutes the named file for the standard index file.

Note: In the following syntax description, brackets are normally used to indicate that an item is optional; a bold-faced bracket or brace, however, should be entered as a literal part of the syntax. A vertical list of items indicates that one and only one must be chosen. The lines in *file* must have the following syntax:

In an index file, the first category of each line must specify the name of an information file (the information file contains the names of files with quiz material). The remaining categories specify the order and contents of the data in each line of the information file. The quiz data in an information files follows the same syntax. A \ (backslash) is an escape character which allows you to quote syntactically significant characters or to insert a new-line character (\n) into a line. When either a question or its answer is blank, quiz does not ask it. The construct alab does not work in an information file. Use $a\{b\}$.

-t Provides a tutorial. Repeats missed questions and introduce new material gradually.

Examples

1. To start a Latin-to-English quiz:

/usr/games/quiz latin english

The quiz command displays Latin words and waits for you to enter what they mean in English.

2. To start an English-to-Latin quiz:

/usr/games/quiz english latin

3. To set up a Latin-English quiz, add the following line to the index file:

```
/usr/games/lib/guiz/latin:latin:english
```

This line specifies that the file /usr/games/lib/quiz/latin contains information about the categories latin and english.

You can add new categories to the standard index file, /usr/games/lib/quiz/index, or to an index file of your own. If you create your own index file, run the quiz command with the -i file flag to give it your list of quiz topics.

4. This is a sample information file:

cor:heart
sacerdos:priest{ess}
quando:when!since!because
optat:{{s}he !it }[desires!wishes]\
Idesire!wish
alb[us!a!um]:white

This information file contains Latin and English words. The: (colon) separates each Latin word from its English equivalent. Items enclosed in { } (braces) are optional. A ! (vertical bar) separates two items when entering either is correct. The [] (brackets) group items separated by vertical bars.

The first line accepts only the answer heart in response to the Latin word cor. The second accepts either priest or priestess in response to sacerdos. The third line accepts when, since, or because for quando.

The \ (backslash) at the end of the fourth line indicates that this entry continues on the next line. In other words, the fourth and fifth lines together form one entry. This entry accepts any of the following in response to optat:

```
she desires
               it desires
                              desire
she wishes
                it wishes
                              wish
he desires
                desires
he wishes
               wishes
```

If you start a Latin-to-English quiz, then the last line of this sample information file instructs quiz to ask you the meaning of albus. If you start an English-to-Latin quiz, then quiz displays white and accepts albus, alba, or album for the answer.

If any of the characters {, }, [,], or I appear in a question item, then quiz gives the first alternative of every I group and displays every optional group. Thus, the English-to-Latin question for the fourth definition in this sample is she desires.

Files

/usr/games/lib/quiz/index /usr/games/lib/quiz/*

rc

Purpose

Performs normal startup initialization.

Syntax

/etc/rc — 1

OL805339

Description

When the init process starts up the system in normal operating mode, it runs the command file /etc/rc to perform the necessary system initialization, including the enabling of various loggers. If the system is being brought up with no file system checking, init passes the argument m to rc. If init determines that the root file system needs consistency checking, it passes the argument d to rc.

The contents of /etc/rc may be installation specific, but there are a few things that it should do:

- Check the default file systems if rc is passed the init -d flag (Run fsck)
- Mount the default file systems (Run mount)
- Purge temporary files
- Start SNA and Distributed Services (Run /etc/rc.sna and /etc/rc.ds)
- Set printer defaults
- Enable default ports (Run pstart)
- Determine whether to set up stand-alone or active-service system (Run chngstate)
- Start the error daemon and run /etc/rc.include.

If all of the necessary operations complete successfully, the file exits with a zero return code that allows init to start loggers to complete normal initialization and startup.

¹ This command is not usually run from the command line.

Notes:

- 1. Many system daemons such as cron are started by rc indirectly when it runs /etc/rc.include.
- 2. The mail facility is started by rc indirectly when it runs /etc/rc.include and /etc/rc.tcpip.
- 3. The root file system is implicitly mounted.

Files

$/\mathrm{etc/rc.ds}$	Performs functions required to start Distributed Services.
/etc/rc.include	Performs functions required to start most program daemons.
/etc/rc.sna	Performs functions required to start SNA.
/etc/rc.tcpip	Performs functions required to start TCPIP.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

rcvstore

Purpose

Incorporates new mail from standard input into a folder.

Syntax

AJ2FL237

Description

The revstore command is used to incorporate incoming messages. revstore is not designed to be run directly by the user; it is designed to be called by /usr/lib/mh/slocal. The revstore command is part of the MH (Message Handling) package.

The revstore command accepts messages from standard input and places them in a specified folder. You can run revstore on all incoming messages by specifying the revstore command in the .maildelivery file.

You can specify revstore flags in \$HOME/.maildelivery or as with most MH commands, in \$HOME/.mh_profile.

Flags

Creates the specified folder in your mail directory if the folder does not -create

exist.

+folder Places the incorporated messages in the specified folder. The default is

+inbox.

Displays help information for the command. -help

-nocreate Does not create the specified folder if the folder does not exist.

Restricts the specified sequence to your usage. -nopublic does not -nopublic

restrict the messages in the sequence, only the sequence. This flag is

the default if the folder is write-protected from other users.

Appends the messages incorporated by revstore to the specified -nozero

sequence (see the -zero flag).

Makes the specified sequence available to other users. -public does not -public

make protected messages available, only the sequence. This flag is the

default if the folder is not write-protected from other users.

Adds the incorporated messages to the specified sequence. -sequence name

-zero Clears the specified sequence before placing the incorporated messages

into the sequence. This flag is the default (see the -nozero flag).

Profile Entries

Folder-Protect:

Sets the protection level for your new folder directories. Sets the protection level for your new message files.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

rcvtty

Purpose

Notifies the user of incoming messages.

Syntax

rcvttv — -help —

AJ2FL238

Description

The revtty command is used to send the user a message when incoming mail has arrived. rcvtty is not designed to be run directly by the user; it is designed to be called by /usr/lib/mh/slocal. The rcvtty command is part of the MH (Message Handling) package.

The rcvtty command sends a one-line scan listing to your terminal. If you give rcvtty a command as an argument, rcvtty executes the command with the incoming message as the command's standard input, and sends the output to the terminal. For rcvtty to write output to your terminal, your terminal's write permission must be set to "All".

You can run revtty on all incoming messages by specifying the revtty command in the .maildelivery file.

Flag

-help Displays help information for the command.

Files

\$HOME/.maildelivery \$HOME/.forward

The user's local mail delivery instructions.

The user's default message filter.

The mh-alias, mh-format, mh-mail, and mh-profile files in AIX Operating System Technical Reference.

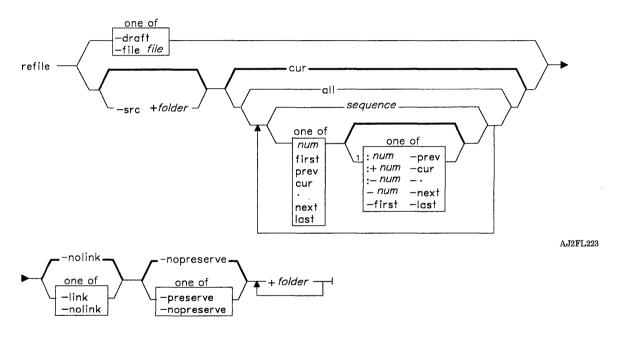

"Overview of the Message Handling Package" in Managing the AIX Operating System.

refile

Purpose

Files messages in other folders.

Syntax

OL805308

¹ Do not put a blank between these items.

Description

The refile command is used to copy and move messages to other files. The refile command is part of the MH (Message Handling) package and can be used with MH and AIX commands.

The refile command copies messages or moves messages from one folder to another folder. If a destination folder does not exist, refile asks if it should create the folder.

Flags

-draft	Copies the current draft message from your mail directory.			
-file file	Copies the specified file. The file must be in valid message format. (Use the inc command to incorporate new messages and to format them correctly.)			
+folder	Copies the messages to the specified folder. Any number of folders can be specified.			
-help	Displays help information for the command.			
-link	Leaves the messages in the source folder or file after they are copied.			
-nolink	Removes the messages from the source folder or file after they are copied. This flag is the default.			
-nopreserve	Renumbers the messages that are copied. Renumbering begins with the number that is one higher than the last message in the destination folder. This is the default.			
-preserve	Preserves the message numbers of the messages that are copied. If messages with those numbers already exist, refile issues an error message and does not alter the contents of the folders.			
-src +folder msgs	Specifies the messages to be copied. You can use the following message references when specifying <i>msgs</i> :			
			prev next sequence t message in the current folder. If a current folder. If the -link flag and	

all are used, the current message does not change. Otherwise, if a message is specified, that message becomes the current message.

Profile Entries

Current-Folder:

Sets your default current folder.

Folder-Protect:

Sets the protection level for your new folder directories.

Path:

Specifies your *user_mh_directory*.

rmmproc:

Specifies the program used to remove messages from a folder.

The mh-profile file in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

regcmp

Purpose

Compiles patterns.

Syntax

OL805211

Description

The **regcmp** command compiles the pattern in *file*, placing its output in *file*.i.

In most cases, **regcmp** makes unnecessary the use of the **regcmp** system call in your C programs, saving execution time and program size. The output of **regcmp** is C source code. Make each file entry a C variable name, followed by one or more blanks, followed by a pattern enclosed in double quotation marks (" "). Compiled patterns are initialized **char** declarations. Thus, *file.*i can be included in C programs, and *file.*c can be a file parameter to the **cc** command. The C program that uses **regcmp** output should use the **regex** subroutine to apply it to a string. (See **regcmp** and **regex** in AIX Operating System Technical Reference.)

Flag

- Places the output in file.c

Related Information

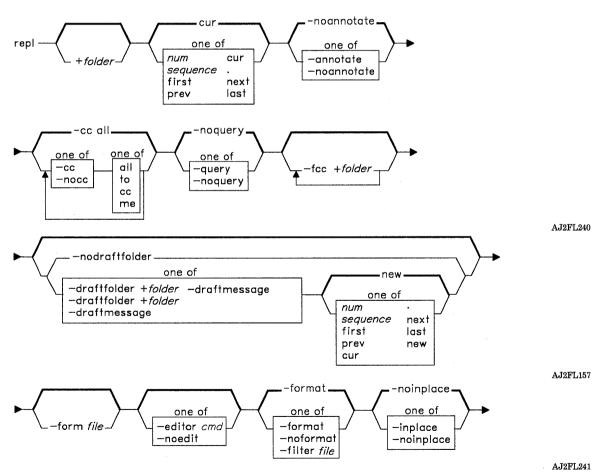

The regcmp subroutine in AIX Operating System Technical Reference.

repl

Purpose

Replies to a message.

Syntax

AJ2FL226

Description

The **repl** command is used to compose a reply to a message. **repl** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

By default, repl copies a message form to a new draft message and invokes an editor. You can then fill in the message header fields To: and Subject:, fill in or delete the other header fields (such as cc: and Bcc:), and add the body of the message. When you exit the editor, the repl command invokes the MH command whatnow. You can press Enter to see a list of the available whatnow subcommands. These subcommands enable you to continue editing the reply, list the reply, direct the disposition of the reply, or end the processing of the repl command. "whatnow" on page 1215 describes the subcommands.

You can specify the message that you want to reply to by using the +folder msg flag. If you do not specify a message, repl replies to the current message.

You can specify the format of the reply by using the **-form** flag. If you do not specify this flag, **repl** uses your default message format located in the file $user_mh_directory/replcomps$. If this file does not exist, **repl** uses the system default message format located in /usr/lib/mh/replcomps.

Note: The line of dashes or a blank line must be left between the header and the body of the message for the message to be identified when it is sent.

Flags

-annotate Annotates the message being replied to with the lines:

Replied: date Replied: addrs

The annotation appears in the original draft message so that you can maintain a complete list of activities associated with the original message. If you do not actually send the reply using the immediate repl command, the **-annotate** flag may fail to provide annotation. The **-inplace** flag forces annotation to be done in place.

-cc names

Specifies the users who will be listed in the cc: field of the reply. You can specify the following for names: all, to, cc, and me. The default is -cc all.

-draftfolder + folder

Places the draft message in the specified folder. If you do not specify this flag, repl selects a default draft folder according to the information supplied in the MH profiles. You can define a default draft folder in **\$HOME/.mh_profile**. If -draftfolder + folder is followed by msg, msg represents the -draftmessage attribute.

-draftmessage msg

Specifies the draft message. You can use one of the following message references as msg:

numsequence first prev cur last next new

The default draft message is **new**.

-editor cmd

Specifies that *cmd* is the initial editor for composing the reply. If you do not specify this flag, repl selects a default editor or suppresses the initial edit, according to the information supplied in the MH profiles. You can define a default initial editor in **\$HOME/.mh_profile**.

-fcc +folder

Places a file copy of the reply in *folder*. If you do not specify this flag, repl will not produce a file copy.

-filter file

Reformats the message being replied to and places the reformatted message in the body of the reply. -filter uses the mhl command and the specified format file. If you do not specify this flag. repl will omit the original message from the reply. The **repl** command does not have a default filter file. Thus, if you specify **-filter**, you must also specify *file*.

+folder msg

Replies to the specified message in the specified folder. You can use one of the following message references as msg:

numsequence first prev cur last next

The default message is the current message in the current folder. If you specify a folder, that folder becomes the current folder. The message being replied to becomes the current message.

-form file Uses the form contained in the specified file for the form of

the reply. repl treats each line in *file* as a format string.

-format Removes duplicate addresses from the fields To:, cc:, and Bcc:

and standardizes these fields. repl also uses the columns specified by the -width flag to determine the format of these

fields. This flag is the default.

-help Displays help information for the command.

-inplace Forces annotation to be done in place in order to preserve

links to the annotated message.

-noannotate Does not annotate the message. This flag is the default.

-nocc names Specifies the users who will not be listed in the cc: field of

the reply. You can specify the following for names: all. to.

cc. and me.

-nodraftfolder Places the draft in the file user_mh_directory/draft.

-noedit Suppresses the initial edit.

-noformat Does not remove duplicate addresses from the fields To:, cc:,

and Bcc: or standardize these fields. repl also does not use the columns specified by the -width flag to determine the

format of these fields.

-noinplace Does not perform annotation in place. This flag is the default.

-noquery Automatically builds the To: and cc: fields. This flag is the

default.

-nowhatnowproc Does not invoke a program that guides you through the reply

tasks. The **-nowhatnowproc** flag also prevents any edit from

occurring.

-query Builds the To and cc: fields by interactively asking you if you

want each address that would normally be placed in these

fields actually placed in these fields.

-whatnowproc cmdstring Invokes cmdstring as the program to guide you through the

reply tasks. See "whatnow" on page 1215 for information about the default whatnow program and its subcommands.

Note: If you specify whatnow for *cmdstring*, **repl** invokes an internal **whatnow** procedure rather than a program with the

file name whatnow.

-width num Sets the width of the address fields. The default is 72 columns.

Profile Entries

Alternate-Mailboxes:

Specifies your mailboxes.

Current-Folder: **Draft-Folder:**

Sets your default current folder. Sets your default folder for drafts.

Editor:

Sets your default initial editor.

fileproc: mhlproc: Specifies the program used to refile messages. Specifies the program used to filter the message for which you

are creating a reply.

Msg-Protect:

Sets the protection level for your new message files.

Path:

Specifies your *user_mh_directory*.

whatnowproc:

Specifies the program used to prompt What now? questions.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

restore

Purpose

Copies back files created by the backup command.

Syntax

Description

The **restore** command reads files written by the **backup** command to a backup medium and restores them to a file system. You can restore files that are backed up on a local system or on a remote system.

There are four ways to use the restore command:

- To display a table of contents for the backup (-T) or to display label information (-t)
- To restore specified files (-x)
- To restore an entire file system (-r) or begin at an arbitrary volume number (-R).
- To restore an entire minidisk (-m).

When you do not specify a restore device, the **restore** command reads files from a default backup device. For restore by name, **restore** -x, the system reads from /dev/rfd0 unless you specify a device with the -f flag. For restore by file system, **restore** -i, or restore by minidisk, **restore** -m, if /etc/filesystems contains a stanza that matches the name you specified and a stanza with a **backupdev** entry, then the system reads from the device specified by **backupdev**. Otherwise, the system reads from /dev/rmt0 or the device specified with the -f flag.

If neither -i nor -u is specified, files are restored to the local node in the current directory. If either -i or -u is specified, the system needs to know where to restore the files. Either a target node or a qualifying directory or both can be used to tell the system where to restore the files. If they are not specified, **restore** looks for the information in the header file of the backup. If you are restoring files backed up with an old version of the **backup** that does not contain a header and you do not specify a target node and a qualifying directory on the command line, the **restore** command ends in an error.

Notes:

- 1. If you restore by file system or by minidisk, the source and target must be on the local system. To restore from a remote system, restore by name with the -i or -u flags. These flags allow users in a distributed services environment to restore files backed up on a remote tape drive.
- 2. If the file system you are restoring is mounted and is not the root file system, **restore** unmounts the file system before it performs an i-node or a minidisk restore and then remounts the file system before quitting. If the file systems you are restoring include the root file system, **restore** ensures that the other file systems are not in use. If one is, it warns you of this and quits.
- 3. Files must be restored using the same method by which they were backed up. For example, if a file system was backed up by minidisk, it must be restored by minidisk.
- 4. When more than one diskette is required, **restore** reads the one mounted, prompts the user for a new one, and waits for the user's response (unless you are in unattended mode). After inserting the new diskette, press **Enter** to continue restoring files.

Flags

-Cnum Specifies the number of blocks to read in a single input operation. If you do not specify this flag, **restore** selects a default value appropriate for the physical device you have selected. Larger values of num result in longer physical transfers from tape devices. **restore** always ignores the value of the -C flag

when it reads a diskette; the input is always read in clusters that occupy a complete track.

Indicates that if *file* is a directory, all files in that directory should be restored. In this case, the name of each restored file is always its name as shown by **restore-T**, whether the backup was by name or by i-node. The *file* names supplied need not be directories. Thus, for i-node backups:

restore -x a/b/file.c

creates a file whose name is its i-node number, while:

restore -xd a/b/file.c

creates a file named a/b/file.c. With this flag, file names can include pattern-matching characters, although you must quote these characters to prevent their expansion by the shell.

Use this flag only when you are restoring by individual file name (-x).

- -fdevice Specifies the input device. Specify device as a file name (such as /dev/rmt0) to get input from the named device or specify (minus) to get input from the standard output device. The feature enables you to improve performance when restoring from streaming tape by piping the output of a dd command to the restore command (see example). The restore command recognizes a special syntax for the names of input files. If the device parameter is a range of names, for example /dev/rfd0-3, restore automatically goes from one drive in the range to the next. After using all of the specified drives, it stops and requests that another diskette be inserted.
- -h Specifies that the access and modification times of restored files are to be set to the time of restoration. (The default action is to set the access and modification times to the file times on the backup medium.) If a restored file is an archive, the modification times in all the member headers are also set to the time of restoration. You can specify this flag only when you are restoring individually named files.
- -i Enables users in a distributed services environment to restore from a backup medium on a remote system in interactive mode (user input is permitted).
- -m Restores an entire minidisk as an exact image.

Note: You can use this flag only with minidisks that are at least as large as the original minidisk that was backed up. If the minidisk is larger than the original, the leftover space becomes unusable after restoring the minidisk. You can use restore -t to see how large a minidisk you need.

-N node Specifies the node on which to restore files. The node can be a node nickname or a node id. The **restore** command uses this node instead of the node in the backup header.

- Specifies that the removable medium is ready to use. In this case, restore -q proceeds without prompting you to prepare the removable medium.
- -Q adir Specifies the qualifying directory in which to restore files. The *qdir* can be a relative or absolute directory. The restore command uses this qualifying directory instead of the directory in the backup header. Current directory relative names extracted from the backup medium are placed in this directory.
- Restores an entire file system. Use this flag with i-node backups only (see -r "backup" on page 88). filesystem can be a device name (block or character special file) or a directory name that restore looks up in /etc/filesystems.

If you are restoring a full (level 0) backup, run the mkfs command to create an empty file system before doing the restore. If you are restoring an incremental backup at, for example, level 2, run mkfs, then restore the appropriate level 0 backup, then the level 1 backup, and finally the level 2 backup.

Warning: If you do not follow this procedure carefully, you can ruin an entire file system. As an added safety precaution, run fsck after vou restore each backup level.

- -R Restarts an aborted restore at a specified point. restore prompts you for the starting volume number. This flag is invalid in combination with the -m flag.
- -T Displays the backup file header and the names of the backed up files. If the backup was made by name (backup -i), the names displayed are the ones you provided to backup. If the backup was made by i-node, restore displays the i-number of each file along with the file name. The names are relative to the root directory of the file system backed up. The only exception is the root directory itself, whose name is given as a slash (/).
- Displays only the backup file header. -t
- Enables users to restore files in unattended mode (user input is not permitted) -u from a backup medium on a remote system. If any user input (such as Please mount volume 1 on /dev/rfd0) is required, the command ends in an error. This enables users to set up a shell file that restores files at night or at other times when a user is unavailable.
- Reports the progress of the restoration as it proceeds. -v
- Restores individually named files. The names must be in the same form as the -X names shown by restore -T. With a name backup, restore gives the restored file whatever name was supplied when the file was backed up. If the original name was specified relative to the current directory, restore creates a file relative to the current directory. restore automatically creates any needed directories. With an i-node backup, the name of the restored file is the same as its i-number. This flag is invalid with the -m flag and the -r flag.

Examples

1. To list the names of files previously backed up:

```
restore -T
```

Information is read from the default backup device /dev/rfd0. If individual files were backed up, then only the file names are displayed. If an entire file system was backed up, the i-number is also shown.

2. To display technical information about a backup:

```
restore -t
```

This command displays information including when the backup was made, which file system was saved, and whether it is a backup by name, a backup by minidisk, or a backup by file system or i-node.

3. To restore files to the main file system:

```
restore -x -v
```

The -x extracts all the files from the backup medium and restores them to their proper places in the file system. The -v displays a progress report as each file is restored. If a file system backup is being restored, then the files are named with their i-numbers. Otherwise, just the names are displayed.

4. To copy selected files:

```
restore -xv /u/jim/manual/chap1
```

This command extracts the file /u/jim/manual/chap1 from the backup medium and restores it. To work properly, /u/jim/manual/chap1 must be a name that can be displayed by restore -T.

5. To copy all the files in a directory:

```
restore -xdv manual
```

This command restores the directory manual and the files in it. If it does not exist, a directory named manual is created in the current directory to hold the files being restored.

6. To restore an entire file system backup:

```
mkfs /dev/hd1 restore -rv /dev/hd1
```

This command restores an entire file system backup onto /dev/hdl. It destroys and replaces any file system that was previously stored on /dev/hdl. If the backup was made using incremental file system backups, restore the backups in increasing backup-level order (0, 1, 2 . . .).

7. To restore a minidisk:

```
restore -m /dev/hd1
```

This restores the exact image of minidisk /dev/hdl. You can also identify the minidisk by its stanza name in the /etc/filesystems file.

8. To restore files in interactive mode from the remote default device specifying a new target node and qualifying directory:

```
restore -xi -N nick -0 /u/nick
```

This command extracts the files from the default remote backup device and restores them to the node nick. Any unqualified names from the media are extracted relative to the directory /u/nick. The contents of the backup header (if a header exists) is ignored.

9. To restore files in unattended mode specifying a target node id:

```
restore -xuN 10813661
```

Files from the default backup device are restored at the node whose node ID is 10813661. Since a qualifying directory is not specified and the backup contains a backup header file, the restore command extracts the files to the qualifying directory specified in the header.

10. To improve performance on streaming tape, pipe the **dd** command to the **restore** command:

```
dd of=/dev/rmt0 bs=30b | restore -xf-
```

The **dd** command copies the files from an output file which is a streaming tape device (of=/dev/rmt0) and specifies a file size of 30 blocks (bs=30b). The output is piped to restore. The restore command gets the input from the standard input device (f-) and restores up by name (X).

The file systems and backup files in AIX Operating System Technical Reference.

"Backing up and Restoring Files" in Using the AIX Operating System.

rexd

Purpose

Handles remote execution requests.

Syntax

/usr/etc/rpc.rexd ____

OL805507

Description

When a remote execution request is made, the **inetd** daemon starts **rexd** if the appropriate entry is in the /etc/inetd.conf file.

Noninteractive programs use standard file descriptors connected directly to Simulates phototypesetter output for a Tektronix 4014 work station connections. Interactive programs use pseudo-terminals, similar to the login sessions provided by **rlogin**. Diagnostic messages are normally displayed on the console and returned to the requestor.

The **rexd** daemon can use NFS to mount file systems specified in the remote execution request.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

/dev/ptsn /etc/passwd /etc/inetd.config Pseudo-terminals used for interactive mode.

List of authorized users. TCP/IP configuration file.

Related Information

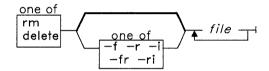

The following command: "on" on page 726.

rm

Purpose

Removes files or directories.

Syntax

OL805212

Description

The **rm** (**delete**) command removes the entries for *files* from a directory. If an entry is the last link to a file, it is destroyed. To remove a file, you must have write permission in its directory, but neither read nor write permission for the file itself if you own it or are acting with superuser authority.

If a file has no write permission and standard input is a work station, **rm** displays the file permission code and reads a line from standard input. If that line begins with y, **rm** deletes the file. If the response is anything other than y, **rm** does nothing.

Japanese Language Support Information

An affirmative response in Japanese Language Support matches one of the elements in the environment variable YESSTR.

Flags

- -f Does not prompt before removing a write-protected file.
- -i Prompts you before deleting each file. When you use both -i and -r together, rm also asks if you want to examine directories.
- -r Permits recursive removal of directories and their contents (for cases where *file* is a directory).

Examples

1. To delete a file:

```
rm myfile
```

If there is another link to this file, then the file remains under that name, but the name myfile is removed. If myfile is the only link, the file itself is deleted.

2. To delete a file silently:

```
rm -f core
```

This removes **core** without asking any questions or displaying any error messages. This is normally used in shell procedures. It prevents confusing messages from being displayed when deleting files that may or may not exist.

3. To delete files one by one:

```
rm -i mydir/*
```

This interactively asks you if you want to remove each file. After each file name is displayed, enter y to delete the file, or press **Enter** to keep it.

Japanese Language Support Information

Enter one of the allowed affirmative responses at the prompts. The allowed affirmative responses are defined in the environment variable **YESSTR**.

4. To delete a directory tree:

```
rm -ir manual
```

This recursively removes the contents of all subdirectories of manual, then removes manual itself, asking if you want to remove each file. For example:

```
You: rm -ir manual
System: directory manual:
You: y
System: directory manual/draft1:
You: y
System: manual/draft1/chapter1:
You: y
System: manual/draft1/chapter2:
You: y
System: manual/draft1:
You: y
System: directory manual/draft2
```

```
You: Y
System: manual/draft2:
  You: n
System: manual:
  You: V
```

Here, rm first asks if you want it to search the directory manual. Because manual contains directories, rm next asks for permission to search manual/draftl for files to delete, and then asks if you want it to delete the files manual/draft1/chapter1 and manual/draft1/chapter2. rm next asks for permission to search the directory manual/draft2, and then asks for permission to delete the directories manual/draft1, manual/draft2, and manual. Because you denied permission to remove manual/draft2, rm will not remove manual. Instead, you will see the message rmdir: manual not empty.

34.

rmail

rmail

Purpose

Handles remote mail received via uucp.

Syntax

AJ2FL255

Description

The rmail command interprets incoming mail received via uucp. It collapses From lines in the form generated by bellmail into a single line of the form:

return-path!sender

It passes the processed mail on to sendmail.

The rmail command works with uucp and sendmail. This is a new command with Version 2.2 of AIX Operating System. It is not the same as the rmail command found in earlier versions of AIX Operating System.

Related Information

The following commands: "uucp" on page 1144 and "sendmail" on page 897.

rmdel

Purpose

Removes a delta from a Source Code Control System (SCCS) file.

Syntax

OL805213

Description

The rmdel command removes the delta specified by SID from each named Source Code Control System (SCCS) file. You can remove only the most recently created delta in a branch, or the latest trunk delta if it has no branches. In addition, the SID you specify must not be a version currently being edited for the purpose of making a delta. To remove a delta, you must either own the SCCS file and the directory, or you must be the user who created the delta you want to remove.

If you specify a directory in place of file, rmdel performs the requested actions on all SCCS files (those with file names that have the s.prefix). If you specify a - (minus) in place of file, rmdel reads standard input, and interprets each line as the name of an SCCS file. rmdel continues to take input until it reads an end-of-file character.

Flag

-rSIDRemoves the delta SID from the SCCS file. This flag is required.

Related Information

The following commands: "delta" on page 310, "get" on page 477, "help" on page 513, and "prs" on page 781.

The sccsfile file in AIX Operating System Technical Reference.

The discussion of SCCS in AIX Operating System Programming Tools and Interfaces.

rmdir

Purpose

Removes a directory.

Syntax

```
rmdir _____directory ____
```

OL805252

Description

The **rmdir** command removes a *directory* from the system. The *directory* must be empty before you can remove it, and you must have write permission in its parent directory. Use the **li** -l command to see if the *directory* is empty.

Example

To empty and remove a directory:

```
rm mydir/* mydir/.*
rmdir mydir
```

This removes the contents of mydir, then removes the empty directory. The rm command displays an error message about trying to remove the directories. (dot) and.. (dot dot), and then rmdir removes them.

Note that rm mydir/* mydir/.* first removes files with names that do not begin with a dot, then those with names that do begin with a dot. You may not realize that the directory contains file names that begin with a dot because the li command does not normally list them.

Related Information

The following command: "rm" on page 833.

The unlink and rmdir system calls in AIX Operating System Technical Reference.

rmf

Purpose

Removes a folder.

Syntax

AJ2FL165

Description

The rmf command is used to remove folders and the messages that they contain. rmf is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

Warning: The rmf command irreversibly deletes messages that do not have other links.

The rmf command deletes all of the messages within the specified folder and then deletes the folder. If the folder contains files that are not messages, rmf does not delete those files and reports an error.

If you have read-only access to the specified folder, rmf does not delete the folder or any of its messages. rmf deletes only your private sequences and your current message information from the profile.

The rmf command does not delete folders recursively. Thus, you cannot remove subfolders by requesting the removal a parent folder.

Flags

+folder Specifies the folder to be removed. If you remove a subfolder, the parent

of that folder becomes the current folder. If you remove the current folder, +inbox becomes current. The default folder is the current folder. If +folder is not specified and rmf cannot find the current folder, rmf.

requests confirmation for removing +inbox.

-help

Displays help information for the command.

-interactive

Requests confirmation before removing the folder. If +folder is not

specified, this is the default.

-nointeractive

Removes the folder and its messages without requesting confirmation. If

+folder is specified, this is the default.

Profile Entries

Current-Folder:

Sets your default current folder.

Path:

Specifies your *user_mh_directory*.

Files

\$HOME/.mh_profile

The MH user profile.

Related Information

The MH command "rmm" on page 841.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

rmm

Purpose

Removes messages.

Syntax

AJ2FL203

AJ2FL202

OL805308

Description

The rmm command is used to remove messages from active status. rmm is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The rmm command renames the specified message files so that their file names have preceding commas. You can use these files as temporary backups and arrange for the cron command to delete your backups periodically.

¹ Do not put a blank between these items.

Flags

+folder msgs

Specifies the messages that you want to remove. msgs can be several messages, a range of messages, or a single message. You can use the following message references when specifying msgs:

numfirstprevcur.nextlastallsequence

The default message is the current message in the current folder. rmm does not change the current message.

-help

Displays help information for the command.

Profile Entries

Current-Folder:

Sets your default current folder.

Path: rmmproc:

Specifies your *user_mh_directory*.

Specifies the program used to remove messages from a folder.

Files

\$HOME/.mh_profile

The MH user profile.

The mh-profile file in AIX Operating System Technical Reference.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

rpcgen

Purpose

Compiles a Remote Procedure Call program.

Syntax

OL805497

Description

The rpcgen command generates C Language code for implementing an RPC protocol. Input to rpcgen is in Remote Procedure Call Language (RPCL). RPCL is similar to the C Programming Language.

The **rpcgen** command operates in the following modes:

- Converts RPCL definitions to C Language definitions and puts them in a header file.
- Compiles the XDR routines that serialize or convert the data between the machine issuing the Remote Procedure Call and the machine carrying it out.
- Compiles converted RPCL definitions and puts them in a header file named infile.h. Compiles the XDR routines and puts them in *infile.c.*

• Compiles an RPC server skeleton. Using the skeleton, you can write local procedures that implement RPC servers without invoking RPC protocols.

In each mode, the input can contain comments (with the same format as C Language comments) and preprocessor directives. The comments are ignored and the directives are copied into the output header file. You can customize XDR routines by leaving some data types undefined. For every undefined data type, **rpcgen** will assume that a routine with an **xdr**- prefix exists.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-c	Compiles XDR routines.
-h	Compiles C data definitions in a header file.
-o outfile	Specifies the name of the output file. If you do not specify an output file, rpcgen uses the standard output as the default.
-s transport	Compiles a server using a specified data transport. This flag can be invoked more than once in order to compile a server that serves multiple transports.

rpcinfo

Purpose

Reports Remote Procedure Call status information

Syntax

OL805495

Description

The **rpcinfo** command reports the status of Remote Procedure Call services on a specified host. The host parameter specifies the Remote Procedure Call server. The program parameter specifies the program used by the remote procedure. It can be a name or a number. The version number of the program used by the remote procedure is specified by version. If you do not specify a version number, rpcinfo searches for all registered version numbers and calls each one.

Note: The rpcinfo command uses version 0 to search for all registered versions, since 0 is not usually assigned as a program's version number. If version 0 is assigned to a program's version number, rpcinfo uses a high level number in its place.

rpcinfo

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -p Queries the *host* portmap service and displays a list of registered RPC programs. If *host* is not specified, the value returned by **hostname** is the default value.
- -t Uses the TCP/IP data transport to make a Remote Procedure Call to **procedure** 0 of the *program* on the specified *host* and report if a response was received.
- -u Use the UDP/IP data transport to make a Remote Procedure Call to **procedure** 0 of the *program* on the specified *host* and report if a response was received.

Files

/etc/rpc RPC program names. /etc/inetd.conf TCP/IP configuration file.

rstatd

Purpose

Returns NFS performance statistics from the kernel

Syntax

/usr/etc/rpc.rstatd——

OL805494

Description

The rstatd daemon returns performance statistics from the kernel. The inetd daemon invokes rstatd.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/inetd.config TCP/IP configuration file.

Related Information

The following command: "rup" on page 854.

runacct

Purpose

Runs daily accounting.

Syntax

OL805253

Description

The runacct command is the main daily accounting shell procedure. Normally initiated by cron, runacct processes connect, fee, disk, queueing system and process accounting data files. It also prepares summary files for the prdaily procedure or for billing purposes.

The runacct command protects active accounting files and summary files in the event of run-time errors. It records its progress by writing descriptive messages into the file /usr/adm/acct/nite/active. When runacct encounters an error, it writes a diagnostic message to /dev/console, sends mail to users root and adm, and exits.

The runacct procedure also creates two temporary files, lock and lock1 in the directory /usr/adm/acct/nite, which it uses to prevent two simultaneous calls to runacct. It uses the file lastdate (in the same directory), to prevent more than one invocation per day.

The runacct command breaks its processing into separate, restartable *states*. As it completes each state, it writes the name of the next state in /usr/adm/acct/nite/statefile. runacct processes the various states in the following order:

State	Actions
SETUP	Moves the active accounting files to working files and restarts the active files.
WTMPFIX	Verifies the integrity of the wtmp file, correcting date changes if necessary.
CONNECT1	Calls acctcon1 to produce connect session records.

CONNECT2 Converts connect session records into total accounting records (tacct.h

format).

PROCESS Converts process accounting records into total accounting records

(tacct.h format).

MERGE Merges the connect and process total accounting records.

FEES Converts the output of chargefee into total accounting records (tacct.h

format) and merges them with the connect and process total accounting

records.

DISK Merges disk accounting records with connect, process, and fee total

accounting records.

QUEUEACCT Sorts the queue (printer) accounting records, converts them into total

accounting records (tacct.h format), and merges them with other total

accounting records.

MERGETACCT Merges the daily total accounting records in daytacct with the

summary total accounting records in /usr/adm/acct/sum/tacct.

CMS Produces command summaries in the file /usr/adm/acct/sum/cms.

USEREXIT If the shell file /usr/adm/siteacct exists, calls it at this point to perform

site-dependant processing.

CLEANUP Deletes temporary files and exit.

To restart runacct after a failure, first check the /usr/adm/acct/nite/active file for diagnostic messages, then fix any damaged data files such as pacct or wtmp. Remove the lock files and lastdate file (all in the /usr/adm/acct/nite directory), before restarting runacct. You must specify the mmdd parameter if you are restarting runacct. It specifies the month and day for which runacct is to rerun the accounting. runacct determines the entry point for processing by reading statefile. To override this default action, specify the desired state on the runacct command line. For a more detailed discussion of restarting runacct, see Managing the AIX Operating System.

It is not usually a good idea to restart runacct in the SETUP state. Instead, perform the setup actions manually and restart accounting with the WTMPFIX state, as follows:

runacct mmdd WTMPFIX

If runacct fails in the PROCESS state, remove the last ptacct file, because it will be incomplete.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Examples

1. To start runacct:

nohup /usr/lib/acct/runacct 2> /usr/adm/acct/nite/accterr &

This starts runacct in the background (&), ignoring all INTERRUPT and QUIT signals (nohup). All standard error output is written to the file /usr/adm/acct/nite/accterr.

2. To restart runacct:

nohup /usr/lib/acct/runacct 0601 2>> /usr/adm/acct/nite/accterr &

This restarts **runacct** for the day of June 1 (0601). **runacct** reads the file /**usr/adm/acct/nite/statefile** to find out the state to begin with. Standard error output is added to the end of the file /usr/adm/acct/nite/accterr.

3. To restart runacct in a specific state, in this case the MERGE state:

nohup /usr/lib/acct/runacct 0601 MERGE 2>> /usr/adm/acct/nite/accterr &

Files

/usr/adm/wtmp
/usr/adm/pacct*
/usr/adm/acct/nite/daytacct
/usr/adm/qacct
/usr/adm/fee
/usr/adm/acct/sum/*

The acct system call and the acct and utmp files in AIX Operating System Technical Reference.

"Running System Accounting" in IBM RT Managing the AIX Operating System.

runcat

Purpose

Pipes data from mkcatdefs to runcat

Syntax

OL805491

Description

The runcat command invokes the **mkcatdefs** command and pipes the message source data (the output from **mkcatdefs**) to the **gencat** program. This method is simpler than using the redirection operator > to capture the output from **mkcatdefs** and then running **gencat**. The format for **runcat** is:

\$ runcat catname sourcefile [catfile]

The file sourcefile contains the message text with your symbolic identifiers. **mkcatdefs** uses catname to generate the name of the symbolic definition file by adding **_msg.h** to the end of catname, and to generate the symbolic name for the catalog file by adding **MF**₋ to the beginning of catname. The definition file must be included in your application program. The symbolic name for the catalog file can be used in **catopen** or **NLcatopen** instead of the actual file name.

catfile is the name of the catalog file created by **gencat**. If you do not specify this parameter, **gencat** names the catalog file by adding .cat to the end of catname. This file name can also be used in catopen or NLcatopen.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

⁸ runcat is an AIX extension to the X/Open standard.

Related Information

The following commands: "dspcat" on page 357, "dspmsg" on page 359, "gencat" on page 470, and "mkcatdefs" on page 651.

rup

Purpose

Displays the status of hosts on a network.

Syntax

OL805492

Description

The **rup** command broadcasts a query on the local network and displays the responses it receives. It gives a status report on system usage times (uptimes) and load averages.

To query specific hosts, list their names as arguments following rup.

Note: Remote hosts respond only if running the rstatd daemon. The rstatd daemon is started from inetd.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

When used without flags, **rup** displays the responses in the order it receives them. Use the following flags to change the display order.

- -h Displays responses alphabetically by host name.
- -l Displays responses by load average.
- -t Displays responses by up time.

Related Information

The following command: "rstatd" on page 847.

rusers

Purpose

Identifies users logged in on network hosts

Syntax

OL805496

Description

The rusers command broadcasts a query on the local network and displays the responses it receives.

To query specific hosts, list their names following the rusers command.

Note: Remote hosts will only respond if they are running the rusersd daemon (started from /etc/inetd.conf).

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

The rusers command displays the responses to the query in the order it receives them. Each machine is listed on a separate line. Use the following flags to change the print order:

- -a Responds for all machines even if no users are logged in.
- -h Sorts responses alphabetically by host name.
- -i Sorts responses by idle time. Idle time is reported if a user has not typed into the system for more than a minute.
- -l Responds with a longer listing in the style of the who command.

Sorts responses by numbers of users. -u

File

/etc/inetd.conf TCP/IP configuration file.

Related Information

The following commands: "who" on page 1219 and "rusersd" on page 858.

rusersd

rusersd

Purpose

Responds to queries from rusers command.

Syntax

/usr/etc/rpc.rusersd____

OL805505

Description

The rusersd daemon allows remote hosts to respond to queries from the rusers command. The inetd daemon invokes rusersd.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/inetd.conf TCP/IP configuration file.

Related Information

The following command: "rusers" on page 856.

rwall

Purpose

Writes to all users over a network.

Syntax

OL805547

Description

The **rwall** command reads a message from standard input and broadcasts it to all users logged in to the specified host machines. It reads the message from standard input until it reaches an **end-of-file** character.

The rwall sends the message with the following introduction line:

Broadcast Message.....

Note: Users can only receive a message if they are running rwalld. This daemon is started by the **inetd** daemon.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-n Sends the message to specific network groups only. Network groups are defined in the netgroup file.

File

/etc/netgroup

Related Information

The following command: "rwalld" on page 861.

The netgroup file format in AIX Operating System Technical Reference.

rwalld

Purpose

Handles requests for the rwall and shutdown commands.

Syntax

/usr/etc/rwalld -----

OL805545

Description

The rwalld daemon handles requests from the rwall and shutdown commands. The inetd daemon invokes rwalld.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/inetd.conf TCP/IP configuration file.

Related Information

The following commands: "rwall" on page 859 and "shutdown" on page 946.

sact

Purpose

Displays current Source Code Control System (SCCS) file editing status.

Syntax

OL805063

Description

The sact. command reads Source Code Control System (SCCS) files and writes to standard output the contents, if any, for the p-file associated with file (see "SCCS Files" on page 478 for information on the contents of the p-file). If - (minus) is specified for file, sact. reads standard input, and interprets each line as the name of an SCCS file. If file is a directory, sact. performs its actions on all SCCS files (that is, those files with the s. prefix).

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Related Information

The following commands: "delta" on page 310, "get" on page 477, and "unget" on page 1116.

The sccsfile file in AIX Operating System Technical Reference.

The discussion of SCCS in AIX Operating System Programming Tools and Interfaces.

sadc

Purpose

Provides a system activity report package.

Syntax

OL805254

Description

The operating system contains a number of counters that are incremented as various system actions occur. They include the following:

- System unit utilization counters
- Buffer usage counters
- Disk and tape I/O activity counters
- tty device activity counters
- Switching and system-call counters
- File-access counters
- Queue activity counters
- Interprocess communications counters

The sadc command and the sa1 and sa2 shell procedures sample, save, and process this data.

Note: These commands only report on local activities.

See the sar command for the format and flag description. Note that you cannot use the -o and -f flags with sa2.

sadc

The **sadc** command, the data collector, samples system data *num* times every *interval* seconds. It writes in binary format to *outfile* or to the standard output. If you do not specify *interval* or *num*, a special record is written. This facility is used at system startup to mark the time when the counter restarts from zero.

sa1

Use the shell procedure sal, a variant of sadc to collect and store binary data in the file /usr/adm/sa/sadd, where dd is the day of the month. The interval and num parameters specify that the record should be written num times at interval seconds. If you do not specify these parameters, one record is written. You must have permission to write in the directory /usr/adm/sa to use this command.

The sal command is designed to be started automatically by the cron command.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

sa2

Use the shell procedure sa2, a variant of the sar command, to write a daily report in the file /usr/adm/sa/sardd. See "sar" on page 867 for a description of the flags.

The sa2 command is designed to be started automatically by the cron command.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Files

/usr/adm/sa/sadd /usr/adm/sa/sardd /tmp/sa.adrfl Daily data file, dd represents the day of the month. Daily report file, dd represents the day of the month. Address file.

Related Information

The following commands: "cron" on page 220, "sag" on page 865, "sar" on page 867, and "timex" on page 1069.

sag

Purpose

Displays a graph of system activity.

Syntax

OL805387

Description

The sag command displays a graph of system activity. It gets information either from the daily activity file usr/adm/sa/sadd or from the binary data file selected by the -f flag. You must have already created this file by running the sar command with the -o flag. (See "sar" on page 867.)

The sag command calls the sar command, selecting the desired data by string-matching the data column header.

Flags

The sag command passes the first four of the following flags to sar in order to collect the desired data for display. The last three flags specify plotting parameters.

-e hh[:mm]Selects data up to the time specified by hh[:mm]. The default time is 18:00.

¹ The default for -y is '% usr 0 100; % usr + % sys 0 100; % usr + % sys + %wio 0 100'

-f file Reads data from file. The default file is /usr/adm/sa/sadd, the current

daily data file.

-i seconds Selects data at intervals as close as possible to seconds.

-s hh[:mm] Selects data later than the specified time. Default is 08:00.

-T workstation Produces output suitable for workstation. (See "tplot" on page 1079 for

known work stations.) If you do not specify a work station, sag uses the

value found in the shell variable \$TERM.

-x spec Specifies the x axis. spec has the following form:

name [opname] . . . [lo hi]

where name is a character string matching a column header in the sar-created data file (with an optional device name in brackets), or it is an integer value. op is +, -, *, or / surrounded by blanks, with up to five names specified. Parentheses are not recognized and evaluation is left to right. Note that + and - have precedence over * and / in evaluating expressions. lo and hi specify numeric scale limits. If these limits are unspecified. sag gets these limits from the data.

-y spec Specifies the y axis. spec has the same form as **x** spec.

Specify only one *spec* for the x axis. If unspecified, the x axis assumes the time specified with the -e and -s flags (or their defaults if they are not used) as x axis limits. You can specify up to five *specs* separated by: (semicolons) for -y. If unspecified, the y axis has the value:

-y "%usr 0 100; %usr + %sys 0 100; %usr + %sys + %wio 0 100"

If you include blanks or an escaped carriage return (\Enter) within the -x and -y specs, enclose them in " " (double quotation marks).

Files

/usr/adm/sa/sadd Daily data file for day dd.

Related Information

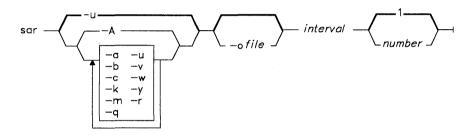

The following commands: "sar" on page 867 and "tplot" on page 1079.

sar

Purpose

Collects, reports, or saves system activity information.

Syntax

OL805390

OL805369

Description

The first format of the sar command writes to standard output the contents of selected cumulative activity counters in the operating system. It writes information a total of number times spaced interval seconds apart. The default value of number is 1. You can also save the collected data in the file specified by -o file.

In the second format (with no sampling interval specified), sar extracts and writes to standard output records previously saved in a file. This file can be either the one specified by the -f flag or, by default, the standard system activity daily data file, /usr/adm/sa/sadd, for the current day, dd.

You can select information about specific system activities with flags. Not specifying any flags selects only **cpu** activity. Specifying the **-A** flag selects all activities.

Note: This command only reports on local activities.

Flags

Reports use of file access system routines: -a iget/s Calls per second to the i-node look-up routine. namei/s Calls per second to the directory search routine. dirblk/s Directory blocks read per second by namei(). -A Report all data. -b Reports buffer activity for transfers, accesses, and cache hit ratios: lread/s, lwrit/s Number of logical read/write requests per interval. bread/s, bwrit/s Number of block read/write operations per interval. %rcache, %wcache Cache hit ratios (for example, 1 - bread/lread). pread/s, pwrit/s Read/writes per interval on seekable raw devices. Reports system calls: -c scall/s Total number of system calls per second. rchar/s, wchar/s Characters transferred per interval by read/write calls. sread/s, swrit/s fork/s, exec/s Specific system calls per second. -e hh[:mm[:ss]]Sets the ending time of the report. The default ending time is 18:00. -f file Extracts records from file (created by -o file). The default file is the current daily data file, /usr/adm/sa/sadd. -i seconds Selects data records at intervals as close as possible to the specified number of seconds. Otherwise, sar reports all intervals found in the data file. -k Reports kernel activity: ksched/s Number of kernel processes assigned to tasks per second. kproc-ov/s Number of overflows occurring between sampling points. kexit/s Number of kernel processes terminating per second.

IPC message primitives per second.

IPC semaphore primitives per second.

Reports message and semaphore activities:

-m

msg/s sema/s -o file Saves the readings in file in binary form. Each reading is in a separate record and each record contains a tag identifying the time of the reading. Reports average queue length while occupied, and percentage of time -q occupied: rung-sz, %runocc Runs queue of processes in memory and runable. Reports VRM paging statistics: -r The number of free pages on the paging minidisk. slots cvcle/s The number of page replacement cycles per second. fault/s The number of page faults per second. The number of nonpaging disk I/Os per second. odio/s -s hh[:mm[:ss]]Sets the starting time of the data. That is, extract records time-tagged at or following the time specified. The default starting time is 08:00. Reports CPU activity (this flag is on by default): -u %usr Percentage of CPU time devoted to the user. %svs Percentage of CPU time devoted to the kernel. %wio Percentage of CPU time waiting for block I/O to complete. %idle Percentage of CPU time idle. Reports status of text, process, i-node, and file tables: -v text-sz, proc-sz, inod-sz, file-sz Entries in use at each sample point for each table. text-ov, proc-ov, inod-ov, file-ov Overflows occurring at each sample point for each table. Reports system switching activity: -w pswch/s Process switches per second. Reports TTY device activity: **-y** TTY raw input queue characters per second. rawch/s canch/s TTY canonical input queue characters per second. outch/s TTY output queue characters per second. revin/s TTY receive interrupts per second. xmtin/s TTY transmit interrupts per second. mdmin/s TTY modem interrupts per second.

Files

/usr/adm/sa/sadd Daily data file, where dd are numbers representing the day of the month.

Related Information

The following command: "sag" on page 865.

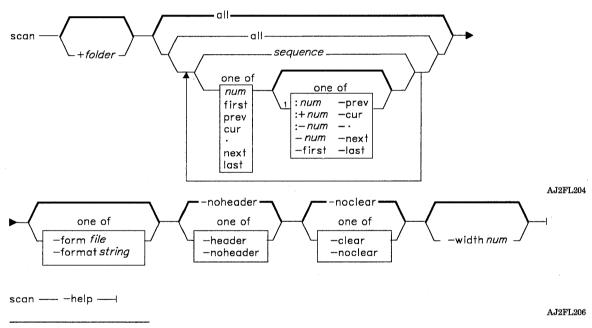

The discussion of monitoring system activity in Managing the AIX Operating System.

scan

Purpose

Produces a one line per message scan listing.

Syntax

¹ Do not put a blank between these items.

OL805308

Description

The scan command is used to display information about the messages in a specified folder. scan is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The **scan** command displays a line of information about each specified message in the specified folder. Each line gives the message number, the date, the sender, the subject, and as much of the message body as possible. If a + symbol is displayed after the message number, the message is the current message for the folder. If a - symbol is displayed, you have replied to the message. If a * symbol is displayed after the date, the **Date:** field was not present and the displayed date is the last date the message was changed.

Flags

-clear Clears the display after sending output. scan uses the values of the

\$TERM and **\$TERMCAP** environment variables to determine how to clear the display. If standard output is not a display, **scan** sends a form

feed character after sending the output.

+folder msgs Displays information about each specified message in the specified folder.

You can use the following message references when specifying msgs:

numfirstprevcur.nextlastallsequence

The default folder is the current folder. If a folder is specified, it becomes

the current folder. The default for msgs is all.

-form file Displays the scan command output in the alternate format described by

file.

-format string Displays the scan command output in the alternate format described by

string.

-header Displays a heading that lists the folder name and the current date and

time.

-help Displays help information for the command.

-noclear Does not clear the terminal after sending output. This is the default.

-noheader Does not display a heading. This is the default.

-width num Sets the number of columns in the scan command output. The default is

the width of the display.

Profile Entries

Alternate-Mailboxes:

Specifies your mailboxes.

Current-Folder:

Sets your default current folder. Specifies your *user_mh_directory*.

Path:

sccsdiff

Purpose

Compares two versions of a Source Code Control System (SCCS) file.

Syntax

OL805258

Description

The sccsdiff command reads two versions of an SCCS file, compares them, and writes to standard output the differences between the two versions. Any number of SCCS files can be specified, but the same arguments apply to all files.

Flags

-p Pipes the output through pr.

-rSID1 Specifies SID1 as one delta of the SCCS file for sccsdiff to compare.

-rSID2 Specifies SID2 as the other delta of the SCCS file for sccsdiff to compare.

-snum Specifies the file segment size for **bdiff** to pass to **diff**. This is useful when **diff** fails due to a high system load.

Related Information

The sccsfile file in AIX Operating System Technical Reference.

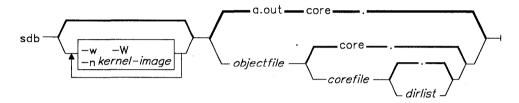

The discussion of SCCS in AIX Operating System Programming Tools and Interfaces.

sdb

Purpose

Provides a symbolic debugger for C and assembler programs.

Syntax

OL805214

Description

The **sdb** command provides a symbolic debugger to be used with C and assembler programs. With it you can examine object and core files and provide a controlled environment for running a program. You can set breakpoints at selected statements or run the program one line at a time. You can debug using symbolic variables and instruct sdb to display them in their correct format.

Normally, objectfile is an executable file produced by invoking cc with the -g flag. If you have not compiled objectfile using the -g flag or if it is not executable (because of compiler or loader errors), the symbolic capabilities of sdb are limited, but you can still examine the file and debug the program. objectfile should always be in the same directory as the source files used to construct it. Its default name is a.out.

The corefile parameter specifies a core image file. Its default is core. The system writes out this core image of a process when it ends abnormally. Specifying - (minus) for corefile instructs sdb to ignore any core image file that may be present. The colon-separated list of directories specified by the dirlist parameter identifies the location of the source files used to build *corefile*. The default is the current directory. If *dirlist* is the name of a file, the contents of the file should be a colon-separated list of directory names.

While running, sdb always recognizes a current line and current file. If corefile exists, sdb initially sets the current line and the current file to the line and the file that contains the source statement at which the process ended. Otherwise, it sets them to the first line in main and the file containing main. There is also a current function, which is the function you are working with at any given time. You can change the current line, file, or function with the e command.

Write variable names as you do in C language programs. Access variables local to a function by using the form *function:variable*. The current function is the default function. You can also specify a variable by its address. Since you can use all forms of integer constants which are valid in C, addresses can be expressed as decimal, octal, or hexadecimal values.

Refer to structure members as *variable.member*, pointers to structure members as *variable->member*, and array elements as *variable[number]*.

If you use the form *number.member* or *number->member*, **sdb** assumes *number* to be the address of the last structure referred to. Generally, **sdb** interprets a structure as a set of variables. Thus, it displays the values of all elements when you request it to display a structure. If, however, you request the address of a structure, it displays this value and not the addresses of individual elements.

Refer to elements of a multidimensional array as variable[number][number] or as variable[number,number]. In place of number, use the form number;number to indicate a range of values. You can also use an * (asterisk) to represent all legitimate values for a subscript or omit subscripts to indicate the full range of values. As with structures, sdb displays all the values of an array or of a section of an array if you omit trailing subscripts. If you omit subscripts, it displays only the address of the array itself or of the section specified.

Refer to a variable on the stack by using the form function:variable,. Here, number specifies the variable's location on the stack, counting the top, or most recently pushed variable, as the first. Use this for recursive function calls. The current function is the default.

Refer to line numbers as filename; number or function; number. The current file and current function are the default values.

Notes:

- 1. Data stored in text sections is indistinguishable from functions.
- 2. Line number information in optimized functions is unreliable, and some information may be missing.
- 3. Source line and local symbol information for routines in shared libraries is not implemented, and these modules should not be compiled with the -g flag. Break points may be set in these routines by address only, and code in shared library modules may be single-stepped by instruction only.
- 4. The **sdb** command cannot comprehend a module in which C functions (as opposed to declarations and preprocessor definitions) occur in include files.

Flags

Specifies the name of the running kernel (or the one running when -n kernel-image corefile was produced). This enables proper traces back through the floating-point emulation code. /unix is the default value.

Allows overwriting of locations in *objectfile*. -w

 $-\mathbf{W}$ Turns off the warnings normally given if source files cannot be found or are newer than objectfile.

Subcommands

Examining Program Data

 \mathbf{T} Displays the top line of the stack trace.

t Displays a stack trace of the program that ended abnormally.

variable/[nlf] Displays variable or n memory locations starting at the address of variable.

> The l parameter selects the number of bytes in one memory location. Your choices are:

b One byte

Two bytes h

Four bytes.

The f parameter selects the display format. This can be one of the following:

- Displays all bytes from the address of the variable to the first null
- Displays a character value. \mathbf{c}
- d Displays a decimal value.
- Displays a 32-bit, single-precision floating-point value. f
- Displays a 64-bit, double-precision floating-point value.
- Interprets values as assembler language instructions and displays numerically.
- i Interprets values as assembler language instructions and displays them numerically and symbolically.
- Displays an octal value. o
- Displays F if *variable* = 0; otherwise, displays T. t.
- Displays a pointer to a function. p
- Treats variable as a string pointer and displays characters beginning with the address to which it points and ending at the first null byte reached.

- u Displays an unsigned decimal value.
- x Displays a hexadecimal value.

If you do not specify n, l, or f, sdb chooses a value appropriate to variable type as declared in the source file. Specifying a memory location size works only with formats c, d, o, u, and x. You can specify the number of memory locations (n) to be displayed by the s or a formats.

For strings that contain 2-byte extended characters, the font shift character is represented by a \ (backslash) followed by lowercase s and the font shift number.

For example, \s1 means that the current byte being displayed is a font shift character. This form of representation for the font shift byte is only available when a count is specified. However, if the first character contained in the address specified by the a format is the second byte of a 2-byte extended character, then that byte is displayed without the proper shift affixed to construct the whole 2-byte sequence. (When Japanese Language Support is installed on your system, the font shift symbols are not used. Strings can contain any combination of ASCII, 1-byte kana, and kanji characters.)

The default action for these formats is to display characters until either a null byte is reached or 128 characters have been displayed. The command ./ (dot slash) re-displays the last variable.

You can use the special **sh** characters * (asterisk) and ? (question mark) in function and variable names, providing a limited form of pattern matching. If you give no function name, global variables and variables local to the current function are matched. If you specify a function name, then only variables local to that function are matched. To match only global variables, use the form :pattern.

The **sdb** command recognizes structures, arrays, and pointers so that all of the following commands work:

```
array[2][3]/
sym.id/
psym->usage/
xsym[20].p->usage/
```

line?[lf] variable?[lf]

Displays the value found in *objectfile* at the address selected by *line* or *variable* (function name), using the specified *l*ength and *f*ormat. The default format is **i**.

line = [lf] variable = [lf] number = [lf]

Displays the address of variable or line or the value of number in the specified length and format. The default is lx. number = [lf] provides a convenient way to convert decimal, octal, and hexadecimal values.

variable!value

Sets *variable* to the given *value*. *value* can be a numeric or character constant or another variable. Expressions that produce more than one value, such as structures, are not allowed as *value*. However, *variable* can be an expression which represents more than one variable, such as an array or structure name.

Specify a character constant with an initial '(single quote), for example, 'c. Numbers are treated as integers unless they contain a decimal point or an exponent. In the latter case, they are treated as having the type double. Register values are viewed as integers. If you give an address of a variable, it is treated as the address of a variable of type int. C conventions are used in any type conversions that are necessary to perform the indicated assignment.

X

Displays the machine registers and the current assembler language instruction.

X

Displays the current assembler language instruction.

Displaying and Manipulating Source Files

e function e file

e dir/

e dir file

Changes the current function, file, or directory. Specifying only function also sets the current file to the one containing the selected function. **sdb** reports the current function, file, or directory for any unspecified parameters.

/pattern/

Searches forward from the current line for a line containing a string matching *pattern*. The trailing / (slash) can be omitted. See "ed" on page 371 for a discussion of pattern notation.

?pattern?

Searches backward from the current line for a line containing a string matching pattern. The trailing? (question mark) can be omitted.

p Displays the current line.

z Displays the current line and the following nine lines. Sets the current line to the last line displayed.

w Displays the 10 lines around the current line (a window).

number Sets the current line to number. Displays the new current line.

number + Advances the current line by the specified number of lines. Displays the

new current line.

number- Decreases the current line by the specified number of lines. Displays the

new current line.

Ctrl-D Scrolls. Pressing Ctrl-D displays the next 10 lines of source or data.

Enter If the previous command displayed a source line, pressing the Enter key advances the current line by one line and displays the new current line. If the previous command displayed a memory location, pressing the Enter

key displays the next memory location.

Controlling the Running of the Source Program

 $[num] \mathbf{r} [p [p2] \dots]$

[num] R

Runs the program with the given parameters. If you specify no parameters with \mathbf{r} , it reuses previously specified parameters. \mathbf{R} runs the program with no parameters. A parameter beginning with < (left angle bracket) or > (right angle bracket) redirects input or output, respectively. If given, num selects the number of breakpoints to be ignored.

[line] **b** [command[; command] . . .]

Sets a breakpoint at the given line. If you specify a function name without a line number, **sdb** places a breakpoint at the first line in the function, even if it was not compiled with the **-g** flag. If you do not specify a *line*, a breakpoint is placed at the current line. If you specify no *commands*, the program stops running just before the breakpoint and returns control to **sdb**. Otherwise **sdb** performs the specified *commands* when the breakpoint is encountered, and then the program being debugged continues. If the **k** command is specified, however, control returns to **sdb**.

В

Lists the currently active breakpoints.

[line] d

Deletes a breakpoint at the selected line. If you select no *line*, breakpoints are deleted interactively. **sdb** displays each breakpoint location and reads a line from standard input. If the line begins with a **y** or **d**, then it deletes the breakpoint.

D

Deletes all breakpoints.

[line] c [num] [line] C [num]

Continues running program after a breakpoint or an interrupt. C continues after resetting the signal that caused the program to stop. c ignores the signal. An optional num selects the number of breakpoints to ignore. If you specify a line, sdb places a temporary breakpoint at the line and continues the program. It deletes the breakpoint when the command finishes.

[line] g [num] Continues after a breakpoint, with execution resumed at the given line. num specifies how many breakpoints to ignore.

Displays the last executed line.

i T

1

Runs the program one machine level instruction at a time, ignoring the signal that stopped the program (i) or passing the signal back to the program (I).

s[num]S[num]

Runs the program for one or the specified number of lines. S is equivalent to s except that it does not stop within called functions. Use S if you are confident that the called function works, but want to test the calling routine.

variable\$m [num]

address:m [num] Runs the program until the specified location is modified with a new value or is modified a specified num of times. The variable must be accessible from the current function.

line a

If line is of the form function: number, this command has the effect of the sdb subcommand: line b]. If line is of the form function:, it has the effect of the sdb subcommand: function: b T.

[level] v

Toggles verbose mode, for use with the S, s or m commands. If you omit level, then just the current source file or subroutine name is displayed when either changes. If level is 1 or greater, each C source line is displayed before it is executed; if level is 2 or greater, each assembler statement is also displayed. If verbose mode is on for any level, another v turns it off.

function(p [p . . .])[/f]

Runs the named function, passing to it the specified parameters. These can be integer, character, or string constants or the names of variables accessible to the current function. You can specify the format of displayed values. The default format is **d** (decimal).

k Kills the program being debugged.

M Displays the address maps. Program addresses are mapped to file addresses using two field triples: b1, e1, f1 and b2, e2, f2. The f1 field is the length of the header at the beginning of the file; the f2 field is the

> displacement from the beginning of the file to the data. For a plain executable file with mixed text and data, this is the same as the length of the header; for shared text and split instruction/data files, this is the length of the header plus the size of the text portion. The b and e fields

are the starting and ending locations for a segment.

Given an address A, calculate its location in the file (either a.out or core) as follows:

If b1 < A < e1then file address = (A-b1) f1

If b2 < A < e2then file address = (A-b2) f2

M[?/][*] b e f

Records new values for the address map. The parameters? and / specify the text and data maps respectively. The first segment is changed unless you specify *. in which case the second segment is changed. (These segments differ only in programs with split instruction and data space. In this case, use the second segment to examine the data section of the a.out file rather than the data section of the core image file.) If you give fewer than three values, the remaining map parameters are left unchanged.

" string

Displays the given string. sdb recognizes C escape sequences of the form $\character.$

!AIX-command Performs the command specified by AIX-command.

<file

Reads commands from file until reaching the end-of-file character and then continues to accept commands from standard input. When a command in such a file tells sdb to display a variable, the variable name is displayed along with the value. This command cannot be nested.

>file

Redirects standard output to file.

q

Exits the debugger.

Debugging the Debugger

 $\overset{\mathbf{Q}}{\mathbf{V}}$

Displays a list of functions and files being debugged.

Displays the version number.

Files

a.out, core

Related Information

The following commands: "cc" on page 140, "ed" on page 371, and "sh" on page 913.

The a.out and core files in AIX Operating System Technical Reference.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

sdiff

Purpose

Compares two files and displays the differences in a side by side format.

Syntax

OL805301

Description

The sdiff command reads file1 and file2, uses diff to compare them, and writes the results to standard output in a side by side format. sdiff displays each line of the two files with a series of blanks between them if the lines are identical, a < (less than sign) in the field of blanks if the line only exists in file1, a > (greater than sign) if the line only exists in file2, and a ! (vertical bar) for lines that are different.

When you specify the -o flag, sdiff produces a third file by merging file1 and file2 according to your instructions.

Note: The sdiff command invokes diff -b to compare two input files. The -b flag causes diff to ignore trailing spaces, tab characters, and consider other strings of blanks as equal.

Flags

- -1 Displays only the left side when lines are identical.
- -o outfile Creates a third file, outfile, by a controlled line-by-line merging of file1 and *file2.* The following subcommands govern the creation of this file:
 - 1 Adds the left side to outfile.
 - Adds the right side to outfile. \mathbf{r}
 - s Stops displaying identical lines.

v Begins displaying identical lines.

e l

e r

e b

e Starts ed with the left side, the right side, both sides, or an empty file, respectively.

Each time you exit from **ed**, **sdiff** writes the resulting edited file to the end of *outfile*. If you fail to save the changes before exiting, **sdiff** writes the initial input to *outfile*.

q Exits the program.

-s Does not display identical lines.

-w num Sets the width of the output line to num, 130 characters, by default.

Examples

1. To print a comparison of two files:

```
sdiff chapl.bak chapl | print
```

This prints a side by side listing that compares each line of chap1.bak and chap1. The I print sends the listing to the **print** command. **sdiff** assumes that your printer has wide paper (130 columns).

2. To display only the lines that differ:

```
spiff -s -w 80 chapl.bak chapl
```

This displays the differences at the work station. The -w 80 sets page width to 80 columns. The -s flag tells sdiff not to display lines that are identical in both files.

3. To selectively combine parts of two files:

```
sdiff -s -w 80 -o chap1.combo chap1.bak chap1
```

This combines chap1.bak and chap1 into a new file called chap1.combo. For each group of differing lines, sdiff asks you which group to keep or whether you want to edit them using ed.

Related Information

The following commands: "diff" on page 320 and "ed" on page 371.

secure

Purpose

Establishes a more secure system configuration.

Syntax

secure ----

OT.805480

Description

The secure command increases the trustworthiness of the system. It configures trusted path management, login protection, and proper file system permissions. This command is a shell script and can be altered by an administrator of the system.

The secure command should be run after the initial system installation. This command can be run more than once, but it will not reverse any previous configuration set by the secure command.

Trusted Path Management

For trusted path management, secure does the following:

- Adds the Sak = on attribute to the default stanza of the /etc/ports file. This attribute enables the secure attention key (SAK) for the ports defined in /etc/ports.
- Adds the synonym = /dev/hft attribute to the /dev/concole stanza of the /etc/ports file. The addition of this attribute ensures that the protection and ownership of all the virtual terminals will match that of the console.
- Adds the shell = /bin/actman attribute to the /dev/concole stanza of the /etc/ports file. This addition will ensure that all the virtual terminals are closed before a user can log off the console.

Login Protection

To enhance login protection, secure does the following:

- Removes any contents from /etc/autolog. This action prevents anyone from logging in without proper authentication.
- Prohibits users from logging in as superusers (root). Superuser privileges can still be obtained with the su command.
- Causes the default shell (or login shell) for root to be the trusted shell /bin/tsh.

File System Permissions

For proper file system permissions, secure does the following:

- Checks the trusted computing base (TCB) to ensure proper permissions. In addition, secure identifies files not in the TCB that might be untrustworthy. This identification is done with the sysck command.
- Adds the **sysck** command to the **/etc/rc** file to run this command at system initialization.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Related Information

The following command: "sysck" on page 1031.

The sysck.cfg and ports file formats in AIX Operating System Technical Reference.

The discussion of security management in Managing the AIX Operating System.

sed

Purpose

Provides a stream editor.

Syntax

OL805302

Description

The sed command modifies lines from the specified file according to an edit script and writes them to standard output. The sed command includes many features for selecting lines to be modified and making changes only to the selected lines.

The sed command uses two work spaces for holding the line being modified: the pattern **space**, where the selected line is held, and the **hold space**, where a line can be stored temporarily.

An edit script consists of individual subcommands, each one on a separate line. The general form of sed subcommands is:

[address-range] function[modifiers]

The sed command processes each input file by reading an input line into a pattern space. applying all sed subcommands in sequence whose addresses select that line, and writing the pattern space to standard output. It then clears the pattern space and repeats this process for each line in the input file. Some of the subcommands use a hold space to save all or part of the pattern space for subsequent retrieval.

When a command includes an address, either a line number or a search pattern, only the addressed line or lines are affected by the command. Otherwise, the command is applied to all lines.

An address is either a decimal line number, a \$ (dollar sign), which addresses the last line of input, or a context address. A context address is a regular expression similar to those used in **ed** except for the following differences:

 You can select the character delimiter for patterns. The general form of the expression is:

\?pattern?

where ? is a character delimiter you select. This delimiter cannot be a 2-byte international character support extended character. The default form for the pattern is:

/pattern/

- The sequence \n matches a new-line character in the pattern space, except the terminating new line.
- A. (dot) matches any character except a terminating new-line character. That is, unlike **ed**, which cannot match a new-line character in the middle of a line, **sed** can match a new-line character in the pattern space.

Certain commands allow you to specify one line or a range of lines to which the command should be applied. These commands are called *addressed commands*. The following rules apply to addressed commands:

- A command line with no address selects every line.
- A command line with one address, expressed in context form, selects each line that matches the address.
- A command line with two addresses separated by commas selects the entire range from the first line that matches the first address through the next line that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line is selected.) Thereafter the process is repeated, looking again for the first address.

Notes:

- 1. The text parameter accompanying the a\, c\, and i\ commands can continue onto more than one line provided all lines but the last end with a\ to quote the new-line character. Back slashes in text are treated like back slashes in the replacement string of an s command and can be used to protect initial blanks and tabs against the stripping that is done on every script line. The rfile and wfile parameters must end the command line and must be preceded by exactly one blank. Each wfile is created before processing begins.
- 2. The sed command can process up to 99 commands in a pattern file.

Flags

- -e "script" Uses the string script as the editing script. If you are using just one -e flag and no -f flag, the -e flag can be omitted.
- -f sfile Uses sfile as the source of the edit script. sfile is a prepared set of editing commands to be applied to file.
- Suppresses all information normally written to standard output. -n

Subcommands

In the following list of functions, the maximum number of permissible addresses for each function is indicated in parentheses. The sed script subcommands are as follows:

(1) a ∖	
text	Places text on the output before reading the next input line.
(2) b $[label]$	Branches to the : command bearing the <i>label</i> . If <i>label</i> is empty, it branches to the end of the script.
(2) c \	
text	Deletes the pattern space. With 0 or 1 address or at the end of a 2-address range, places <i>text</i> on the output. Starts the next cycle.
(2) d	Deletes the pattern space. Starts the next cycle.
(2) D	Deletes the initial segment of the pattern space through the first new-line character. Starts the next cycle.
$(2)\mathbf{g}$	Replaces the contents of the pattern space by the contents of the hold space.
(2) G	Appends the contents of the hold space to the pattern space.
(2) h	Replaces the contents of the hold space by the contents of the pattern space.
(2) H	Appends the contents of the pattern space to the hold space.
(1)i ∖	
text	Writes <i>text</i> to standard output before reading the next line into the pattern space.
(2)1	Writes the pattern space to standard output showing nondisplayable characters as 2- or 4-digit hexadecimal values. Long lines are folded.
(2) n	Writes the pattern space to standard output. Replaces the pattern space with the next line of input.
(2) N	Appends the next line of input to the pattern space with an embedded new-line character. (The current line number changes.) You can use this to

search for patterns that are split onto two lines.

(2)pWrites the pattern space to standard output. $(2)\mathbf{P}$ Writes the initial segment of the pattern space through the first new-line character to standard output. (1)qBranches to the end of the script. Does not start a new cycle. (2)**r** rfileReads the contents of rfile. Places contents on the output before reading the next input line. (2)s/pattern/replacement/flags Substitutes replacement string for the first occurrence of the pattern in the pattern space. Any character appearing after the s can substitute for the / separator. **Japanese Language Support Information** Any single-byte character appearing after the s can substitute for the /. You can add zero or more of the following flags: Substitutes all nonoverlapping instances of the pattern rather than just the first one. Writes the pattern space to standard out if a replacement was made. w wfile Writes the pattern space to wfile if a replacement was made. Appends the pattern space to wfile. If wfile was not already created by a previous write by this sed script, sed creates it. (2)tlabelBranches to :label in the script file if any substitutions were made since the most recent reading of an input line execution of a t subcommand. If you do not specify *label*, control transfers to the end of the script. (2)wwfile Appends the pattern space to wfile. (2)xExchanges the contents of the pattern space and the hold space. (2)y/pattern1/pattern2/ Replaces all occurrences of characters in pattern1 with the corresponding characters pattern2. The byte lengths of pattern1 and pattern2 must be equal. **Japanese Language Support Information**

The character lengths of these two patterns must be equal.

Applies the specified sed subcommand only to lines not selected by the (2)!sed-cmdaddress or addresses.

(0): labelThis script entry simply marks a branch point to be referenced by the b and t commands. This label can be any sequence of eight or fewer bytes.

(1) =Writes the current line number to standard output as a line.

(2){subcmd

} Groups subcommands enclosed in {} (braces).

Examples

1. To perform a global change:

```
"s/happy/enchanted/g" chap1 >chap1.new
```

This replaces each occurrence of happy found in the file chap1 with enchanted, and puts the edited version in a separate file named chap1. new. The q at the end of the s subcommand tells sed to make as many substitutions as possible on each line. Without the q, sed replaces only the first happy on a line.

The **sed** stream editor operates as a filter. It reads text from standard input or from the files named on the command line (Chap1 in this example), modifies this text, and writes it to standard output. Unlike most editors, it does not replace the original file. This makes sed a powerful command when used in pipelines.

2. To use **sed** as a filter in a pipeline:

```
pr chap2 | sed "s/Page *[0-9]*$/(&)/" | print
```

This encloses the page numbers in parentheses before printing chap2. The pr command puts a heading and page number at the top of each page, then sed puts the page numbers in parentheses, and the **print** command prints the edited listing.

The sed pattern /Page *[0-9]*\$/ matches page numbers that appear at the end of a line. The s subcommand changes this to (&), where the & stands for the page number that was matched.

3. To display selected lines of a file:

This displays each line in chap3 that contains the word food. Normally, sed copies every line to standard output after it is edited. The -n flag stops sed from doing this. You then use subcommands like p to write specific parts of the text. Without the -n,

this example would display all the lines in Chap3, and it would show each line containing food twice.

4. To perform complex editing:

```
sed -f script.sed chap4 >chap4.new
```

It is always a good idea to create a **sed** script file when you want to do anything very complex. You can then test and modify your script before using it. You can also reuse your script to edit other files. Create the script file with an interactive text editor.

5. A sample sed script file:

```
:join
/\\$/{N
s/\\\n//
b join
}
```

This sed script joins each line that ends with a \ (backslash) to the line that follows it. First, the pattern /\\\$/ selects a line that ends with a \ for the group of commands enclosed in $\{$ $\}$. The N subcommand then appends the next line, imbedding a new-line character. The s/\\\n// deletes the \ and imbedded new-line character. Finally, b join branches back to the label : join to check for a \ at the end of the newly joined line. Without the branch, sed writes the joined line and read the next one before checking for a second \.

Note: The N subcommand causes **sed** to stop immediately if there are no more lines of input (that is, if N reads an end-of-file character). It does not copy the pattern space to standard output before stopping. This means that if the last line of the input ends with a \setminus , then it is not copied to the output.

Related Information

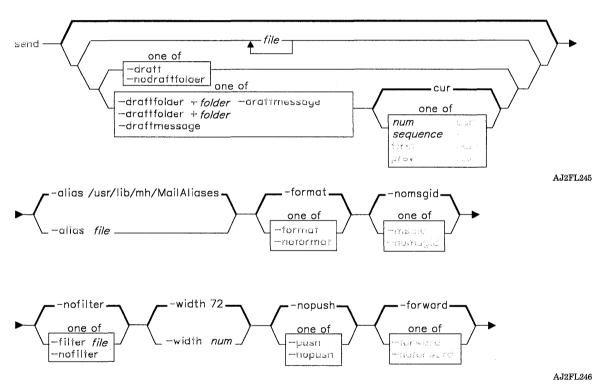

The following commands: "awk" on page 81, "ed" on page 371, and "grep" on page 501. The discussion of Japanese Language Support in Japanese Language Support User's Guide.

send

Purpose

Sends a message.

Syntax

AJ2FL170

Description

The **send** command is used to route messages to the mail delivery system by way of the **post** command or the **spost** command. **send** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The send command causes From: and Date: fields to be added to each specified message. send places the sender's address in the From: field unless a \$SIGNATURE environment variable is set or a signature: profile entry is present. In either of these cases send uses the signature. send puts the current date in the Date: field. If the dist command calls send, send prepends Resent- to the From:, Date:, and Message-ID: fields.

The **send** command then takes each of the specified message files and calls the **post** command or the **spost** command to deliver them. After successful delivery, **send** renames the message file by placing a comma in front of the file name. This comma removes the message from the folder without actually deleting the file. The file is retrievable until you send another message. If the delivery fails, **send** displays an error message.

Flags

-alias file Specifies that file is a mail alias file to be searched for aliases. The

default alias file is /usr/lib/mh/MailAliases.

-draft Uses the current draft message if no file is specified. Without this

flag, send asks the user if the current draft message is the one to

use when no file is specified.

-draftfolder + folder Specifies the draft folder that contains the draft message to be sent.

If -draftfolder + folder is followed by msg, msg represents the

-draftmessage attribute.

-draftmessage msg Specifies the draft message to be sent. You can use one of the

following message references as msg:

first numsequence prev cur last next new

The default draft message is cur.

Uses the format instructions in the specified file to reformat copies -filter file

of the message sent to **Bcc**: recipients.

-format Puts all recipient addresses in a standard format for the delivery

transport system. This flag is the default.

-forward Adds a failure message to the draft message and returns it to the

sender if the send command fails to deliver the draft. This flag is

the default.

-help Displays help information for the command.

Adds a message-identification component (such as **Message-ID**:) to -msgid

the message.

-nodraftfolder Undoes the last occurrence of -draftfolder + folder. This flag is

the default.

-nofilter Removes the **Bcc**: header from the message for recipients listed in

> the To: and cc: fields, and sends the message with minimal headers to recipients listed in the Bcc: field. This flag is the

default.

-noformat Does not alter the format of the recipient addresses.

-noforward Does not return the draft message to the sender if delivery fails.

Does not add a message-identification component. This flag is the -nomsgid

default.

Runs the send command in the foreground (see the -push flag). -nopush

This flag is the default.

-noverbose Does not display information during the delivery of the message to

the **sendmail** command. This flag is the default.

-nowatch Does not display information during delivery by the sendmail

command. This flag is the default.

Runs the **send** command in the background. **send** does not display -push

> error messages on the terminal if delivery fails. You can use the -forward flag to return messages to you that fail on delivery.

send

-verbose Displays information during the delivery of the message to the

sendmail command. This information allows you to monitor the

steps involved.

-watch Displays information during the delivery of the message by the

sendmail command. This information allows you to monitor the

steps involved.

-width num Sets the width of components that contain addresses. The default

is 72 columns.

Profile Entries

Draft-Folder:

Sets your default folder for drafts.

mailproc:

Specifies the program used to post failure notices.

Path:

Specifies your *user_mh_directory*.

postproc: Signature: Specifies the program used to post messages.

Sets your mail signature.

Files

\$HOME/.mh_profile

The MH user profile.

sendmail

Purpose

Routes mail for local or network delivery.

Syntax

 $^{1}default = -bm for sendmail$ -bp for maila -bi for newaliases

AJ2FL126

/usr/lib/mailq — I

AJ2FL145

/usr/lib/newaliases ----

AJ2FL147

Description

The sendmail program receives formatted text messages and routes the message to one or more other users on the local system, or if connected to a network, to users on other systems. The program translates the format of message heading information to match the requirements of the destination system. It determines which network to use based on the syntax and content of the addresses.

The program can deliver messages to:

- Users on the local system
- Users connected to the local system using the TCP/IP protocol
- Users connected to the local system using the **uucp** protocol.

The **sendmail** program operates mainly as a background, mail-routing program. Other programs, such as **Mail** and the message handler routines, provide user interfaces for generating and receiving mail that **sendmail** handles. However, if you enter the **sendmail** command with no flags, it reads standard input for the message text until it receives a **Ctrl-D** or a line with only a single period, designating the end of the message. Then it sends a copy of the message to all addresses listed. For example, the following input at the command line sends the message This is a test message to the mailbox for user george on the local system:

```
$ /usr/lib/sendmail george
This is a test message
:
```

The **sendmail** program uses a configuration file (/usr/adm/sendmail/sendmail.cf by default) to set many operational parameters and to determine how the program parses addresses. This file is a text file that you can edit. However, **sendmail** uses a compiled form of this file (/usr/adm/sendmail/sendmail.cfDB). For any changes made to this file to be effective, you must build a new copy of the compiled configuration file by running **sendmail** with the **-bz** flag.

The sendmail program also allows you to define aliases to use when addressing mail handled by the local sendmail program. Aliases are alternate names that can be used in place of elaborate network addresses. You can also use aliases to build distribution lists. Define aliases in /usr/adm/sendmail/aliases. This file is a text file you can edit. However, sendmail uses a database version of this file that is kept in the directory /usr/adm/sendmail/aliasesDB. For any changes made to the aliases file to be effective, you must build a new alias database by running sendmail with the -bi flag. If the sendmail daemon is running, you must also stop that process and start the daemon again before it recognizes the new alias data base file. Normally the sender of a message is not included when sendmail expands an alias address. For example, if amy sends a message to alias D998 and she is defined as a member of that alias, sendmail does not send a copy of the message to amy.

Every system must have a user or user alias designated **postmaster**. Assign this alias in the file /usr/adm/sendmail/aliases. Unless you change the entry in this file, this alias is assigned to root. This alias allows other users outside your system to send mail to a known ID (i.e. postmaster) to get information about mailing to users on your system. Also, users on your system can send problem notifications to this ID.

Two additional commands are links to **sendmail**:

/usr/lib/mailq Prints the contents of the mail queue. This command is the same

as running sendmail with the -bp flag.

/usr/lib/newaliases Builds a new copy of the alias data base from the file

/usr/adm/sendmail/aliases. This command is the same as

running sendmail with the -bi flag.

Mail Addresses

Mail addresses are based on the domain address (Arpanet) protocol. These addresses have the following form:

user@host.domain

Note: The configuration file provided with sendmail specifies that blanks in addresses be converted to periods before being transmitted. This convention follows the Arpanet mail protocol as described in RFC822, but does not match the Arpanet mail protocol as described in RFC733 (NIC41952). You can change this setting by setting the **OB** option in the sendmail configuration file.

A **domain** is a logical grouping of systems that are connected together by physical network links. No direct relationship exists between the actual physical interconnections and the way in which the systems are grouped in the domain. The **domain name** identifies a specific domain within a larger group of domains. The domain name has the format of a tree structure. Each node (or leaf) on the tree corresponds to a resource set, and each node can create and contain new domains below it. The actual domain name of a node is the path from the root of the tree to that node. Domain names do not correspond to system names, host addresses, or any other type of information.

For example, if node hera is part of the domain IBM, which is in turn a subdomain of COM, and a message is sent to geo at that address it is sent to:

geo@hera.IBM.COM

The message router (usually **sendmail**) must determine how to send the message to its final destination. If the router is at hera, it delivers the message to user geo. If the router is at another system within the IBM domain, it corresponds with the name server for that domain to find out how to deliver the message. If the router is not a part of the IBM domain, but is in a domain that is under the COM domain, it corresponds with the name server for the COM domain to find out how to deliver the message. The respective name server returns a network address to the router. That network address determines the actual path that the message takes to its destination.

The domain address is read from right to left, with each domain in the address separated from the next domain with a . (period). This format does not imply any routing. Thus, although the example is specified as a COM address, the message might actually travel by a different route if that were more convenient or efficient. At some sites, the message associated with the sample address might go directly from the sender to node hera over a local area network. At other sites it might be sent over a uucp network or a combination of other delivery methods.

Normally, the actual routing of a message is handled automatically. However, you can route the message manually through several specified hosts to get it to its final destination. An address using intermediate hosts, called a *route address*, has the following form:

@hosta,@hostb:user@hostc

This address specifies that the message should go first to the remote system represented by *hosta*, then to the remote system represented by *hostb*, and finally to the remote system represented by *hostc*. This path is forced even if there is a more efficient route to *hostc*.

In some cases the user can abbreviate the address rather than typing the entire domain name. In general, systems in the same domain do not need to use the full domain name. For example, a user on node zeus. IBM. COM can send a message to geo@hera. IBM. COM by typing only geo@hera, because they are in the same local domain, IBM. COM.

Other mail address formats exist that are used by other mail routing programs (for example, **uucp**). The mail routing program (**sendmail**) converts most of these other formats to a format that the network routing system can use. However, if you use the domain address format, the routing program operates more efficiently.

For example, if sendmail receives an address in the following format:

@host:user

It converts it to the corresponding domain address format:

user@host

Similarly, if sendmail receives an address in the following format:

host!user

The mail routing program routes the message directly to the **uucp** command (part of the Basic Networking Utilities (BNU)) However, when sending mail via **uucp**, you must include a route address that indicates which BNU host(s) to send the message through to get to the final destination.

To route messages through the BNU network, use one of the following domain address formats. Your choice depends on the way in which the systems at your site are connected:

1. @system_name.domain_name:uucp-route!user-ID

For example, the address:

@zeus:hera!amy

sends a message to user amy on uucp host hera by way of system zeus. The address: @apollo.802:merlin!lgh

sends a message to user 1gh on uucp host merlin via system apollo under the local domain 802.

2. uucp-route!user-ID@system_name.domain_name

In this case, the address:

merlin!arthur!amy@hera.802

sends a message to user amy on system hera under domain 802 via the BNU link merlin through arthur.

3. system_name.domain_name:uucp-route!user-ID@system_ name.domain_name In this example, the address:

@apollo.802:merlin!arthur!amv@hera.802

sends a message to user amy on system hera under domain 802 that first goes through apollo, the gateway node for domain 802, and then through the BNU link merlin through arthur. (Including 802 in this example is optional, since the two domain names are identical.)

4. hosta!hostb!hostc!user

This example is a purely **uucp** route address:

zeus!hera!kronos!amy

sends a message to amy on kronos, via the BNU link zeus through hera.

5. @hosta.UUCP:@hostb.UUCP:user@hostc

This example, like the previous one, is a purely **uucp** route address:

@zeus.UUCP:@hera.UUCP:amy@kronos.UUCP

sends a message to amy on kronos, via the BNU link zeus through hera.

Return Codes

The **sendmail** program returns an exit status code. These exit codes are defined in /usr/include/bsd/sysexits.h. The following table summarizes the meanings of these return codes:

Return Code	Meaning
EX_CANTCREAT	The sendmail program cannot create a file that the user specified.
EX_DATAERR	The user's input data was not correct.
EX_IOERR	An error occurred during I/O.
EX_NOHOST	The sendmail program could not recognize the specified host name.
EX_NOINPUT	The sendmail program either could not find, or could not read, the specified input file.
EX_NOPERM	The user does not have the needed permissions to perform the requested operation.
EX_NOUSER	The sendmail program could not recognize a specified user ID.
EX_OK	The sendmail program successfully completed the operation for all addresses.
EX_OSERR	A temporary operating system error occurred. An example of such an error is cannot fork because too many processes are currently running.
EX_OSFILE	A system file error occurred. For example, a system file (such as /etc/passwd) does not exist, cannot be opened or has another type of error preventing it from being used.
EX_PROTOCOL	The remote system returned something that was incorrect during a protocol exchange.
EX_SOFTWARE	An internal software error occurred (including bad arguments).

		sendmail	
Return Co	de	Meaning	
EX_TEMPFAIL		The sendmail program could not create a connection. Try the request again later.	
EX_UNAV	AILABLE	A service or resource that sendmail needed was not available.	
EX_USAGE		The command syntax was not correct.	
-ba	Starts sendmail in Arpanet mode. All input lines to the program must end with a carriage return and a line feed (CR-LF). The program generates messages with a CR-LF at the end. The program looks at the from and the sender fields to find the name of the sender.		
-bd	Starts sen	Starts sendmail to run in the background as a TCP/IP mail routing daemon.	
-bi	/usr/adm/	Builds the alias database files from information defined in /usr/adm/sendmail/aliases. Running sendmail with this flag is the same as running the command, /usr/lib/newaliases.	
-bm	Delivers m	Delivers mail in the usual way. This is the default.	
-bp		Prints a listing of the mail queue. Running sendmail with this flag is the same as running the command, /usr/lib/mailq.	
-bs		Uses the simple mail transfer protocol (SMTP) as described in RFC821. This flag implies all of the operations of the -ba flag that are compatible with SMTP.	
-bt	addresses : parse the a	dmail in address test mode. This mode allows you to enter interactively and watch as sendmail displays the steps it takes to address. Use this mode for debugging the address parsing rules in a guration file.	

Flags

new configuration file. Starts sendmail with a request to verify the user IDs provided in the address -bv field of the command. The program responds with a message telling which IDs can be resolved to a mailer program. It does not try to collect or deliver a message. Use this mode to validate the format of user IDs, aliases, or mailing lists.

- Builds the compiled version of the configuration file from information in -bz /usr/adm/sendmail/sendmail.cf.
- -Cfile Starts sendmail using an alternate configuration file specified by the file parameter. Use this flag together with -bt to test a new configuration file before installing it as the running configuration file.

sendmail

-dXSets debugging value to X.

-Ffullname Sets the full name of the sender to be the string provided in the fullname

parameter.

-fname Sets the name of the from person (the sender of the mail). This flag can be

used only by those administrative user IDs designated in the configuration

file with the T control line, or if your ID is the ID supplied in name.

-hNSets the hop count to N. The **hop count** is the number of times that the

> message has been processed by a sendmail program (not just the local copy of sendmail). The program increments the hop count every time the message is processed. When it reaches a limit, the message is returned with an error

message usually caused by alias looping.

Does not do aliasing. -n

-ox[value]Sets option x. If the option is a valued option, you must also specify value.

See Figure 10 on page 905 for possible options, values, and their meanings.

-q[time] Processes saved messages in the queue at the intervals specified by time. If time is not specified, this flag processes the queue at once. You can specify

time as a tagged number using the tag s for seconds, m for minutes, h for hours, d for days, and w for weeks. If the tag letter is omitted and just a number is specified, sendmail uses days as the unit of time. For example, -q2m processes the queue every two minutes, but -q2 processes the queue

every two days.

An alternate and obsolete form of the -f flag. -rname

Reads the To:, Cc:, and Bcc: lines of the message header to determine -t where to send the message: deletes the BCC: line before transmitting the

message; and deletes any addresses in the argument list of the sendmail

command.

Starts sendmail in verbose mode. The program displays messages regarding -v the status of transmission, the expansion of aliases and any errors that may

occur during the sending of the message.

You can also set or remove sendmail processing options. Normally, the person responsible for the mail system uses these options. To set these options, use the -o flag on the command line or the 0 control line in the configuration file (sendmail.cf).

Option	Function	
A file	Uses the named file as an alternate alias file.	
$\mathbf{B}c$	Sets the blank substitution character to the character specified in the parameter c . The sendmail program replaces unquoted spaces in addresses with this character. The supplied configuration file uses the period (.) for this character.	
c	If an outgoing mailer program is specified in the configuration file as expensive to use, this option causes sendmail to queue messages for that mailer program without sending them. The queue can be run later when costs are lowest or when the queue is large enough to send the messages efficiently.	
d x	Sets the delivery mode to x . Delivery modes are i for interactive (synchronous) delivery, b for background (asynchronous) delivery, and q for queue only (next time the queue is run) delivery. The supplied configuration file uses a value of b .	
$\mathbf{e}x$	Sets error processing to mode x. Valid modes are:	
	 m Mails the error message to the user's mailbox. w Writes the error message to the terminal or mails it if the user is not logged in. 	
	p Displays the error message on the terminal (default). q Throws away error message and returns the exit status only. e Mails the error message to the user's mailbox, but always exits with a zero exit status (normal return).	
	If the text of the message is not mailed by modes m or w and if the sender is a local user, a copy of the message is appended to the file dead.letter in the sender's home directory.	
f	Saves From lines at the front of messages. These lines are normally discarded.	
$\mathbf{g}N$	Sets the default group ID to use when calling mailers to the value specified by N .	
H file	Specifies the name of the SMTP help file (/usr/adm/sendmail/sendmail.hf by default).	

Figure 10 (Part 1 of 3). Configuration Options

Option	Function		
i	Does not interpret a period (.) on a line by itself as a message terminator.		
$\mathbf{I}c$	Interpret the special character specified by c as a space character and all real spaces as delimiters when processing address parsing rules. Use this control line if using an editor that saves tabs as spaces (such as INed) to edit the configuration file. The default setting of this line is I .		
$\mathbf{L}n$	Specifies the log level to be the value supplied in the n parameter. Valid levels and the activities that they represent are (each number includes the activities of all numbers of lesser value and adds the activity that it represents):		
	Level Activity Logged		
	 Prevents logging. Logs major problems only. Logs message collections and failed deliveries. Logs successful deliveries. Logs messages deferred (for example, because the host is down). Logs messages that are placed in the queue (normal event). Logs unusual but benign incidents (for example, trying to process a locked file). Logs internal queue ID to external message ID mappings. This can be useful for tracing a message as it travels between several hosts. Logs messages that are of interest when debugging. Logs verbose information regarding the queue. 		
$\mathbf{M}x$ value	Sets the macro x to value. Use this option from the command line only (with the -o flag).		
m	Sends to the sender (me) also, if the sender is in an alias expansion. Normally, the sender does not receive a copy of the message.		
Nnetname	Sets the name of the host network to <i>netname</i> . The sendmail program compares the argument of an SMTP HELO command to <i>hostname.netname</i> (it gets the value of <i>hostname</i> from the kernel). If these values do not match, it adds the <i>hostname.netname</i> string to the Received: lines in the message so that messages can be traced accurately.		

Figure 10 (Part 2 of 3). Configuration Options

Option	Function
0	This option indicates that this message may have old style headers. Without this option, the message has new style headers (commas instead of spaces between addresses). If this option is set, an adaptive algorithm correctly determines the header format in most cases.
$\mathbf{Q}dir$	Sets the directory in which to queue messages to the directory specified by the dir parameter. That directory must exist.
rtime	Sets the timeout for reads from a mailer program to the value specified by <i>time</i> . If no timeout value is set, sendmail waits indefinitely for a mailer to respond. The default value for this timeout is 5 minutes.
Sfile	Sets the mail statistics file to the <i>file</i> . If this file exists, sendmail stores statistics about mail traffic in a database format in this file. Use the mailstats command to read the information in this file. If the indicated file does not exist, no statistic information is saved.
s	Interactive mode delivers mail without going through the mail queue. When this option is specified, mail is passed through the mail queue in interactive mode also. This action ensures that the message being sent is not lost if a delivery problem occurs.
Ttime	Sets the timeout on messages in the queue to the specified <i>time</i> . After a message has been in the queue for this amount of time, sendmail returns the message to the sender. In sendmail.cf that is provided with sendmail , this value is set to three days.
$\mathbf{u}N$	Sets the default user ID to use when calling mailers to the value specified by N .
v .	Run in verbose mode.
Y	When this option is specified, sendmail delivers each message in the mail queue from a separate process. This option uses less memory to process the mail queue. Use of this option is not recommended.

Figure 10 (Part 3 of 3). Configuration Options

Files

/usr/lib/sendmail	Contains the sendmail program.
/usr/lib/mailq	Displays list of the mail queue.
/usr/lib/newaliases	Builds alias database.

sendmail

/usr/lib/mailstats Displays sendmail statistics found in /usr/adm/sendmail/sendmail.st. /usr/lib/sendmail.sh Contains a shell script replacement for sendmail when sendmail is not installed. Only local mail can be delivered with this shell script acting as sendmail. Contains the text version of sendmail aliases. /usr/adm/sendmail/aliases /usr/adm/sendmail/aliasesDB/DB.dir Contains one of the alias database files. /usr/adm/sendmail/aliasesDB/DB.pg Contains one of the alias database files. /usr/adm/sendmail/aliasesDBl Contains the alias database lock file. /usr/adm/sendmail/sendmail.hf Contains the SMTP help file. /usr/adm/sendmail/sendmail.cf Contains the text version of the sendmail configuration file. /usr/adm/sendmail/sendmail.cfDB Contains the sendmail configuration database file. /usr/adm/sendmail/sendmail.cfDBl Contains the sendmail configuration database lock /usr/adm/sendmail/sendmail.st Contains the sendmail statistics file. /usr/adm/sendmail/smdemon.cleanu Maintains aging copies of the log file in /usr/spool/mqueue. /etc/rc.sendmail Contains the shell script to start the sendmail daemon. /usr/spool/mqueue Contains the log file and temporary files associated with the messages in the mail queue (the mail queue directory). Temporary files have names that include the mail queue ID (maid) of the message for which the file was created: dfmqidData file lfmqid Lock file nfmaidBackup file afmaid Queue control file tfmqid Temporary control file xfmaidTranscript file for session. /usr/spool/cron/crontabs/root Contains a commented entry to run sendmail periodically for use when not routing mail to a network. Uncomment that entry to process the mail queue at the interval specified in that **cron** file.

Contains the mailer program to deliver **uucp** mail.

Contains the mailer program to deliver local mail.

/bin/uux

/bin/bellmail

setdma

setdma

Purpose

Sets the DMA channel of the specified adapter.

Syntax

```
one of

eesdi 0
eesdi 1
```

OL805466

Description

The **setdma** command sets the DMA channel of the specified adapter. The **eesdi 0** sets the DMA adapter channel to 0. The **eesdi 1** sets the DMA adapter channel to 1.

Related Information

Installing and Customizing the AIX Operating System.

setmnt

Purpose

Creates mount table.

Syntax

```
setmnt —
```

OL805062

Description

The setmnt command reads lines from standard input and writes the /etc/mnttab table to standard output (see the mnttab file in AIX Operating System Technical Reference). The /etc/mmttab is needed for both the mount and unmount commands. setmnt creates a mnttab entry for each line read. Input lines have the format:

```
filesvs directory
```

where filesys is the name of the file system's special file and directory is the root name of that file system. Thus, filesys and directory become the first two strings in the mnttab entry. filesys and directory must not be longer than 100 characters.

The setmnt command enforces an upper limit on the maximum number of mnttab entries.

Example

To set the mount table after it has been destroyed or made invalid:

```
setmnt <<end
hd1 /u
fd0
    /a
fd1
    /b
end
```

This command sets the mount table to show /dev/hd1 mounted on /u, /dev/fd0 on /a, and /dev/fd1 on /b.

The <<end and end define a Here Document, which uses the text entered before the end line as the standard input for the **setmnt** command. For more details, see "Inline Input Documents" on page 928.

Files

/etc/mnttab

The mnttab file in AIX Operating System Technical Reference.

sh

Purpose

Interprets commands read from a file or entered at the keyboard.

Syntax

¹ Do not put a blank between these items.

OL805308

OL805425

Description

The **sh** command is a system command interpreter and programming language. It is not a part of the operating system *kernel*, but an ordinary user program that reads commands entered at the keyboard and arranges for their execution. In addition, it can read commands that you have saved in a file. Such a file is usually called a *shell procedure* or a *command file*. For a complete description of how to write shell procedures to take advantage of this useful tool, see *Using the AIX Operating System*.

A restricted version of shell (the **Rsh** command) is available in the /bin/Rsh file that allows you to create user environments with a limited set of privileges and capabilities. See "Restricted Shell" on page 935 for additional information on the restricted shell.

Commands

A *command* is either a simple command or a *control command* (see "Control Commands" on page 930).

A **simple command** is a sequence of **words** separated by blanks or tabs. A word is a sequence of characters and/or numerals that contains no unquoted blanks. The first word in the sequence (numbered as 0), usually specifies the name of a command. Any remaining words, with a few exceptions, are passed to that command.

The *value* of a simple command is its exit value if it ends normally or (octal) 200 status if it ends abnormally. For a list of status values, see the **signal** system call in AIX Operating System Technical Reference.

A pipeline is a sequence of one or more commands separated by a I (vertical bar) or, for historical compatibility, by a ^ (circumflex). In a pipeline, the standard output of each command becomes the standard input of the next command. Each command runs as a separate process, and the shell waits for the last command to end. A filter is a command that reads its standard input, transforms it in some way, then writes it to its standard output. A pipeline normally consists of a series of filters. Although the processes in a pipeline (except the first process) can execute in parallel, they are synchronized to the extent that each program needs to read the output of its predecessor.

The exit value of a pipeline is the exit value of the last command.

A *list* is a sequence of one or more pipelines separated by; (semicolon), & (ampersand), && (two ampersands), or !! (two vertical bars) and optionally ended by a; (semicolon) or an & (ampersand). These separators and terminators have the following effects:

- ; Causes **sequential execution** of the preceding pipeline (the shell waits for the pipeline to finish).
- & Causes asynchronous execution of the preceding pipeline the shell does not wait for the pipeline to finish).
- && Causes the list following it to be executed *only* if the preceding pipeline returns a zero exit value.
- Causes the list following it to be executed *only* if the preceding pipeline returns a nonzero exit value.

Note: The cd command is an exception. If it returns a nonzero exit value, no subsequent commands in a list are executed, regardless of the separator characters.

The; and & separators have equal precedence, as do && and II. The single-character separators have lower precedence than the double-character separators. An unquoted new-line character following a pipeline functions the same as a; (semicolon).

The shell treats as a comment any word that begins with a # character and ignores that word and all characters following up to the next new-line character.

Command Execution

Each time the shell executes a command, it carries out the substitutions discussed in the following text. If the command name matches one of the built-in commands discussed in "Built-in Commands" on page 931, it executes it in the shell process. If the command name does not match a built-in command but matches the name of a defined function, it executes the function in the shell process. The shell sets the positional parameters to the parameters of the function.

If the command name matches neither a built-in command nor the name of a defined function and the command names an executable file that is a compiled (binary) program. the shell (as **parent**) spawns a new (**child**) process that immediately runs the program. If the file is marked executable but is not a compiled program, the shell assumes that it is a shell procedure. In this case, the shell spawns another instance of itself (a *subshell*), to read the file and execute the commands included in it (note how this differs from the execution of functions). The shell also executes a parenthesized command in a subshell (see page 931). From your point of view as a user, a compiled program is run in exactly the same way as a shell procedure.

The shell normally searches for commands in four places in the file system. The shell first looks for the command in the /bin directory. If it does not find the command there, it looks in the /usr/bin directory. If this also fails, it looks in the /etc directory and then, finally, in the current directory. You can also give a specific path name when you invoke a command, for example /bin/sort, in which case the shell does not search any directories other than the one you specify in the path name. If the command name contains a / (slash), the shell does not use the search path (note that the restricted shell will not execute such commands). You can give a full path name that begins with the root directory (as in /bin/sort), or a path name relative to the current directory, for example bin/myfile. In this last case, the shell looks in the current directory for a directory named bin and in that directory for myfile.

You can change the particular sequence of directories searched by resetting the PATH variable (page 923).

The shell remembers the location in the search path of each executed command (to avoid unnecessary execs later). If the command was found in a relative directory (one whose name does not being with /), the shell must redetermine its location whenever the current directory changes. The shell forgets all remembered locations whenever you change the **PATH** variable or execute the hash -r command (page 932).

Signals

The shell ignores INTERRUPT and QUIT signals for an invoked command if the command is terminated with a & (that is, if it is running in the background). Otherwise signals have the values inherited by the shell from its parent, with the exception of signal 11 (see also the built-in **trap** command on page 934).

The .profile File

When you log in, the shell is called to read your commands. Before it does that, however, it checks to see if a file named /etc/profile exists on the system, and if it does, it reads commands from it (this file should set variables needed by all users). After this, the shell looks for a file named .profile in your login directory. If it finds one, it executes commands from it. Finally, the shell is ready to read commands from your standard input.

File-name Substitution

Command parameters are very often file names. You can automatically produce a list of file names as parameters on a command line by specifying a pattern that the shell matches against the file names in a directory.

Most characters in such a pattern match themselves, but you can also use some special pattern-matching characters in your pattern. These special characters are:

- * Matches any string, including the null string.
- ? Matches any one character.
- [. . .] Matches any one of the characters enclosed in square brackets.
- [! . . .] Matches any character *other than* one of the characters that follow the exclamation mark within square brackets.

Inside square brackets, a pair of characters separated by a - (minus) specifies a set of all characters lexically within the inclusive range of that pair, according to the current collating sequence (see "ctab" on page 257). The NLCTAB environment variable controls the collating sequence.

The current collating sequence may group characters into *equivalence classes* for the purpose of defining the end points of a range of characters. For example, if the collating sequence defines the lexical order to be AaBbCc . . . and groups upper- and lower-case characters into equivalence classes, then all the following have the same effect: [a-C], [A-C], [a-C], and [A-C].

Japanese Language Support Information

A collating sequence in Japanese Language Support does not define equivalence classes for use in range expressions. To avoid unpredictable results when using a range expression to match a class of characters, use a *character class expression* rather than a standard range expression. For information about matching file names using character class expressions, see "File-name Substitution in Japanese Language Support" on page 917. See also the discussion of this topic included in the description of the command "File Name Substitution" on page 4.

Pattern matching has some restrictions. If the first character of a file name is a . (dot), it can be matched only by a pattern that literally begins with a dot. For example, * matches the file names myfile and yourfile but not the file names .myfile and .yourfile. To match these files, use a pattern such as the following:

.*file

If a pattern does not match any file names, then the pattern itself is returned as the result of the attempted match.

File and directory names should not contain the characters *, ?, [, or] because they can cause infinite recursion (that is, infinite loops) during pattern-matching attempts.

Japanese Language Support Information

File-name Substitution in Japanese Language Support

You can also use the following notation to match file names within a range indication:

[:charclass:]

This format instructs the system to match any single character belonging to class: the defined classes correspond to **ctype** subroutines. Following are the names of these classes:

alnum	jalpha
alpha	jdigit
digit	jhira
lower	jkanji
print	jkata
punct	jparen
space	jpunct
upper	jspace
xdigit	jxdigit

For example, the expression that matches any single kanji character would be the following:

```
[[:jkanji:]]
```

For additional information about character class expressions, see the discussion of this topic included in the description of the command "ed" on page 371.

Shell Variables and Command-Line Substitutions

The shell has several mechanisms for creating variables (assigning a string value to a name). Certain variables, positional parameters and keyword parameters, are normally set only on a command line. Other variables are simply names to which you or the shell can assign string values.

Positional Parameters

When you run a shell procedure, the shell implicitly creates positional parameters that reference each word on the command line by its position on the command line. The word in position 0 (the procedure name), is called \$0, the next word (the first parameter) is called \$1, and so on up to \$9. To refer to command line parameters numbered higher than 9, use the built-in **shift** command (page 934).

You can also assign values to these positional parameters explicitly by using the built-in set command (page 933).

Notes:

- 1. When an argument for a position is not specified, its positional parameter is set to null.
- 2. Positional parameters are global and can be passed to nested shell procedures.

User-defined Variables

The shell also recognizes alphanumeric variables to which string values can be assigned. You assign a string value to a *name*, as follows:

name=string

A name is a sequence of letters, digits, and underscores that begins with an underscore or a letter. To use the value that you have assigned to a variable, add a \$. (dollar sign) to the beginning of its name. Thus \$name yields the value string. Note that no blanks surround the = (equal sign) in an assignment statement. (Positional parameters cannot appear in a assignment statement; they can only be set as described earlier.) You can put more than one assignment on a command line, but remember: the shell performs the assignments from right to left.

If you surround *string* with quotation marks, either double or single (" " ' '), the shell does not treat blanks, tabs, semicolons, and new-line characters within it as word delimiters but imbeds them literally in the string.

If you surround *string* with double quotation marks (""), the shell still recognizes variable names in the string and performs *variable substitution*; that is, it replaces references to positional parameters and other variable names that are prefaced by \$ with their corresponding values, if any. The shell also performs *command substitution* (see "Command Substitution" on page 925) within strings that are surrounded by double quotation marks.

If you surround *string* with single quotation marks (''), the shell does no variable or command substitution within the string. The following sequence illustrates this difference:

```
You: stars=****
       asterisks1="Add $stars"
       asterisks2='Add $stars'
       echo $asterisks1
System: Add ****
  You: echo $asterisks2
System: Add $stars
```

The shell does not reinterpret blanks in assignments after variable substitution (see "Blank Interpretation" on page 930). Thus the following assignments result in \$first and \$second having the same value:

```
first='a string with embedded blanks'
second=$first
```

When you reference a variable, you can enclose the variable name (or the digit designating a positional parameter) in { } (braces) to delimit the variable name from any following string. In particular, if the character immediately following the name is a letter, digit, or underscore and the variable is not a positional parameter, then the braces are required:

```
You: a='This is a'
      echo "${ a } n example"
Display: This is an example
  You: echo "$a test"
Display: This is a test
```

Note: The { } operator requires a space following the opening brace and a space preceding the closing brace.

See "Conditional Substitution" on page 920 for a different use of braces in variable substitutions.

A Command's Environment

All the variables (with their associated values) that are known to a command at the beginning of its execution constitute its environment. This environment includes variables that a command inherits from its parent process and variables specified as keyword parameters on the command line that calls the command.

The shell passes to its child processes the variables that have been named as arguments to the built-in export command. export places the named variables in the environments of both the shell and all its future child processes.

Keyword parameters are variable-value pairs that appear in the form of assignments, normally before the procedure name on a command line (but see also the -k flag on page 933). Such variables are placed in the environment of the procedure being called.

For example, given the following simple procedure that echoes the values of two variables (saved in a command file named key_command):

```
# key_command
echo $a $b
```

the following command lines produce the output shown:

```
You: a=key1 b=key2 key_command
Display: key1 key2
You: a=tom b=john key_command
Display: tom john
```

A procedure's keyword parameters are not included in the parameter count stored in \$#.

A procedure can access the values of any variables in its environment; however, if it changes any of these values, these changes are not reflected in the shell environment. They are local to the procedure in question. To place these changes in the environment that the procedure passes to its child processes, you must export these values within that procedure.

To obtain a list of variables that have been made exportable from the current shell, enter:

```
export
```

(You will also get a list of variables that have been made **readonly**.) To get a list of name-value pairs in the current environment, enter:

env

Conditional Substitution

Normally, the shell replaces \$variable with the string value assigned to variable, if there is one. However, there is a special notation that allows **conditional substitution**, depending on whether the variable is set and/or not null. By definition, a variable is **set** if it has ever been assigned a value. The value of a variable can be the null string, which you can assign to a variable in any one of the following ways:

```
A=
bcd=""
Efg=''
set ''"
```

The first three of these examples assign the null string to each of the corresponding variable names. The last example sets the first and second positional parameters to the null string and unsets all other positional parameters.

The following is a list of the available expressions you can use to perform conditional substitution:

- \$\{\ variable\text{-string}\}\ If the variable is set, substitute the value of variable in place of this expression. Otherwise, replace this expression with the value of string.
- \$\{\ variable:\text{-string}\}\ If the variable is set and is not null, substitute the value of variable in place of this expression. Otherwise, replace this expression with the value of string.
- \$\{\ variable = string\} If the variable is set, substitute the value of variable in place of this expression. Otherwise, set variable to string and then substitute the value of the variable in place of this expression. You cannot assign values to positional parameters in this fashion.
- \${ variable:=string } If the variable is set and is not null, substitute the value of variable in place of this expression. Otherwise, set variable to string and then substitute the value of the *variable* in place of this expression. You cannot assign values to positional parameters in this fashion.
- \$\{\ variable?string\}\ If the variable is set, substitute the value of variable in place of this expression. Otherwise, display a message of the form:

variable: string

and exit from the current shell (unless the shell is the login shell). If you do not specify string, the shell displays the following message:

parameter null or not set variable:

\$\{\ variable:\text{?string}\}\ \] If the variable is set and not null, substitute the value of variable in place of this expression. Otherwise, display a message of the form:

> variable: string

and exit from the current shell (unless the shell is the login shell). If you do not specify *string*, the shell displays the following message:

variable: parameter null or not set

\${ variable + string }

If the variable is set, substitute the value of string in place of this expression. Otherwise, substitute the null string.

\${ variable: + string } If the variable is set and not null, substitute the value of string in place of this expression. Otherwise, substitute the null string.

In conditional substitution, the shell does not evaluate *string* until it uses it as a substituted string, so that, in the following example, the shell executes the **pwd** command only if d is not set or is null:

echo \${ d:-'pwd' }

Variables Used by the Shell

The shell uses the following variables. The shell sets some of them, and you can set or reset all of them:

CDPATH

The search path for the **cd** (change directory) command (see the **PATH** variable in the following list for an explanation of search paths).

HOME

The name of your *login directory*, the directory that becomes the current directory upon completion of a login. The *login* program initializes this variable. The *cd* command uses the value of **\$HOME** as its default value. If you use this variable in your shell procedures rather than using an explicit full path name, your procedures run even if your login directory is changed or if another user runs them.

LIBPATH

The search path for shared libraries.

LOGNAME

Your login name, marked readonly in the /etc/profile file.

MAIL

The path name of the file used by the mail system to detect the arrival of new mail. If MAIL is set, the shell periodically checks the modification time of this file and displays the value of \$MAILMSG if this time changes and the length of the file is greater than zero.

You should set MAIL in your .profile file. The value normally assigned to it by users of the mail command is /usr/mail/\$LOGNAME.

MAILCHECK

The number of seconds that the shell lets elapse before checking again for the arrival of mail in the files specified by the MAILPATH or MAIL parameters. The default value is 600 seconds (10 minutes). If you set MAILCHECK to 0, the shell checks before each prompt.

MAILPATH

A colon-separated list of file names (see PATH). If you set this parameter, the shell informs you of the arrival of mail in any of the files specified in the list. You can follow each file name by a % (percent sign) and a message to be displayed when mail arrives. Otherwise, the shell uses the value of MAILMSG or by default "you have mail".

Note: When MAILPATH is set, these files are checked instead of the file set by MAIL. To check the files set by MAILPATH and the file set by MAIL, specify the MAIL file in your list of MAILPATH files.

MAILMSG

The mail notification message. If you explicitly set MAILMSG to a null string (MAIL=""), no message is displayed.

NLCTAB

Defines the collating sequence to use when sorting names and when character ranges occur in patterns. If absent, it may be taken form the parameter NLFILE. If both are absent, the American English collating sequence is used.

Japanese Language Support Information

When Japanese Language Support is installed, the default collating sequence, based on the character's value, is used. See "Overview of International Character Support" in Managing the AIX Operating System for further information.

PATH

An ordered list of directory path names separated by colons. The shell searches these directories in the specified order when it looks for commands. A null string anywhere in the list represents the current directory.

PATH is normally initialized in the /etc/profile file, usually to /bin:/usr/bin:/etc::. You can reset this variable to suit your own needs. Thus if you wish to search your current directory first, rather than last. you would enter:

PATH=:/bin:/usr/bin:/etc

where, by definition, a null string is assumed in front of the leading colon. If you have a personal directory of commands (say, \$HOME/bin) that you want searched before the standard system directories, set your **PATH** as follows:

PATH=\$HOME/bin:/bin:/usr/bin:/etc::

The best place to set your PATH to something other than the default value is in your .profile file (see "The .profile File" on page 915). You cannot reset PATH if you are executing commands under the restricted shell.

PS₁

The string to be used as the primary system prompt. An interactive shell displays this prompt string when it expects input. The default value of PS1 is "\$" (a \$ followed by a blank).

PS₂

The value of the secondary prompt string. If the shell expects more input when it encounters a new-line character in its input, it prompts with the value of PS2. The default value of PS2 is "> " (a > followed by a blank). IFS The characters that are internal field separators (the characters that

the shell uses during blank interpretation, see "Blank Interpretation" on page 930). The shell initially sets IFS to include the blank, tab, and

new-line characters.

SHACCT The name of a file that you own. If this parameter is set, the shell writes

an accounting record in the file for each shell script executed. You can use accounting programs such as acctom and acctoms to analyze the

data collected.

SHELL A path name whose simple part (the part after the last /) contains the

letter r if you want the shell to become restricted when invoked. This should be set and exported by the \$HOME/.profile file of each restricted

login.

TIMEOUT A number of minutes. After the shell displays its prompt, you have

TIMEOUT minutes to enter a command. If you fail to do so, the shell exits; in the login shell, such an exit is a logoff. Setting TIMEOUT to 0

inhibits automatic logoff.

Predefined Special Variables

Several variables have special meanings; the following are set *only* by the shell:

- \$# The number of positional parameters passed to the shell, not counting the name of the shell procedure itself. \$# thus yields the number of the highest-numbered positional parameter that is set. One of the primary uses of this variable is to check for the presence of the required number of arguments.
- \$? The exit value of the last command executed. Its value is a decimal string. Most UNIX commands return 0 to indicate successful completion. The shell itself returns the current value of \$? as its exit value.
- The process number of the current process. Because process numbers are unique among all existing processes, this string of up to five digits is often used to generate unique names for temporary files. The following example illustrates the recommended practice of creating temporary files in a directory used only for that purpose:

temp=\$HOME/temp/\$\$
1s >\$temp

rm \$temp

\$! The process number of the last process run in the background (using the & terminator). Again, this is a string of up to five digits.

\$-A string consisting of the names of the execution flags (page 933) currently set in the shell.

Command Substitution

To capture the output of any command as an argument to another command, place that command line within grave accents (' '). This concept is known as command substitution. The shell first executes the command or commands enclosed within the grave accents, and then replaces the whole expression, grave accents and all, with their output. This feature is often used in assignment statements:

```
todav='date'
```

This statement assigns the string representing the current date to the variable today. The following assignment saves, in the variable files, the number of files in the current directory:

```
files='ls | ws -l'
```

You can enclose any command that writes to standard output in grave accents. You can nest command substitutions as long as you quote the inside sets of grave accents with a preceding \ (backslash):

```
logmsg='echo Your login directory is \'pwd\'`
```

You can also give values to shell variables indirectly by using the built-in read command. read takes a line from standard input (usually your keyboard), and assigns consecutive words on that line to any variables named. For example,

```
read first init last
```

will take an input line of the form:

```
J. Q. Public
```

and have the same effect as if you had typed:

```
first=J.
          init=0. last=Public
```

read assigns any excess words to the last variable.

Quoting Mechanisms

Many characters have a special meaning to the shell; sometimes you want to conceal that meaning. Single ('') and double ("") quotation marks surrounding a string or a backslash (\) before a single character provide this function in somewhat different ways.

Within single quotation marks, all characters (except the single quotation character itself). are taken literally, with any special meaning removed. Thus:

```
stuff='echo $? $*: 1s * ! wc'
```

results only in the literal string echo \$? \$*; 1s * | wc being assigned to the variable stuff; the echo, 1s, and wc commands are not executed, nor are the variables \$? and \$* and the special character * expanded by the shell.

Within double quotation marks, the special meaning of certain characters (the \$, `, and ") does persist, while all other characters are taken literally. Thus, within double quotation marks, command and variable substitution takes place. In addition, the quotation marks do not affect the commands within a command substitution that is part of the quoted string, so characters there retain their special meanings.

Consider the following sequence:

```
You: ls *
Display: file1
file2
file3
You: message="This directory contains 'ls * ' "
echo $message
Display: This directory contains file1 file2 file3
```

This shows that the * special character inside the command substitution was expanded.

To hide the special meaning of $\$, ', and " within double quotation marks, precede these characters with a \ (backslash). Outside of double quotation marks, preceding a character with \ is equivalent to placing it within single quotation marks. Hence, a \ immediately preceding the new-line character (that is, a \ at the end of the line) hides the new-line character and allows you to continue the command line on the next physical line.

Redirection of Input and Output

In general, most commands do not know or care whether their input or output is associated with the keyboard, the display screen, or a file. Thus a command can be used conveniently either at the keyboard or in a pipeline.

Standard Input and Standard Output

When a command begins running, it usually expects that three files are already open: standard input, standard output, and diagnostic output (sometimes called error output or standard error output). A number called a file descriptor is associated with each of these files as follows:

```
File descriptor 0 Standard input
File descriptor 1 Standard output
File descriptor 2 Diagnostic (error) output
```

A child process normally inherits these files from its parent; all three files are initially assigned to the work station (0 to the keyboard, 1 and 2 to the display). The shell permits them to be redirected elsewhere before control is passed to a command. Any argument to the shell in the form < file or > file opens the specified file as the standard input or output, respectively. In the case of output, this process destroys the previous contents of file, if it already exists. An argument in the form >> file directs the standard output to the end of file, thus allowing you to add data to it without destroying its existing contents. If file does not exist, the shell creates it.

Such redirection arguments are subject only to variable and command substitution; neither blank interpretation nor pattern matching of file names occurs after these substitutions. Thus:

```
echo 'this is a test' > *.ggg
```

produces a one-line file named *.qqq (a disastrous name for a file), and:

cat < ?

produces an error message, unless you have a file named? (also a bad choice for a file name).

Diagnostic and Other Output

Diagnostic output from UNIX commands is normally directed to the file associated with file descriptor 2. You can redirect this error output to a file by immediately preceding either output redirection arrow (> >>) with a 2 (the number of the file descriptor). For example, the following line adds error messages from the **cc** command to the file ERRORS:

```
cc testfile.c 2>> ERRORS
```

Note that there must be no blanks between the file descriptor and the redirection symbol; otherwise, the shell interprets the number as a separate argument to the command.

You can also use this method to redirect the output associated with any of the first 10 file descriptors (numbered 0 through 9) so that, for instance, if a command (CMd) writes to file descriptor 9 (although this is not a recommended programming habit), you can capture that output in a file savedata as follows:

```
cmd 9> savedata
```

If a command writes to more than one output, you can independently redirect each one. Suppose that a command directs its standard output to file descriptor 1, directs its error output to file descriptor 2, and builds a data file on file descriptor 9. The following command line redirects each of these outputs to a different file:

```
cmd > standard 2> error 9> data
```

Inline Input Documents

Upon seeing a command line of the form:

cmd << eofstring

where *eofstring* is any string that does not contain any pattern-matching characters, the shell takes the subsequent lines as the standard input of CMd until it reads a line consisting of only *eofstring* (possibly preceded by one or more tab characters). The lines between the first *eofstring* and the second are frequently referred to as a *here document*. If a - (minus) immediately follows the <<, the shell strips leading tab characters from each line of the input document before it passes the line to the command.

The shell creates a temporary file containing the input document and performs variable and command substitution on its contents before passing it to the command. It performs pattern matching on file names that are a part of command lines in command substitutions. If you want to prohibit all substitutions, quote any character of *eofstring*:

cmd << \eofstring

The here document is especially useful for a small amount of input data that is more conveniently placed in the shell procedure rather than kept in a separate file (such as editor "scripts"). For instance, you could enter:

cat <<- xyz

This message will be shown on the display with leading tabs removed.

xyz

This feature is most useful in shell procedures. Note that inline input documents *cannot* appear within grave accents (command substitution).

Input and Output Redirection Using File Descriptors

As discussed previously, a command occasionally directs output to some file associated with a file descriptor other than 1 or 2. The shell also provides a mechanism for creating an output file associated with a particular file descriptor. By entering:

fd1>&fd2

where fd1 and fd2 are valid file descriptors, you can direct the output that would normally be associated with file descriptor fd1 to the file associated with fd2. The default value for fd1 and fd2 is 1 (standard output). If, at execution time, no file is associated with fd2, then the redirection is void. The most common use of this mechanism is to **direct** standard error output to the same file as standard output, as follows:

cmd 2>&1

If you want to *redirect* both standard output and standard error output to the same file. enter:

cmd > file 2>&1

The order here is significant. First, the shell associates file descriptor 1 with file; then it associates file descriptor 2 with the file that is currently associated with file descriptor 1. If you reverse the order of the redirections, standard error output will go to the display and standard output would go to file because at the time of the error output redirection, file descriptor 1 was still associated with the display.

You can also use this mechanism to redirect standard input. You could enter:

 $fda \leq & fdb$

to cause both file descriptors to be associated with the same input file. For commands that run sequentially, the default value of fda and fdb is 0 (standard input). For commands that run asynchronously (commands terminated by &), the default value of fda and fdb is /dev/null. Such input redirection is useful for commands that use two or more input sources.

Summary of Redirection Options

The following can appear anywhere in a simple command or can precede or follow a command, but they are not passed to the command:

<file Use file as standard input.

>file Use file as standard output. Create the file if it does not exist; otherwise

truncate it to zero length.

> > *file* Use file as standard output. Create the file if it does not exist; otherwise

add the output to the end of the file.

< < [-]*eofstr* Read as standard input all lines from *eofstr* up to a line containing only eofstr or up to an end-of-file character. If any character in eofstr is quoted, the shell does not expand or interpret any characters in the input lines; otherwise, it performs variable and command substitution and ignores a quoted new-line character (\new-line). Use a \to quote characters within eofstr or within the input lines.

> If you add a - (minus) to < < then all leading tabs are stripped from eofstr and from the input lines.

< &digit Associate standard input with file descriptor digit.

> & digit Associate standard output with file descriptor digit.

< &-Close standard input. > &- Close standard output.

The restricted shell does not allow the redirection of output.

Blank Interpretation

After the shell performs variable and command substitution, it scans the results for internal field separators (those defined in the shell variable IFS, see page 924). It splits the line into distinct words at each place it finds one of these characters. It retains explicit null arguments ("" ') and discards implicit null arguments (those resulting from parameters that have no values).

Control Commands

The shell provides several flow control commands that are useful in creating shell procedures:

```
for name [ in word . . . ]
```

do list

For each word, sets name to word and executes the commands in list. If you omit in word . . ., then the for command executes list for each positional parameter that is set. Execution ends when there are no more words in the word list.

```
case word in
pattern [\pattern] . . . ) list;;
[.
...
pattern [\pattern] . . . ) list;;]
```

esac

Executes the commands in the *list* associated with the first *pattern* that matches *word*. Uses the same character-matching notation in patterns that you use for file-name substitution (see "File-name Substitution" on page 916), except that you do not need to match explicitly a slash, a leading dot, or a dot immediately following a slash.

if list
then list
[elif list] . . .
[else list]
fi

Executes the *list* following the **if** keyword. If it returns a zero exit value, execute the *list* following the first **then**. Otherwise, execute the *list* following **elif** (if there is an **elif**), and if its exit value is zero, execute the next **then**. Failing that, execute the *list* following the **else**.

If no else *list* or then *list* is executed, the if command returns a zero exit value.

while list do list done

Executes the *list* following the **while**. If the exit value of the last command in the list is zero, executes the *list* following **do**. Continue looping through the *list*s until the exit value of the last command in the **while** *list* is nonzero. If no commands in the **do** *list* are executed, the **while** command returns a zero exit value.

until list do list done

Executes the *list* following the **until**. If the exit value of the last command in the list is nonzero, executes the *list* following **do**. Continues looping through the *list*s until the exit value of the last command in the **until** *list* is zero. If no commands in the **do** *list* are executed, the **until** command returns a zero exit value.

(list)

Executes the commands in *list* in a subshell.

{ *list*; }

Executes the commands in *list* in the current shell process (does not

spawn a subshell).

name () { list; }

Defines a function that is referenced by *name*. The body of the function is the *list* of commands between the braces.

The following words are recognized only as the first word of a command and when not quoted:

if then else elif fi case esac for while until do done { }

Built-in Commands

: Does nothing. This null command returns a zero exit value.

. file

Reads and executes commands from *file* and returns. Does not spawn a subshell. The search path specified by **PATH** is used to find the

directory containing file.

break [n]

Exits from the enclosing for, while, or until loop, if any. If n is specified, then breaks n levels.

continue [n]

Resumes the next iteration of the enclosing for, while, or until loop. If n is specified, resumes at the nth enclosing loop.

cd [dir]

Changes the current directory to dir. The value of the shell variable **HOME** is the default dir. The shell variable **CDPATH** defines the search path for the directory containing dir. Alternative directory names appear in a colon-separated list. A null path name specifies the current directory (which is the default path). This null path name can

appear immediately after the equal sign in the assignment or between the colon delimiters anywhere else in the path list. If *dir* begins with a slash, the shell does not use the search path. Otherwise, the shell searches each directory in the path. **cd** cannot be executed by the restricted shell.

dirstyle

Indicates whether directories should be interpreted in either raw or System V format. A + flag indicates path names from remote file systems should be converted to System V format. A - flag indicates path names from remote file systems should not be converted to System V.

Note: Use this only when reading the contents of a directory that is not formatted in System V. Otherwise, use opendir, readdir, and closedir library functions.

- echo [arg . . .] Writes arguments to standard output. See "echo" on page 369 for a discussion of its usage and parameters.
- eval [arg . . .] Reads arguments as input to the shell and executes the resulting command(s).
- exec [arg...] Executes the command specified by argument in place of this shell without creating a new process. Input and output arguments can appear and, if no other arguments appear, cause the shell input or output to be modified (not a good idea with your login shell).
- exit [n] Causes a shell to exit with the exit value specified by n. If you omit n, the exit value is that of the last command executed (Ctrl-D will also cause a shell to exit). The value of n can be from 0 to 255, inclusive.
- export [name . . .]

 Marks the specified names for automatic export to the environments of subsequently executed commands. If you do not specify names, export displays a list of all names that are exported in this shell. You cannot export function names.

$\mathbf{hash} \ [\mathbf{-r}] \ [name \ . \ . \ . \]$

For each name, finds and remembers the location in the search path of the command specified by name. The -r flag causes the shell to forget all locations. If you do not specify the flag or any names, the shell displays information about the remembered commands. In this information, hits is the number of times a command has been run by the shell process. Cost is a measure of the work required to locate a command in the search path. There are certain situations that require that the stored location of a command be recalculated (for example, the location of a relative path name when the current directory changes). Commands for which that might be done are indicated by an asterisk next to the hits information. Cost is incremented when the recalculation is done.

newgrp [arg . . .]

Executes the newgrp command in the current shell process. See "newgrp" on page 689 for a discussion of command options.

pwd

Displays the current directory. See "pwd" on page 800 for a discussion of command options.

read [name . . .] Reads one line from standard input. Assigns the first word in the line to the first name, the second word to the second name, and so on, with leftover words assigned to the last name. This command returns a 0 unless it encounters an end of file.

readonly [name . . .]

Marks the specified names readonly. The values of these names cannot be reset. If you do not specify any names, readonly displays a list of all readonly names.

return [n]

Cause a function to exit with a return value of n. If you do not specify n, the function returns the status of the last command executed in that function. This command is valid only when executed within a shell function.

set $[flag \dots [arg] \dots]$

- -a Marks for export all variables that are modified or changed.
- Exits immediately if a command exits with a nonzero exit value.
- Disables file-name substitution.
- -h Locates and remembers the commands called within functions as the functions are defined (normally these commands are located when the function is executed—see the hash command on page 932).
- -k Places all keyword parameters in the environment for a command. not just those that precede the command name.
- -n Reads commands but do not execute them.
- Exits after reading and executing one command.
- Treats an unset variable as an error when performing variable substitution.
- Displays shell input lines as they are read.
- Displays commands and their arguments as they are executed.
- Does not change any of the flags. This is useful in setting \$1 to a string beginning with a - (minus).

Using a + (plus) rather than a - (minus) unsets flags. You can also specify these flags on the shell command line. The special variable \$contains the current set of flags.

Any arguments to set are positional parameters and are assigned, in order, to \$1, \$2, and so on. If you do not specify flags or parameters. set displays all names.

shift [n]

Shifts command line arguments to the left; that is, reassign the value of the positional parameters by discarding the current of value of \$1 and assigning the value of \$2 to \$1, of \$3 to \$2, and so on. If there are more than 9 command line arguments, the tenth is assigned to \$9 and any that remain are still unassigned (until after another shift). If there are 9 or fewer arguments, a shift unsets the highest-numbered positional parameter.

\$0 is never shifted. The command **shift** n is a shorthand notation for nconsecutive shifts. The default value of n is 1.

test expr | [expr] Evaluates conditional expressions. See "test" on page 1064 for a discussion of command options.

times

Displays the accumulated user and system times for processes run from the shell.

trap [arg][n] . . .

Runs the command specified by arg when the shell receives signal(s) n. (Note that the shell scans parm once when the trap is set and once when the trap is taken). trap commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective.

If you do not specify an arg, then all trap(s) n are reset to their current values. If arg is the null string, then this signal is ignored by the shell and by the commands it invokes. If n is 0, then arg is executed on exit from the shell. If you specify no arg and no n, trap displays a list of commands associated with each signal number.

For each *name*, indicates how the shell would interpret it as a tvpe [name . . .] command name.

ulimit [-b [m]] [-f] [n] [-s [m]]

Sets or queries size limits. The **-b** flag sets the break value to m. This limits the size of data segment to m pages. If you specify -b with no m, ulimit displays the current break value. The -f flag imposes a size limit of n blocks on files written by the child processes (files of any size can be read). Without n, ulimit displays the current limit (this is the default action of ulimit).

Notes:

- Since the shell rounds n down to the nearest cluster size, it is best to make it a multiple of 4 (for example, specifying values of 1, 2, or 3 for n all result in a size limit of 0).
- 2. Any user can decreased this limit, but only a user operating with superuser authority can increase the limit.

The -s flag imposes a size limit of m pages on the stack. If you specify -s with no m. ulimit displays the current stack size limit.

umask [nnn]

Sets the user file-creation mask to nnn (see the umask system call). If you omit nnn. umask displays the current value of the mask.

unset [name . . .]

For each *name*, removes the corresponding variable or function. The variables PATH, PS1, PS2, MAILCHECK and IFS cannot be unset.

wait [n]

Waits for the child process whose process number is n to end and reports its termination status. If you do not specify n, then the shell waits for all currently active child processes and the return value is 0.

Running the Shell

The sh command can be run either as a *login shell* or as a login shell subshell under the login shell. Only the login command can call sh as a login shell. It does this by using a special form of the sh command name: -sh. When called with an initial - (minus), the shell first reads and runs commands found in the system profile file and your \$HOME/.profile, if one exists. It then accepts commands as described in the following discussion of flags. Once logged in and working under a login shell, you can call sh with the command name Sh. This command runs a subshell, a second shell running as a child of the login shell.

Restricted Shell

The restricted shell, Rsh, is used to set up login names and environments whose capabilities are more controlled than those of the standard shell. The actions of Rsh are identical to those of sh, except that the following are not allowed:

- Changing directory (see "cd" on page 150)
- Setting the value of **\$PATH**
- Specifying path or command names containing /
- Redirecting output (> and >>).

The restrictions above are enforced after .profile is interpreted, meaning that the restrictions can override settings originally set in .profile.

When a command to be run is found to be a shell procedure, **Rsh** starts **sh** to run it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and run permissions in the same directory.

The net effect of these rules is that the writer of the .profile has complete control over user actions, by performing setup actions and leaving the user in an appropriate directory (probably not the login directory).

When called with the name -Rsh, Rsh reads the user's .profile (from \$HOME/.profile). It acts as the standard sh while doing this, except that an interrupt causes an immediate exit instead of a return to command level.

Flags

The following flags are interpreted by the shell only when you call it. Note that unless you specify either the -c or -s flag, the shell assumes that the next parameter is a command file (shell procedure). It passes anything else on the command line to that command file (see "Positional Parameters" on page 918).

-c cmdstring

Runs commands read from *cmdstring*. The shell does not read additional commands from standard input when you specify this flag.

- -i Makes the shell interactive, even if input and output are not from a work station. In this case the shell ignores the TERMINATE signal (so that kill 0 does not stop an interactive shell) and traps an INTERRUPT (so that you can interrupt wait). In all cases, the shell ignores the QUIT signal. (See the signal system call in AIX Operating System Technical Reference and "kill" on page 552 for more information about signals.)
- -r Creates a restricted shell (the same as running Rsh).
- Reads commands from standard input. Any remaining parameters specified are passed as positional parameters to the new shell. Shell output is written to standard error, except for the output of built-in commands (see "Built-in Commands" on page 931).

The remaining flags and parameters are described in the built-in set command on page 933.

"Overview of International Character Support" in Managing the AIX Operating System.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

shell

Purpose

Executes a shell in a user's login environment

Syntax

AJ2FL133

Description

The **shell** command returns a user to an environment that is equivalent to the user's login environment. This command issues a **frevoke** system call to end all processes accessing the port. It re-establishes the terminal modes and environment variables then runs the user's login shell or the specified shell.

Only a person with superuser authority can specify *port* and *shell*. This command ignores any other arguments. When *port* and *shell* are not specified, the shell is found in /etc/passwd and the terminal is the one from which this command is issued.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/passwd

Specifies the user's login shell.

Related Information

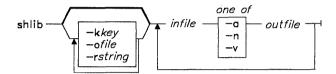

See the section on trusted path management in Managing the AIX Operating System.

shlib

Purpose

Creates a shared library.

Syntax

OL805448

Description

The shlib command creates a shared library from a set of unshared object and/or archive files. The shared library it creates has two parts:

- A single shared library text image that contains the code, and only the code, from all of the input files.
- Modified archive or object files that refer to the text image, each of which corresponds to one of the shlib input files.

By default, shlib uses the name of the first input file to generate the shared library key. It does this by removing any directory path from the file name and, if the file name does not contain a suffix, adding the suffix .yyddd, where yy is the last two digits of the current year and **ddd** is the number of the day. **shlib** puts this key in each of the modified output files. By default, it also uses this key as the name of the shared library text image, which contains the shared library key in a form that can be found by the what command.

The shlib command transforms each input file specified on the command line and copies it to (or verifies it against) an output file. Each output object module differs from the corresponding input object module in that the text portion has been removed and added to the end of the shared library text image. shlib also appends the shared library key to each output module and marks its a.out header so the ld command recognizes that the file refers to a shared library and relocates references appropriately.

Once you create an archive for a shared library, you can use the ar command to replace individual object files. The new object files will not refer to the shared library, thus allowing you to patch shared libraries.

The shlib command can process all cc and f77 programs. Other programs must have KCALL relocation entries as the only external references within the text portion (see the a.out file in AIX Operating System Technical Reference). KCALL relocation entries are replaced by balax instructions to location 0xC00, which contain a code fragment to continue calls across segments. That code requires that register 0 point to the constant pool of the called routine, the first entry of which is the entry point of the invoked routine.

Flags

-a outfile	Adds new object modules in archives to <i>outfile</i> . This lets you add functions to a shared library, replacing the shared library text image without relinking programs that refer to it. The entire shared library image must be rebuilt.
-kkey	Uses the shared library key in the output object modules to refer to the shared library text image. If key does not contain a . (period), a suffix in the form .yyddd is added.
-n outfile	Makes a new output file for each input file.
-ofile	Assigns the name <i>file</i> to the shared library text image. shlib always makes a new shared library text image, replacing the old one.
-rstring	Adds <i>string</i> to the end of the shared library key in the what string. This only applies to the text image file.
- v outfile	Verifies components of a changed shared library, thus ensuring that the resulting object files are the same as the files previously created by shlib . Changes can be made to C source code as long as references to external names are not added, deleted, or rearranged and no floating point, string, or static initial values are modified.

Examples

1. To create a new shared text image:

```
shlib -kclibs -r"C shared library text" \
   /lib/libc.a -n /lib/libcs.a /lib/librts.a -n /lib/librtss.a
```

This creates shared libraries libcs.a and libraries.a and the text image file clibs.86133 (86133 indicates that this file was produced on 13 May 1986).

2. To modify an existing shared text image:

```
shlib -kclibs -r"C shared library text" \
   /lib/libc.a -a /lib/libcs.a /lib/libm.a -n /lib/libms.a
```

This updates the shared library libcs.a, creates the shared library libms.a, and updates the shared text image clibs.86133. (libc.a may contain new members that are added to the shared library and the text image.)

3. To create a shared text image with a different name than its key:

```
shlib -kclibs -octext_image -r"C shared library text" \
   /lib/libc.a -n /lib/libcs.a /lib/librts.a -n /lib/librtss.a
```

This produces a text image file named ctext_image. Note that you must use the -k flag when you compile programs that use this text image, since the key and the file name are not the same:

```
cc myproj.c -kclibs:ctext_image -lrtss -lcs
```

The discussion of shared libraries in AIX Operating System Programming Tools and Interfaces.

show

Purpose

Shows messages.

Syntax

Description

The **show** command is used to display a list of messages. **show** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The show command sends a listing of each of the specified messages to standard output. If standard output is not a display. show lists each message with a one-line header and two separation lines.

The **show** command invokes a program to perform the listing. The system default is /bin/pg. You can define your own default with the showproc: entry in \$HOME/.mh-profile. If you set showproc: entry to mhi, show calls an internal mhl routine instead of the mhl command. You can also specify the program to perform a listing in the *cmdstring* of the **-showproc** flag.

The show command passes any flags that it does not recognize to the program performing the listing. Thus, you can specify flags for the listing program, as well as the flags described in this command section.

If the Unseen-Sequence entry is present in \$HOME/.mh_profile and is not empty, show removes each of the messages shown from each sequence named by the profile entry.

Flags

-draft	Shows the file $user_mh_directory/\mathbf{draft}$ if it exists.		
+folder msgs	Specifies the messages that you want to show. <i>msgs</i> can be several messages, a range of messages, or a single message. You can use the following message references when specifying <i>msgs</i> :		
	num cur last	first all	prev next sequence
		ges are specified, t	message in the current folder. he last message shown becomes
-header	Displays a one-line description of the message being shown. The description includes the folder name and the message number. If you show more than one message, this flag does not produce message headers. This flag is the default.		
-help	Displays help inf	formation for the	command.
-noheader	Does not display shown.	a one-line descrip	otion of each message being
-noshowproc	Uses /bin/cat to	perform the listing	ng.
-showproc cmdstring	Uses the specifie	ed command string	to perform the listing.

Profile Entries

Path:

Current-Folder:

Sets your default current folder. Specifies your *user_mh_directory*.

showproc:

Specifies the program used to show messages.

Unseen-Sequence: Specifies the sequences used to keep track of your unseen messages.

Files

\$HOME/.mh_profile The MH user profile. user_mh_directory/draft The draft file.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

showmount

Purpose

Shows all file systems that are mounted remotely in an NFS environment.

Syntax

OL805502

Description

The showmount command lists the clients that have mounted a file system from an NFS server. This information is maintained by the network daemon mountd which runs continuously on the server. The daemon saves this information to the file /etc/rmtab for use if the server crashes.

The default value for *host* is the value returned by the command **hostname**.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- Displays all remote mounts in the format hostname: directory, where hostname -a specifies the name of the client and directory specifies the root of the mounted file system.
- -d Lists directories that have been remotely mounted by clients.
- Prints the list of exported file systems. -е

shutdown

Purpose

Ends system operation.

Syntax

OL805215

Description

The **shutdown** command brings the AIX Operating System from distributed mode to multiuser mode, from multiuser mode to maintenance mode, or halts the operating system completely. You can run **shutdown** only if you are a member of the system group or if you have superuser authority.

During the default shutdown, users are notified (by a wall command) of the impending system shutdown with the message: THE SYSTEM IS COMING DOWN NOW. However, the shutdown is not complete until the user receives the message: ...shutdown completed.... Do not attempt to reboot the system (Ctrl-Alt-Pause) or turn off the system before this message is displayed; otherwise, file system damage may result.

During the shutdown, the **hold** command prevents any new logins. After the specified number of *seconds* (60 by default), the system stops the accounting and error-logging processes. **shutdown** then runs the **killall** command to end any remaining processes and runs the **sync** command to flush all memory resident disk blocks. Finally, it unmounts the file systems and sends the appropriate signal to **init**. These signals are:

SIGINT Maintenance mode SIGTERM Virtual machine halt.

Note: Users who have files open on the node that is running shutdown, but who are not logged in to that node are not notified about the shutdown.

If there are no other users on the system and you want to shutdown the system quickly, you may want to use **shutdown** -f. This option bypasses messages to users and brings the system down as quickly as possible.

If you request a complete halt to the operating system, shutdown kills all processes, unmounts all file systems, and sends init the SIGTERM signal.

Warning: If you are bringing the system down to maintenance mode, you must run shutdown from the root directory to ensure that it can cleanly unmount the file systems.

Flags

- -d Brings the system down from a distributed mode to a multiuser mode.
- -f Does a fast shutdown, bypassing the messages to other users and bringing the system down as quickly as possible. If you do not specify this flag, shutdown sends a message to each logged-in user and waits a certain amount of time before bringing the system down, to allow each user to log off cleanly.
- -m Brings the system down to maintenance mode. From maintenance mode, you can return to multiuser mode.
- Causes the system to automatically reboot (Ctrl-Alt-Pause) after the user receives the message .. shutdown completed.
- Halts the operating system completely.

Examples

1. To tell the operating system you are about to turn off the machine:

shutdown

This shuts down the system, waiting 60 seconds before stopping the user processes and the init process.

2. To give users and the system more time to finish what they are doing:

shutdown -m 120 *

This brings the system down from multiuser mode to maintenance mode after waiting 120 seconds.

Files

/etc/shutdown.sh /etc/fshutdown.sh

The dsstate and signal system calls in AIX Operating System Technical Reference.

size

Purpose

Displays the section sizes of common object files.

Syntax

OL805216

Description

The size command writes to the standard output the number of bytes required by the text, initialized data, and uninitialized data, along with their sum for each file. The default file is a.out.

Flags

The output is in decimal notation unless you change the output with the following flags:

- Writes in octal notation.
- Writes in hexadecimal notation.

Examples

1. To display the size of a.out in decimal:

size

This displays the size in bytes of the executable file a.out. The size of each section of the object file is given, followed by the total. The three sections are program text, data, and bss (uninitialized data). The values are in decimal.

2. To display the size of an object file in octal:

size -o driver.o

This displays the size of the object file driver. 0 in octal.

3. To display the size of several object files in hexidecimal:

This displays in hexadecimal the size of each file in the current directory ending with .0.

The discussion of the a.out and ar files in AIX Operating System Technical Reference.

skulker

Purpose

Cleans up file systems by removing unwanted files.

Syntax

skulker ---

OL805217

Description

Warning: Because this command file runs with superuser authority and its whole purpose is to remove files, it has the potential for unexpected results. Before installing a new skulker, test any additions to its file removal criteria by running it manually using the xargs -p command. After you have verified that the new skulker removes only the files you want removed, you can install it.

The skulker command is a shell command file for periodically purging obsolete or unneeded files from file systems. Candidate files include those in /tmp, .bak files older than a specified age, and files named a.out, core, or ed.hup.

The **skulker** command is normally invoked daily, often as part of an accounting procedure run by cron during off-peak periods. Individual sites should modify skulker to suit local needs following the patterns shown in the distributed version. Local users should be made aware of the criteria for automatic file removal.

The find and xargs commands form a powerful combination for use in skulker. Most file selection criteria can be expressed conveniently with find expressions. The resulting file list, generated with the -print flag of the find command, can then be segmented and inserted into rm commands using xargs to reduce the overhead that would result if each file were deleted with a separate command.

Related Information

The following commands: "cron" on page 220, "find" on page 422, "rm" on page 833, and "xargs" on page 1232.

The section on using the skullker in Managing the AIX Operating System.

sleep

Purpose

Suspends execution for an interval.

Syntax

```
sleep - seconds -
```

OL805218

Description

The **sleep** command suspends execution of a process for the interval specified by *seconds*. *seconds* can range from 1 to 65,536 seconds.

Examples

1. To run a command after a certain amount of time has passed:

```
echo "SYSTEM SHUTDOWN IN 10 MINUTES!" | wall (sleep 300; echo "SYSTEM SHUTDOWN IN 5 MINUTES!" | wall) & (sleep 540; echo "SYSTEM SHUTDOWN IN 1 MINUTE!" | wall) & (sleep 600; shutdown) &
```

This command sequence warns all users 10 minutes, 5 minutes, and 1 minute before the system is shut down.

2. To run a command at regular intervals:

```
while true
do
date
sleep 60
done
```

This shell procedure displays the date and time once a minute. To stop it, press INTERRUPT (Alt-Pause).

Related Information

The following commands: "shutdown" on page 946 and "wall" on page 1208.

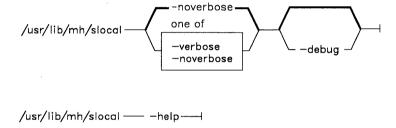

The alarm system call and the sleep, pause, and signal subroutines in $AIX\ Operating\ System\ Technical\ Reference$.

slocal

Purpose

Processes incoming mail.

Syntax

AJ2FL259

Description

The **slocal** command is used to perform a set of actions each time a message is sent to the user. **slocal** is not designed to be run directly by the user; it is designed to be called by the **sendmail** command. The **slocal** command is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The **sendmail** command invokes the **slocal** command when it encounters the following line in **\$HOME/.forward**:

```
| /usr/lib/mh/slocal
```

For each new incoming message, slocal performs the actions specified in the .maildelivery file. If slocal cannot find the file \$HOME/.maildelivery, slocal uses the default file /usr/lib/mh/maildelivery. If the delivery request fails, slocal delivers the message to /usr/mail/\$USER.

The actions that can be specified in .maildelivery are described in AIX Operating System Technical Reference under mhooks.

Flags

-debug Provides information for debugging.

-help Displays help information for the command.

-noverbose

Does not display information as the system executes commands in the

maildelivery file. This flag is the default.

-verbose

Displays information as the system executes commands in the

maildelivery file.

Files

/usr/lib/mh/mtstailor /usr/lib/mh/maildelivery \$HOME/.maildelivery \$HOME/.forward

The MH tailor file.

The default MH local delivery instructions file.

The user's local delivery instructions file.

The user's default message filter file.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

sno

Purpose

Provides a SNOBOL interpreter.

Syntax

OL805219

Description

The **sno** command provides a SNOBOL compiler and interpreter, with some differences from standard SNOBOL. It reads the named *files* and the standard input. It compiles all input through a statement containing the label **end**. The rest is available to **syspit**. The **sno** command differs from SNOBOL in the following ways:

• There are no unanchored searches. To get the same effect:

```
a ** b Unanchored search for b a *x* b = x c Unanchored assignment.
```

• There is no back referencing.

```
x = "abc"
a *x* x Unanchored search for abc.
```

• Function declaration is done at compile time by the use of the (nonunique) label define. Execution of a function call begins at the statement following the define. Functions cannot be defined at run time, and the use of the name define is pre-empted. There is no provision for automatic variables other than parameters. Examples:

```
define f()
define f(a, b, c)
```

- All labels except define (even end), must have a nonempty statement.
- Labels, functions, and variables must all have distinct names. In particular, the nonempty statement on **end** cannot merely name a label.
- If start is a label in the program, program execution begins there. If not, execution begins with the first executable statement. **define** is not an executable statement.
- There are no built-in functions.

- Parentheses for arithmetic are not needed. Normal precedence applies. Because of this, the arithmetic operators \ (backslash) and * (asterisk) must be set off by spaces.
- The right side of assignments must be nonempty.
- Either ' (single quotation mark) or " (double quotation mark) can be used for literal quotation marks.
- The pseudo-variable sysppt is not available.

Related Information

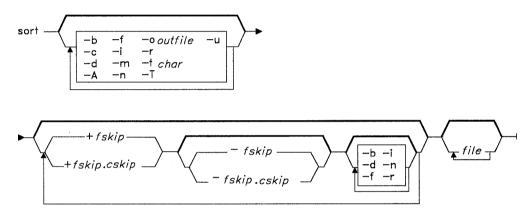

The following command: "awk" on page 81.

sort

Purpose

Sorts or merges files.

Syntax

OL805380

Description

The sort command sorts lines in its input *files* and writes the result to standard output. It treats all of its input *files* as one file when it performs the sort. A - (minus) in place of a file name specifies standard input. If you do not specify any file names, it sorts standard input.

The default sort key (the part of the line used for sorting) is an entire line. Default ordering is lexicographic by characters in the collating sequence. The file /usr/pub/ascii shows the default collating sequence. To change the default collating sequence, see "ctab" on page 257.

The two numbers, *fskip* and *cskip*, specify the sort key. Both numbers have two parts, as follows:

- +fskip.cskip
- -fskip.cskip

The fskip specifies the number of fields to skip from the beginning of the input line, and cskip specifies the number of additional characters to skip to the right beyond that point. For both the starting point (+fskip.cskip) and the ending point (-fskip.cskip) of a sort key, fskip is measured from the beginning of the input line, and cskip is measured from the last field skipped. If you omit .cskip, .0 is assumed. If you omit fskip, 0 is assumed. If you omit the ending field specifier (-fskip.cskip), the end of the line is the end of the sort key.

You can supply more than one sort key by repeating + fskip.cskip and -fskip.cskip. In cases where you specify more than one sort key, keys specified further to the right on the command line are compared only after all earlier keys are sorted. For example, if the first key is to be sorted in numerical order and the second in dictionary order, all strings that start with the number one are sorted alphabetically before the strings that start with the number two. Lines that are identical in all keys are sorted with all characters significant. You can also specify different flags for different sort keys in multiple sort keys. See the examples for illustration.

A field is one or more characters bounded by the beginning of a line and the current field separator, or one or more characters bounded by a the field separator on either side. The space character is the default field separator.

Notes:

- 1. Lines longer than 1024 are truncated.
- The maximum number of fields on a line is 10.
- The sort command will not process files containing imbedded commands.

Flags

- -A Sorts on a byte-by-byte basis. This sort is functionally compatible with the Version 1.1 sort command, prior to the addition of international character support.
- -b Ignores leading blanks, spaces, and tabs in sort key comparisons.
- Checks that the input is sorted according to the ordering rules specified in the -c flags. Displays nothing unless the file is not sorted.
- Sorts in dictionary order. Only letters, digits and blanks are considered in -d comparisons.
- -f Merges uppercase and lowercase letters. Case is not considered in the sorting, so that initial-capital words and all-capital words are not grouped together at the beginning of the output.

-i	Sorts only by characters in the ASCII range octal 040-0176 (all printable characters and the space character) in non-numeric comparisons.	
	Japanese Language Support Information Sorts only by printable characters in non-numeric comparisons.	
-m	Merges only; the input is already sorted.	
-n	Sorts any initial numeric strings (consisting of optional blanks, optional minus signs, and zero or more digits with optional decimal point) by arithmetic value. The -n flag automatically gives you the -b flag.	
-o outfile	Directs output to <i>outfile</i> instead of standard output. <i>outfile</i> can be the same as one of the input <i>files</i> .	
-r	Reverses the order of the specified sort.	
-tchar	Sets field separator character to <i>char</i> . To specify the tab character as the field separator, you must enclose it in single quotation marks (' ').	
-T	Uses current directory instead of default directory for temporary files.	
-u	Suppresses all but one in each set of equal lines. Ignored characters (such as leading tabs and spaces) and characters outside of sort keys are not considered in this type of comparison.	

Examples

1. To perform a simple sort:

sort fruits

This displays the contents of fruits sorted in ascending lexicographic order. This means that the characters in each column are compared one by one, including spaces, digits, and special characters. For instance, if fruits contains the text:

banana orange Persimmon apple %%banana apple ORANGE

then sort displays:

%%banana ORANGE Persimmon apple apple banana orange

This order follows from the fact that in the ASCII collating sequence, % (percent sign) precedes the uppercase letters, which precede the lowercase letters. If the system uses a character set other than ASCII, your results may be different.

2. To sort in dictionary order:

```
sort -d fruits
```

This sorts and displays the contents of fruits, comparing only letters, digits, and blanks. If fruits is the same as in Example 1, then sort displays:

ORANGE Persimmon apple apple %%banana banana orange

The -d flag tells sort to ignore the % character because it is not a letter, digit, or blank. This puts %%banana next to banana.

3. To group lines that contain uppercase and special characters with similar lowercase lines:

```
sort -d -f fruits
```

This ignores special characters (-d) and differences in case (-f). Given the fruits of Example 1, this displays:

apple apple %%banana banana ORANGE orange Persimmon 4. To sort as in Example 3 and remove duplicate lines:

```
sort -d -f -u fruits
```

The -u flag tells sort to remove duplicate lines, making each line of the file unique. This displays:

apple %%banana orange Persimmon

Note that not only was the duplicate apple removed, but banana and ORANGE as well. These were removed because the -d told sort to treat %%banana as if it were banana, and the -f told it to treat ORANGE as orange. Thus, sort considered %%banana to be a duplicate of banana and ORANGE a duplicate of orange.

Note: There is no way to predict which duplicate lines sort -u will keep and which it will remove.

5. To sort as in Example 3 and remove duplicates, unless capitalized or punctuated differently:

```
sort -u +0 -d -f +0 fruits
```

The +0 -d -f does the same type of sort done with -d -f in Example 3. Then the +0 performs another comparison to distinguish lines that are not actually identical. This prevents -u from removing them.

Given the fruits file shown in Example 1, the added +0 distinguishes %%banana from banana and ORANGE from orange. However, the two instances of apple are identical, so one of them is deleted.

apple %%banana banana ORANGE orange Persimmon

6. To specify the character that separates fields:

```
sort -t: +1 vegetables
```

This sorts vegetables, comparing the text that follows the first colon on each line. The +1 tells sort to ignore the first field and to compare from the start of the second field to the end of the line. The -t: tells sort that colons separate fields. If vegetables contains:

```
yams:104
turnips:8
potatoes:15
carrots:104
green beans:32
radishes:5
lettuce:15
```

then sort displays:

carrots:104 vams:104 lettuce:15 potatoes:15 green beans:32 radishes:5 turnips:8

Note that the numbers are not in numeric order. This happened because a lexicographic sort compares each character from left to right. In other words, "3" comes before "5" and "2" comes before ", so "32" comes before "5".

7. To sort numbers:

```
sort -t: +1 -n vegetables
```

This sorts vegetables numerically on the second field. If vegetables is the same as in Example 6, then **sort** displays:

```
radishes:5
turnips:8
lettuce:15
potatoes:15
green beans:32
carrots:104
yams:104
```

8. To sort on more than one field:

```
sort -t: +1 -2 -n +0 -1 -r vegetables
```

This performs a numeric sort on the second field (+1 -2 -n). Within that ordering, it sorts the first field in reverse alphabetic order (+0 -1 -r). The output looks like this: radishes:5 turnips:8 potatoes:15 lettuce:15 green beans:32 yams:104 carrots:104

Now the lines are sorted in numeric order. When two lines have the same number, they appear in reverse alphabetic order.

9. To replace the original file with the sorted text:

```
sort -o vegetables vegetables
```

This stores the sorted output into the file vegetables (-o vegetables).

sortm

Purpose

Sorts messages.

Syntax

Description

The sortm command is used to sort messages. The sortm command is part of the MH (Message Handling) package and can be used with MH and AIX commands.

The **sortm** command sorts the messages according to the date in a header field. By default, **sortm** parses the **Date**:, but you can use the **-datefield** flag to specify another field. **sortm** numbers the sorted messages consecutively beginning with 1 (one). Messages that are in the folder, but not specified to be sorted, are placed after the sorted messages. **sortm** displays a message if it cannot parse a date field.

Flags

-datefield field Specifies the header field to be used in the sort. The default field is

Date:.

+folder msgs Specifies the messages to be sorted. You can use use the following

message references when specifying msgs:

numfirstprevcur.nextlastallsequence

The default is all messages in the current folder. If you specify a folder, it becomes the current folder. The current message remains the current

message, even if it moves during the sort.

-help Displays help information for the command.

-noverbose Does not display information during the sort. This flag is the default.

-verbose Displays information during the sort. This information allows you to

monitor the steps involved.

Profile Entries

Current-Folder: Path:

Sets your default current folder. Specifies your user_mh_directory.

Files

\$HOME/.mh_profile

The MH user profile.

The mh-profile file in AIX Operating System Technical Reference.

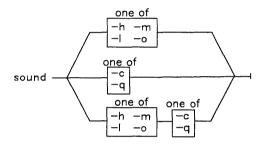

The "Overview of the Message Handling Package" in Managing the AIX Operating System.

sound

Purpose

Controls the volume and click of the keyboard speaker.

Syntax

OL805415

Description

The sound command controls the volume of the sound output (the console bell and the keyboard click) and, additionally, whether or not the keyboard click is produced. You can modify these two sound characteristics independently of each other.

The system startup process sets the sound volume to medium.

Note: You can run **sound** only from the console (**/dev/console**).

Flags

You must select at least one flag from the following two groups of flags or, optionally, one flag from each of the two groups. The first group of flags controls the volume of all sound output:

- Sets the volume to high. -h
- -1 Sets the volume to low.
- Sets the volume to medium.
- Turns the volume off. -0

sound

The second group of flags controls whether or not click sounds are produced:

- -c Turns clicking on.
- -q Turns clicking off (quiet).

Example

To set the volume to low and turn the click function on:

sound -1c

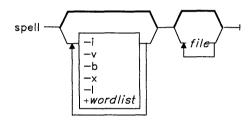

In addition to turning on the keyboard click (-c), this command sets the volume of both the bell and the click to low (-1).

spell

Purpose

Finds spelling errors.

Syntax

/usr/lib/spell/hashmake — /usr/lib/spell/spellin - num -/usr/lib/spell/hashcheck — spellinglist —

OL805304

Description

The **spell** command reads words in *file* and compares them to those in a spelling list. Words that cannot be matched in the spelling list or derived from words in the spelling list (by applying certain inflections, prefixes, and/or suffixes) are written to standard output. If you do not specify a file to read, spell reads standard input.

The spell command ignores the same troff, tbl, and eqn constructs as the deroff command.

The coverage of the spelling list is uneven. You should create your own dictionary of special words used in your files.

Certain auxiliary files can be specified by file name parameters; see "Files" on page 971. Copies of all output are accumulated in the history file.

Three routines help maintain and check the hash lists used by spell.

/usr/lib/spell/hashmake Reads a list of words from standard input and

writes the corresponding nine-digit hash code to

standard output.

/usr/lib/spell/spellin num Reads num hash codes from standard input and

writes a compressed spelling list to standard

output.

/usr/lib/spell/hashcheck spellinglist Reads a compressed spellinglist and recreates the

nine-digit hash codes for all the words in it; it

writes these codes to standard output.

Flags

-b Checks British spelling.

-i Suppresses processing of included files.

-1 Follows the chain of all included files (.so and .nx formatting commands). Without this flag, spell follows chains of all included files except for those

beginning with /usr/lib.

Displays all words not literally in the spelling list and indicates plausible $-\mathbf{v}$ derivations from the words.

Displays every plausible word stem with an = (equal sign). -x

+ wordlist

Checks wordlist for additional word spellings. wordlist is the name of a file you provide that contains a sorted list of words, one per line. With this flag, you can specify a set of correctly spelled words (in addition to spell's own

spelling list) for each job.

Examples

1. To check your spelling:

spell chap1 >mistakes

This creates a file named mistakes containing all the words found in chap1 that are not in the system spelling dictionary. Some of these may be correctly spelled words that spell does not know about. It is a good idea to save the output of spell in a file because the word list may be long.

2. To check British spelling:

spell -b chap1 >mistakes

This checks Chap1 against the British dictionary and writes the questionable words in mistakes.

3. To see how spell derives words:

This lists the words that are not found literally in the dictionary, but are derived forms of dictionary words. The prefixes and suffixes used to form the derivative are indicated for each word. Words that do not appear in the dictionary at all are also listed.

4. To check your spelling against an additional word list:

This checks the spelling of words in Chapl against the system dictionary and against newwords. The file newwords lists words in alphabetical order, one per line. You can create this file with a text editor, such as **ed**, and alphabetize it with the **sort** command.

Files

D_SPELL = /usr/lib/spell/hlist[ab] S_SPELL = /usr/lib/spell/hstop H_SPELL = /usr/lib/spell/spellhist /usr/lib/compress /usr/lib/spell/spellprog Hashed spelling lists, American and British. Hashed stop list. History file.

History file.

Executable shell program to compress the history file. Program.

spline

Purpose

Interpolates smooth curve.

Syntax

OL805261

Description

The **spline** command reads from the standard input pairs of numbers that represent the coordinates of a point on an x,y axis. From this input, **spline** calculates the coordinates of points to form a smooth curve through the points in the input set. It then writes these points to standard output. The output points are approximately equally spaced and includes the points that you provided as input. The cubic spline output has two continuous derivatives, and enough points so that when plotted with the **graph** command it looks smooth.

When data is not strictly monotone in x, spline reproduces the input without interpolating extra points.

You can only use 1,000 input points.

Flags

-anum Supplies abscissas automatically; spacing is given by the next parameter

or is assumed to be 1 if the next parameter is not a number.

-knum Uses the constant num in the boundary value calculation:

 $y_0 = ky_1$, y = numy

The default for num is zero.

- n num	Spaces output points so that approximately num intervals occur between the lower and upper x limits (set with the -x flag). The default num is 100.
- p	Makes output periodic, that is, matches derivatives at ends. First and last input values should normally agree.
$-\mathbf{x}lowlim[uplim]$	Sets lower and upper x limits as <i>lowlim</i> and <i>uplim</i> . Normally, these limits are calculated from the data. Automatic abscissas start at lower limit, defaults to zero.

Related Information

The following command: "graph" on page 494.

split

Purpose

Splits a file into pieces.

Syntax

OL805262

Description

The **split** command reads *file* and writes it in *num*-line pieces (default 1000 lines) to a set of output files. The name of the first output file is *prefix***aa**, the second is *prefix***ab**, and so on lexicographically, through *prefix***zz** (a maximum of 676 files). *prefix* cannot be longer than 12 characters. If you do not specify an output name, **x** is assumed.

If you do not specify an input file, or if you specify - (minus) in place of *file*, then **split** reads standard input.

Examples

1. To split a file into 1000-line segments:

split book

This splits book into 1000-line segments named xaa, xab, xac, and so forth.

2. To split a file into 50-line segments and specify the file name prefix:

split -50 book sect

This splits book into 50-line segments named sectaa, sectab, sectac, and so forth.

Related Information

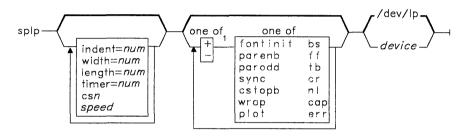

The following commands: "bfs" on page 110 and "csplit" on page 252.

splp

Purpose

Changes or displays printer driver settings.

Syntax

OL805263

OL805308

Description

The splp command changes or displays settings for a printer driver (device). The default device is /dev/lp0. If you do not specify any flags, splp reports the current settings for the specified device. Select flags to change the current settings. No other processing is done, and there is no other output.

The changes that splp makes remain in effect until the next time you restart the system or rerun splp. You can run splp from the /etc/rc command file to configure your printer each time you start up the system.

Note: When the print command is used with the backend piobe, splp is set as +plot. Any parameters set by the user are ignored. If a file is redirected using the cat command instead of the **print** command, the **splp** settings are active.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

¹ Do not put a blank between these items.

Flags

+ascii)-ascii(Selects ASCII)PostScript(mode for the Personal Proprinter Adapter. timer = numSets the time out period to num seconds, where num is an integer. indent = numIndents num columns, where num is an integer. length = numPrints num lines per page, where num is an integer. width = numPrints num columns, where num is an integer +bs(-bs)Sends (does not send) backspaces to the printer. +cap (-cap) Converts (does not convert) all lowercase characters to uppercase. +cr(-cr)Sends carriage returns (translates carriage returns to carriage return - line feeds). +cstopb (-cstopb) Selects 2 (1) stop bits per character. cs5 cs6 cs7 cs8 Selects character size. See termio in AIX Operating System Technical Reference for additional information on character size. Issues (does not issue) a signal (SIGIOINT) upon receiving a VRM error +err (-err) and attempts to resume I/O. + ff (-ff)Sends form feeds (simulates a form feed with line feeds or carriage returns). + fontinit (-fontinit) Indicates that fonts are (are not) loaded. Use this flag to control the initialization of fonts for the 3812 Pageprinter or the Personal Proprinter Adapter. +nl(-nl)Sends line feeds (translates line feeds to line feed - carriage returns). + parenb (-parenb) Enables (disables) parity generation and detection. + parodd (-parodd) Selects odd (even) parity. +plot Sends all characters to the printer unmodified. This overrides other settings. -plot Translates characters according to the settings. +sync (-sync) Does not (does) return immediately without waiting for all data to be sent out.

+ tb (-tb)

Expands (does not expand) tabs on eight position boundaries.

+wrap (-wrap)

Wraps (truncates) characters beyond the specified width to the next line and (with +wrap), prints "..." before the new-line character.

50 75 110 134 150 300 600 1200 1800 2400 4800 9600 exta extb

Sets the speed to the specified number of bits per second (exta is 19200).

Examples

1. To display the current printer settings:

alda

2. To change the printer settings:

splp width=80 +wrap +cap

This changes the settings of the /dev/lp printer for 80-column paper (width = 80). It wraps each line that is more than 80 columns wide onto a second line (+wrap), and prints all alphabetic characters in uppercase (+cap).

Related Information

The following command: "lp" on page 593.

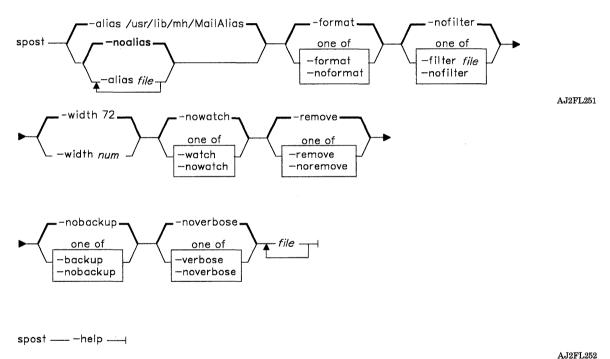

The lp file in AIX Operating System Technical Reference.

spost

Purpose

Delivers a message.

Syntax

Description

The **spost** command is used to route messages to the proper destinations. **spost** is not designed to be run directly by the user; it is designed to be called by other programs. The **spost** command is part of the MH (Message Handling) package.

The **spost** command searches all components of a message that specify a recipient's address and parses each address to check for proper format. **spost** puts proper addresses in the standard format and invokes the **sendmail** command. **spost** perform a similar function as the **post** command, but **spost** does less internal error checking than **post**.

Flags

-alias Files	Searches the specified mail alias file for addresses. You can use this flag repetitively to specify multiple mail alias files. spost automatically searches the file /usr/lib/mh/MailAliases.
-backup	Renames the message file by placing a , (comma) before the file name after spost successfully posts the message.
-filter Files	Uses the header components in the specified file for copies of the message sent to Bcc: recipients.
-format	Puts all recipient addresses in a standard format for the delivery transport system. This flag is the default.
-help	Displays help information for the command.
-nofilter	Strips the Bcc : header from the message and sends it to recipients specified in the Bcc : component. This flag is the default.
-noalias	Does not use any alias files for delivering the message.
-nobackup	Does not rename the message after posting the file. This flag is the default.
-noformat	Does not alter the format of the recipient addresses.
-noremove	Does not remove the temporary message file after posting the message.
-noverbose	Does not display information during the delivery of the message to the sendmail command. This flag is the default.
-nowatch	Does not display information during delivery by the sendmail command. This flag is the default.
-remove	Removes the temporary message file after the successful completion of posting the message. This flag is the default.
-verbose	Displays information during the delivery of the message to the sendmail command. This information allows you to monitor the steps involved.
-watch	Displays information during the delivery of the message by the sendmail command. This information allows you to monitor the steps involved.
-width num	Sets the width of components that contain addresses. The default is 72 columns.

Files

\$HOME/.mh_profile /temp/pstnum

The MH user profile.
The temporary message file.

"Overview of the Message Handling Package" in Managing the AIX Operating System.

spray

Purpose

Sends specified number of packets to host when NFS is installed.

Syntax

OL805509

Description

The spray command sends a one-way stream of packets to host using RPC. It reports how many packets were received, and at what transfer rate. The host parameter can be a network address or a name.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- Specifies the number of packets to send. The default is the number of packets -c required to make the total stream size 100,000 bytes.
- -d Specifies the time, in microseconds, the system pauses between sending each packet. The default is 0.
- -i Specifies ICMP echo packets rather than RPC. Since ICMP echoes automatically, it creates a two-way stream.
- -1 Number of bytes in the Ethernet packet that holds the RPC call message. The default is 86 bytes, which is the length of RPC and UDP/IP headers.

The data is encoded using XDR. Since XDR deals only with 32-bit quantities, spray rounds smaller length values up to the nearest 32-bit value.

Note: If the **length** is greater than 1514, the RPC call does not fit into one Ethernet packet, and the **length** field will not have a simple correspondence to the Ethernet packet size.

Related Information

The following command: "sprayd" on page 983.

sprayd

Purpose

Receives packets sent by the spray command

Syntax

/usr/etc/rpc.sprayd -----

OL805510

Description

The sprayd daemon receives the packets sent when the spray command is issued. The inetd daemon invokes sprayd.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/inetd.conf TCP/IP configuration file.

Related Information

The following command: "spray" on page 981.

stat

Purpose

Provides tools for analyzing numerical data.

Description

The stat commands, residing in /usr/bin/graf, provide a package of tools for analyzing data. All numerical data are stored in vectors. A *vector* is a sequence of numbers separated by delimiters, where a number has the form:

```
[sign](digits)(.digits)[\mathbf{e}[sign]digits]
```

Fields surrounded by brackets are optional; one or both of those surrounded by parentheses are required. Any input character that is not part of a number is assumed to be a delimiter.

Vectors are text strings that can be stored in text files and created and modified by text editors.

Note: Some commands limit the size of an input vector.

These commands can be divided into four classes:

- Those that produce an output vector based upon definable parameters (generators).
- Those that operate upon an input vector and output the resulting value (transformers).
- Those that perform mathematical or statistical operations on vectors (summarizers).
- Those that convert vectors into a format that can be viewed pictorially (translators).

The following parameters are used to designate the expected type of the value:

- c A character value.
- i An integer value.
- f A floating-point or integer value.
- file A file name.

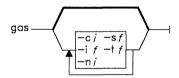

vector A vector taken from standard input or the name of a file containing a vector. Except for the gas, prime, and rand commands, all of the commands discussed under stat read vectors from standard input (by default) or from text files as specified on the command line. A file name of - (minus) specifies standard input in a file list.

string A character string (quoted if it includes white space).

Commands That Produce Definable Vectors (Generators)

gas

Syntax

OL805513

Description

The gas command produces an additive sequence.

Flags

- Specifies the number of columns per line of output (5 by default). -ci
- -if Specifies the increment between successive elements (1 by default).
- Specifies the number of elements in the vector (10 by default). -ni
- -sf Specifies the starting point of the sequence (1 by default).
- -tfSpecifies the end of the sequence (infinity by default).

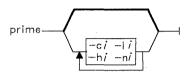

Examples

- 1. To generate the numbers 1 through 10: gas
- 2. To generate the sequence .01 .02 .03 .04 .05:

3. To generate the sequence 3 5 3 5:

prime

Syntax

OL805514

Description

The prime command generates consecutive prime numbers.

Flags

-ci Specifies the number of columns per line of output (5 by default).

-hi Specifies the high boundary (infinity by default).

-li Specifies the low boundary (2 by default).

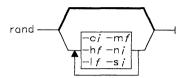

-ni Specifies the number of elements in the sequence (10 by default).

Example

To generate all prime numbers between 200 and 300:

rand

Syntax

OL805515

Description

The rand command generates a random sequence of numbers.

Flags

-ci Specifies the number of columns per line of output (5 by default).

-hf Specifies the high boundary (1 by default).

-lf Specifies the low boundary (0 by default).

-mf Specifies the high boundary where hf = mf + lf.

-ni Specifies the number of elements in the sequence (10 by default).

-si Specifies a seed number (1 by default).

Example

To produce a random sequence:

rand

This generates ten random numbers between 0 and 1.

rand -110,m25,c3

This generates ten random numbers between 10 and 35, three per line.

Commands That Map Input to Output (Transformers)

abs

Syntax

OL805516

Description

The abs command provides the absolute value of a number.

Flag

-ci Specifies the number of columns per line of output (5 by default).

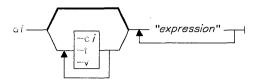

Example

To obtain the absolute value of each element in a vector:

This produces the absolute value of each number in the file myfile and displays these values three per line.

af

Syntax

OL805517

Description

The **af** command performs arithmetic operations on numbers.

Expressions

Vectors

Expression operands are:

File names with the restriction that they must begin with a letter and be composed only of letters, digits, and the _ (underscore) and . (dot) characters. The first unknown file name (one not in the current directory) references

standard input.

Functions The name of a command followed by the command arguments in parentheses.

List arguments as you would on the command line.

Constants Floating-point and integer numbers (but not E notation).

Expression operators are, in order of decreasing precedence:

′υ The next value from vector v.

The value x raised to the power y; the negation of x. Both associate right to left.

 $x^*y \quad x/y$

The value x multiplied by, divided by, modulo y, respectively. All associate left to right.

The value x plus or minus y. Both associate left to right. x + y x - y

The value of x followed by the value of y. This associates from left to right. x,y

You can use parentheses to alter precedence. Because many of the operator characters are special to the shell, it is good practice to quote expression arguments.

Flags

- -ci Specifies the number of columns per line of output (5 by default).
- -t Cause the output to be titled from the vector on standard input.
- -v Echoes function expansions.

Examples

1. To perform arithmetic operations:

This yields 23.

2. To produce a matrix:

This yields a four-column matrix with columns of:

- a. odd elements from vector A
- b. even elements from A
- c. sum of adjacent odd and even elements from A
- d. elements from vector B.
- 3. To use functions:

This yields the square of the sin of the elements of vector A.

ceil

Syntax

OL805518

Description

The ceil command rounds a number up to the next integer.

Flag

-ci Specifies the number of columns per line of output (5 by default).

cusum

Syntax

OL805519

Description

The **cusum** command calculates a cumulative sum. Output is a vector with the ith element being the sum of the first i elements from the input vector.

Flag

-ci Specifies the number of columns per line of output (5 by default).

exp

Syntax

OL805549

Description

The \exp command provides the exponential function. Output is a vector with elements e raised to the x power, where e is approximately 2.71828 and x is each element in the input vector.

Flag

-ci Specifies the number of columns per line of output (5 by default).

floor

Syntax

OL805550

Description

The floor command rounds a number down to the nearest integer.

Flag

-ci Specifies the number of columns per line of output (5 by default).

gamma

Syntax

OL805551

Description

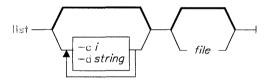

The gamma command provides the gamma function.

Flag

-ci Specifies the number of columns per line of output (5 by default).

list

Syntax

OL805552

Description

The list command lists vector elements.

Flags

Specifies the number of columns per line of output (5 by default). -ci

Specifies delimiter characters. If you do not specify -d, any character that is not -dstring part of a number is considered a delimiter. If you specify -d, the space, tab, and new-line characters, plus the characters in string are delimiters.

Only numbers surrounded by delimiters are listed.

Examples

1. To output each element:

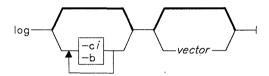

This outputs each element in myfile, three per line.

2. To specify delimiters:

This outputs each element of myfile that is delimited by commas or white space, five per line. A comma requires two backslashes because it is a special character for list.

log

Syntax

OL805520

Description

The log command provides the logarithmic function.

Flag

-ci Specifies the number of columns per line of output (5 by default).

-bf Specifies the base (e by default).

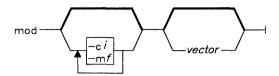

Example

To calculate a logarithm:

This outputs the logarithm base 2 of each element in mydata, three per line.

mod

Syntax

OL805521

Description

The **mod** command returns the modulo. The output is a vector with each element being the remainder of dividing the corresponding element from the input vector by the modulus.

-ci Specifies the number of columns per line of output (5 by default).

-mf Specifies the modulus (2 by default).

Example

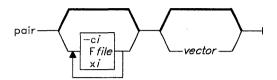

To output remainders:

mod -m8,c3 mydata

This outputs the elements of mydata modulo 8, three per line.

pair

Syntax

OL805522

Description

The pair command pairs elements. Output is a vector with elements taken alternatively from a base vector and from another input vector.

Flags

- -ci Specifies the number of columns per line of output (5 by default).
- -Ffile The file containing the base vector. If you do not specify -F, then the base vector comes from standard input. If both the base vector and the paired vector come from standard input, the base vector precedes the paired vector.
- -xi The number of elements per group in the base vector (1 by default).

Example

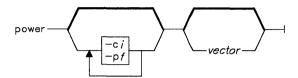

To pair elements:

pair -x3, Fbasefile datafile

This outputs a vector with three elements from basefile, one from datafile, three from basefile, one from datafile, and so on.

power

Syntax

OL805523

Description

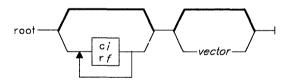

The power command raises a number to a power.

Flag

- -ci Specifies the number of columns per line of output (5 by default).
- -pf Specifies the power (2 by default).

root

Syntax

OL805524

Description

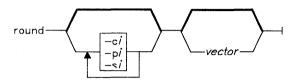

The root command takes the root of a number.

Flags

- -ci Specifies the number of columns per line of output (5 by default).
- -rf Specifies the root (2 by default).

round

Syntax

OL805525

Description

The round command rounds a number to the nearest integer (.5 rounds to 1).

Flags

-ci Specifies the number of columns per line of output (5 by default).

-pi Specifies the number of places after the decimal point (0 by default).

-si Specifies the number of significant digits.

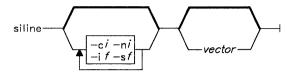

Example

To round numbers to two significant digits:

round -s2,c3 mydata

siline

Syntax

OL805526

Description

The siline command generates a line, given slope and intercept.

Flags

-ci Specifies the number of columns per line of output (5 by default).

-if Specifies the intercept (0 by default).

-ni Specifies the number of positive integers.

-sf Specifies the slope of the line.

Example

To output a linear fit:

This outputs a simple linear fit of vector B on vector A (The o flag of lreg outputs the slope and intercept in option form of B regressed on A.)

sin

Syntax

OL805527

Description

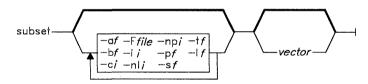

The sin command provides the sine function.

Flags

-ci Specifies the number of columns per line of output (5 by default).

subset

Syntax

OL805528

Description

The subset command produces a subset of the numbers in a vector.

Flags

-af Specifies the number above which subset members are selected.

-bf Specifies the number below which subset members are selected.

-ci Specifies the number of columns per line of output (5 by default).

-Ffile Specifies the file containing the master vector.

-ii Specifies the increment between successive elements (1 by default).

- -lf The number of elements to leave.
- -nli Specifies that the master file contains element numbers to leave.
- -npi Specifies that the master file contains element numbers to pick.
- -pf The number of elements to pick.
- -sf Specifies the starting point of the sequence (1 by default).
- -tf Specifies the end of the sequence (32,767 by default).

Examples

1. To specify the even elements of a vector:

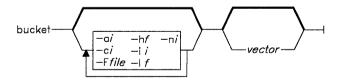

2. To specify corresponding elements:

For each element in B with a 1, output the corresponding element in A.

Commands That Calculate Statistics (Summarizers)

bucket

Syntax

OL805529

Description

The **bucket** command groups numbers into buckets. The input vector must be sorted. The output vector consists of odd (parenthesized) elements that are bucket limits and even elements that are bucket counts. The count is the number of elements greater than or equal to the lowest limit and less than or equal to the higher limit. Unless otherwise specified, bucket limits are generated based on the input date and the following rule:

#buckets = 1 + log2(#elements)

Flags

-ai Specifies the average size of the bucket.

-ci Specifies the number of columns per line of output (5 by default).

-Ffile Specifies the file containing bucket boundaries.

-hf Specifies the high boundary (by default, the largest element in the input vector).

-ii Specifies the interval between successive elements.

-li Specifies the low boundary (by default, the smallest element in the input vector).

-ni Specifies the number of buckets.

Example

To divide elements into buckets:

bucket -a12,1-5 myfile

This outputs limits and counts for the elements of myfile, where the lowest limit is -5 and the average bucket count is 12.

cor

Syntax

OL805530

Description

The **cor** command provides the ordinary correlation coefficient. Use the **F** flag to specify the base vector; otherwise it is assumed to come from standard input. Each *vector* is compared to the base vector (both must be of the same length).

Flag

-Ffile Specifies the file containing base vector.

Example

To obtain correlation coefficients:

cor -Ffilea olddata newdata

This outputs the ordinary correlation coefficients between vectors filea and olddata and vectors filea and newdata.

hilo

OL805531

Description

The hilo command finds high and low values across all of the input vectors.

- -h Finds the high value only.
- -l Finds the low value only.
- -o Outputs the high and low values in option form (suitable for plot).
- -ox Outputs the high and low values in option form with x prefixed.
- -oy Outputs the high and low values in option form with y prefixed.

Example

To find the lowest value:

hilo -ox, 1 file1 file2

This finds the lowest value in vectors file1 and file2 and outputs it with x1 prefixed to it.

lreg

Syntax

OL805532

Description

The **lreg** command provides linear regression. Output is the slope and intercept from a least squares linear regression of each vector on a base vector. The default base vector is the ascending positive integers from zero.

Flags

- -Ffile Specifies a file containing the first vector.
- -i Outputs only the intercept.
- -o Outputs the slope and intercepts in option form (suitable for siline).
- -s Outputs only the slope.

Example

To output only the intercept:

lreg -Fbase, i mydata

This outputs the intercept from the linear regression of vector mydata on base vector base.

mean

Syntax

mean
$$\underbrace{\begin{array}{c} \text{one of} \\ -\text{f } f \\ -\text{n } i \\ -\text{p } f \end{array}}_{}$$

OL805533

Description

The mean command calculates the (trimmed) arithmetic mean.

Flags

-ff Specifies the fraction of elements to trim from each end. This is calculated as follows:

(1/f) k

where k is the total number of elements.

Specifies the number of elements to trim from each end. -ni

Specifies the percentage of elements to trim from each end. **-p**f

Example

To output the mean:

mean -p.25 mydata

This outputs the mean of the middle 50% of the elements of mydata; that is, mydata is trimmed by 25% of its elements from both ends.

point

Syntax

point one of
$$-s$$
 vector $-s$

OL805534

Description

Output from the **point** command is a linearly interpolated value from the empirical cumulative density function for the input vector. By default, **point** returns the median (50% point).

Flags

-ff Returns the (1/f)*100 percent point.

-ni Returns the ith element.

-pf Returns the f*100 percent point.

-s Specifies that the input has been sorted.

Example

To output the 25% point:

point -s,p.25 mydata

prod

Syntax

prod ----

OL805556

Description

The **prod** commands calculates an internal product. Output is the product of the elements in the input vectors.

qsort

Syntax

OL805536

Description

The **qsort** command does a quick sort. Output is a vector of the elements from the input vector in ascending order.

Flag

-ci Specifies the number of columns per line of output (5 by default).

rank

Syntax

OL805535

Description

The rank command ranks vectors. Output is the number of elements in each input vector.

total

Syntax

OL805537

Description

The total command calculates a sum total. Output is the sum total of the elements in the input vector(s).

var

Syntax

OL805538

Description

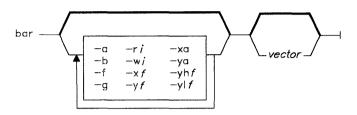

The var command calculates the variance.

Commands That Produce Pictorial Output (Translators)

Input to these commands can be either a vector or a **GPS** object (a format for storing a picture). A picture is defined in a Cartesian plane of 64K points on each axis. The plane, or universe, is divided into 25 square regions numbered 1 to 25 from the lower left to the upper right.

har

Syntax

OL805539

Description

The bar command builds a bar chart. It operates on an input vector, each element of which defines the height of a bar (y-axis). By default, the x-axis is labeled with positive integers, beginning at 1. For other labels, see label.

Flags

- -a Suppresses the axes.
- -b Plots the bar chart with bold weight lines (medium is the default weight).
- -f Does not build a frame around the plot area.
- -g Suppresses the background grid.
- -ri Puts the bar chart in **GPS** region i, where i is between 1 and 25 inclusive (13 by default).
- -wi Specifies the ratio of the bar width to center-to-center spacing expressed as a percentage (50 by default, giving equal bar width and bar space).
- -xf
 -yf Positions the bar chart in the **GPS** universe with the x-origin (y-origin) at f.
- -xa
 -ya Does not label the x-axis (y-axis).
- -yhf Specifies the y-axis high boundary.
- -ylf Specifies the y-axis low boundary.

Example

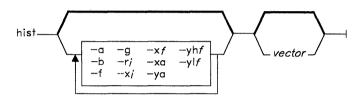

To produce a bar chart:

bar -r10,xa,w75 myfile

This outputs the bar chart described by vector myfile, located in region 10 of the GPS universe, with no x-axis labels. The bar width is 75% of center-to-center spacing.

hist

Syntax

OL805540

Description

The **hist** command builds a histogram. The input vector is the type produced by **bucket**, of odd rank, with odd elements being limits and even elements being bucket counts.

Flags

- -a Suppresses axes.
- -b Plots histogram with bold weight lines (the default weight is medium).
- -f Does not build a frame around the plot area.
- -g Suppresses the background grid.
- -ri Puts the histogram in **GPS** region i, where i is between 1 and 25 inclusive (13 by default).
- -xf
 -yf Positions the histogram in the GPS universe with the x-origin (y-origin) at f.
- -xa
 -ya Does not label the x-axis (y-axis).
- -yhf Specifies the y-axis high boundary.
- -ylf Specifies the y-axis low boundary.

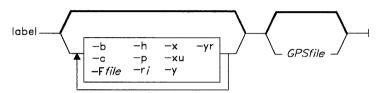

Example

To produce a histogram:

This outputs the histogram described by vector myfile and locates it in region 5 of the GPS universe, with no y-axis labels.

label

Syntax

OL805541

Description

The label command labels the axis of a GPS file.

Flags

- -b Assumes that the input is a bar chart.
- Retains lowercase letters in labels; otherwise all letters are uppercase. -c
- -Ffile Specifies a label file. Each line of the file is taken as one label. Blank lines yield null labels. Either the GPS or the label file, but not both, can come from standard input.
- -h Assumes that the input is a histogram.
- Assumes that the input is an x-y plot. This is the default assumption. -p
- Rotates labels i degrees. The pivot point is the first character. -ri
- Labels the x-axis. This is the default action. -x
- Labels the upper x-axis (the top of the plot). -xu
- Labels the y-axis. -y
- -yr Labels the right y-axis (the right side of the plot).

Examples

1. To label a plot:

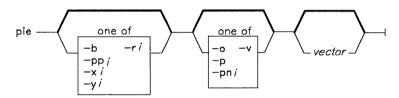

The file A.g, assumed to be an x-y plot, is labeled with labels from the file labs.

2. To label a plot from labels taken from standard input:

The file A.g is labeled from the standard input. The labels are printed at 45 degrees below the horizontal.

pie

Syntax

OL805542

Description

The **pie** command builds a pie chart. The input vector has a restricted format. Each input line represents a slice of the pies and has the following form:

with brackets indicating optional fields. The control field options have the following effects:

- i The slice will not be drawn, though a space will be left for it.
- e The slice is "exploded" or moved away from the pie.
- f The slice is filled. The angle of fill lines depends on the color of the slice.

ccolor The slice is drawn in the specified color rather than the default black. Legal values are **b** (black), **r** (red), **g** (green), and **u** (blue).

The pie is drawn with the value of each slice printed inside and the label printed outside.

Flags

- Draws pie chart with bold weight lines (the default weight is medium). -b
- Places output values around the outside of the pie. -0
- Expresses output values as a percentage of the total pie. -p
- Expresses output values as a percentage, but the total of the percentages equals i $-\mathbf{pn}i$ rather than 100.
- -ppi Draws only i percent of the pie.
- -ri Puts the pie chart in GPS region i, where i is between 1 and 25 inclusive (13 by default).
- Does not output values. -v
- -xi
- Positions the pie chart in the GPS universe with x-origin (y-origin) at i. -yi

Example

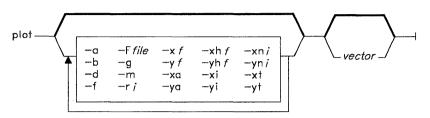

To draw a pie chart:

pie -pp80,pn80 chartfile

This draws the pie chart specified by chartfile in 80% of a circle and outputs the values as percentages of that total 80 percent.

plot

Syntax

OL805543

Description

The plot command plots a graph. The input vectors contain the y values of an x-y graph. Values for the x-axis come from the file specified by -F. Axis scales are determined from the first vector plotted.

Flags

- -a Suppresses the axes.
- -b Plots the graph with bold weight lines (medium is the default weight).
- -d Does not connect plotted points (this implies -m).
- -f Does not build a frame around the plot area.
- -Ffile Uses the specified file for x values; otherwise the positive integers are used. You can specify this flag more than once, causing a different set of x values to be paired with each input vector. If there are more input vectors than sets of x values, the last set applies to the remaining vectors.
- -g Suppresses the background grid.
- -m Marks the plotted points.
- -ri Puts the graph in GPS region i, where i is between 1 and 25 inclusive (13 by default).
- -xf
- -yf Positions the graph in the GPS universe with the x-origin (y-origin) at f.
- -xa
- -ya Does not label the x-axis (y-axis).

-xhf
-yhf Specifies the x-axis (y-axis) high boundary.
-xlf
-ylf Specifies the x-axis (y-axis) low boundary.
-xni
-yni Specifies the approximate number of ticks on the x-axis (y-axis).
-xt
-yt Omits the x-axis (y-axis) title.

Examples

1. To plot against the positive integers:

2. To customize x- and y-axes:

This plots vector yfile against vector xfile, with y-axis ticks beginning at zero, no x-axis labels printed, and the plot placed in region 5 of the GPS universe.

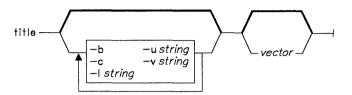

This plots vectors filea and fileb against the positive integers, with y-axis ticks going from the lowest to the highest values in the two vectors.

```
plot -Ffilea, Ffileb filec filed filee
```

This plots vectors filec against filea; filed and filee against fileb. The y-axis scale is determined from filec; the x-axis scale from filea.

title

Syntax

OL805544

Description

The title command prefixes a title to a vector or appends one to a GPS object.

Flags

-b Makes the GPS title bold.

-c Retains lowercase letters in the title; otherwise all letters are uppercase.

-lstring Uses the specified string as a GPS lower title.

-ustring Uses the specified string as a GPS upper title.

-vstring Labels a vector with the specified string.

Related Information

The following commands: "ged" on page 463, "graphics" on page 497, and "spline" on page 972.

The gps file in AIX Operating System Technical Reference.

strip

Purpose

Removes symbol and line number information from a common object file.

Syntax

OL805265

Description

The **strip** command removes the symbol table and line number information from common object files, including archive libraries. Once you use this command, symbolic debugging of the file is difficult; therefore, you should normally run **strip** only on production modules that you have debugged and tested. Using **strip** reduces the file storage overhead required by an object file.

For each object module, **strip** removes all symbol table information. For each archive, **strip** removes the local symbol table information from each member.

You can restore a stripped symbol table to an archive or library file by using the ar -s command.

Flag

-H Removes the object file header as well as all symbol table information.

Files

/usr/tmp/strp*

Related Information

The following commands: "ar" on page 55, "as" on page 61, "cc" on page 140, "dump" on page 366, "ld" on page 557, "nm" on page 705, and "size" on page 949.

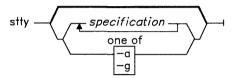

The ar and a.out files in AIX Operating System Technical Reference.

stty

Purpose

Sets, resets, or reports work station operating parameters.

Syntax

OL805266

Description

The stty command sets certain work station I/O options for the device that is the current standard input. If you run it without any specifications, stty writes to standard output information about any system adapters installed and reports the settings of certain options.

If you list any work station specifications, stty sets or resets the specified work station options.

You can find detailed information about the modes listed in the first six of the following groups in the discussion of the **termio** special facility in AIX Operating System Technical Reference. The last group contains options produced by combining options in the first six groups.

Note: The stty command does not make compatibility checks on any parameter combinations.

Flags

- -a Writes the current state of all option settings to standard output.
- -g Writes option settings to standard output in a form usable by another stty command.

Specifications

Control Modes

The following options apply only when your work station connects to the system through an asynchronous line adapter. See asy in AIX Operating System Technical Reference for detailed information about this group.

parenb (-parenb) Enables (disables) parity generation and detection.

parodd (-parodd) Selects odd (even) parity.

cs5 cs6 cs7 cs8

Selects character size.

Note: See termio in AIX Operating System Technical Reference for additional information on character size.

0

Hangs up phone line immediately.

50 75 110 134 150 300 600 12001800 2400 4800 9600 19200 19.2 38400 38.4 exta extb

Sets the work station speed to the specified number of bits per second (exta, 19200, and 19.2 are synonyms; extb, 38400, and 38.4 are synonyms). Regardless of the baud rate, the software requires that terminals generate and support the ASCII character set.

hupcl (-hupcl)

hup (-hup)

Hangs up (does not hang up) dial-up connection on the last close.

cstopb (-cstopb) Selects 2 (1) stop bits per character.

The next two options apply to all work stations, regardless of the line adapter:

cread (-cread)

Enables (disables) the receiver.

clocal (-clocal)

Assumes a line without (with) modem control. The status of **clocal** is displayed when you use the -a flag. You cannot change this status with the stty command.

Input Modes

ignbrk (-ignbrk) Ignores (does not ignore) BREAK on input.

brkint (-brkint) Signals (does not signal) INTR on break.

ignpar (-ignpar) Ignores (does not ignore) parity errors.

parmrk (-parmrk)

Marks (does not mark) parity errors.

inpck (-inpck) Enables (disables) input parity checking. istrip (-istrip) Strips (does not strip) input characters to 7 bits. inlcr (-inlcr) Maps (does not map) NL to CR on input. igner (-igner) Ignores (does not ignore) CR on input. icrnl (-icrnl) Maps (does not map) CR to NL on input. iucle (-iucle) Maps (does not map) uppercase alphabetic characters to lowercase. Enables (disables) START/STOP output control. Once START/STOP ixon (-ixon) output control has been enabled, you can pause output to the work station by pressing Ctrl-S and resume output by pressing Ctrl-Q. Allows any character (only Ctrl-Q) to restart output. ixany (-ixany) ixoff (-ixoff) Sends (does not send) START/STOP characters when the input queue is nearly empty/full. **Output Modes** opost (-opost) Processes output (does not process output: that is, it ignores all other output options). olcuc (-olcuc) Maps (does not map) lowercase alphabetic characters to uppercase on output. onler (-onler) Maps (does not map) NL characters to CR-NL characters. ocrnl (-ocrnl) Maps (does not map) CR-NL characters to NL characters. onocr (-onocr) Does not (does) output CR characters at column zero. onlret (-onlret) On the terminal, NL performs (does not perform) the CR function. ofill (-ofill) Uses fill characters (uses timing) for delays. ofdel (-ofdel) Uses **DEL** (**NUL**) characters for fill characters.

Selects style of delay for CR characters.

Selects style of delay for NL characters.

cr0 cr1 cr2 cr3

nl0 nl1

tab0 tab1 tab2 tab3

Selects style of delay for horizontal tabs.

bs0 bs1

Selects style of delay for backspaces.

ff0 ff1

Selects style of delay for form feeds.

vt0 vt1

Selects style of delay for vertical tabs.

Local Modes

isig (-isig) Enables (disables) the checking of characters against the special

control characters INTR and QUIT.

icanon (-icanon) Enables (disables) canonical input (canonical input allows input-line

editing with the ERASE and KILL characters).

xcase (-xcase) Echoes (does not echo) uppercase characters on input, and displays

uppercase characters on output with a preceding \ (backslash).

echo (**-echo**) Echoes (does not echo) every character typed.

echoe (-echoe) Echoes (does not echo) the ERASE character as the

backspace-space-backspace string.

Note: This mode does not keep track of column position, so you may

get unexpected results when erasing tabs, escape sequences, and the

like.

echok (-echok) Echoes (does not echo) a NL character after a KILL character.

lfkc (-lfkc) Functions the same as **echok**. This is an obsolete mode.

echonl (-echonl) Echoes (does not echo) the NL character.

noflsh (-noflsh) Does not clear (does clear) buffers after INTR or QUIT.

Control Assignments

control-character c Set control-character to c, where control-character is erase, kill, intr. quit, eof, eol, min, or time. (Use min and time with -icanon.) If c is in the form $\^c$ (backslash circumflex c), then its value is the corresponding Ctrl character. A \^? (backslash circumflex question mark) is interpreted as **DEL**. A \^- (backslash circumflex minus) is interpreted as undefined.

enhedit (-enhedit)

Enters (leaves) the enhanced line editing discipline (see the termio special facility in AIX Operating System Technical Reference).

Note: When Japanese Language Support is installed, enhedit is not supported.

ascedit (-ascedit)

Enters (leaves) the ASCII keyboard mode for **dosedit**.

line i

Sets the line discipline. i can be either 0 or 1. stty line 0 is the same as sttv -enhedit. sttv line 1 is the same as sttv enhedit.

Screen Length

page (-page)

Pauses (does not pause) during output after each screen displayed. Typing any character during the pause causes output to resume. Typing a space during the pause causes output to continue uninterrupted until the next command is entered.

length n

Sets screen length to n lines, where n is an integer from 1 through 255. An automatic pause in output occurs after n lines if **page** is enabled.

Combination Modes

evenp | parity

Enables parenb and cs7.

oddp

Enables parenb, cs7, and parodd.

-parity, -evenp, -oddp

Disables **parenb** and sets **cs8**.

raw (-raw | cooked) Enables (disables) raw input and output (no ERASE, KILL, INTR, QUIT, EOT, or output processing).

nl (-nl) Unsets (sets) icrnl and onlcr. Specifying -nl sets icrnl and onlcr

and also unsets inler, igner, ocrnl, and onlret.

lcase (-lcase)

LCASE (-LCASE) Sets xcase, iucle, and olcuc. (Used for work stations with

uppercase characters only.)

tabs (-tabs | tab3) Preserve tabs (expand to spaces) when printing.

ek Sets ERASE and KILL characters to Ctrl-H and Ctrl-U,

respectively.

sane Resets parameters to "reasonable" values.

term Sets all parameters according to work station type term, where term

is one of tty33, tty37, vt05, tn300, ti700, or tek.

Terminal Mapping

dmap mapname Deactivates a loaded map. Any user can deactivate a map.

imap mapname Loads and activates /etc/nls/termmap/mapname.in as the terminal

input map. If no mapname is defined, imap activates the previously

specified map.

Note: You must be a superuser or a member of the system group to

load a map. Any user can activate a loaded map with imap.

omap mapname Loads and activates /etc/nls/termmap/mapname.out as the terminal

output map. If no mapname is defined, omap activates the previously

specified map.

Note: You must be a superuser or a member of the system group to

load a map. Any user can activate a loaded map with omap.

Examples

1. To display a short listing of your work station configuration:

stty

This lists settings that differ from the defaults.

2. To display a full listing of your work station configuration:

stty -a

3. To enable a key sequence that stops listings from scrolling off the screen:

stty ixon ixany

This sets ixon mode, which lets you stop runaway listings by pressing Ctrl-S. The ixany parameter allows you to resume the listing by pressing any key. The normal

work station configuration includes ixon and -ixany, which allows you to stop a listing with Ctrl-S, but only Ctrl-Q will restart it.

4. To prevent all listings from scrolling off the screen:

```
stty page length 24
```

This sets page mode with a page (screen) length of 24 lines. When a listing is more than 24 lines long, the system pauses after each page. It beeps, reminding you to press any key (except the **Spacebar**) to view the next page. Press the **Spacebar** to let the rest of the listing scroll off the screen and get to the end. Paging then resumes with the next listing.

5. To reset the configuration after it has been messed up:

```
Ctrl-J stty sane echo -tabs Ctrl-J
```

Sometimes the information displayed on the screen may look strange, or the system won't respond when you press the **Enter** key. This can happen when you use **stty** with parameters that are incompatible or that do things you don't understand. It can also happen when a screen-oriented text editor ends abnormally and doesn't have a chance to reset the work station configuration.

Entering Stty Sane sets a reasonable configuration, but it may differ slightly from your normal configuration. That is why this example also includes two commonly used parameters, echo (erase characters as you backspace over them) and -tabs (expand tab characters to spaces on the display screen).

Press Ctrl-J before and after the command instead of Enter. The system usually recognizes Ctrl-J when the parameters that control the Enter key processing are messed up.

6. To save and restore the work station's configuration:

```
OLDCONFIG='stty -g' # save configuration
stty -echo # do not display password
echo "Enter password: \c"
read PASSWD # get the password
stty $OLDCONFIG # restore configuration
```

This saves the work station's configuration, turns off echoing, reads a password, and restores the original configuration. The '...' (grave accents) in the first command tell the shell to insert the standard output of stty -g into the OLDCONFIG=... command. This is called **command substitution**. For more information, see "Command Substitution" on page 925.

The stty -echo turns off echoing, which means that the password does not appear on the screen when you type it at the keyboard. This has nothing to do with the **echo** command, which displays a message on the screen.

Related Information

The following command: "tabs" on page 1041.

The ioctl system call and the terminfo and config files in AIX Operating System Technical Reference.

The discussion of stty and "Overview of International Character Support" in IBM RT Managing the AIX Operating System.

su

Purpose

Obtains the privileges of another user, including superuser authority.

Syntax

OL805267

Description

The **su** command runs a shell and lets you operate there with the privileges of the specified *user* (by default root). If you are not already operating with superuser authority, **su** prompts for the password associated with *user* before granting you these privileges. Upon successful authentication, **su** will set the audit classes for the new shell to those specified in /etc/security/passwd.

If the terminal is in a trusted state, the shell will be tsh and the prompt will be set to tsh.

If you use **su** to become the superuser (*user* is root), **su** sets the **PATH** variable to /**bin:**/**etc:**/**usr/bin** and changes the prompt to # (pound sign). Notice that this **PATH** does not include the current directory.

To restore your normal privileges, press END OF FILE (Ctrl-D). This action ends the shell called by su and returns you to the previous shell and ID.

If you need to run only one command as *user*, you can run the desired command by including it (along with any of its associated flags) on the command line as an argument to the shell -c flag (see "sh" on page 913 for a description of this flag). In this case, su calls sh to run the command and then exits automatically.

Each time someone uses su to become the superuser, su writes a record in the file /usr/adm/sulog, creating this file if necessary.

Note: If the -c flag is not specified, su execs the shell listed in the shell field of the /etc/passwd file. If the -c flag is specified, su ignores the passwd file entry and runs /bin/sh. All exported environment variables are available unless you use the - flag when you call su.

Flags

Creates the user's login environment by calling the new shell as a *login* **shell** (see "sh" on page 913). It reads the system **profile** file and the user's \$HOME/.profile file. The environment variables NLLDATE and **NLTIME** control the appearance of the date and time. The **TERM** and TZ variables are an exception. They are preserved at their current values. These variables are normally set by **init** or **getty** prior to login: as a result, su handles them differently.

Note: This flag modifies the environment of the current shell only if the optional program named in the shell field of the passwd file is a program like sh.

-c "cmdstring"

Runs the **/bin/sh** shell, processes the specified *command*, and then exits the shell. This flag causes su to ignore the shell specified in the passwd file.

Examples

1. To obtain superuser authority:

su

This runs a subshell with the effective user ID and privileges of user root. The su command asks for a password, as if you were logging in as root. Now the commands you run have superuser authority. Press END OF FILE (Ctrl-D) to end the subshell and return to your original shell session and privileges.

2. To obtain jim's privileges:

su jim

This runs a subshell with the effective user ID and privileges of jim.

3. To set up the environment as if you had logged in as jim:

su - jim

This runs a subshell with the effective user ID and privileges of jim. The - (minus) causes the shell variable LOGNAME to be set to jim, HOME to be set to the path name of jim's home directory, and jim's \$HOME/.profile shell procedure file to be run before prompting for the first shell command.

4. To run a single command with superuser authority:

This runs the shell command backup -9 -u with superuser authority (if you know the password assigned to root).

Related Information

The following command: "sh" on page 913.

sum

Purpose

Displays the checksum and block count of a file.

Syntax

OL805268

Description

The **sum** command reads *file* and calculates a 16-bit checksum for the *file* and the number of blocks in the file. The checksum and number of blocks are written to standard output. The **sum** command is generally used to determine if a file that has been copied or communicated over transmission lines is an exact copy of the original.

Flag

-r Uses an alternate algorithm to compute the checksum (rigorous byte-by-byte computation rather than the default word by word computation).

Example

To display the checksum of, and the number of blocks in datafile:

sum datafile

If the checksum of datafile is 1605 and if the file contains 3 blocks, then **sum** displays: 1605 3 datafile

Related Information

The following command: "wc" on page 1211.

sync

Purpose

Updates the superblock and writes buffered files to the fixed disk.

Syntax

sync ----

OL805221

Description

The **sync** command runs the **sync** system primitive. If you have to stop the system, you must run **sync** to ensure file system integrity. **sync** writes all unwritten system buffers to disk. This includes modified superblocks, modified i-nodes, delayed block I/O, and read-write mapped files.

Note: The writing, although scheduled, is not necessarily complete upon return from the **sync** system call.

Related Information

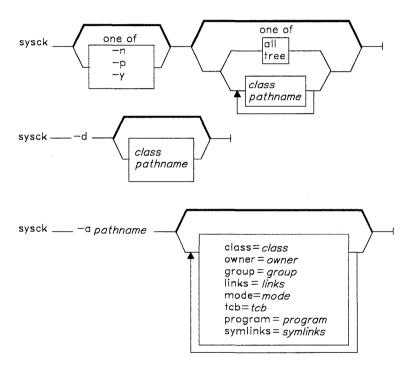

The sync system call in AIX Operating System Technical Reference.

sysck

Purpose

Verifies the secure system state

Syntax

OL805503

Description

The **sysck** command checks the installation of files relevant to security. Each such file must have a corresponding stanza in **/etc/security/sysck.cfg**. The **sysck** command also adds or deletes file descriptions from **/etc/security/sysck.cfg**.

When invoked with no flags and with no arguments, the sysck command prints a synopsis of its usage.

Adding a File Description

When invoked with the -a flag, the sysck command adds or modifies a stanza in the /etc/security/sysck.cfg file. The added or modified stanza describes the file specified by pathname. The file attributes are taken from:

- The old stanza for the file (if it exists).
- The file (which must exist).
- The attribute = value arguments on the command line (if there are any).

You may specify that an attribute is not to appear in the stanza by specifying an empty string as the value for the attribute. See the discussion of the **sysck.cfg** file in AIX Operating System Technical Reference for a description of the attributes recorded in /etc/security/sysck.cfg.

Deleting a File Description

When invoked with the -d flag, the sysck command deletes the specified stanzas from /etc/security/sysck.cfg. A stanza may be deleted by specifying its pathname or by specifying the value of its class attribute.

Checking a File Description

When invoked with neither the -a nor -d flags, the sysck command checks the installation of files described in /etc/security/sysck.cfg. Any inconsistency can be fixed by changing the file to match the description in /etc/security/sysck.cfg.

The arguments to the sysck command specify which stanzas are to be checked:

pathname Specifies the name of a stanza. This must be an absolute path name (i.e., begin with a /).

class Specifies all stanzas whose class attribute has the value class. Note that a class name cannot begin with a /.

all Specifies all stanzas.

Specifies all stanzas. When **tree** is specified, the **sysck** command not only checks the installation of files described in **/etc/security/sysck.cfg**, but it also checks that there are no other files in the file system which should be described by **/etc/security/sysck.cfg**.

The following checks are performed on each file *not* described by a stanza in /etc/security/sysck.cfg:

- If the file is a hard link to a file described in /etc/security/sysck.cfg, but is not listed in the value of the links attribute, the link is removed.
- If the file is a symbolic link to a file described in /etc/security/sysck.cfg, but is not listed in the value of the symlinks attribute, the symbolic link is removed.

- If the file is a regular file, the file owner ID is 0, and the file mode has the **S_ISUID** bit set, the **S_ISUID** bit is cleared.
- If the file is a regular file, the file group ID is 0, and the file mode has the S_ISGID and S_IXGRP bits set, the S_ISGID bit is cleared.
- If the file has the **tcb** attribute set, the **tcb** attribute is cleared.
- If the file is a block or character device, all permission bits of the file are set to 0.

The action to be taken when a configuration error is found is determined by any -n, -p, or -y flag supplied to the sysck command.

The following checks are performed if the stanza has the specified attribute. If an inconsistency is found, **sysck** performs the action specified by the flag supplied with the **sysck** command.

class

The value of this attribute is the name of a group of stanzas. The **sysck** command performs no checks based on the value of this attribute. The **class** attribute is used to specify a group of stanzas to be checked by the **sysck** command.

owner

The value of this attribute is a decimal user ID, or the login name of a user in /etc/passwd. The file owner ID should be this user ID.

group

The value of this attribute is a decimal group ID, or the name of a group in /etc/group. The file group ID should be this group ID.

mode

The value of this attribute can be an octal numeral, or a string in the form -r-Sr-x--T. The file mode should be this value.

links

The value of this attribute is a comma-separated list of additional links to the file.

symlinks

The value of this attribute is a comma-separated list of symbolic links to the file. Note that **sysck** will find additional symbolic links only if given the **tree** argument.

tcb

The value of this attribute is **true** or **false**. If **true**, the file should be flagged as part of the trusted computing base.

program

The value of this attribute is the full path name of a program that performs additional consistency checks on the file. Arguments to the program also appear with this attribute. Note that the value of an attribute must be enclosed in double quotes if it has embedded spaces. The **sysck** command will execute this program with any arguments preceded by the same flags (-n, -p, or -y) as were provided on the **sysck** command line.

Consistency Checks

Two consistency check programs are supplied: pwdchk and grpchk.

/etc/security/pwdchk

The **pwdchk** program checks the /etc/passwd and /etc/security/passwd files for internal and mutual consistency. Consistency checks are not applied to lines in /etc/passwd with start with - (minus) or + (plus).

The internal consistency checks for /etc/passwd include the following:

- Each line must have seven colon-separated fields. Any malformed entry is reported but not corrected.
- The password field of each entry must be! (exclamation point). An invalid entry is reported and set to! (exclamation point); if the password file is 13 or more characters, the leading 13 characters become the value of the password attribute in /etc/security/passwd.
- The *uid* field of each entry must be decimal numeral. An invalid entry is reported and the value of the **restrictions** attribute in /etc/security/passwd is set to nouse.
- The gid field of each entry must be decimal numeral which corresponds to a group described in /etc/group. An invalid entry is reported and the value of the restrictions attribute in /etc/security/passwd is set to nouse.
- The *directory* field must be **NULL** or a full path name. An invalid entry is reported but not corrected.
- The *shell* fields must be **NULL** or a full path name. An invalid entry is reported but not corrected.

The mutual consistency checks for /etc/passwd and /etc/security/passwd include the following:

- For every entry in /etc/passwd, there must be a stanza with the same user name in /etc/security/passwd. A stanza is created in /etc/security/passwd for any extra entries in /etc/passwd.
- For every entry in /etc/security/passwd, there must be a corresponding entry in /etc/passwd. Extra entries in /etc/security/passwd are reported and deleted.
- Each entry in /etc/passwd must have a unique user ID, unless /etc/security/passwd has a stanza for this user in which the restrictions attribute is none. Only one login account is allowed for each unique user ID unless specifically allowed by restrictions = none in etc/security/passwd. Subsequent entries with the same user ID as a previous entry are reported and the value of the restrictions attribute is set to nologin.

/etc/security/grpchk

The grpchk program checks the /etc/group and /etc/security/group files for internal and mutual consistency.

The internal consistency checks for **/etc/group** include the following:

- Each line must have three colon-separated fields. Any malformed entry is reported, but not corrected.
- Each group name must be unique. A duplicate entry is reported, but not corrected.
- The gid field of each entry must be unique. An invalid entry is reported, but not corrected.
- Each user listed as a member of the group must have an entry in /etc/passwd. An unknown user name is reported, but not corrected.

The mutual consistency checks for /etc/group and /etc/security/group include the following:

- For every entry in /etc/group, there must be a stanza with the same group name in /etc/security/group. A stanza is created in /etc/security/group for any extra entries in /etc/group.
- For every entry in /etc/security/group, there must be a stanza with the same group name in /etc/group. A stanza is created in /etc/group for any extra entries in /etc/security/group.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- Adds (to /etc/security/sysck.cfg) the description of a file.
- Deletes (from /etc/security/sysck.cfg) the description of the files specified by the -d arguments.
- Checks the installation of the files specified by the arguments. Any inconsistencies are reported. No changes will be made to either the file or to /etc/security/sysck.cfg.
- Checks the installation of the files specified by the arguments. Any inconsistencies are **not** reported. Changes are made to files so they match the description in /etc/security/sysck.cfg.
- Checks the installation of the files specified by the arguments. Any inconsistencies are reported. Changes are made to files so they match the description in /etc/security/sysck.cfg.

Example

The following command assures all files described by /etc/security/sysck.cfg are properly installed:

sysck -y all

The following command can be used to construct an /etc/security/sysck.cfg file which reflects the current state of the system:

sysck tree

Files

/etc/security/sysck.cfg

Defines installation assertions for security relevant files and directories.

Related Information

The following file format: sysck.cfg in AIX Operating System Technical Reference.

The discussion of the trusted computing base in Managing the AIX Operating System.

syslogd

Purpose

Reads and logs messages.

Syntax

AJ2FL148

Description

The **syslogd** command reads and logs messages into a set of files described by the configuration file **/etc/syslog.config**. This daemon configures itself when it starts up and whenever it receives a hangup signal.

Each message read by **syslogd** is one line. A message can contain a priority code (marked by a number in $\langle \rangle$ brackets at the beginning of the line) and message text. Priorities are defined in **sys/syslog.h**. The **syslogd** command reads from the AIX domain socket /dev/log or from an Internet domain socket specified in /etc/services.

Each line in the syslogd configuration file must consist of two parts:

- A selector to determine the message priorities to which the line applies
- An action.

The two fields must be separated by one or more tabs. Here is an example of the line in a configuration file:

The first part, the selector, is semicolon-separated list of priority specifiers. Each priority specifier consists of a facility describing the part of the system that generated the message, a . (period), and a level indicating the severity of the message. Symbolic names may be used and an * (asterisk) specifies all facilities. All messages of the specified level or higher (greater severity) are selected. In the previous example, **syslogd** selects the mail facility at the info level (or higher) and all facilities at the notice level (or higher).

More than one facility may be selected using commas to separate them. For example:

*.emerg;mail,daemon.crit

selects all facilities at the emerg level (or higher) and the mail and daemon facilities at the crit level (or higher).

Known facilities and levels recognized by **syslogd** are those listed under **syslog** in the AIX Operating System Technical Reference. When you specify the name of a facility or level in a **syslogd** configuration file, omit the **LOG**_ prefix used by **syslog** in the name. For example, **syslog** lists **LOG_DEBUG** as the lowest level. To specify this level in a **syslogd** configuration file, specify debug.

In addition to these facilities, there is a **mark** facility. This facility has messages at priority **info** sent to it every 20 minutes. You can change the mark time interval with the **-m** flag. The **mark** facility is not enabled by a facility field containing an asterisk; you must explicitly enable it. For example:

kern, mark. debug

logs kernel messages and 20-minute marks of debug level (or higher).

The level none may be used to disable a particular facility. For example:

*.debug; mail.none

logs all messages except mail messages.

The second part of each line, the action, describes where the message is to be logged if the line is selected. There are four forms:

- A file name beginning with a leading / (Selected messages are appended to this file)
- A host name preceded by a @ (Selected messages are forwarded to **syslogd** on the named host)
- A comma-separated list of users (Selected messages are written to those users, if they are logged in)
- An * (Selected messages are written to all logged-in users).

For example:

logs critical (or higher) messages into /usr/adm/critical, forwards kernel messages of error severity (or higher) to **syslogd** on the host nick, informs the users bobbi and kristi of any alert (or higher) messages, and informs all logged-in users of any emergency messages.

Blank lines and lines beginning with # are ignored.

The syslogd command creates the file /etc/syslog.pid, containing a single line with its process ID. This file can be used to kill or reconfigure syslogd. To bring syslogd down, it should be sent a terminate signal. For example:

```
kill 'cat /etc/syslog.pid'
```

Flags

-d Turns on debugging.

-f configfile Specifies an alternate configuration file.

-m markinterval Specifies the number of minutes between mark messages.

Example

To start syslogd daemon and and change the mark interval:

syslogd -m30

This command changes the mark interval to 30 minutes. If the configuration file contains:

kern, mark. notice /usr/adm/notice kern.err @scott /usr/spool/adm/syslog *.info;mail.none *.alert;auth.warning darlene

syslogd logs kernel messages and 30-minute marks at notice level (or higher) in the file /usr/adm/notice, forwards kernel messages at err level (or higher) to syslogd on the host scott, logs messages at info level (or higher) except mail messages in the file /usr/spool/adm/syslog, and informs the user darlene of any warning message (or higher) from the authorization system.

Files

/etc/services Contains definition of the Internet domain socket. /etc/syslog.conf Contains the configuration file. /etc/syslog.pid Contains the process id. /dev/log Contains AIX domain datagram log socket.

Related Information

The syslog system call in AIX Operating System Technical Reference.

tab, untab

Purpose

Changes spaces into tabs or tabs into spaces.

Syntax

OL805069

OL805065

Description

The **tab** command reads *files* (standard input by default), and replaces spaces in the input with tab characters wherever it can eliminate one or more spaces. It writes the resulting file back to *file* or, if the input was standard input, to standard output. **tab** assumes that the tab stops are set every eight columns starting with column nine.

The untab command reads files or standard input, replaces tabs in the input with space characters and writes back to the original file or to standard output.

Flag

• Replaces only those spaces at the beginning of a line up to the first nonspace character.

Related Information

The following command: "newform" on page 686.

tabs

Purpose

Sets tab stops on work stations.

Syntax

OL805381

Description

The **tabs** command clears up to 20 previous tabs and sets up to 40 tabs on the work station according to the supplied *tabspec*. *tabspec* can be either a flag indicating an available code or column numbers. The available codes cover formats required by most structured programming languages.

When you use the **tabs** command, always see the leftmost column number as 1, even if your work station refers to it as zero (0).

If you do not specify a tabspec, the default value is -8.

Tabspecs

- -a Sets the tabs to 1, 10, 16, 36, and 72 (IBM S/370 Assembler first format)
- -a2 Sets the tabs to 1, 10, 16, 40, and 72 (IBM S/370 Assembler second format)
- -c Sets the tabs to 1, 8, 12, 16, 20, and 55 (COBOL normal format)
- -c2 Sets the tabs to 1, 6, 10, 14, and 49 (COBOL compact format, columns 1-6 omitted). With this code, the first column position corresponds to card column 7. One space gets you to column 8, and a tab reaches column 12. Files using this code should include a format specification of:

¹ Do not put a space between these items.

For an explanation of format specifications, see the **fspec** file in AIX Operating System Technical Reference.

-c3 Sets the tabs to 1, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62, and 67 (COBOL compact format with more tabs than -c2. This is the recommended format for COBOL. Files using this code should include a format specification of:

<:t-c3 m6 s66 d:>

-f Sets the tabs to 1, 7, 11, 15, 19, and 23 (FORTRAN).

-p Sets the tabs to 1, 5, 9, 13, 17, 21, 25, 29, 33, 37, 41, 45, 49, 53, 57, and 61 (PL/I).

-s Sets the tabs to 1, 10, and 55 (SNOBOL).

-u Sets the tabs to 1, 12, 20, and 44.

In addition to the preset formats, three other types of tabspecs are available:

-num Sets regularly repeating tabs at every numth column. (-8 is the standard AIX tab setting and the one required for use with the **nroff** -h flag.) Another special case is -0, which implies no tabs at all.

num[,num] . . . Sets tabs at the named column numbers (a comma-separated list in ascending order). You may specify up to 40 numbers. If any number except the first has a plus sign prefix, the prefixed number is added to the previous number for the next setting. Thus, the tab lists 1,10,20,30 and 1,10,+10,+10 provide the same tab settings.

Reads the first line of the named *filep* for a format specification. If it finds one, it sets tabs the same way. If it does not find a format specification, it sets tabs to the system default (-8). Use this *tabspec* to make sure that a file has the same tab settings as those in a file already correctly formatted.

Flags

--filep

Note: If the same flag occurs more than once, only the last one takes effect.

-Tworkstation Identifies the work station so that tabs can set tabs and margins correctly.

workstation is one of the work stations listed under the greek command.

If you do not provide a -T flag, tabs uses the shell variable \$TERM. If no workstation can be found, tabs tries a general value that works for most work stations.

+ mnum Moves all tabs to the right num columns, and makes column num1 the left margin. If m is given without a value, 10 is assumed. The leftmost margin on most work stations is defined by m0.

Related Information

The following commands: "greek" on page 499, "nroff, troff" on page 709, and "troff" on page 710.

The discussion of term and environ in AIX Operating System Technical Reference.

tail

Purpose

Writes a file to standard output, beginning at a specified point.

Syntax

OL805303

OL805308

Description

The tail command writes the named file (standard input by default) to standard output, beginning at a point you specify. It begins reading at +[num] lines from the beginning of file or -[num] lines from the end of file. The default num is 10. num is counted in units of lines, blocks, or characters, according to the subflag appearing after num (see the following flags).

Flags

-f

Does not end after it copies the line of the input file if the input file is not read from a pipe, but enters an endless loop in which it sleeps for a second and then attempts to read and copy further records from the input file. Thus, it can be used to monitor the growth of a file being written by another process.

- +[num]1
- $+[num]\mathbf{b}$
- +[num]c

Begins reading num lines (1), blocks (b), or bytes (c) from the beginning of the input.

¹ Do not put a blank between these items.

-[num]1 $-[num]\mathbf{b}$ -[num]c

Begins reading num lines (1), blocks (b), or bytes (c) from the end of the input.

Japanese Language Support Information

+ [num]k $-[num]\mathbf{k}$

Begins reading num characters (k) from the beginning of the input. Begins reading num characters (c) from the end of the input.

The c flag in Japanese Language Support begins reading as closely as possible to the number of bytes requested, without breaking a 2-byte character. The number of characters in input containing SJIS characters may not equal the number of bytes. To get, or skip, precisely num characters, use the k flag.

Examples

1. To display the last 10 lines of a file:

tail notes

2. To specify how far from the end to start:

tail -20 notes

This displays the last 20 lines of notes.

3. To specify how far from the beginning to start:

This displays notes a page at a time starting with the 200th character from the beginning.

4. To follow the growth of a file:

tail -1 -f accounts

This displays the last line of accounts. Once a second, tail displays any lines that have been added to the file. This continues until stopped by pressing INTERRUPT (Alt-Pause).

Related Information

The following commands: "dd" on page 301 and "pg" on page 744.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

tapechk

Purpose

Performs consistency checking of the streaming tape device.

Syntax

OL805445

Description

The **tapechk** command performs rudimentary consistency checking on an attached streaming tape device. Some hardware malfunctions with a streaming tape drive can be detected by simply reading a tape. **tapechk** provides a way to perform tape reads on the file level.

Since the streaming tape drive cannot backspace over physical data blocks or files, tapechk rewinds the tape to its starting position prior to each check. You can specify numeric arguments to control the number of files checked or skipped. If you do not specify any arguments, tapechk rewinds the tape and checks only the first physical block.

Note: The **backup** command allows you to archive files selectively or as an entire file system. It writes data as a continuous stream terminated by a file mark, regardless of the number of files specified. The **tapechk** command perceives each stream of data as a single file. This is important when you specify numeric arguments with the **tapechk** command.

Although you can use **tapechk** on any streaming tape cartridge, it is primarily designed for checking tapes written by the **backup** command.

Flags

num1 Checks data for the next num1 files.

num2 Skips the next num2 files from the beginning of the tape.

? Explains the format of the tapechk command.

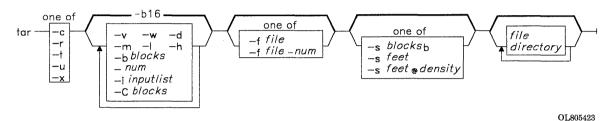

Note: If you specify this argument, it must be the first argument.

tar

Purpose

Manipulates archives.

Syntax

Description

The tar command writes files to or retrieves files from an archival storage medium. The tar command looks for archives on the default device (usually tape), unless you specify another device with the -f flag. File names must not be longer than 100 bytes and must not contain blanks. Characters following the first blank are ignored.

When writing to an archive, tar uses a temporary file (/tmp/tar*) and maintains in memory a table of files with several links. You will receive an error message if tar cannot create the temporary file, or if there is not enough memory available to hold the link tables.

Notes:

- 1. When the storage device is an ordinary file or a block special file, -u and -r flags backspace. However, raw magnetic tape devices do not support backspacing. So when the storage device is a raw magnetic tape, the -u and -r flags rewind the tape, open it, and then read it again.
- 2. Records are one block long on block magnetic tape, but they are typically less than half as dense on raw magnetic tape. As a result, although a blocked raw tape must be read twice, the total amount of tape motion is less than it is when reading one-block records from a block magnetic tape once.

- 3. The structure of a streaming tape device does not support the addition of information at the end of a tape. Consequently when the storage device is a streaming tape, the -u and -r flags are not valid options. An attempt to use these flags results in the error message tar: Update and Replace options not valid for a streaming tape drive.
- 4. There is no way to ask for any occurrence of a file other than the last.
- 5. There is no recovery from tape errors.

Flags

u

 \mathbf{x}

You must supply one of the following five function flags to control the actions of tar:

c Creates a new archive and writes the *file* at the beginning of the archive.

writes the *file* at the end of the archive. Since the structure of a streaming tape device does not support the addition of information at the end of a tape, this option is not a valid flag when the archival storage device is a streaming tape.

t Lists the files in the order in which they appear in the archive. Files may appear more than once.

Adds *file* to the end of the archive only if it is not in the archive already or if it has been modified since it was written to the archive. Since the structure of a streaming tape device does not support the addition of information at the end of a tape, this is not a valid flag when the archival storage device is a streaming tape.

Extracts file from the archive. If you specify a directory, tar extracts all files in that directory from the archive. If you do not specify a file or a directory, tar extracts all of the files from the archive. When an archive contains multiple copies of the same file, tar extracts only the last one and overwrites all earlier ones. If you have superuser authority (see "su" on page 1026), tar creates all files and directories with the same user and group IDs as on the tape. If you do not have superuser authority, the files and directories have your user and group IDs.

The other optional flags to tar are listed below. In all cases, a directory parameter refers to all the files and subdirectories, recursively, within that directory. Flags without corresponding parameters may appear separately or be grouped together. Flags that take parameters may have them adjacent to the flag letter or as the entire following argument.

-bblocks Specifies the number of 512-byte blocks per record. The default is 16, which is appropriate for tape records. Due to the size of inter-record gaps, tapes written with large blocking factors can hold much more data than tapes with only one block per record.

The block size is determined automatically when tapes are read (function flags -x or -t). When archives are updated with the -u and -r functions, the existing record size is used. The tar command writes archives using the specified blocks value only when creating new archives with the -c flag.

For output to ordinary files with the -f flag, you can save disk space by using a blocking factor that matches the size of disk blocks (for example, -b4 for 2048-byte disk blocks). Ordinary files must be read using the same blocking factor used when they were created.

-Chlocks

Allows tar to use very large clusters of blocks when it deals with streaming tape archives. Note, however, that on input, tar cannot automatically determine the block size of tapes with very long block sizes created with this flag. In the absence of a -Cnum argument, the largest block size that tar can automatically determine is 20 blocks.

-d

Makes separate entries for directories, blocks and character special files, and FIFOs. Normally, tar writes only ordinary files to an archive, and extracts only ordinary files and the directories required to contain them as determined by the path names in the archive. When writing to an archive with the -d flag, tar makes it possible to preserve the directory permission codes and to restore empty directories, special files, and FIFOs with the -x flag.

Note: Although anyone can archive special files, only a user with superuser authority can extract them from an archive.

 $-\mathbf{f}file[-num]$

Uses *file* as the archive to be read or written. When this flag is not specified, **tar** uses a system-dependent default file name of the form /dev/rmt?. If the *file* specified is - (minus), **tar** writes to standard output or reads from standard input. If you write to standard output, the -c flag must be used (see example).

If you specify *num*, **tar** provides automatic spill over from one archive storage unit to another. This feature allows the operator of a system with multiple tape drives to use multitape archives without having to change tapes. For example, -f/dev/rmt0-2 writes or reads /dev/rmt0, followed by /dev/rmt1, and then /dev/rmt2 before requesting that additional volumes be mounted.

-h

Ignores header checksum errors. The **tar** command writes a file header containing a checksum for each file in the archive. When this flag is not specified, the system verifies the contents of the header blocks by recomputing the checksum, and aborts with a directory checksum error when a mismatch occurs. When this flag is specified, **tar** logs the error and then scans forward until it finds a valid header block. This permits restoring files from later volumes of a multivolume archive without reading earlier volumes.

-iinputlist Writes the files listed in the inputlist file to the archive. The inputlist should contain one file name per line. Files from inputlist are not treated recursively. If you include the name of a directory in inputlist, tar does not write that directory's subdirectories to the tape, only that directory's files. If you also list files or directories on the command line, the contents of inputlist are included after tar has written all the files or the directories and their subdirectories to the archive. -1 Writes error messages to standard output if tar cannot resolve all of the links to the files archived. When you do not specify this flag, the system does not display these messages.

preserve the modification time of the files.

- -s blocksb
- -s feet

-m

-s feet @density

Specifies the number of 512-byte blocks per volume (first format), independent of the tape blocking factor. You can also specify the size of the tape in feet by using the second form, and tar assumes a default density. The third form allows you to specify both tape length and density. Feet are assumed to be 11 inches long to be conservative. This flag lets you deal more easily with multivolume tape archives, where tar must be able to determine how many blocks fit on each volume.

Uses the time of extraction as the modification time. The default is to

Note: Tape drives vary in density capabilities. The *density* parameter calculates the amount of data a system can fit on a tape. This allows the correct amount of data to be written to a tape when using tape drives other than the IBM 6157 tape drive, which has a density of 700.

Lists the name of each file as it is processed. With the -t flag, -v gives more information about the tape entries, including file sizes, times of last modification, UID, and GID, and permissions.

Displays the action to be taken followed by the file name, then waits for user confirmation. If the response begins with a y or Y, then the action is performed. If the response is not affirmative, then the file is ignored.

Japanese Language Support Information

An affirmative response in Japanese Language Support matches one of the elements in the environment variable YESSTR.

-V

-w

-num

Uses /dev/rmtnum instead of the default. For example, -2 is the same as -f/dev/rmt2. In AIX systems with multidensity tape drives, this flag allows selecting a particular density. The default unit is system dependent and is chosen to match the default density, as described under the -s flag.

Examples

1. To write file1 and file2 to a new archive on the default tape drive:

tar -c file1 file2

2. To extract all files that are in the /tmp directory from the archive file on the tape device /dev/rmt2 and use the time of extraction as the modification time:

tar -xm -f/dev/rmt2 /tmp

3. To create a new archive file that contains file1 and pass the archive file to the **dd** command to be written to the device /dev/rmt1:

tar -cvf - file1 | dd of=/dev/rmt1

4. To display the names of the files in the disk archive file **out.tar** on the current directory:

tar -vtf out.tar

5. To expand the compressed archive file fil.tar.z, pass the file to the tar command, and extract all files from the expanded archive file:

pcat fil.tar.z | tar -xvf -

Files

/dev/rmt? /tmp/tar*

Related Information

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

tbl

Purpose

Formats tables for the nroff, troff and troff commands.

Syntax

OL-805222

Description

The **tbl** command is a preprocessor that formats tables for **nroff** and **troff**. It reads the specified *files* or, if you do not specify any file names or you specify a - (minus) as a file name, it reads standard input. The input is copied unchanged to standard output, except for text between lines containing **.TS** and **.TE**. This text describes tables, and is reformatted by **tbl**. The **.TS** and **.TE** lines are not altered by **tbl**. For more detailed information on how to format text for **tbl**, see *Text Formatting Guide*.

Note: When tbl is used with eqn or neqn, tbl should come first to minimize the volume of data passed through pipelines.

At the start of **tbl** text, you should include a line containing **.TS**. You can follow this with a line containing global options. The available global options are:

centercenters the table (the default is left-adjusted).expandMakes the table as wide as the current line length.

box Encloses the table in a box.

doublebox Encloses the table in a doublebox

doublebox Encloses the table in a double box.

Encloses each item of the table in a box.

tab(x) Uses the character x instead of a tab to separate items in a line of input

data.

linesize (n) Sets lines and rules for boxes in point size n. **delim** (x,y) Sets x and y as the **eqn** and **neqn** text delimiters.

End the list of global options with a; (semicolon).

After the global options, enter lines describing the format of each row in the table. Each format line (except the last) describes one row of the table. The last one describes all remaining rows of the table. This must end with a period to indicate that it is the end of the format specification. Each column of the table is described by a single keyletter.

The available keyletters are:

- c Centers the item in the column.
- r Right-adjusts the item in the column.
- 1 Left-adjusts the item in the column.
- n Adjusts the numerical items in the column to line up at the decimal point or right-adjusts them if there are no decimal points.
- s Allows the previous item on the left to spill over into this column if the item is too wide for its column.
- a Centers the longest line in this column and then left-adjusts all other lines in it with respect to the centered line.
- ^ Allows the item above to spill over into this column if the item is too large.
- Replaces this entry with a horizontal line.
- = Replaces this entry with a double horizontal line.

After the keyletter, you can enter specifiers that determine where vertical lines appear between columns, column width, inter-column spacing, and the font and point size of the item. The following table lists the legal specifiers.

Specifier	Meaning	Specifier	Meaning
e or E	Equal width columns	w or W	Minimum width column
f or F	Font change	z or Z	Zero width column
nnn	Column separation	.xx	Included troff request
p or P	Point size change	l .	Vertical line
s or S	Spanned item	11	Double vertical line
t or T	Vertical spanning at top	\^	Vertical span
$T\{\ldots T\}$	Text block	_	Short horizontal line
u or U	Staggered columns	$\backslash \mathbf{R}x$	Repeat character
v or V	Vertical spacing change		

Figure 11. tbl Column and Item Specifiers

The format lines are followed by lines containing data for the table. The last line consists of .TE. Within the data lines, data items are separated by tab characters, unless the global option, delim is used.

If a data line consists of only $_$ (underscore) or = (equal sign), a single or double line is drawn across the table at that point. If an entry in a data line consists of only $_$ or =, then that item is replaced by a single or double line.

Flag

-TX Uses only full vertical line motions, making the output suitable for line printers and other devices that do not have partial vertical line motions.

The discussion of thl in Text Formatting Guide.

\mathbf{tc}

Purpose

Simulates phototypesetter output for a Tektronix 4014 work station.

Syntax

OL805271

OL805308

Description

The **tc** command interprets its input, either a *file* or standard input, as a **troff** document. It then simulates the typesetter output for a Tektronix 4014 work station with ASCII and APL character sets and writes the results to standard output (usually the work station display). The 16 typesetter sizes are mapped into the 4014's four sizes; the entire **troff** character set is drawn using the 4014's character generator, with overstruck combinations where necessary.

At the end of each page, to waits for a new-line character from the keyboard before continuing to the next page. While it is waiting, the command e suppresses the screen erase before the next page. !AIX-cmd sends AIX-cmd to the shell.

There are no font distinctions in the display.

Flags

-pnum letter Sets page length to num and scale to letter. letter may include the scale factors **p** (points), **i** (inches), **c** (centimeters), and **P** (picas). The default is picas. Do not put a space between num and letter.

-t Does not wait between pages (use in a pipeline).

¹ Do not put a blank between these items.

Example

To use to in a pipeline with troff: troff -t chapter1 | tc

Related Information

The following commands: "sh" on page 913, "tplot" on page 1079, "troff" on page 710, and "4014" on page 1264.

tctl

Purpose

Gives commands to streaming tape.

Syntax

OT 805397

Description

The tctl command gives subcommands to a streaming tape device. If you do not specify the -f flag with tapename, the environment variable TAPE is used. If the environment variable does not exist, tctl uses the device /dev/rmt4. The tapename parameter must be a raw (not block) tape device. You can specify more than one operation with count.

Subcommands

eof weof

Writes *count* end-of-file markers at the current position on the tape.

 $\mathbf{f}\mathbf{s}\mathbf{f}$

Moves the tape forward count files.

fsr

Moves the tape forward count records.

rewind

Rewinds the tape. The count parameter is ignored.

Note: It is sometimes necessary to issue a reset before issuing a rewind subcommand.

subc

offline rewoffl

reset

Places the tape drive off-line. The count parameter is ignored.

erase

Erases all contents on the tape and rewinds it.

retension

Moves the tape to the beginning, the end, and back to the beginning of the tape. If you have excessive read errors during a restore operation, you should

run the retension subcommand. If the tape has been exposed to

environmental extremes, you should run the retension subcommand before

the save operation.

ras1

Performs a checksum on the tape drive.

ras2

Checks the capstan speed, verifies the operations of the BOT, EOT, and SAFE sensors, and writes a worst case pattern on the tape and attempts to verify the pattern.

Files

/dev/rmt?? The raw streaming tape interface.

Related Information

The following command: "dd" on page 301.

The ioctl system call and the tape and environ files in AIX Operating System Technical Reference.

tee

Purpose

Displays the output of a program and copies it into a file.

Syntax

OL805272

Description

The **tee** command reads standard input and writes the output of a program to standard output and copies it into *file* at the same time.

Flags

- -a Adds the output to the end of file instead of writing over it.
- -i Ignores interrupts.

Note: If you specify both flags, each must appear separately on the command line, preceded by a - (minus).

Examples

1. To view and save the output from a command at the same time:

```
lint program.c | tee program.lint
```

This displays the standard output of the command lint program.c at the work station, and at the same time saves a copy of it in the file program.lint. If program.lint already exists, it is deleted and replaced.

2. To display and append to a file:

lint program.c ! tee -a program.lint

This displays the standard output of lint program.c at the work station and at the same time appends a copy of it to the end of program.lint. If the file program.lint does not exist, it is created.

termdef

Purpose

Queries terminal characteristics.

Syntax

OL805454

Description

The termdef command identifies the current display type, the active lines setting, or the current columns setting, thus simplifying the task of resetting the lines and columns when you switch fonts or of resetting the \$TERM environment variable when you switch displays. The terminfo file defines the default number of lines and columns for each display, but the lines and columns can change depending upon which font is currently active. In addition, the \$TERM environment variable does not automatically reflect the display currently being used. If you are using a display other than the ibm5151, you must explicitly reset this variable to access the terminfo correctly.

Flags

- -c Returns the current column value.
- -I Returns the current lines value.
- -t Returns the name of the current display (this is the default action).

Example

To set environment variables according to the values of the currently active font and display, add the following lines to the /etc/rc file:

```
TERM='termdef'
COLUMNS='termdef -c'
LINES='termdef -l'
export TERM LINES COLUMNS
```

Related Information

The following command: "display" on page 332.

The terminfo file and the hft special file in AIX Operating System Technical Reference.

test

Purpose

Evaluates conditional expressions.

Syntax

OL805273

Description

The test command evaluates expression and, if its value is true, returns a zero (true) exit value. otherwise it returns a nonzero (false) exit value; test also returns a nonzero exit value if there are no parameters.

Note: In the second form of the command, that is the one that uses square brackets ([]), rather than the word test, the brackets must be surrounded by blanks.

Functions

All the functions and operators are separate parameters to **test**. The following functions are used to construct *expression*:

-r file	True if file exists and has read permission.
-w file	True if file exists and has write permission.
- x file	True if file exists and has execute permission.
- f file	True if file exists and is a regular file.
-d file	True if file exists and is a directory.
-c file	True if $file$ exists and is a character special file.
-b file	True if file exists and is a block special file.
-p file	True if file exists and is a named pipe (FIFO).
-u file	True if file exists and its set-user-ID bit is set.

-g file	True if file exists and its set-group-ID bit is set.	
- \mathbf{k} file	True if file exists and its sticky bit is set.	
-s file	True if file exists and has a size greater than zero.	
-t [filedescr]	True if the open file with file descriptor number <i>filedescr</i> (1 by default) is associated with a work station device.	
-z <i>s1</i>	True if the length of string s1 is zero.	
-n s1	True if the length of the string s1 is nonzero.	
s1 = s2	True if strings s1 and s2 are identical.	
s1! = s2	True if strings s1 and s2 are not identical.	
s1	True if s1 is not the null string.	
n1 -eq n2	True if the integers $n1$ and $n2$ are algebraically equal. Any of the comparisons -ne, -gt, -ge, -lt, and -le can be used in place of -eq.	
These functions can be combined with the following operators:		
!	Unary negation operator.	
-a	Binary AND operator.	
-o	Binary OR operator (-a has higher precedence than -o).	
$\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ $	Parentheses for grouping.	

Examples

1. To test whether a file exists and is not empty:

```
if test ! -s "$1"
then
   echo $1 does not exist or is empty.
fi
```

If the file specified by the first positional parameter to the shell procedure does not exist, this displays an error message. If \$1 exists, it displays nothing. Note that there must be a space between -s and the file name.

The double quotation marks around \$1 ensure that the test will work properly even if the value of \$1 is the empty string. If the double quotation marks are omitted and \$1 is the empty string, test displays the error message test: parameter expected.

2. To do a complex comparison:

```
if [ $# -lt 2 -o ! -s "$1" ]
then
    exit
fi
```

If the shell procedure was given fewer than two positional parameters or the file specified by \$1 does not exist, then this exits the shell procedure. The special shell variable \$# represents the number of positional parameters entered on the command line that started this shell procedure. For more details, see "Shell Variables and Command-Line Substitutions" on page 917.

Related Information

The following commands: "find" on page 422 and "sh" on page 913.

tic

Purpose

Translates **terminfo** files from source to compiled format.

Syntax

OL805340

Description

The tic command translates terminfo files from the source format into the compiled format. tic places the results in the directory /usr/lib/terminfo. If the environment variable TERMINFO is set, the results are placed there instead of in /usr/lib/terminfo.

The tic command compiles all terminfo descriptions in files. When tic finds a use = field, it searches first the current file, then the master file, ./terminfo.src.

The total compiled entries cannot exceed 4096 bytes and the name field cannot exceed 128 bytes.

Flag

Writes trace information on the progress of tic. num is an integer that increases the level of the verbosity.

Files

/usr/lib/terminfo/?/*

Compiled terminal capability database.

Related Information

The curses subroutine and the terminfo file in AIX Operating System Technical Reference.

time

Purpose

Times the execution of a command.

Syntax

```
time - command -
```

OL805274

Description

The time command times the execution of the named *command*. time writes to standard error the elapsed time of the command, the system time used, and the execution time, in seconds.

Examples

1. To measure the time required to run a program:

```
time a.out
```

This runs the program a.out and writes to the standard error output the amount of real, system, and user time that it uses:

```
real 10.5
user 0.3
sys 3.6
```

2. To save a record of the time information in a file:

```
time a.out 2> a.time
```

Related Information

The following commands: "csh" on page 225 and "timex" on page 1069.

Note: The **csh** command contains a built-in subcommand named **time**. The command and subcommand do not necessarily work the same way. For information on the subcommand, see the **csh** command.

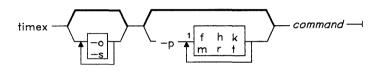

The times system call in AIX Operating System Technical Reference.

timex

Purpose

Times a command, and reports process data and system activity.

Syntax

¹Do not put a blank between these items.

OL805275

Description

The timex command reports, in seconds, the elapsed time, user time, and system execution time for command where command is a local command. With flags specified, timex can list or summarize process accounting data for command and all of its children, and report total system activity during the execution interval. Output is written to standard error. The system uses the /usr/adm/pacct to select process records associated with command and includes background processes having the same user ID, work station ID, and execution time window.

Flags

- -o Reports the total number of blocks read or written and total characters transferred by command and all its children.
- -p Lists process accounting records for *command* and all its children. The number of blocks read or written and the number of characters transferred are always reported. The f, h, k, m, r, and t arguments, defined in the acctcom command, modify the other data items reported.
- -s Reports total system activity that occurred during the execution of *command*. All the data items listed in the sar command are reported.

Related Information

The following commands: "acctcom" on page 20 and "sar" on page 867.

tlog

Purpose

Stops or restarts sending of terminal I/O to a daemon.

Syntax

AJ2FL106

Description

The tlog command stops and restarts the sending of terminal I/O data to the message queue of the terminal-logging daemon, tlogger. tlog off stops I/O from going to the daemon. tlog on restarts the sending of the I/O.

The tlog command uses the TCLOG ioctl () system call to stop and restart the flow of I/O to the daemon.

Files

/etc/tlogger

Daemon writes terminal data to a log file.

Related Information

The following commands: "tlogger" on page 1072.

tlogger

Purpose

Gathers I/O from a terminal and writes it to a log file.

Syntax

Description

The terminal-logging daemon tlogger collects data read or written to its associated terminal and writes that data to a log file. Each time the daemon is started, the contents of the current log file replace the backup log file. A new current log file is created with permissions set to allow read and write by the owner.

The associated terminal is identified in the following manner: Standard error is assumed to be the correct terminal if it is a terminal device (isatty() returns true). Otherwise, the process's usrinfo is used to identify the login terminal, and that device is used.

The tlogger daemon creates a message queue, and passes that queue ID to the associated terminal using the ioctl TCLOG system call. The daemon then loops waiting on message queue data; it writes any message queue data it receives to the end of the current log file. The terminal log daemon will catch all signals (except SIGKILL). On receipt of a signal, the daemon issues an ioctl TCLOG to its associated terminal to turn off logging. This causes the terminal to stop sending log messages. The daemon then removes the message queue and exits. The daemon also terminates if it can no longer write to the log file due to file size constraints. In this case, an error message is written to standard error.

The tlogger daemon should be started in the background either from /etc/rc, or from the command line. This starts the terminal sending its I/O data to the daemon. The tlog command can then be used to stop or restart the sending of terminal I/O to the daemon. The daemon itself may be terminated with the kill command, but would ordinarily continue to run until shutdown occurs.

Notes:

- 1. **SIGKILL** should not be used to stop the daemon, since cleanup of system resources cannot be done in that case.
- 2. It may be necessary to prevent passwords from showing up in the terminal logs. You can prevent the system from logging passwords by having the **getpass()** subroutine turn off terminal logging while it is reading the password. The **login**, **adduser**, **newgrp**, and **passwd** commands use this subroutine.

Flags

-b filename

Specifies a file to be used as the backup log file. The default backup

file is /usr/adm/ras/tlogfile.bk.

-c filename

Specifies a file to be used as the current log file. The default

current file is /usr/adm/ras/tlogfile.

Files

/etc/rc /usr/adm/ras/tlogfile /usr/adm/ras/tlogfile.bk

System startup file. Default current log file. Default backup log file.

Related Information

The following commands: "tlog" on page 1071, "shutdown" on page 946, and "kill" on page 552.

The ioctl system call and the getpass subroutine in AIX Operating System Technical Reference.

toc

Purpose

Provides graphical table of contents routines.

Syntax

OL777076

Description

All of the commands listed below reside in /usr/bin/graf (see "graphics" on page 497).

dtoc

The **dtoc** command makes a textual table of contents, **TTOC**, of all subdirectories beginning at *directory* (by default the current directory.). The list has one entry per directory. The entry fields from left to right are level number, directory name, and the number of ordinary readable files in the directory. **dtoc** is useful in making a visual display of all or parts of a file system. The following will make a visual display of all the readable directories under the root directory (/):

dtoc / | vtoc | td

ttoc

Output is the table of contents generated by the .tc macro of the mm command translated to TTOC format. The input is assumed to be a mm file that uses the .H family of macros for section headers. If no file is given, the standard input is assumed.

vtoc

The **vtoc** command produces a **GPS** describing a hierarchy chart from a **TTOC**. The output drawing consists of boxes containing text connected in a tree structure. If no *file* is given, the standard input is assumed. Each **TTOC** entry describes one box and has the form:

id[line-weight,line-style]"text"[mark]

where:

id

is an alternating sequence of numbers and dots. The id specifies the position of the entry in the hierarchy. The id 0. is the root of the tree.

line-weight is either:

n, normal-weight; or m, medium-weight; or

b, bold-weight.

line-style is either:

so, solid-line; do, dotted-line; dd, dot-dash line; da, dashed-line; or ld, long-dashed

text

is a character string surrounded by quotes. The characters between the quotes become the contents of the box. To include a quote within a box, it must be escaped ($\$ ').

mark

is a character string (surrounded by quotes if it contains spaces). To include a dot within a box, it must be escaped (\.). The string is put above the top right corner of the box. To include either a quote or a dot within a mark it must be escaped.

Entry example:

1.1b,da"ABD" DEF

Entries may span more than one line by escaping the new-line (\new-line).

Comments are surrounded by the /*,*/ pair. They can appear anywhere in a TTOC.

Flags

- c Uses text as entered (default is all upper case).
- d Connects the boxes with diagonal lines.

hnum Sets horizontal interbox space to num% of box width.

- i Suppresses the box id.
- m Suppresses the box mark.
- s Do not compact boxes horizontally.

vnum Vertical interbox space is num% of box height.

Related Information

The following command: "graphics" on page 497.

The gps file in AIX Operating System Technical Reference.

touch

Purpose

Updates the access and modification times of a file.

Syntax

OL805276

Description

The **touch** command updates the access and modification times of each *file* or *directory* named to the one specified on the command line. If you do not specify a time, **touch** uses the current time. If you specify a file that does not exist, **touch** creates a file with that name unless you request otherwise with the **-c** flag.

The environment variables **NLDATE** and **NLTIME**, if defined, specify the order of month and day in the date specification and of hour and minute in the time specification. Otherwise, these orders default to *mmdd* and *hhmm*.

The return code from **touch** is the number of files for which the times could not be successfully modified (including files that did not exist and were not created).

Flags

- -a Changes only the access time.
- -c Does not create the file if it does not already exist.
- -m Changes only the modification time.

¹The current year is the default year.

Examples

1. To update the access and modification times of a file:

```
touch program.c
```

This sets the last access and last modification times of program.c to the current date and time. If program.c does not exist, touch creates an empty file with that name.

2. To avoid creating a new file:

```
touch -c program.c
```

3. To update only the modification time:

```
touch -m *.o
```

This updates only the last modification times of the files in the current directory that end with .0. touch is often used in this way to alter the results of the make command.

4. To explicitly set the access and modification times:

```
touch -c 02171425 program.c
```

This sets the access and modification dates to 14:25 (2:25 p.m.) February 17 of the current year.

Related Information

The following command: "date" on page 281.

The utime system call in AIX Operating System Technical Reference.

"Overview of International Character Support" in Managing the AIX Operating System.

tplot

Purpose

Produces plotting instructions for a particular work station.

Syntax

OL805277

Description

The **tplot** command reads plotting instructions from standard input or from *file*, if specified. (For more information about plotting instructions, see the **plot** file format AIX Operating System Technical Reference). **tplot** writes instructions suitable for the specified workstation to standard output. If workstation is not specified, the environment variable **TERM** is used. (For more information about environment variables, see the **environ** file in AIX Operating System Technical Reference).

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flag

 $\textbf{-} \textbf{T} work station \quad \textbf{Uses the plotting instructions for } work station. \quad \textbf{The known } work station \text{ is:} \\$

lp IBM PC graphics printer

Files

/usr/lib/tcolor /usr/lib/tprint

Related Information

The following commands: "graph" on page 494 and "splp" on page 975.

The plot subroutine and the plot file in AIX Operating System Technical Reference.

tput

Purpose

Queries the terminfo file.

Syntax

OL805398

Description

The **tput.** command uses the **terminfo** file to make terminal-dependent information available to the shell. The output of **tput.** is a string if the attribute *capname* (for capability name) is of type string or an integer if the attribute is of type integer. If the attribute is of type Boolean, **tput.** simply sets the exit value (0 for TRUE, 1 for FALSE), and produces no other output.

Flags

-Ttype Indicates the type of work station. Normally, the value of type is supplied by the environment variable **\$TERM**.

capname Indicates the attribute from the terminfo file. For more information, see the terminfo file in AIX Operating System Technical Reference.

Examples

1. To echo the clear-screen sequence for the current work station:

tput clear

2. To display the number of columns for the current work station:

tput cols

3. To display the number of columns for the 450 work station:

tput -T450 cols

4. To set the shell variable bold to the highlight mode sequence for the current work station:

```
bold='tput smso'
```

This might be followed by a prompt:

```
echo "${bold}Please type in your name: \c"
```

5. To set the exit value to indicate if the current work station is a hardcopy terminal:

```
tput hc
```

Files

```
/usr/lib/terminfo/?/*
/usr/include/term.h
/usr/include/curses.h
```

Terminal descriptor files. Definition files.

Related Information

The following command: "stty" on page 1018.

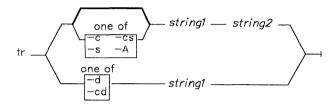

The terminfo file in AIX Operating System Technical Reference.

tr

Purpose

Translates characters.

Syntax

OL805278

Description

The tr command copies characters from the standard input to the standard output with substitution or deletion of selected characters. Input characters from *string1* are replaced with the corresponding characters in *string2*. tr cannot handle an ASCII NUL (\000) in *string1* or *string2*; it always deletes NUL from the input.

Abbreviations that can be used to introduce ranges of characters or repeated characters are:

[a-z] Stands for a string of characters whose ASCII codes run from character a to character z, inclusive.

[a*num] Stands for num repetitions of a. num is considered to be in decimal unless the first digit of num is 0; then it is considered to be in octal.

Use the escape character \setminus (backslash) to remove special meaning from any character in a string. Use the \setminus followed by 1, 2, or 3 octal digits for the ASCII code of a character.

Japanese Language Support Information

You can use two octal sequences to specify a 2-byte kanji character. If you specify ranges of kanji characters, they are interpreted for translation as a string of kanji characters in ascending sequence in their binary representation.

Flags

- -A Translates on a byte-by-byte basis. When you specify this flag, **tr** does not support extended characters.
- -c Complements (inverts) the set of characters in *string1* with respect to the universe of characters whose ASCII codes are 001 through 377 octal, if you specify -A, and all characters, if you do not specify -A.
- -d Deletes all input characters in string1.
- -s Changes characters that are repeated output characters in *string2* into single characters.

Examples

1. To translate braces into parentheses:

This translates each { to (and each } to). All other characters remain unchanged.

2. To translate lowercase characters to uppercase:

3. This is what happens if the strings are not the same length:

This translates each 0 to a # (number sign).

Note: If the two character strings are not the same length, then the extra characters in the longer one are ignored.

4. To translate each digit to a #:

The * tells tr to repeat the # enough times to make the second string as long as the first one.

5. To translate each string of digits to a single num:

6. To translate all ASCII characters that are not specified:

tr -c '[-
$$\sim$$
]' '[A- $_$]?' newfile

This translates each nonprinting ASCII character to the corresponding control key letter ($\setminus 001$ translates to A, $\setminus 002$ to B, etc.). ASCII DEL ($\setminus 177$), the character that follows \sim (tilde), translates to ?.

7. To create a list of the words in a file:

tr -cs
$$'[a-z][A-Z]'$$
 $'[\012*]'$ $<$ textfile $>$ newfile

This translates each string of nonalphabetic characters to a single new-line character. The result is a list of all the words in textfile, one word per line.

The ascii file in AIX Operating System Technical Reference.

"Overview of International Character Support" in Managing the AIX Operating System.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

trace

Purpose

Starts the trace function.

Syntax

OL805279

Description

The trace command starts the trace function in the background. This trace function provides a base for debugging the system. trace monitors the occurrence of selected events in the system and records on disk important data specific to each of these events. You can format this output with the trcrpt command.

Any user or program that needs the trace process enabled for debugging or error determination can start **trace**. When starting **trace**, you must provide a *profile*. This allows you to tailor the output of the trace session to individual needs. The default *profile* is /etc/trcprofile.

There may be more than one trace profile in the file system at a time. The trace profile contains the classes of events that you can select to trace, listed by event class and by a descriptive label. See "Example" on page 1089 for a sample profile. You may keep different profiles to trace different combinations of event classes. **trace** also takes additional information about the trace session from the configuration file /etc/rasconf (see AIX Operating System Technical Reference for a discussion of this file). You set the name and size of the output file in this configuration file.

In a multiuser environment, trace records all system events, not just events at one virtual terminal.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

-g filedes

Indicates that this is a *generic* trace session. Generic tracing applies only to the VRM. In this type of session, events to be recorded do not necessarily have a fixed event class, but are allocated to a temporary event channel by the trace device driver, /de v/vrmtrace. Thus, starting a generic trace does not require a trace profile. Generic traces are started and stopped by other processes, such as communications session managers. Therefore, the interface to the daemon is somewhat different. The -g flag is useful only when **trace** is started by another process.

The *filedes* parameter is a file descriptor from the parent process. **trace** writes this following information to this file descriptor:

- The process ID of the **trace** demon
- The address of the trace buffer
- The size (in bytes) of the trace buffer
- The temporary channel bit allocated to this event.

When tracing a generic event, the **trace** demon does not record its process ID so that it can be stopped by the **trcstop** command. Thus, more than one trace demon may be running at any time, but there may be as many as seven traces in the system at once (one normal trace and from one to six generic traces).

Use the trc_start and trc_stop subroutines to start and stop a generic trace.

Indicates that the VRM trace device driver should log only the last buffer filled before the **trace** demon stops. This flag is valid only during a generic trace (-g).

Specifies the name of the log file into which the trace demon stores the trace data. For generic traces (-g), this name must be different from the default file name specified in the configuration file /etc/rasconf.

Specifies the number of entries in the trace buffer. trace multiplies this number by the size of the entries (see the -s flag) and uses the resulting value to size the trace buffer. If you do not specify this flag, trace uses the buffer size specified in the configuration file /etc/rasconf.

-o name

-n num

-s size

Specifies the size (in bytes) of the entries that the **trace** demon will be handling. The default size is 40 bytes. The size can be no less than 20, which is the number of bytes in the trace header for each entry. All entries must be the same size in a particular trace log file.

Example

```

The rasconf configuration file in AIX Operating System Technical Reference.

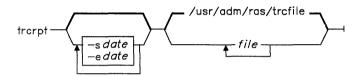

The discussion of trace in AIX Operating System Programming Tools and Interfaces.

trcrpt

Purpose

Formats a report from the trace log file.

Syntax

OL805280

Description

The trcrpt command writes to standard output a chronological listing in readable format of the trace log file or files specified. You can specify a maximum of ten log files. If you do not specify any files, trcrpt reads /etc/rasconf for a file name. This name is usually /usr/adm/ras/trcfile.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flags

- -e date Ends the report time with entries on or before date. The format of date is the same as the date command, MMddhhmmyy.
- -s date Starts the report with entries on or later than date. The format of date is the same as the date command, MMddhhmmyy. If you do not specify this flag, trcrpt formats the entire log file.

Example

To format a trace log file:

trcrpt -s0109100384 -e0109100584 /u/dave/trc_log | print

trcrpt

This formats the log file /u/dave/trc_log, starting with entries from January 09, 1984 at 10:03 and ending at 10:05. It pipes the formatted output to the print queue.

Files

/usr/adm/ras/trcfile Default log file. /etc/trcfmt Trace format file. /usr/adm/ras/.trcevents Trace event types table.

Related Information

The following commands: "trace" on page 1086 and "trestop" on page 1093.

The rasconf file in AIX Operating System Technical Reference.

The discussion of trcrpt in AIX Operating System Programming Tools and Interfaces.

trestop

Purpose

Stops the trace function.

Syntax

trostop ---

OL805223

Description

The trestop command sends a Software Terminate signal to the trace background process. This gracefully ends trace and forces cleanup.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Files

/tmp/trc_PIDs

Related Information

The following commands: "trace" on page 1086 and "trcrpt" on page 1091.

The discussion of trestop in AIX Operating System Programming Tools and Interfaces.

trcupdate

Purpose

Updates trace format templates.

Syntax

OL805399

Description

The trcupdate command adds, replaces, or deletes trace report format templates in the files /etc/trcfmt and /usr/adm/ras/.trcevents and event types in the file /etc/trcprofile. trcupdate creates three undo files in the current directory named file.undo.trc, .trcevents.undo.evt, and file.undo.pro. These undo files can be used as input to trcupdate with the -o (override) flag to undo the changes trcupdate has just made.

The **trcupdate** command reads three files named *file*.**trc**, *file*.**evt**, and *file*.**pro**. The **trc** file contains trace format templates; the **evt** file contains trace event types and their corresponding hook IDs; the **pro** file contains the event type line for the trace profile.

The first field of each template contains an operator:

- + To add or replace a template
- To delete a template.

If the operation is +, then the following fields contain the template to be replaced. The hook ID of the template is also added to the /usr/adm/ras/.trcevents file, and the event type line is added to the trace profile /etc/trcprofile. If the operation is a -, then the second field contains the hook ID of the template to delete. That hook ID is also deleted in /usr/adm/ras/.trcevents, and the event type line is deleted from /etc/trcprofile.

When adding or replacing, trcupdate compares the version numbers of each input template with the version number of the existing template of the same hook IDs. If the version number of the input template is later, it replaces the old template with the input template. If the template does not already exist, then it is added to the file. The input file must contain the identifier * /etc/trcfmt on the first line.

The file.evt file contains a table of trace system event types and hook IDs that fall under these types. trcupdate reads in the file /usr/adm/ras/.trcevents and adds in any hook IDs from file.evt that are not already accounted for or reassigns/deletes hook IDs to the event type given in the update file. The first line of the event/hook update file must be:

* /ras/.trcevents or trcupdate rejects the input file.

The file.pro contains the lines that are to be added to or deleted from /etc/trcprofile. trcupdate reads /etc/trcprofile and adds or deletes the specified event type line from file.pro. The first line of the event type file must be: * /etc/trcprofile or trcupdate rejects the input file.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Flag

-o Does no version number checking.

Examples

- 1. The following is a sample trc file:
 - * /etc/trcfmt
 - + 355 1.0 new_fmt
 - 351
 - 352
- 2. The following is a sample evt file:

```
* ras/.trcevents
350 355 356 357
```

Files

/etc/trcfmt /usr/adm/ras/.trcevents file.evt file.undo.evt file.trc file.undo.trc file.pro file.undo.pro

Related Information

The following command: "trcrpt" on page 1091.

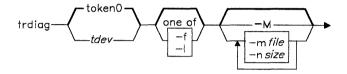

AIX Operating System Programming Tools and Interfaces.

trdiag

Purpose

Starts diagnostics on the Token-Ring Network.

Syntax

AJ2FL129

Description

The **trdiag** command starts the Token-Ring Diagnostics. Specify the device name of the token-ring adapter with *tdev* if you are not using **token0**.

Flags

- -f Selects full error reporting. This flag cannot be used with the -l flag.
- -l Selects limited error reporting. This flag cannot be used with the -f flag.
- -M Requests logging of MAC frames. This flag uses the MAC frame log file and size specified in the MAClog stanza of the /etc/trdconf file.
- -m file Specifies the MAC frame log file. The default file is specified in the MAClog stanza of the /etc/trdconf file.
- -n size Specifies the size, in 1024 byte blocks, for the MAC frame log file. The default size is specified in the MAClog stanza of the /etc/trdconf file.

trdiag

- -p queue Specifies the printer queue. If you do not specify the -p flag the default printer queue is used.
- -s size Specifies the size, in 1024 byte blocks, for the Token-Ring Diagnostic log file.

 The default is specified in the trdlog stanza of the /etc/trdconf file.
- -t file Specifies the file for the Token-Ring Diagnostic log file. The default file is specified in the trdlog stanza of the /etc/trdconf file.

Examples

- 1. To start Token-Ring Diagnostics with one token-ring adapter installed: trdiag
- 2. To start Token-Ring Diagnostics with full error reporting enabled: trdiag -f

Files

/etc/trdconf Default configuration file.

Related Information

"Token-Ring Diagnostics" in Managing the AIX Operating System.

true

Purpose

Returns an exit value of zero.

Syntax

```
true ----
false —
```

OL805064

Description

The true command returns a zero exit value. The false command returns a nonzero value. These commands are usually used in input to the sh command.

Example

To construct an infinite loop in a shell procedure:

```
while true
do
   date
   sleep 60
done
```

This shell procedure displays the date and time once a minute. To stop it, press INTERRUPT (Alt-Pause).

Related Information

The following command: "sh" on page 913.

tsh

Purpose

Interprets commands in a trusted shell.

Syntax

```
^X^R<sup>1</sup> — |
/bin/tsh — |

1
Press Ctrl-X Ctrl-R
```

AJ2FL136

Description

The AIX trusted shell (tsh) is a command interpreter which provides a subset of the functions of the sh command. The secure attention key (Ctrl-X, Ctrl-R) sequence (SAK) invokes the trusted shell. The trusted shell should be the login shell of the superuser. This command can also be issued by a program.

The following features are added to those of sh for the trusted shell (tsh):

- The shell command allows the user to return to the normal execution environment from tsh.
- The **logout** command allows the user to log off the system from **tsh**. This destroys any virtual terminals that the user may have opened.
- If /bin/tsh has the tcb attribute set, the user can only run trusted programs. A program must have the tcb attribute set to be executable by tsh.

The following sh features are not supported by tsh:

- PATH and IFS variable redefinition.
- Function/alias definition.

When started, this command interprets the /etc/tsh file. This file may contain a definition of the PATH variable.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

Contains initialization commands. /etc/tsh_profile

Related Information

The following commands: "init" on page 521 and "shell" on page 938 The discussion of the trusted path and sak in Managing the AIX Operating System.

tsort

Purpose

Sorts an unordered list of ordered pairs (a topological sort).

Syntax

OL805224

Description

The **tsort** command reads from *file* or standard input an unordered list of ordered pairs, it builds a completely ordered list, and writes it to standard output.

The input *file* should contain pairs of nonempty strings separated by blanks. Pairs of different items indicate a relative order. Pairs of identical items indicate presence, but no relative order. You can use **tsort** to sort the output of the **lorder** command.

If file contains an odd number of fields, tsort writes the error message Odd data.

Example

To create a subroutine library:

```
lorder charin.o scanfld.o scan.o scanln.o \
tsort | xargs ar qv libsubs.a
```

This creates a subroutine library named libsubs.a that contains Charin.o, scanfld.o, scan.o, and scanln.o. The ordering of the object modules in the library is important. The ld command requires each module to precede all the other modules that it calls or references. The lorder and tsort commands together add the subroutines to the library in the proper order.

Suppose that scan.o calls scanfld.o and scanln.o. scanfld.o also calls charin.o. First, the lorder command creates a list of pairs that shows these dependencies:

```
charin.o charin.o
scanfld.o scanfld.o
scan.o scan.o
scanln.o scanln.o
scanfld.o charin.o
scanln.o charin.o
scan.o scanfld.o
```

Next, the I (vertical bar) sends this list to the tsort command, which converts it into the ordering needed:

```
scan.o
scanfld.o
scanln.o
charin.o
```

Note that each module precedes the module it calls. charin.o, which does not call another module, is last.

The second I then sends this list to xargs, which constructs and runs the following ar command:

```
ar qv libsubs.a scan.o scanfld.o scanln.o charin.o
```

This ar command creates the properly ordered library.

Related Information

The following commands: "ar" on page 55, "lorder" on page 591, and "xargs" on page 1232.

ttt

Purpose

Plays tic-tac-toe.

Syntax

OL805282

Description

The ttt game plays the popular X and O game. This is a learning version, but it learns slowly. It loses nearly 80 games before completely mastering the game.

Flags

- -e Increases the speed of the learning.
- -i Displays the instructions prior to the start of the game.

To quit the game, press INTERRUPT (Alt-Pause) or END OF FILE (Ctrl-D).

Files

/usr/games/ttt.a Learning file.

tty

Purpose

Writes to standard output the full path name of your work station.

Syntax

OL805283

Description

The tty command writes the name of your work station to standard output.

Flag

- Suppresses reporting the path name. The exit value has the following possible meanings:
 - Standard input is a work station.
 - Standard input is not a work station. 1
 - Invalid flags specified.

If your standard input is not a work station and you do not specify the -s flag, you get the message not a tty.

Examples

1. To display full path name of your work station:

```
tty
```

2. To test whether or not the standard input is a work station:

```
if tty -s
  echo 'Enter the text to print:' >/dev/tty
print
```

If the standard input is a work station, this displays the message Enter the text to print: as a prompt and prints the text that the user types. If the standard input is not a work station, this displays nothing. It merely prints the text read from the standard input.

The echo . . . >/dev/tty displays the prompt on the screen even if you redirect the standard output of the shell procedure. This way the prompt is never written into an output file. The special file /dev/tty always refers your work station, although it also has another name like /dev/console or /dev/tty2.

turnon

Purpose

Turns on execute permission for games.

Syntax

turnon — OL805405

turnoff — OL805406

Description

The turnon and turnoff commands are shell procedures that set the permission codes of files in the /usr/games directory. You must be operating with superuser authority to run this command.

The turnon command looks for files with permissions set to 000 and sets them to 111 (execute permission for all users).

The turnoff command looks for files in /usr/games whose permissions are set to 111 and sets these permissions to 000.

If you install any new games in the /usr/games directory, set their permissions to 111.

tvi

Purpose

Acts as trusted editor for system administration.

Syntax

OL805557

Description

The tvi command provides an editor that works with a subset of the functions of the vi editor. It creates files only when called by the user. When auditing is enabled, and a file is edited using this command, an audit record of the type tvi is created.

The following vi features are not supported by tvi:

- Shell escapes
- User-defined macros
- Key mapping
- Keeping customized changes
- The -r [file] and -t tag flags
- Preserve or recover text operations
- Tags

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Related Information

The "vi, vedit, view" on page 1187 commands.

ugtable

Purpose

Creates, displays, and changes the Distributed Services Network Users/Groups Table.

Syntax

ugtable ---

OL805469

Description

The ugtable command lets you build, examine, or modify the Distributed Services Network Users/Groups Table. Only members of the system group or users operating with superuser authority can use ugtable to change the state of the Distributed Services Network Users/Groups Table (see "su" on page 1026). Other users can use ugtable to browse the Network Users/Groups Table.

Related Information

"Getting Started With Distributed Services Configuration Menus" in Managing the AIX Operating System.

umask

Purpose

Displays and sets file-creation permission code mask.

Syntax

OL805286

Description

The umask command sets your file-creation mask to nnn, three octal digits that represent the read/write/execute permissions for owner, group, and others, respectively. When you create a file, the system ANDs the complement of nnn to 777 for directories and 666 for files, in effect removing the corresponding permissions. (See "chmod" on page 160 for more information on file and directory permission codes.)

If you do not specify *nnn*, **umask** displays the current value of your file-creation permission code mask. The initial system mask (set in /etc/profile) is 022.

Examples

1. To display the current file creation mask:

umask

2. To prevent other people from writing to your directories or files:

umask 022

This sets the file creation mask to 022, which takes away write permission for group members and others. Directories are created with the permission code 755. Files are created with 644.

3. To prevent other people from using your files:

umask 077

This sets the file creation mask to 077, which removes read, write, and execute permission for group members and others. Now files are created with permission code 600.

Related Information

The following commands: "chmod" on page 160, "csh" on page 225, and "sh" on page 913.

Note: The **csh** command contains a built-in subcommand named **ummask**. The command and subcommand do not necessarily work the same way. For information on the subcommand, see the **csh** command.

The creat, chmod, mknod, open, and umask calls in AIX Operating System Technical Reference.

The discussion of file permissions in Using the AIX Operating System.

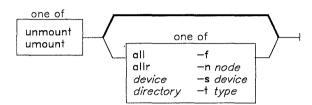

The discussion of tailoring the user environment in Managing the AIX Operating System.

umount, unmount

Purpose

Unmounts a previously mounted file system, directory, or file.

Syntax

OL805225

Description

The **umount** command unmounts a previously mounted file system, directory, or file. Processing on the file system, directory, or file completes and it is unmounted. Members of the system group and users operating with superuser authority can issue any **umount** command. Other users can unmount any directory or file if they have write permission to the mounted directory or file. For local mounts, you can specify the file system, directory, or file as either the *directory* or *device* on which it is mounted.

You can also specify one of the following parameters:

all

Unmounts all mounted file systems.

allr

Unmounts all remote mounted file systems.

Note: For remote mounts, specify the directory of the file as directory. If you specify allr, umount unmounts all remote mounts.

Flags

-f

Forces the unmount of one or more virtual file systems. Use in a distributed services or NFS environment to free a client when the server is down and server path names cannot be resolved.

-n node	Specifies the node which holds the mounted directory that you want to unmount. For Distributed Services, <i>node</i> can be a nickname or a node ID. For NFS, <i>node</i> can be a host name or an alias. The umount -n <i>node</i> command unmounts all remote mounts made from <i>node</i> .
-s device	Prohibits the use of the /etc/mnttab file if it is damaged or not writable. If you use this flag, you must specify the name of the device to be unmounted.
-t type	Unmounts all stanzas in /etc/filesystems that contain type = type and are mounted. (type is a string value, such as remote.)

Note: You cannot use the umount command on a device that is in use. A device is in use if any file is open for any reason or if a user's current directory is on that device.

Examples

1. To unmount a diskette drive:

umount /dev/fd0

2. To unmount the device mounted on /diskette0:

umount /diskette0

3. To unmount all mounts from a remote node:

umount -n nodeA

4. To unmount files and directories of a specific type:

umount -t remote

This unmounts all files or directories that have a stanza in the /etc/filesystems file that contains the attribute type = remote.

Files

/etc/filesystems Descriptions of mountable file systems.
/etc/mnttab Table of currently mounted file systems.

Related Information

The following command: "mount" on page 669.

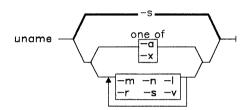

The mount, umount, vmount, uvmount, and mntctl system calls and the mnttab file in AIX Operating System Technical Reference.

uname

Purpose

Displays the name of the current operating system.

Syntax

OL805287

Description

The uname command writes to the standard output the name of the operating system that you are using.

Flags

- -a Displays all information specified with the -m, -n, -r, -s, and -v flags.
- -l Displays the LAN network number. (When Japanese Language Support is installed on your system, the -l flag is inactive.)
- -m Displays the type of hardware running the system.
- -n Displays the name of the node (this may be a name the system is known by to a uucp communications network).
- -r Displays the release number of the operating system.
- -s Displays the system name. (This flag is on by default.)
- -S Sets the uucp node name to the arguments parameter list.
 - Note: You must be superuser to use this flag. No other flags are permitted.
- -v Displays the operating system version.
- -x Displays the information specified with the -a flag and the LAN network number. (When Japanese Language Support is installed, the -x flag is inactive.)

If you enter a flag that is not valid, uname exits with an error message, an error return status, and no output.

Example

To display the complete system name and version banner:

uname -a

To set the node name to lance:

uname -S lance

Related Information

The uname system call in AIX Operating System Technical Reference.

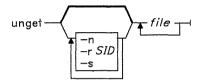

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

unget

Purpose

Cancels a previous get command.

Syntax

OL805284

Description

The unget command allows you to restore a g-file created with get -e before the new delta is created, and therefore discarding the changes (see "get" on page 477 and "delta" on page 310). If you specify a - (hyphen) in place of file, standard input is read, and each line of standard input is interpreted as the name of an SCCS file. unget continues to take input until it reaches an end-of-file character, which is Ctrl-D if entered from the keyboard.

If you specify a directory in place of *file*, **unget** performs the requested actions on all SCCS files (those files with the s. prefix).

Flags

Each flag or group of flags applies independently to each named file.

- -n Prevents the automatic deletion of the g-file. This flag allows you to retain the edited version of the file without making a delta.
- -rSID Specifies the new delta that would have been created by the next use of the **delta** command. You must use this flag if you have two or more pending deltas to the file under the same login name. You can look at the p-file to see if you have more than one delta pending to a particular SID under the same login name. The SID specification must unambiguously specify only one SID to discard, or **unget** displays an error message and stops running.
- -s Suppresses writing the deleted SID to standard output.

Example

To discard the changes you have made to an SCCS file after entering a **get -e**: unget s.prog.c

Related Information

The following commands: "delta" on page 310, "get" on page 477, and "sact" on page 862.

The sccsfile file in AIX Operating System Technical Reference.

The discussion of SCCS in AIX Operating System Programming Tools and Interfaces.

uniq

Purpose

Deletes repeated lines in a file.

Syntax

OL805285

Description

The **uniq** command reads standard input or *infile*, compares adjacent lines, removes the second and succeeding occurrences of a line, and writes to standard output or the specified file *outfile*. *infile* and *outfile* should always be different files. Repeated lines must be on consecutive lines in order to be found. You can arrange them with the **sort** command (see page 958) before processing.

Flags

-c Precedes each output line with a count of the number of times each line appears in the file. This flag supersedes -d and -u.

-d Displays only the repeated lines.

-u Displays only the unrepeated lines.

-num Skips over the first num fields. A field is a string of nonspace, nontab characters separated by tabs and or spaces from adjacent data on the same line.

+ num Skips over the first num characters. Fields specified by num are skipped before characters.

Related Information

The following commands: "comm" on page 183 and "sort" on page 958.

units

Purpose

Converts units in one measure to equivalent units in another measure.

Syntax

units----

OL805226

Description

The units command converts quantities expressed in one measurement to their equivalents in another. units is an interactive command. It prompts you for the unit you want to convert from and the unit you want to convert to (see "Examples" on page 1120). This command only does multiplicative scale changes. That is, it can convert from one value to another only when the conversion is done with a multiplication factor. For example, it cannot convert between degrees Fahrenheit and degrees Celsius, because 32 must be added or subtracted in the conversion.

You can specify a quantity as a multiplicative combination of units, optionally preceded by a numeric multiplier.

Indicate powers by suffixed positive integers and division by / (slash).

The units command recognizes lb as a unit of mass, but considers pound to be the British pound sterling. Compound names are run together (such as lightyear). Prefix British units differing from their American counterparts with br (brgallon for instance). The file /usr/lib/unittab contains a complete list of the units that the units command uses.

Most familiar units, abbreviations, and metric prefixes are recognized, together with the following:

pi	Ratio of circumference to diameter
\mathbf{c}	Speed of light
e	Charge on an electron
g	Acceleration of gravity
force	Same as g
mole	Avogadro's number

water Pressure head per unit height of water

au Astronomical unit.

Japanese Language Support Information

This command has not been modified to support Japanese characters.

Examples

To start the units command, enter:

units

Now you can try the following examples. In these examples, the text that you enter is shown in **bold type** and the output from **units** is shown in non-bold type.

1. To display conversion factors:

```
you have: in
you want: cm
* 2.540000e+00
/ 3.937008e-01
```

The output from units tells you to multiply the number of inches by 2.540000e+00 to get centimeters, and to multiply the number of centimeters by 3.937008e-01 to get inches.

These numbers are in standard exponential notation, so 3.937008e-01 means 3.937008×10^{-1} , which is the same as 0.3937008. The second number is always the reciprocal of the first. That is, $2.54 = 1 \div 0.3937008$.

2. To convert a measurement to different units:

```
you have: 5 years
you want: microsec
* 1.577846e+14
/ 6.337753e-15
```

The output shows that **5 years** equals 1.577846×10^{14} microseconds, and that one microsecond equals 6.337753×10^{-15} years.

3. To give fractions in measurements:

```
you have: 1:3 mi
you want: km
* 5.364480e-01
/ 1.864114e+00
```

The I (vertical bar) indicates division, so 113 means one-third. This shows that one-third mile is the same as 0.536448 kilometers.

4. To include exponents in measurements:

```
you have: 1.2-5 gal
you want: floz
* 1.536000e-03
/ 6.510417e+02
```

The expression 1.2-5 gal stands for 1.2×10^{-5} . Do *not* type an e before the exponent. This example shows that 1.2×10^{-5} (0.000012) gallons equal 1.536×10^{-3} (0.001536) fluid ounces.

5. To specify complex units:

```
you have: gram centimeter/second2
you want: kg-m/sec2
* 1.000000e-05
/ 1.000000e+05
```

The units gram centimeter/second2 mean "grams \times centimeters \div second²." Similarly, kg-m/sec2 means "kilograms \times meters \div sec²," which is often read as "kilogram-meters per seconds squared." Note that you can show multiplication of units with a - (hyphen) or with a blank.

6. If the units you specify after "you have" and "you want" are incompatible:

```
you have: ft
you want: lb
conformability
3.048000e-01 m
4.535924e-01 kg
```

The message conformability means that the units you specified cannot be converted. Feet measure length, and pounds measure mass, so converting from one to the other doesn't make sense. Therefore, the units command displays the equivalent of each value in standard units.

In other words, this example shows that one foot equals 0.3048 meters and that one pound equals 0.4535924 kilograms. **units** shows the equivalents in meters and kilograms because the command considers these units to be "standard" measures of length and mass.

Files

/usr/lib/unittab

updatep

Purpose

Updates one or more programs.

Syntax

Description

Warning: Before you apply or reject an update, restart your system and make sure no other programs are running and no other work stations are enabled.

OL805392

The **updatep** command controls the update process for one or more programs. It also lets you determine the status of pending program updates and provides documentation about the updates. In addition, **updatep** can provide a list of the committed updates for each licensed program and the information changed by the update. You must be a member of the system group or operating with superuser authority to run this command.

The **updatep** command supports an apply/commit/reject philosophy. To apply one or more programs, use the **-a** or the **-ai** flags. Then use either the **-c** flag to commit the program or the **-r** flag to reject the program. Normally you do not use **-r** until you have tested the program on your system. If you specify **-ac** or **-aci**, you can apply and commit in one operation. The **-r** flag must be used separately. During an apply, **updatep** normally saves the current versions of files that are being updated. If needed, these files can be used to do a recovery or reject.

You are responsible for reserving update save space in the /usr file system. The updatep command checks to insure there is adequate save space in /usr before it applies an update. If there is insufficient free space, updatep gives you the option of either ending the command or allowing it to continue. If you end the command, you can take action to increase the free space in your /usr file system. If you continue, no current versions of files are saved, and updatep automatically commits the update, even though you may not have requested a commit originally. Normally, you should reserve 4000 blocks (2 megabytes) of free space in the /usr file system for updates.

You cannot use **INTERRUPT** (Alt-Pause) to stop the **updatep** command. To stop **updatep**, press **QUIT WITH DUMP** (Ctrl-V). Use only in extreme circumstances since the state of the system cannot be predicted. For example:

- The write-verify feature may be left on for all minidisks. See "verify" on page 1186.
- All terminals other than the console may be disabled. See "pstart, penable, pshare, pdelay" on page 791.
- Some update control files may need to be deleted.

Flags

- -a Shows authorized program analysis reports (APARs) that have been fixed for the licensed program products (LPPs) specified if none are given. This flag then shows all installed LPPs.
- -a[i] Applies the updates for one or more programs. If there is a pending update for any program on the system, **updatep** does not permit an apply. You must either commit or reject all pending updates before it accepts another update apply.

The **updatep** command asks you to select the program you wish to update. After you select a program, **updatep** runs the **inudocm** command for any specific update instructions. If it finds any, it copies them into the /usr/lpp/pgm-name/ui.vv.rr.llll. file, where vv is the version, rr the release, and llll the level of the program. Review instructions before continuing. To restart the update procedure and ignore the check for existing update instructions, enter updatep -ai or updatep -aci.

The **updatep** command applies the update for each program by running **inuupdt** for each name. After each update, it deletes the /usr/lpp/pgm-name/inst_updt directory. It then runs **inudocm** to check for any update documentation. If there is information for a manual, **updatep** copies it into the /usr/lpp/pgm-name/me.vv.rr.lll file and writes a message.

-A programname

Displays a record of the applied licensed programs on your system. When used with this flag **updatep** also displays the specific areas corrected in each

program. If you specify the name of the program, **updatep** displays information for only that program.

- -b Runs the **bffcreate** command to create a backup format file from the distribution media. Then tells **updatep** to use the backup file as the distribution media for the update. Use this flag to update in a code service environment.
- -c Commits a previous update apply. The **updatep** presents selection information for programs that have pending updates. You select the programs that you want to commit.

Any programs that you apply as a group must be committed as a group. Management control information about the update changes to indicate that the program is committed. **updatep** deletes the directory that contains the update recovery information, /usr/lpp/pgm-name/inst_updt.save.

-d device Specifies the input device name. The default input device is /dev/rfd0.

- -n user Lets you specify a name in the program history file that is responsible for the program. The default is the value of the system variable \$LOGNAME. If you specify user, the first eight nonblank characters are stored in the program history file.
- -q Runs in quiet mode, suppressing most of the interactive queries.
- -r Rejects a previous update apply for one or more programs. **updatep** presents selection information for the programs that have pending updates. You select the programs to reject.

Any programs that are grouped together by the system must be rejected or applied as a group. Specify -r without -x if you want automatic recovery of saved files. If you specify the -x flag, the management control information about the update reflects that the update is rejected, but updatep does not recover saved files. To recover the necessary files, look at the information in /usr/lpp/pgm-name/inst_updt.save. This flag should only be used by someone very knowledgeable about the system.

- -s Writes status information about all pending program updates.
- -x Cancels the automatic recovery of saved files. (Use with -r.)

The **updatep** command receives the following exit codes indirectly from **update** through **inuupdt**:

- 0 Normal return, no errors indicated.
- 2 Use the **sync** command to update the super blocks, i-nodes, and delayed block I/O and then restart the AIX Operating System.
- Build the kernel, then update the superblocks, i-nodes, and delayed block I/O (sync) and shut down the AIX Operating System.

- 4 Use the **cfgaply** subroutine to build the kernel. Use the **sync** command to update the super blocks, i-nodes, and delayed block I/O and then restart the AIX Operating System.
- 5 Installation cancelled without errors.
- 6 Update superblocks, i-nodes, and delayed block I/O (sync), then shut down the AIX Operating System.
- 7 Update cancelled by update procedure; recovery needed.

If it receives any other exit code, it runs the recovery function **inurecv**. If the system cannot run **updatep**, it returns an exit code of 1.

Internal Commands

The **updatep** command uses the **inudocm** command for update documentation control. It uses the **inuupdt** command to apply an update to a single program. **inuupdt** runs a program-provided update procedure, **update**. **updatep** passes the following parameters to the **update** procedure:

- The full path name of the apply-list.
- The full path name of the device (file), where the update information is stored in backup format.

In addition to the commands discussed here, program-provided update procedures can use all of the internal commands discussed in "installp" on page 529. Since they are internal commands, they do minimum validation of input parameters. Their purpose is to provide common code for functions frequently needed by most program-provided procedures. Since these internal commands function as subcommands, they return exit values rather than issue error messages. However, messages may come from other system commands that they run. C Language programmers of update procedures that call these commands can use the /usr/include/inu21.h file to define the return codes for them.

inudocm

The **inudocm** command is normally used as an internal command to get copies of specific update instructions or manual errata information that you can print out. There can be cases, however, when you would enter this command from the command line (for example, if you misplace the manual errata information that came with a previous update). You must be a member of the system group or operating with superuser authority to run this command. When auditing is on, an audit record of the type, **inudocm** is created.

The inudocm command has the following syntax:

inudocm -eu [-d device] [pgm-name] [level] [-f file]

where pgm-name specifies the name of the program being checked. It must be specified unless you use the -f flag. It can be a maximum of eight characters. level specifies the current level of pgm-name. This value must be identical to the level value for the last

committed entry in /usr/lpp/pgm-name/lpp.hist. It must be specified unless you use the -f flag.

Flags

- -d device Restores file from this device. The device variable must be the full path name of a device special file. The default device is /dev/rfd0. Do not specify this flag if you use the -f flag.
- Requests the existing update documentation information for pgm-name from level. If you select this flag, inudocm uses the ar x command to extract the archive file /usr/sys/inst_updt/pgm-name_erata. If this file is not present, no information is available. inudocm extracts any level-dependent manual errata information files if there are any more recent than the current level. Selected files are moved to /usr/lpp/pgm-name/me.vv.rr.llll.
- -f file Identifies a file that already contains the pgm-name and the level. Only updatep itself should use this flag.
- -u Requests the existing specific update instructions for pgm-name from level. If you select this flag, inudocm uses the ar x command to extract the archive file /usr/sys/inst_updt/pgm-name_instr. If this file is not present, no information is available. inudocm extracts any level-dependent specific update instruction files if there are any more recent than the current level. Selected files are moved to /usr/lpp/pgm-name/ui.vv.rr.llll.

The inudocm command returns the following exit values:

- **0** Normal return, no error occurred.
- 1 The system cannot run inudocm.
- 2 Specific update instruction files were requested but not found.
- 4 Manual errata information was requested, but not found.
- 6 Specific update instructions and manual errata were both requested but not found.
- 201 An invalid flag was specified, or the first argument was not -e, -eu, or -u.
- 202 One or more parameters were missing.
- 204 Too many parameters were entered.
- 250 The level parameter did not contain exactly 4 characters, or they were not numeric.
- 251 An error occurred while attempting to restore /usr/sys/inst_updt/control.
- 253 The directory /usr/lpp/pgm-name does not exist.

inuupdt

The inuupdt command provides a common interface for applying an update to a single program. Normally, updatep runs inuupdt.

The inuupdt command has the following format:

inuupdt -d device current-level new-level pgm-name

where pgm-name is the name of a program and current-level specifies the current maintenance level. new-level is the level of the update to be applied. pgm-name can be a maximum of eight characters and current-level must be identical to the level value in the /usr/lpp/pgm-name/lpp.hist file.

The inuupdt command passes the following exit values to the process that called it:

0	Normal return.
2	Use the sync command to update the super blocks, i-nodes, and delayed
	block I/O, and then restart the VRM.
3	Build the kernel, then update the superblocks, i-nodes, and delayed block
	I/O (sync) and shut down the VRM.
4	Use the cfgaply subroutine to build the kernel. Use the sync command to
	update the super blocks, i-nodes, and delayed block I/O and then restart the
	VRM.
5	Installation cancelled without errors.
6	Update superblocks, i-nodes, and delayed block I/O (sync), then shut down
	the VRM.
7	Update cancelled by update procedure, recovery needed.
101-102	Places error code in the history file.
104-107	Places error code in the history file.
201-202	Places error code in the history file.
204-208	Places error code in the history file.
	· · · · · · · · · · · · · · · · · · ·

The inuupdt command returns the following exit status values:

- 100 Unknown return code received by **inuupdt**. It changes any unknown return code to 100 and logs it in the history file.
- 103 The restore of the archive file that contains the update control list, /usr/lpp/pgm-name/inst_updt/arp, failed.
- 201 An invalid flag was specified.
- 202 One or more parameters were missing.
- 203 Apply list does not exist or was not readable.
- 204 Too many parameters were entered.

Flag

-d device Updates the program from the specified device.

The discussion of updating programs in AIX Operating System Programming Tools and Interfaces.

users, adduser

Purpose

Adds, deletes, and changes user and group information.

Syntax

OL805076

Description

The users command lets you add, change, or delete user and group information in the /etc/passwd, /etc/group, /etc/security/passwd, and /etc/security/group files. To use the users command, you must be a member of the system group or have superuser authority (see "su" on page 1026).

The users command does all of its work in temporary files. When you enter the quit subcommand, the temporary files become the permanent files. The old versions of /etc/passwd and /etc/group are renamed /etc/opasswd and /etc/ogroup. The old versions of /etc/security/passwd and /etc/security/group are renamed /etc/security/opasswd and /etc/security/ogroup. If users is ended by an INTERRUPT (Alt-Pause), it removes the temporary files, and the system files remain as they were before the session. However, any directories created still exist, so you may have to remove directories after sending an INTERRUPT.

For configuration, **users** uses the file /**usr/adm/user.cfile**, the file specified with *configfile*, or the default parameters that follow:

Parameter	Default Value	Description
udir	/u/	Prefix of user home directory names.
program	null	The name of the user login program.
siteinfo	null	Any site-specific information.

Figure 12 (Part 1 of 2). Configuration File Parameters

Parameter	Default Value	Description
filesize	null	Size, in blocks, of the largest file that a user can make.
gname	staff	Name of the group to which a user is initially assigned.
minid	200	Minimum number that can be assigned as a user or group ID.
maxid	60000	Maximum number that can be assigned as a user or group ID.
pfile	/etc/passwd	Name of the password file.
gfile	/etc/group	Name of the group file.
owner	bin	Name of the owner of password and group files.
invalid	/usr/lib/sorry	Program for invalid accounts.

Figure 12 (Part 2 of 2). Configuration File Parameters

For information on how to use the users command, see Managing the AIX Operating System.

Notes:

- 1. The following files must exist on the same node:
 - /etc/passwd
 - /etc/opasswd
 - /etc/security/passwd
 - /etc/security/opasswd
 - /etc/group
 - /etc/ogroup
 - /etc/security/group
 - /etc/security/ogroup
 - /usr/adm/user.cfile
- 2. Each group has a limit of 500 users with eight-character IDs. Shorter IDs may allow more users per group.
- 3. It is possible to delete a user who still owns files or to delete a group that still has members. However, if you do this, it may cause problems later if the user name or group name is reused.

Subcommands

add Adds a new user or group.

Changes data for an existing user or group. change

delete Deletes an existing user or group.

Displays a summary of available commands. Entering a question mark (?) help

also works for help.

invalidate Changes a user's shell to a do-nothing program.

quit Updates files and exits.

show Shows information about a user or group.

The initial letter of each subcommand is recognized as the subcommand name.

Examples

The following is a sample /usr/adm/user.cfile:

pfile /etc/passwd qfile /etc/group owner root

200 minid 1000 maxid udir /u/ /bin/sh program

/etc/ogroup

staff gname /usr/lib/sorry invalid

Files

Default configuration file. /usr/adm/user.cfile

/usr/adm/newuser.svs Initialization shell file for added users. /usr/adm/newuser.usr Initialization shell file for added users. Password file that identifies all known users. /etc/passwd

/etc/security/passwd A file which in conjunction with /etc/passwd contains

information about user passwords.

/etc/group Group file that identifies all known groups.

A file which in conjunction with /etc/group contains /etc/security/group

information about group passwords.

/etc/opasswd Saved previous version of the password file. /etc/security/opasswd

Saved previous version of the security password file.

Saved previous version of the group file.

/etc/security/ogroup Saved previous version of the security group file.

uucpadm

Purpose

Enters basic **uucp** configuration information

Syntax

uucpadm ——

A5AC5023

Description

The **uucpadm** command provides interactive entry and modification of basic **uucp** configuration information for the Devices, Systems, Permissions, Poll, and Dialcodes files.

The **uucpadm** command uses a copy of a file to record changes. The original file remains unchanged until you enter Ctrl-U or Ctrl-X at the appropriate menu. You can use uucpadm repeatedly to adjust the same file.

The **uucpadm** program checks the data as it is entered. If an inconsistency in the **uucp** files is found, **uucpadm** displays a warning message.

The help routine provides instructions for each data field. Enter a? (question mark) at any menu component to access the help routine for that field. Enter a ~ (tilde) at any menu component to edit the appropriate file for that field. The uucpadm command invokes the editor designated by the EDITOR environmental variable. If EDITOR is not set, uucpadm invokes /usr/bin/vi.

If your entry for the first menu item matches an existing record, uucpadm retrieves that record for update. The uucpadm program also tells you how many records have that first entry.

Initial **uucp** configuration requires that local network information be included in the Devices, Systems, and Permissions files, in that order. The help routine provides examples of initial entries for these files.

The Devices file contains profiles of all physical devices which uucp can use to establish a connection with a remote host. The first field in the **Devices** file is type, used to indicate the type of communications device.

uucpadm

The following keywords are recognized by type:

Direct A direct link to another computer.

ACU An automatic call unit.

Built-in A built in or standard function, such as TCP.

System name A direct link to a specific computer.

The *line1* field specifies the device name associated with this entry. The *line2* field specifies the device name associated with a dialer. The *dialers* field is actually a dialer token pair field with the token optional. If the device is an automatic dialing modem, *dialers* is usually the brand name of the modem. In all cases the *dialers* field matches a record in the **Dialers** file.

A **Systems** file entry is required for each machine you communicate with. Unless remote.unknown is configured on your system, a **Systems** file entry is required for each machine that communicates with you. The remote.unknown entry allows access by unknown hosts.

The name field is the short node name of the remote host. The uname -n command can be used to obtain the name field. For example, if the uname -n command returns lance.aus.ibm.com, enter lance for name. The time field specifies when calls are permitted.

The **Permissions** file specifies options for machine access, file access, and command execution. These options take effect when a remote host logs in to your machine or you log in to a remote host.

The first prompt for an entry to the **Permissions** file is L/M. This entry must be either LOGNAME=(login) or MACHINE=(short node name). If LOGNAME is entered, permissions are defined which will take effect when a remote host enters this login ID. If MACHINE is entered, permissions are defined which take effect when you log in to a remote host.

The **Poll** file specifies machines in your **uucp** network to be polled. Each entry contains the name of the machine to be polled and the hours the machine should be called.

The **Dialcodes** file specifies dial code abbreviations to be used in the phone number entry of the **Systems** file. Each record contains an entry for abbreviation and dial code.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Examples

1. An entry to the **Devices** file with a direct 9600 baud connection to the lance machine on /dev/tty2:

```
Type = lance
line1 = ttv2
line2 = -
class = 1200
dialers = direct
```

2. An entry to the systems file of the lance.aus.ibm.com system connected to an ACU device in class 2400:

```
Name = lance.aus.ibm.com
Time = Anv
Tvpe = ACU
Class = 2400
Phone = 997 - 7942
Login = nuucp
Password = saysme
```

A LOGNAME entry to the **Permissions** file:

```
L/M: LOGNAME=uucpz
Request: yes
Sendfiles: yes
Read: /
Write: NOWRITE=/etc
Callback:
Commands:
Validate: lance:backwoods
```

If the remote machine is lance or backwoods, the login ID must be UUCPZ. Remote hosts using this ID can Request to receive files, and your host can Sendfiles as requested. Users with this ID can read all files with other permissions and can write to all files, except those in /etc, with other permissions.

uucpadm

4. A MACHINE entry to the **Permissions** file:

L/M: MACHINE=lance
Request: yes
Sendfiles:

Read: NOREAD=/etc
Write: NOWRITE=/etc

Callback: Commands: ALL Validate:

The machine ID is lance. Requests for file transfers can be made. The user can Read all files and can Write to all files except those in /etc. The execution of all Commands is permitted.

5. An entry to the **Poll** file consisting of the **lance.aus.ibm.com** system to be polled at 12pm, 9am, 1pm, and 6pm:

6. An entry to the **Dialcodes** file with LA as the abbreviation for the Los Angeles area code:

Files

/usr/adm/uucp/Devices /usr/adm/uucp/Dialcodes /usr/adm/uucp/Dialers /usr/adm/uucp/Permissions /usr/adm/uucp/Poll /usr/adm/uucp/Systems Information about available devices. Dialing code abbreviations. Initial handshaking on a link. Access permission codes. Machines to be polled. Accessible remote systems.

Related Information

The following commands: "uucp" on page 1144, and "uname" on page 1114.

uucheck

Purpose

Checks for files and directories required by BNU.

Syntax

AJ2FL107

Description

The uucheck command checks for the presence of the files and directories required by the Basic Networking Utilities (BNU) facility. The command also checks for errors in the permissions file, /usr/adm/uucp/Permissions.

Note: The uucheck command does not check file/directory modes or some errors in the permissions file, such as duplicate login or machine names.

When BNU is installed, uucheck verifies that the directories, programs, and support files required to operate the networking facility are present. The command is executed automatically, as one of the first steps in the installation process, before the required BNU directories, programs, and files are actually installed.

Note: The uucheck command can be issued from the command line if the user has superuser privileges. For example, it would be useful to issue uucheck after making changes in part of the BNU facility such as the **Permissions** file.

Flags

Gives a detailed explanation of how the BNU programs interpret the $-\mathbf{v}$ permissions file.

-x debug_level Displays debugging information on the screen of the local terminal. The valid range for debug_level is 0 to 9. The higher the number, the more detailed the final report.

uucheck

Files

/etc/locks/LCK*
/usr/adm/uucp/Devices
/usr/adm/uucp/Maxuuscheds
/usr/adm/uucp/Maxuuxqts

uucico

Purpose

File transport program for the BNU facility.

Syntax

AJ2FL108

Description

The **uucico** program transports Basic Networking Utilities (BNU) requests. The BNU commands **uucp** and **uux** both queue jobs that are transferred to the specified computer by **uucico** after the required data, work, or execute files have been created.

The **uucico** program is normally started by the scheduler, **uusched**, but it can be started manually for debugging. The BNU commands **uutry**, **Uutry**, **Nutry**, and **uukick** also start **uucico** with debugging turned on.

The **uucico** program is a BNU daemon (a program executed internally to handle file transfers and command executions). It selects the device used for the communications link, establishes the connection to the remote computer, and performs the required login sequence. The program also performs permission checks, transfers data (**D.***) and command (**C.***) files, logs results, and notifies specified users of transfer requests.

Flags

- -r role_number The role numbers are the number 1 for the server mode and the number 0 for client mode. The default is 0. If **uucico** is started manually, this flag should be set to 1.
- -x debug_level Displays debugging information on the screen of the local terminal. The valid range for debug_level is 0 to 9. The higher the number, the more detailed the final report. This flag is useful in correcting problems with the expect-send sequence in the Systems file.

-s system_name

The name of the remote system. Use only when starting **uucico** manually. The *system_name* is supplied internally when **uucico** is started automatically. System names must contain only ASCII characters.

Files

/etc/locks/LCK*
/usr/adm/uucp/Devices
/usr/adm/uucp/Dialcodes
/usr/adm/uucp/Dialers
/usr/adm/uucp/Maxuuscheds

The following commands: "cron" on page 220, "uucp" on page 1144, "uusched" on page 1156, "uustat" on page 1158, "uutry, Uutry, uukick" on page 1164, and "uux" on page 1166.

uucleanup

Purpose

Deletes selected files older than a specified number of hours from the BNU spool directory or a named directory.

Syntax

AJ2FL109

Description

The Basic Networking Utilities (BNU) program **uucleanup** scans the spool directory (/**usr/spool/uucp**) for old files and takes appropriate action to remove them in a useful way. Used primarily by the BNU program administrator, **uucleanup** performs the following tasks:

- Informs the requester of send/receive requests for systems that cannot be reached
- Warns users about requests that have been waiting for a given number of days; the default is 1 day
- Returns mail that cannot be delivered to the sender
- Removes all other files older than a specified number of days from the spool directory.

uucleanup

The uucleanup program is started by the shell uudemon.cleanup, located in /usr/adm/uucp, which in turn is started by the cron script, located in /usr/spool/cron/crontabs/uucp. In general, uucleanup is executed automatically. You can also start the uucleanup program manually if you have superuser privileges.

Note: When BNU is installed, automatic cleanup is not enabled. Edit the file /usr/spool/cron/crontabs/uucp and remove the comment character "#" from the beginning of the uudemon.cleanup line.

Flags

-Ctime Removes any C.* (command) files as old as, or older than, the number of days specified in *time*, and sends appropriate information to the requester. Unless specified otherwise, the default *time* is 7 days.

-Dtime Removes any **D.*** (data) files as old as, or older than, the number of days specified in *time*. Also attempts to deliver any remaining mail messages. The default *time* is 7 days.

-Wtime Sends a mail message to the requester warning that C. files as old as, or older than, the number of days specified in time are still in the spool directory. The message includes the job ID and, in the case of mail, the mail message. The administrator may use the -m option to include a message line telling whom to call to check the problem. The default time is 1 day.

-Xtime Removes any X.* (execute) files as old as, or older than, the number of days specified in time. The default time is 2 days.

Note: There are probably no related data files. If any related data files remain, however, they are handled by **D.*** processing, as described above.

-mstring Includes a specified line of text in the warning message generated by the -Wtime option. The default line is: See your local administrator to locate the problem.

-otime Removes other files as old as, or older than, the number of days specified in time. The default time is 2 days.

-ssystem Executes **uucleanup** only on the spool directory specified by system The default is to clean up all BNU spool directories. System names can contain only ASCII characters.

Note: Unless one of the *time* flags is set to a specific number of days, **uucleanup** uses the default *times* values.

Files

/etc/cron /usr/adm/uucp /usr/spool/cron/crontabs/uucp /usr/spool/uucp File that starts uudemon.cleanup. Directory with commands used internally by uucleanup. File containing uudemon.cleanup.

Spooling directory.

Related Information

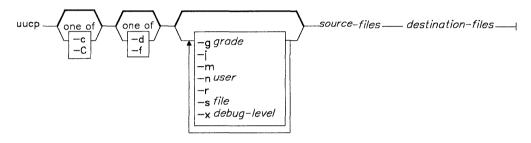

The following commands: "cron" on page 220, "uucp" on page 1144, and "uux" on page 1166.

uucp

Purpose

Copies files from one AIX system to another AIX system.

Syntax

OL805382

Description

The Basic Networking Utilities (BNU) command **uucp** copies one or more source files from one AIX system to one or more destination files on another AIX system.

The **uucp** command accomplishes the file transfer in two steps: first, by creating a command (C.*) file in the spooling directory on the local computer, and then by sending the request to the specified computer via the **uucico** command.

Command files include information such as the full path name of the source and destination files, the sender's login name, and so on. The full path name of a command file is a form of the following:

/usr/spool/uucp/system_name/C.system_nameNxxxx

where N is the grade of the request and xxxx is the hexadecimal sequence number used by BNU.

Note: If the uucp command is used with the -C flag to copy the files to the spool directory for transfer, uucp creates not only a command file, but also a data (D.*) file that contains the actual source file. The full path name of a data file is a form of the following:

/usr/spool/uucp/system_name/D.system_namexxxx###

Once the command files (and data files, if necessary) are created, **uucp** then calls the **uucico** daemon, which in turn attempts to contact the remote computer to deliver the files.

Note: It is useful to issue the **uuname** command to determine the exact name of the remote system before issuing **uucp**. The **uulog** command provides information about **uucp** activities on a system.

Path Names Used with uucp

Path names for the source and destination of the **uucp** transfer may be one of the following:

- A full path name
- A relative path name
- A path name preceded by ~user, where user is a login name on the specified system. The specified user's login directory is then considered the destination of the transfer.

If the user specifies an invalid login name, the files are transferred to the public directory, /usr/spool/uucppublic, which is the default.

• A path name preceded by ~/destination, where destination is appended to /usr/spool/uucppublic.

This destination is treated as a file name unless more than one file is being transferred by this request, or the destination is a directory. To ensure that it is a directory, follow the destination name with a / (slash). For example, ~/amy/ as the destination creates the directory /user/spool/uucppublic/amy, if it does not already exist, and puts the requested files in that directory.

Note: Path names can contain only ASCII characters.

Source and Destination File Names

• A file name can be a path name on the local system, or can have the following form:

system_name!path_name

where system_name is taken from a list of system names that BNU knows about.

• The destination system_name can also be a list of names, such as the following:

```
system\_name!system\_name! \dots ! system\_name!path\_name
```

In this case, an attempt is made to send the file via the specified route to the destination. Make sure that intermediate nodes in this route are willing to forward information (see *Managing the AIX Operating System*).

• The shell pattern-matching characters ?, *, and [. . .] may be used in the path names; the appropriate system expands them.

Note: The shell pattern-matching characters should not be used in the path name of the destination file.

• If the *destination* is a directory rather than a file, **uucp** uses the last part of the *source* name.

Permissions

- The system administrator should restrict the access to local files by users on other systems.
- When transmitting files, **uucp** preserves execute permissions and grants read and write permissions to the owner, the group, and all others. (The **uucp** command owns the file.)
- Sending files to arbitrary *destination* path names on other systems, or getting files from arbitrary *source* path names on other systems, often fails because of security restrictions. The files specified in the path name must give read or write permission not only for the same group of users, but also for any group.
- Protected files and files in protected directories owned by the requestor can be sent by **uucp**.

Note: File names and system names can contain only ASCII characters.

Flags

-c	Transfers the source files to the destination on the specified computer. The source files are not transferred via the spool directory. This saves the system from copying possibly large files to the spooling directory for transfer. (See the discussion of the -C flag.) This flag is on by default.
-C	Copies local files to the spool directory for transfer. Depending on the configuration of the Poll and Systems files, and on how often the uusched command is run, the files could be transferred immediately (on demand polling), or in the future.
	Note: Occasionally, there are problems in transferring a source file; for example, the remote computer may not be working, or the login attempt may fail. In such a case, the file remains in the spool directory until it is either transferred successfully or removed by the uucleanup command.
-d	Creates any intermediate directories needed to copy the source files to the destination. This flag is on by default.
-f	Does not create intermediate directories during the file transfer.
-g grade	Specifies when the files are to be transmitted during a particular connection. <i>Grade</i> is a single number (0-9) or letter (A-Z, a-z); lower ASCII-sequence characters cause the files to be transmitted earlier than do higher sequence characters. The number 0 is the highest (earliest) grade; z is the lowest (latest) grade. The default is N.

-j

Displays the job identification number of the transfer operation on standard output. This job ID can be used by the BNU command **uustat** to obtain the status of a information about the status of a particular job, or with **uustat** -k to terminate the transfer before it is completed.

-m

Sends mail to the requester when the transfer to the remote system is completed. The message is sent to the requester's mailbox, /usr/mail/user_name. The mail command does not send a message for a local transfer.

Note: The -m flag works only when sending files or receiving a single file. It does not work when forwarding files. Receiving multiple files specified by the shell pattern-matching characters?, *, and [. . .] does not activate the -m option.

-nuser_name

Notifies the user specified by *user_name* on the designated system that files have been sent. The mail system does not send a message for a local transfer.

Note: User names can contain only ASCII characters.

-r

Prevents the starting of the file transfer program, **uucico**, even if the command was issued at a time when calls to the remote system are permitted. By default, a call to the remote system is attempted if the command is issued during a time period specified in the **Poll** and **Systems** files.

-sfile

Reports the status of the transfer to the specified file. In this case, the *file* designation must be a full path name.

-xdebug_level

Displays debugging information on the screen of the local system. The *debug_level* is a number between 0 and 9. The higher number gives a more detailed report.

Examples

- 1. To copy one or more files locally, within the same directory: uucp file1 file2
- 2. To copy multiple files locally, from one directory to another directory: uucp /dev/geo/project /usr/test/marg
- 3. To copy file f1 from the local system to a remote system named hera: uucp /u/geo/f1 hera!/u/geo/f1
- 4. To copy file f2 from the remote system hera and place it in the public directory: uucp hera!geo/f2 /usr/spool/uucppublic/f2

uucp

5. To place the f2 file in a directory other than the public directory:

uucp hera!geo/f2 /u/geo/f2

In this case, make sure that the geo login directory allows write permission to both "other" user and "other" group (for example, with mode 777).

Files

/usr/spool/uucp /usr/spool/uucppublic /usr/lib/uucp Spooling directory.
Public directory.
Contains **uucico** daemon.

The information about international character support in Managing the AIX Operating System.

uulog

Purpose

Provides information about uucp and uux activities on a system.

Syntax

AJ2FL111

Description

The Basic Networking Utilities (BNU) command uulog displays the contents of a log file of uucico or uuxqt activities. Individual log files are created for each remote system with which the local system communicates using the uucp, uuto, or uux commands.

The log file of uucico activities is named /usr/spool/uucp/.Log/uucico/system. The log file of uuxqt activities is named /usr/spool/uucp/.Log/uuxqt/system.

Flags

-fsystem Performs a "tail-f" on the file transfer log for the specified system, in this case

displaying the end of the log file. Use INTERRUPT (Alt-Pause) to leave the

file and return to the prompt.

-ssystem Prints information about copy requests involving the specified system.

Note: System names can contain only ASCII characters.

-x Looks in the **uuxqt** log file for the given system.

-number Indicates that a tail command should be executed for the specified number of

lines.

Files

/usr/bin Contains **uulog** command. /usr/spool/uucp Spooling directory. /usr/spool/uucppublic Public directory.

Related Information

The following commands: "tail" on page 1044, "uucp" on page 1144, "uuname" on page 1151, and "uux" on page 1166.

The information about international character support in *Managing the AIX Operating System*

uuname

Purpose

Provides information about other systems accessible to the local system.

Syntax

AJ2FL112

Description

The Basic Networking Utilities (BNU) command uuname displays a list of all the computers networked to the local system; the list of accessible systems is displayed on the screen of the local terminal.

In order for a local system to communicate with a remote system via BNU, the remote system must:

- have a UNIX-based operating system
- be connected to the local system.

Note: BNU can be used to communicate between an RT work station and a non-UNIX-based operating system, but such communications may require special hardware or software. The remote systems accessible with BNU commands are identified when the BNU programs are installed, and are listed in /usr/adm/uucp/Systems.

Before copying a file to another system with the uucp command, issue uuname to determine the exact name of the remote system.

Flags

-1 Displays the name of the local system.

Examples

1. To identify the remote systems connected to the local systems:

uuname

The system responds with a list like the following:

hera zeus merlin arthur

2. To identify the local system:

uuname -1

The system responds:

venus

Files

/usr/spool/uucp /usr/spool/uucppublic /usr/adm/uucp Spooling directory. Public directory.

Directory containing Systems file.

Related Information

The following commands: "uucp" on page 1144, "uulog" on page 1149, and "uux" on page 1166.

uupick

Purpose

Accepts or rejects files transmitted to a user.

Syntax

A5AC5019

Description

The Basic Networking Utilities (BNU) command uupick accepts or rejects files that the BNU command **uuto** has transmitted to a designated user **ID**.

After the files have arrived, the rmail command notifies the specified user. At that point, the user issues uupick to receive and handle the files.

Specifically, uupick searches the public directory on the local system for files with some form of the following name:

/usr/spool/uucppublic/receive/user_ID/system/file

For each entry (file or directory) found, uupick displays the following message on the screen of the local system:

```
from system: [file file-name] [dir dirname]
```

It then waits for a response from standard input to determine the disposition of the file. Issuing the uupick command with the appropriate file-handling option completes the transfer.

File-Handling Options

After notifying the specified user that a file has been sent from system, uupick displays a question mark (?), prompting for one of the following file-handling options:

* Displays all the file-handling options.

Enter Moves on to the next entry in the receive directory.

a [dir] Moves all **uuto** files currently in the **receive** directory into a specified directory on the local system. The default is the current working directory. Use a full or relative path name to specify dir.

d Deletes the specified file.

m [dir] Moves the specified file to a specified directory. If dir is not specified as a complete path name, a destination relative to the current directory is assumed. If no destination is given, the default is the current working directory on the local system.

p Displays the contents of the file on the work station screen.

q Stops processing and exits from the uupick command.

Ctrl-D Same as q.

Escapes to a shell to run the specified AIX command. After the command executes, returns automatically to **uupick** so the user can continue to handle the **uuto** files in the **receive** directory.

Flags

-ssystem

!cmd

Searches /usr/spool/uucppublic/receive/user_ID/system/file only for files sent from the specified system.

Note: System names can contain only ASCII characters.

Examples

1. To receive file1 sent with the **uuto** command from user msg on system apollo:

uupick

The system responds:

from system apollo: file file1
?

2. Enter an asterisk (*) to display the uupick file-handling options:

The system responds:

```
usage [d] [m dir] [a dir] [p] [q] [cntl d] [!cmd] [*] [new-line]
```

Enter the appropriate option, or use the q option or the Ctrl-D sequence to exit from the uupick command.

Files

/usr/spool/uucppublic

Public directory.

Related Information

The following commands: "bellmail" on page 104, "uuto" on page 1162, "uucp" on page 1144, and "uux" on page 1166.

uusched

Purpose

Schedules work for the BNU file transport program.

Syntax

AJ2FL113

Description

The **uusched** program is the Basic Networking Utilities (BNU) file-transport scheduler. It is one of the BNU daemons (a program executed internally to handle file transfers and command executions).

The uusched daemon schedules the transfer of files that are queued in the /usr/spool/uucp directory. The scheduling program first randomizes the work and then starts the uucico daemon with the -s option. This option specifies the computer for which the particular job is scheduled.

The uusched program itself is usually started by the shell uudemon.hour, which is started from /usr/spool/cron/crontabs/uucp, which is, in turn, started by cron.

Flags

-udebug_level Passes as -xdebug_level to uucico. The debug_level is a number from 0 to 9. Higher numbers give more detailed debugging information, which is

displayed on the screen of the local system.

-xdebug_level Outputs debugging messages from uusched. The debug_level is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files

/etc/locks/LCK* Prevents multiple use of device.
/usr/adm/uucp/Devices Information about available devices.
/usr/adm/uucp/Dialcodes Dialing code abbreviations.
/usr/adm/uucp/Dialers Initial handshaking on a link.

/usr/adm/uucp/Permissions /usr/adm/uucp/Systems /usr/spool/cron/crontabs/uucp /usr/spool/uucp/* /usr/spool/uucppublic/*

Access permission codes. Accessible remote systems. Contains uudemon.cleanup. Spooling directory. Public directory.

Related Information

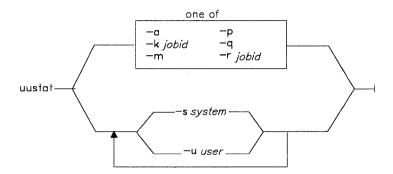

The following commands: "cron" on page 220, "uucico" on page 1139, "uucp" on page 1144, "uustat" on page 1158, and "uux" on page 1166.

uustat

Purpose

Reports the status of and provides rudimentary job control for BNU commands.

Syntax

AJ2FL114

Description

The Basic Networking Utilities (BNU) command uustat displays status information about several types of BNU operations. It is particularly useful in monitoring transfer (copy) requests issued with the uucp and uuto commands, and requests to run an AIX command(s) on a remote system made with the uux command.

In addition, **uusta**t also gives a user limited control over BNU jobs queued to run on remote systems. By issuing the command with the appropriate flag, a user can check the general status of BNU connections to other systems, and cancel copy requests made with **uucp** and **uuto**.

If **uustat** is issued without any flags, the command reports the status of all BNU requests issued by the current user since the last time the holding queue was cleaned up (see the description of the -a flag for an explanation of the BNU queues). Such status reports are displayed in the following format:

jobid date/time status system_name user_ID size file

See "Examples" on page 1160 for an explanation of this format.

Note: When sending files to a system that has not been contacted recently, it is a good idea to use **uustat** to see when the last access occurred, as the remote system may be down or out of service.

Flags

The following flags are mutually exclusive; you can use only one at a time with the **uustat** command:

-a Displays information about all the jobs in the holding queue, regardless of the user who issued the original BNU command.

Note: There are two types of BNU queues.

- The current queue lists the BNU jobs either queued to run on, or currently executing on, one or more specified computers. Use the **uustat -q** command to examine this queue.
- The holding queue, accessed with the -a flag, lists all jobs that have not executed during a set period of time.

After the set time period has elapsed, the entries in the holding queue are deleted either manually, with the BNU command **uucleanup**, or automatically, with the file /usr/spool/cron/crontabs/uucp (which includes **uudemon.cleanup**), which is started by **cron**.

-k jobid Cancels (kills) the BNU process specified by the jobid. The person using this flag must either be the one who made the **uucp** request now being canceled, or must be operating with superuser authority.

Note: This flag cancels a process only when that job is still on the local computer. Once BNU has moved the job to a remote system for execution, -kjobid cannot be used to cancel the remote job.

- -m Reports the status of the most recent attempt to contact the specified system with a BNU command. If the BNU request was completed, the status report is SUCCESSFUL. If the job was not completed, the status report is an error message such as LOGIN FAILED.
- -p Runs a ps -flp (process status: full, long list of specified process IDs) for all PID numbers in the lock files.
- -q Lists the jobs currently queued to run on each system; these jobs are either waiting to execute or in the process of executing. If a status file exists for the system, its date, time, and status information are reported. Once the job is finished, BNU removes that job listing from the current queue.

Note: In a status report, a number in parentheses next to the number of a C.* (command) file or an X.* (execute) file represents the age in days of the oldest C.*/X.* file for that system. The retry field represents the number of times BNU tried and failed to execute the command because of such factors as a failed login, locked files, an unavailable device, and so on.

-r jobid Marks the files in the holding queue specified by jobid with the current date and time. Use this flag to ensure that a cleanup operation does not delete files until the job's modification time reaches the end of the specified period.

You can use either one or both of the following flags with **uustat**:

- -ssystem Reports the status of BNU requests for the work station specified by system.
- -uuser_ID Reports the status of BNU requests by the specified user for any work station.

Note: System and user names can contain only ASCII characters.

Examples

1. To display the status of all BNU jobs in the holding queue:

```
uustat -a
```

The system responds with a display like the following:

```
heraC3113 11/06-17:47 S hera amy 289 D.venus471afd8 zeusN3130 11/06-09:14 R zeus geo 338 D.venus471bc0a merlinC3120 11/05-16:02 S merlin amy 828 /u/amy/tt merlinC3119 11/05-12:32 S merlin msg rmail amy
```

The first field is the job ID of the operation, which is followed by the date and time the BNU command was issued. The third field is either an S or an R, depending on whether the job is to send or request a file. The fourth field is the name of the system on which the command was entered, followed by the user ID of the person who issued the command. The sixth field is the size of the file, or, in the case of a remote execution like the last entry in the example, the name of the remote command. When the size is given, as in the first three lines of the example output, the file name is also displayed. The file name can be either the name given by the user, as in the /u/amy/tt entry, or a name that BNU assigns internally to data files associated with remote executions, such as D.venus471afd8.

2. To display the status of all jobs in the current queue:

```
uustat -q
```

The system responds:

```
merlin 3C 07/15-11:02 NO DEVICES AVAILABLE hera 2C 07/15-10:55 SUCCESSFUL zeus 1C (2) 07/15-10:59 CAN'T ACCESS DEVICE
```

The output tells how many C.* (command) files are waiting for each system. The date and time refer to the current interaction with the system, followed by a report of the status of the interaction. The number in parentheses (2) in the third line of the example indicates that the C.* file has been in the queue for two days.

3. To display all process IDs in the lock file:

```
uustat -p
LCK..tty0: 881
LCK.S.0: 879
LCK..hera: 881
   S UID PID PPID C PRI NI ADDR SZ WCHAN
                                                STIME
                                                         TTY
101 S uucp 881 879 26 39 39 370 296 3fffe800 09:57:03
      COMD
TIME
      UUCICO -rl -shera
0:00
101 S uuc 879 1
                   11 33 39 770
                                  156 8d874
                                                09:57:02 -
0:00
      /usr/lib/uucp/uusched
```

4. To cancel a job in the current queue, first determine the job ID and then execute the uustat -k command:

```
uustat -a
heraC3113 11/06-17:47 S hera amy 289 D.venus471afd8
merlinC3119 11/06-17:49 S merlin geo 338 D.venus471bcOa
uustat -k heraC3113
```

5. To report the status of jobs requested by system hera:

```
uustat -s hera
heraNlbd7 07/15-12:09 S hera amy 522 /user/amy/A
heraClbd8 07/15-12:10 S hera amy 59 D.3b2a12ce4924
heraC3119 07/15-12:11 S hera amy rmail msg
```

6. To report the status of jobs requested by user amy:

```
uustat -u amy
```

This flag displays output similar to that produced by the -s flag.

Files

```
/etc/locks/LCK* Prevents multiple use of device. /usr/spool/uucp Spooling directory.
```

Related Information

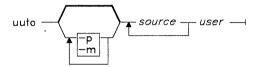

The following commands: "ps" on page 786, "uucp" on page 1144, "uuto" on page 1162, and "uux" on page 1166.

uuto

Purpose

Copies public files from one AIX system to another AIX system, with local system control of file access.

Syntax

OL805290

Description

The Basic Networking Utilities (BNU) command **uuto** copies one or more source files from one AIX system to a specified user on another AIX system. The **uuto** command calls the BNU command **uucp** for the actual file transfer, but **uuto** enables the recipient to use the **uupick** options to handle the transferred files on the local system.

The *source* entry is the name of the files on the local system, or a path name to the files on the system that runs the command. The *user* is a specific user ID. This entry has the following format:

system!user

where system is the name of a remote system connected to the local system, and user is the login name of the recipient of the transferred files on the specified system.

Note: When copying a file from one user to another user on the local system, omit the *system* entry; the destination is simply the ID of the user to whom the file is being sent. System names can contain only ASCII characters.

The **uuto** command sends files to /**usr/spool/uucppublic** on the designated *system*; this is a public directory. The command also creates an additional directory called **receive** (if it does not already exist), plus the directory /*user/system*. The full path names to the copied files are therefore some form of the following:

 $/{\bf usr/spool/uucppublic/receive}/ user/system/files$

Once the copied file is in the **receive** directory, **uuto** notifies the recipient by **rmail** that the file has arrived. The recipient then issues the **uupick** command, which searches the public directory for files sent to the specified user ID, displaying the message that file name has arrived from system name for each file it locates. The user then enters one of the **uupick** file-handling options to delete the file, move it to another directory, and so on.

Flags

- -m Notifies the sender by bellmail when the copy is complete.
- -p Copies the source file to the spool directory on the local system. The source file resides in the spooling directory for a set period of time (defined in the **uusched** program) before the **uucp** command calls the **uucico** daemon, which actually transfers the copy to the public directory on the specified remote system. The default is to transfer a source file directly to the specified user.

Files

/usr/spool/uucppublic

Public directory.

Related Information

The following commands: "bellmail" on page 104, "uucleanup" on page 1141, "uucp" on page 1144, "uupick" on page 1153, "uusched" on page 1156, "uustat" on page 1158, and "uux" on page 1166.

uutry, Uutry, uukick

Purpose

Contacts a remote system with debugging turned on.

Syntax

AJ2FL258

Description

The **uutry** command contacts a specified system with debugging turned on, thus providing a means of checking call processing capabilities with debugging output. This command invokes the **uucico** program, which in turn establishes the actual connection to the remote system.

The debugging output (information about the progress of **uucico** in establishing the connection, performing the remote login, and so on) is scrolled on the screen of the local system. Once the system has finished displaying this information, use **INTERRUPT** (Alt-Pause) to return to the prompt.

The debugging information scrolls rapidly, so you may want to direct that output to a file by issuing **Uutry** rather than **uutry**.

The Uutry command (note the uppercase "U") works almost exactly like uutry, with one exception. In addition to displaying the debugging output on the screen, **Uutry** also directs this information to a file named /tmp/system_name. Again, when the last of the output has been displayed, use INTERRUPT to return to the prompt.

Note: You can also press INTERRUPT while the system is scrolling the output generated by **Uutry**. This returns you to the prompt, while the **uucico** program continues to place the debugging information in /tmp/system_name. Use the pg command to examine this file.

Note: System names can contain only ASCII characters.

The uukick command also works just like the uutry command. The only difference between the two commands is that uukick takes only the -xdebug_level flag. You cannot override the retry time with the -rsystem_name flag.

Flags

-xdebug_level

Used in debugging to override the default level of 5, and produce a detailed output of the program execution. The debugging level is a single digit between 0 and 9. Higher numbers produce more detailed debugging information, which is displayed on the screen of the local system.

-r

Overrides the retry time specified in /usr/spool/uucp/.Status.

Files

/etc/locks/LCK* /tmp/system_name /usr/adm/uucp/Devices /usr/adm/uucp/Dialcodes /usr/adm/uucp/Dialers /usr/adm/uucp/Masuuscheds /usr/adm/uucp/Masuuxgts /usr/adm/uucp/Permissions /usr/adm/uucp/Systems /usr/spool/uucp/* /usr/spool/uucppublic/*

Prevents multiple use of device. Temporary data file. Information about available devices. Dialing code abbreviations. Initial handshaking on a link. Limits scheduled jobs. Limits remote command executions. Access permission codes. Accessible remote systems. Spooling directory. Public directory.

Related Information

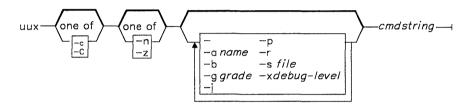

The following commands: "uucico" on page 1139, "uucp" on page 1144, and "uux" on page 1166.

uux

Purpose

Runs a command on another AIX system.

Syntax

AJ2FL116

Description

The Basic Networking Utilities (BNU) command uux runs a specified AIX command on a specified AIX system.

The command gathers various files from the designated systems, if necessary. It then runs a specified command on a designated system. The user can direct the output from the command to a specified file on a specified system.

Note: For security reasons, many installations permit uux to run only the rmail command.

The uux command creates execute (X.*) files that run AIX commands on the local system. In addition, uux also creates both command (C.*) files and data (D.*) files. Execute files contain the command string to be executed on the designated system. Command files contain the same information as those created by the uucp command. Data files either contain the data for a remote command execution, or else become X.* files on remote systems for remote command executions.

Note: The full path name of an execute file is a form of the following:

/usr/spool/uucp/system_name/X.system_nameNxxxx

After creating the files in the spooling directory, **uux** calls the **uucico** daemon, which in turn attempts to contact the designated system to deliver the files. Once the files are transferred, the **uuxqt** daemon executes the *cmdstring* on the specified system.

The *cmdstring* is made up of one or more arguments that look like an AIX command line, except that *cmdstring* may be prefixed by *system_name*!. The default *system_name* is the local system.

Note: To run commands on more than one system, type the information on separate command lines:

```
uux merlin!print /reports/memos/charles
uux zeus!print /test/examples/examp1
```

Unless the -n or -z flag is specified, uux notifies the user if the remote system fails to run the command. The response comes by mail from the other system.

File Names, Path Names, and System Names

- When specifying the destination of the output of a command, **uux** may be entered in either one of the following formats:
 - uux [options] "cmdstring > destination_name"
 - uux [options] cmdstring \{destination_name\}
- Destination names may be either of the following:
 - a full path name.
 - a full path name preceded by ~user, where user is a login name on the specified system. The uux command replaces this path name with the user's login directory.
- The shell pattern-matching characters?, *, and [. . .] can be used in the path name of a "source" file (such as files compared by the **diff** command); the appropriate system expands them. However, using the * character may occasionally produce unpredictable or unanticipated results.

Note: Shell pattern-matching characters should not be used in the destination path name.

- Place either two backslashes (\ . . . \) or a pair of quotation marks (" . . . ") around pattern-matching characters in a path name so the local shell cannot interpret them before uux sends the command to a designated system.
- If using the special shell characters > (greater than), < (less than), ; (semicolon), or | (vertical bar) in a path name, place either \ . . . \ or " . . . " around the individual character or around the entire command string.
- Do not use the shell redirection characters < < or > > in a path name.
- The uux command attempts to move all files specified on the command line to the designated system. Enclose the names of all output files in parentheses so that uux does not try to transfer them.
- When specifying a system_name, always place it before the cmdstring in the entry.

Note: System names can contain only ASCII characters.

- The exclamation point preceding the name of the local system in a command is optional. If you choose to include the! to run a command on the local system using files from two different remote systems, use! instead of system! to represent the local system, and add system! as the first entry in any path name on the remote systems.
- The exclamation point representing a remote system in BNU syntax has a different meaning in C shells (csh). When running uux in a C shell, place a backslash (\) before the exclamation point in a system name.
- If the command being executed requests two files stored on the same system, or two files with the same name that are stored on separate systems, the command will execute, but will not produce the desired results.

The following two commands will execute:

```
uux "hera!/bin/diff /usr/amy/out1 hera!/u/amy/out > ~uucp/DF"
uux "hera!/bin/diff hera!/usr/amy/out1 venus!/u/amy/out > ~uucp/DF"
```

Note: The notation ~uucp is the shorthand way of specifying the public spooling directory /usr/spool/uucppublic.

In the first command, diff is on system hera, the first source file is on the local system, the second source file (with a different name) is on system hera, and the output is directed to the file DF in the public directory on the local system. In the second command, diff is again on hera, the first file is also on hera, the second file (with a different name) is on venus, and the output is again directed to DF in the ~uucp directory.

The following command will not execute properly:

```
uux "hera!/bin/diff venus!/u/amy/out merlin!/u/amy/out > ~uucp/DF"
```

This command will not execute because, although the files are on two different systems, they still have the same file name.

Flags

- Makes the standard input to uux the standard input to the <i>cmdstring</i>

-aname Replaces the user ID of the person issuing the command with user ID specified with name.

-b Returns standard input to the command if the exit status is not zero.

-c	Transfers the source files to the destination on the specified system. The source files are not copied into the spool directory for transfer. (See the discussion of the -C flag.) This flag is on by default.		
-C	Transfers the source files to the spool directory. After a set period of time (specified in the uusched program), the uucico daemon attemptransfer the files to the destination on the specified computer.		
	Note: Occasionally, there are problems in transferring a source file; for example, the remote computer may not be working, or the login attempt may fail. In such cases, the file remains in the spool directory until it is either transferred successfully or removed by the uucleanup command.		
-g grade	Specifies when the files are to be transmitted during a particular connection. <i>Grade</i> is a single number (0-9) or letter (A-Z, a-z); lower ASCII-sequence characters cause the files to be transmitted earlier than do higher sequence characters. The number 0 is the highest (earliest) grade; z is the lowest (latest). The default is N.		
-j	Displays the job identification number of the process that is running the command on the specified system. Use this job ID with the BNU command uustat to check the status of the command, or with uustat -k to terminate the process.		
-n	Prevents user notification by mail of the success or failure of a command. The default is to notify the user if the command fails.		
- p	Uses the standard input to uux as the standard input to <i>cmdstring</i> . A - (minus) has the same effect.		
-r	Prevents the starting of the spooling program that transfers files between systems. The default is to start the spooling program.		
-sfile	Reports the status of the transfer in a file specified by <i>file</i> on the designated system.		
	Note: File names can contain only ASCII characters.		
-x debug_level	Displays debugging information on the screen of the local system. The $debug_level$ is a number between 0 and 9. The higher number gives a more detailed report.		
-z	Notifies the user if the command completes successfully. This flag is the opposite of the system default, which is to notify the user of failure.		

Examples

1. To get the *jobid* of a job and then compare a file on the local system Zeus with a file on a remote system when the **diff** command is stored on the local system, use either of the following formats:

```
uux -j "/bin/diff /usr/amy/f1 hera!/u/amy/f2 > ~uucp/f1.diff"
or
uux -j /bin/diff /usr/amy/f1 hera!/u/amy/f2 \{~uucp/f1/diff\}
```

This command gets the file /usr/amy/fl from the remote system hera, compares it to the file /u/amy/f2 on the local system (zeus), and places the output of the command in the local public directory in a file named fl.diff. (The full path name of this file is /usr/spool/uucppublic/fl.diff.) Using the -j option produces the output zeusN52d9.

Note: As shown in the example, the destination name must be entered either preceded by a > with the whole command string enclosed in "...", or entered enclosed in braces and backslashes, as $\setminus \{....\}$.

2. To compare files that are located on two different remote systems, hera and venus, using the **diff** command on the local system:

```
uux "!/bin/diff hera!/usr/amv/f1 venus!/u/amv/f2 > !f1.diff"
```

This command gets the /usr/amy/f1 file from the system hera and the /u/amy/f2 file from venus, runs a **diff** command on the two files, and places the results in the file f1.diff, located in the current working directory on the local system.

- This output file must be write-enabled. If you are uncertain about the permission status of a specific target output file, direct the results to the public directory, as in the first example.
- The exclamation points representing the local system are optional.
- Both of the examples above use a > symbol preceding the name of the output file. When using the special shell characters >, <,;, or |, either put the entire cmdstring in quotation marks, or put the special characters as individual arguments in quotation marks.
- 3. To specify an output file on a different remote system:

```
uux hera!uucp venus!/u/amy/f1 \{merlin!/u/geo/test\}
```

This command runs **uucp** on system hera. The **uucp** command then sends the file /u/amy/f1, stored on system venus, to user geo on system merlin as test.

4. To get selected fields from a file on system hera and place them in a file on the local system:

```
uux "cut -f1 -d: hera\!/etc/passwd > ~uucp/passw.cut"
```

This command runs cut on the local system, gets the first field from each line of the password file on system hera, and places the output in the file passw.Cut in the public directory on the local system.

Note: In this example, **uux** is running in a c shell, so a \ (backslash) must precede the exclamation point in the name of the remote system.

Files

/usr/spool/uucp /usr/lib/uucp Spooling directory.
Contains the **uucico** daemon.

Related Information

uuxqt

Purpose

Executes remote command requests.

Syntax

AJ2FL117

Description

The Basic Networking Utilities (BNU) program **uuxqt** executes specified commands on designated remote systems.

Once **uux** is entered by a user, the program creates the necessary command (C.*), data (D.), and execute (X.*) files and places them in the spooling directory on the designated system. The **uux** command then calls the **uucico** daemon, which in turn attempts to contact the designated system to deliver the files. When the files have been transferred, **uuxqt** executes the commands on the designated system.

The uuxqt program searches the spool directories on the designated system for X.* files whose names indicate that they have been sent from another system. The command checks each execute file to make sure that:

- All the required data (D.*) files are available and accessible
- File commands are permitted for the requesting system.

Note: BNU uses the **Permissions** file to validate file accessibility and command execution permission.

The **uuxqt** program, one of the Basic Networking Utilities (BNU) daemons (a program executed to handle file transfers and command executions), can be executed manually by an individual with superuser privileges. This daemon is executed automatically by the **uudemon.hour** shell script, which is started periodically by **cron**.

Flags

-ssystem

The name of the remote system. Use only when starting uuxqt manually.

The system name is supplied internally when **uuxqt** is started

automatically.

Note: System names can contain only ASCII characters.

-xdebug_level Displays debugging information on the screen of the local system. The debugg_level is a single digit between 0 and 9. The higher the number, the

more detailed the debugging information.

Files

/etc/locks/LCK* /usr/adm/uucp/Maxuuxqts /usr/adm/uucp/Permissions /usr/spool/uucp/*

Prevents multiple use of device. Limits remote command executions.

Access permission codes.

Spooling directory.

The following commands: "uucico" on page 1139, "uucp" on page 1144, "uustat" on page 1158, and "uux" on page 1166.

val

Purpose

Validates Source Code Control System (SCCS) files.

Syntax

OL805292

Description

The val command reads *file*s and determines if the specified *file* is an **Source Code Control System (SCCS)** file meeting the characteristics specified by the flags. If you specify a - (minus) for *file*, val reads standard input and interprets each line of standard input as val flags and the name of an SCCS file. val continues to take input until it reaches an end-of-file character (Ctrl-D).

The val command displays error messages to standard output for each file processed. val also returns a single 8-bit code upon exit. The 8-bit code indicates possible mismatches or errors. It is interpreted as a bit string in which set bits (from left to right) are interpreted as follows:

bit 0 = missing file parameter

:55 1 = unknown or duplicate flag

bit 2 = damaged SCCS file

bit 3 = cannot open file or file not SCCS

bit 4 = SID is invalid

bit 5 = SID does not exist

bit 6 = %Y%, -y mismatch

bit 7 = % M%, -m mismatch

When val processes two or more files on a given command line or multiple command lines (when reading the standard input), a code is returned that is a logical OR of the codes generated for each command line and file processed. val can process up to 50 files on a single command line. Any number above 50 produces a dump.

Flags

Each flag or group of flags applies independently to each named file. The flags can appear in any order.

-mname Compares the value name with the SCCS %M% identification keyword in file. See "Identification Keywords" on page 480 for more information on the %M% keyword.

-rSID Specifies the SID of the file to be validated. The SID must be valid and unambiguous.

-s Suppresses the error message normally written to standard output.

-ytype Specifies a type to compare with the SCCS %Y% identification keyword in file. See "Identification Keywords" on page 480 for more information on the %Y% keyword.

varyoff

Purpose

Removes an external disk drive from the operating system configuration.

Syntax

AJ2FL119

Description

The **varyoff** command removes an external disk drive and any minidisks residing on the disk from the existing AIX Operating System hardware and minidisk configurations. File systems residing on minidisks are unmounted and file system consistency checks are performed.

Flags

-c Does not perform file consistency checking.

-d hdisknum . . . Specifies the system device name for an external disk drive, where num is an integer from 0 to 33, inclusive. The corresponding drive and the minidisks residing on that drive are removed from the AIX Operating System. unmount and fsck are performed on each file system defined on the disk.

-r Removes information about all minidisks on the external disk drive from the files /etc/system and /etc/filesystems.

Examples

1. To remove a disk from the AIX Operating System using its name:

varyoff -d hdisk7

This command unmounts and performs fsck functions on each file system defined on the disk drive named hdisk7. hdisk7 and all of its minidisks are removed from the operating system.

2. To remove more than one disk:

varyoff -d hdisk9 hdisk7 hdisk12

This command removes disk drives hdisk9, hdisk7, and hdisk12 from the operating system.

3. To remove information about all minidisks on an external disk drive from the system configuration files:

varyoff -r -d hdisk10

This command removes information about all minidisks on the external disk drive hdisk10 from the files /etc/system and /etc/filesystems.

4. To avoid **fsck** functions when removing a disk:

varyoff -c -d hdisk7

Files

/etc/filesystems

Descriptions of mountable file systems.

/etc/system

Default system file.

/etc/system.varv.bk System backup of /etc/system.

/etc/varyoff.out

Default message output file.

varyon

Purpose

Makes an external disk drive and any minidisks or file systems defined on it available for use.

Syntax

OL805455

Description

The varyon command adds an external disk drive and any minidisks or file systems residing on the disk to the existing AIX Operating System hardware and minidisk configurations. varyon runs the fsck command to perform file system consistency checks and mounts the file system if the attributes vcheck = true and vmount = true are present in the corresponding stanza of the /etc/filesystems file. By default, varyon sends only generalized completion messages to standard output, routing more detailed error messages to the file /etc/varyon.out.

Flags

-c Specifies that varyon not perform file consistency checking.

-d hdisknum . . . Specifies the system device name for an external disk drive, where num is an integer from 0 to 33, inclusive. The varyon command uses vrmconfig to configure minidisks residing on the drive. It uses fsck to check each file system whose stanza in the /etc/filesystems file contains the attribute vcheck = true. It mounts each file system that has the attribute vmount = true.

Operates in quiet mode; does not prompt the user about minidisk names or rename the minidisks. If /etc/system and /etc/filesystems contain information about minidisks on the external disk drive, this option adds the minidisks to the system configuration using the existing minidisk names and mount directory.

Examples

1. To configure an entire external disk drive:

```
varyon -d hdisk7
```

This command configures a disk drive, hdisk7, into the operating system, configures any minidisks defined on the disk, and performs **fsck** and **mount** functions on file systems as specified by the **/etc/filesystems** file.

2. To configure more than one external disk drive:

```
varyon -d hdisk9 hdisk7 hdisk12
```

This command makes disk drives hdisk9, hdisk7, and hdisk12 available for use.

3. To configure an external drive without performing **fsck** functions:

```
varyon -c -d hdisk7 hdisk8 hdisk11
```

4. To make the external disk drive available without prompting the user, even if minidisks are already defined in the system configuration files:

```
varyon -q -d hdisk3
```

This command adds the minidisks to the system without prompting the user if /etc/system and /etc/filesystems contain information about any of the minidisks on the drive. If information exists the system uses the existing minidisk names and mount directory.

\mathbf{vc}

Purpose

Substitutes assigned values in place of keywords.

Syntax

OL805293

Description

The **vc** command is used to control writing different versions of a file to standard output. However, since Source Code Control System commands ("**admin**" on page 41, "**get**" on page 477, and "**delta**" on page 310) provide more efficient and complete control, they should be used instead of **vc**.

The **vc** command copies lines from standard input to standard output. The flags and keywords on the command line and control statements in the input modify the resulting output. **vc** replaces user declared keywords with their value assigned on the command line. These keywords can be replaced both in text and in control statements.

Control Statements

A control statement is a single line beginning with a control character (the default control character is a : (colon)). They provide conditional processing of the input. The allowable types of control statements are:

if condition

text

:end

Writes all the lines between the **:if** statement and the matching **:end** to standard output only if *condition* is true. You can nest **:if-:end** statements, but once a condition is false, all remaining nested **:if-:end** statements are ignored. See "Condition Syntax" on page 1183 for the syntax of conditions and allowable operators.

:dcl keyword [, keyword . . .]

Declares keywords. All keywords must be declared.

:asg keyword = value

Assigns value to keyword. An :asg statement takes precedence over keyword assignment on the vc command line. A later :asg statement overrides all earlier assignments of the associated keyword. keywords declared, but not assigned values have null values.

:: text

Removes the two leading control characters and replaces *keywords* with their *values*, and then copies the line to the standard output.

on

Turns on or off keyword replacement on all lines.

:ctl char

Changes the control character to char.

:msg message

Writes a message to standard error output in the form:

Message(n): message

where n is number of the input line on which the message appeared.

:err message

Writes an error message to standard error in the form:

ERROR: message

ERROR: err statement on line n (vc15)

vc stops processing and returns an exit value of 1.

Condition Syntax

Statements Allowed
::=or statement
::=not or statement
::=and statement
::=and statement or statement
::=expression
::=expression & and statement
::=(or statement)
::=value operator value
::== or != or < or >
::=ASCII string

Item

Statements Allowed

::=numeric string

The available condition operators and their meanings are as follows:

- equal
 not equal
 and
 or
 greater than
- less than
 used for logical groupings
- not may only occur immediately after the *if*, and when present, inverts the value of the entire condition.

The > and < (greater than and less than symbols) operate only on unsigned integer values; for example: 012 > 12 is false. All other operators take strings as modifiers; for example 012 != 12 is true. The precedence of the operators, from highest to lowest precedence, is as follows:

```
= != > < all of equal precedence
&
.</pre>
```

Parentheses can be used, of course, to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

Keyword Replacement

A keyword must begin and end with the same control character used in control statements. A keyword may be up to nine alphanumeric characters, where the first character must be alphabetic. Keyword values can be any ASCII string. A numeric keyword value is an unsigned string of digits. values cannot contain tabs or spaces.

Examples of keyword = value assignments are:

```
numlines=4
prog=acctg
pass4=yes
```

The **vc** command removes all control characters and *keywords* from input text lines marked with two control characters as it writes the text to standard output. To prevent a control character from being interpreted, precede it with a backslash, as in the following example:

```
::the :prog: program includes several of the following\:
```

The keyword :prog: is replaced by its *value*, but the \: is passed to standard output as : (colon).

Input lines beginning with a \ (backslash) followed by a control character are not control lines, and are copied to standard output without the backslash. **vc** writes lines beginning with a backslash and no following control character without any changes (including the initial backslash).

Flags

- -a Replaces *keywords* surrounded by control characters with their assigned *value* in all text lines (not just those beginning with two control characters).
- **-c**char Uses char as the control character.

Japanese Language Support Information

char must be an ASCII character.

- -s Does not display the warning messages normally displayed to standard error.
- -t Ignores all characters from the beginning of a line up to and including the first tab character for detecting a control statement. If **vc** finds a control character, it ignores all characters up to and including the tab.

Related Information

The following commands: "admin" on page 41, "delta" on page 310, and "get" on page 477.

The discussion of Japanese Language Support in Japanese Language Support User's Guide.

verify

Purpose

Turns write verification on or off for a particular minidisk.

Syntax

OL805446

Description

The verify command turns write verification on or off for the specified minidisk *device*. The name must be a stanza name in the /etc/system file.

When write verification is on, the system checks each write operation to the minidisk by comparing the data written to disk with the data in the write buffer. If it detects an uncorrectable error, then it passes an error code back from the write operation.

At system startup, write verification is turned off.

Flags

- -o Turns write verification off.
- -q Tells you whether write verification is set on or off.
- -v Turns write verification on.

Files

/dev/config /etc/system

The mdverify subroutine in AIX Operating System Technical Reference.

OL805424

vi, vedit, view

Purpose

Edits files with a full screen display.

Syntax

Description

The **vi** command starts a display editor based on an underlying line editor (**ex**). The **view** command is a read-only version of **vi**. In it, the **readonly** option is set to protect files during browsing. The **vedit** command is a version of **vi** intended for beginners. In it, the **report** option is set to 1, and the **showmode** and **novice** options are set. Since **novice** is set, it is a line editor. For more information on these options, see "Setting Options" on page 1189.

The *file* parameter specifies the file or files to be edited. If you supply more than one *file* on the command line, vi edits each file in the specified order.

When you use vi, changes made to a file are reflected automatically in your display. The position of the cursor on the display indicates its position within the file. The subcommands affect the file at the cursor position.

The following list provides the maximum limits of the **vi** editor. These counts assume single-byte characters.

- 2048 characters per line
- 256 characters per global command list
- 128 characters in the previous inserted and deleted text
- 128 characters in a shell escape command
- 128 characters in a string-valued option
- 30 characters in a tag name
- 1,048,560 lines of 2048 characters per line silently enforced
- 128 map macros with 2048 characters total.

Editing States

The vi editor has the following operational states:

command state

This is the initial state. Any subcommand can be entered (except commands that can only be used in the text input state). When subcommands and other states end, they return to this state. Pressing **Esc** cancels a partial command.

text input state

You use vi in this state when you add text. Entered this state with the a, A, i, I, o, O, c, C, s, S, and R subcommands. After entering one of these commands, you can enter text into the editing buffer at the current cursor position. To return to the command state, press Esc for normal exit or press INTERRUPT (Alt-Pause) to end abnormally.

last line state

Some subcommands (subcommands with the prefix:, /, ?, !obj, or !!) read input on a line displayed at the bottom of the screen. When you enter the initial character, vi places the cursor at the bottom of the screen, where you enter the remaining characters of the command. Press the Enter key to run the subcommand and INTERRUPT (Alt-Pause) to cancel it. When! ! is used, the cursor moves only after both!s are entered. When you use: (colon) to enter the last line state, special meaning is given to the following characters when they are used before commands which specify counts.

% All lines regardless of cursor position

\$ Last line

Current line

Character Sets with vi

The collation table defines the alphanumeric set used by your system. This table affects the performance of **vi** macros and subcommands. If you intend to use non-ASCII extended characters with **vi** macros, it may be necessary to revise this table using the **ctab** command.

The vi editor uses the collation table to distinguish between a *small word* and a *big word*. A small word is bounded by alphabetic characters or numbers that are not defined in the collation table. For example, isn't is two small words. The ' (apostrophe) is not a number or an alphabetic character, and it bounds both the small word t and the small word isn. A big word is bounded by blanks, tabs, and new-line indicators. For example, stop is a big word. For more information see "ctab" on page 257 in this book. For more information on extended characters, international characters, and collation tables see *Managing the AIX Operating System*.

Setting Options

The **vi** editor allows you to customize options so that you can use the editor for a specific task. Use the **set** command to set or change an option. You set some options to a string or a number value, other options you simply turn on or off. To change an option set to a value, enter a command in the form :**set** option = value. To toggle an option that can be set to on or off, enter a line of the form :**set** option to set it on or :**set** no option to set it off. To view the current setting of all the options, enter :**set** all while in the **vi** command state.

You can abbreviate options with the set command. The following table lists commonly used options, abbreviations, and descriptions:

Option	Abbreviation	Description
autoindent	ai	Indents automatically in text input mode to the indentation on the previous line by using the spacing between tab stops specified by the shiftwidth option. The default is noai . To back the cursor up to the previous tab stop, type Ctrl-D . This option is not in effect for global commands.
autoprint	ар	Prints the current line after any command that changes the editing buffer. The default is ap . This option applies only to the last command in a sequence of commands on a single line, and is not in effect for global commands.
autowrite	aw	Writes the editing buffer to the file automatically before the :n, :ta, Ctrl-A, and ! subcommands if the editing buffer changed since the last write command. The default is noaw.
beautifying text	bf	Prevents the user from entering control characters (except for tab, new-line, and scans form feed) in the editing buffer during text entry. The default is nobf . This option applies to command input.
closepunct	cp =	Handles a list of closing punctuation specially when wrapping text (see wraptype). Precedes multi-character punctuation with the number of characters. Example: cp=3;)}. The vi command does not split closing punctuation when wrapping. To set the default value, run kanji-compatible vi and enter :set cp.
directory	dir=	Displays the directory that contains the editing buffer. The default is dir=/tmp.

Option	Abbreviation	Description
edcompatible ed		Retains global (g) and confirm (c) subcommand suffixes during multiple substitutions and causes the read (r) suffix to work like the r subcommand. The default is noed .
hardtabs	ht =	Tells vi the distance between the hardware tab stops on your display. The default is $ht = 8$.
ignorecase	ic	Ignores distinction between upper- and lower-case while searching for regular expressions. The default is noic .
lisp	lisp	Removes the special meaning of (), {}, [[and]] and enables the = (formatted print) operator for S-expressions, so you can edit LISP programs. The default is nolisp .
list	list	Displays text with tabs and the end of lines marked. Tabs display as ^I and the end of lines as \$. The default is nolist .
magic	magic	Treats the characters . (period), [, and * as special characters when scanning. In off mode, only the () and \$ retain special meanings. However, you can evoke special meaning in other characters by preceding them with a \ (back slash). The default is magic .
modeline	modeline	Runs an editor command line if found in the first five or the last five lines of the file. An editor command line can be anywhere in a line. For the editor to recognize a command line, the line must contain a space or a tab followed by the string ex: or vi:. The command line is ended by a second: (colon). The editor tries to interpret any data between the first and second colon as editor commands. The default is nomodeline.
number	nu	Displays lines prefixed with their line numbers. The default is nonu .
optimize	opt	Speeds up the operation of terminals that lack cursor-addressing. The default is noopt .
paragraphs	para=	Defines vi macro names that start paragraphs. The default is para = IPLPPPQPP LIpplpipnpbp. Single-letter nroff macros, such as .P, must include the space as a quoted character if respecifying a paragraph.

Option	Abbreviation	Description
partialchar	pc=	Appears in the last display column where a double-wide character would not display completely. The default character is - (dash).
redraw	redraw	Simulates a smart work station on a dumb work station. The default is nore .
report	report=	Sets the number of times you can repeat a command before a message is displayed. For subcommands that produce many messages, such as global subcommands, the messages are displayed when the command sequence completes. The default is report = 5.
scroll	scr=	Sets the number of lines to be scrolled when the user scrolls up or down. The default is scroll=12 .
sections	sect =	Defines to vi macro names that start sections. The default is sect = NHSHH HUuhsh+c . Single-letter nroff macros, such as .P , must include the space as a quoted character if respecifying a paragraph.
shell	$\mathbf{sh} =$	Defines the shell for ! or :! commands. The default is the login shell.
shiftwidth	sw =	Sets the distance for the software tab stops used by autoindent, the shift commands (> and <), and the text input commands (Ctrl-D and Ctrl-T). The default is sw = 8.
showmatch	sm	Shows the matching open parenthesis (or open bracket { as you type the close parenthesis) or close bracket }. The default is nosm .
slowopen	slow	Postpones updating the display during inserts. The default is noslow .
tabstops	ts=	Sets distance between tab stops in a displayed file. The default is $\mathbf{ts} = 8$.
term	term =	Sets the type of work station you are using. The default is term = \$TERM where \$TERM is the value of the shell variable TERM.

Option	Abbreviation	Description
terse	terse	Allows vi to display the short form of messages. The default is noterse.
timeout	to	Sets a time limit of two seconds on entry of characters. This limit allows the characters in a macro to be entered and processed as separate characters when timeout is set. To resume use of the macro, set notimeout . The default is to .
warn	warn	Displays a warning message before the ! subcommand executes a shell command if it is the first time you issued a shell command after changes were made in the editing buffer but not written to a file. The default is warn.
window	wi =	Sets the number of lines displayed in one window of text. The default is dependent on the baud rate at which you are operating: 600 baud or less / 8 lines, 1200 baud / 16 lines, higher speeds / full screen minus one.
wrapmargin	wm=	Sets the margin for automatic word wrapping from one line to the next. The default is wm = 0 . A value of zero turns off word wrapping.
wrapscan	ws	Allows string searches to wrap from the end of the editing buffer to the beginning. The default is ws.
wraptype	wt=	Determines how a line splits for word wrapping. The default is general . The default causes vi to insert a new line after a white space. Any characters following the insert point begin the new line. White space immediately before the inserted line is deleted. When Japanese Language Support is installed and wraptype=general , vi inserts a new line to wrap one character. One character forming closing punctuation is allowed past the right margin.
writeany	wa	Turns off the checks usually made before a write command. The default is nowa .

Defining Macros

If you use a subcommand or sequence of subcommands frequently, you can create a macro that will issue the subcommand or sequence. To create a macro, enter the sequence of subcommands into an editing buffer named with a letter of the alphabet. When used, $\mathbf{a} - \mathbf{z}$ overlay the contents of the buffer; $\mathbf{A} - \mathbf{Z}$ append text to the previous contents of the buffer, allowing the building of a macro piece by piece.

To invoke the macro, enter 0x where x is the letter name of the buffer. Enter 00 to repeat the last macro you invoked.

Mapping Keys

You can use the **map** command to map a keystroke to a subcommand or a sequence of subcommands. To map a key, enter :**map** key subcommand where key is the key you want to assign to a subcommand or sequence of subcommands, and subcommand is the subcommand or sequence of subcommands. For example, to map @ to delete lines, enter:

In this example, @ is the key to which the subcommand is assigned and dd is the subcommand.

In the next example, a subcommand sequence is mapped to a key:

The * is the key to which the subcommand sequence is assigned and {>} is the subcommand sequence. The { moves the cursor to the beginning of the paragraph and the > indents the paragraph to the next shiftwidth.

While in text input state, enter the command :map! to display a list of the current key mappings. To remove a key map, enter :unmap string or :unmap! string, where string is the string used after the :map command to set the key and subcommand sequence. For example, to remove key map for the previous example, enter:

If function keys are defined for your terminal, you can include them in the map or unmap command by typing Ctrl-V before pressing the desired key. It is useful to define keys seldom used in editing with another key or function key (F0 - F12). For example, the Shift, Ctrl, or Alt can be defined in this way.

The abbreviation command :ab is similar to the :map command. For example, if you set the letter S equal to Sam with a :map command and then entered the following sentence,

it would display as

Sam ate applesam.

The :map command does not recognize the difference between the macro S and the text S. With some restrictions, the :ab command does distinguish between text and a macro. Setting the macro in the previous example with the :ab command,

```
:ab s Sam
```

and typing the same sentence would result in the correct sentence, Sam ate apples. The **:ab** command only recognizes a macro when it is proceeded by a blank space or tab character. If the following were entered,

Sam swims

the ab macro would translate the sentence as:

Sam Samwims

The abbreviated item can occupy more than one line. However, you must use the **ex** editor to remove a macro that contains a **Ctrl-M** (enter sequence). After entering **ex**, issue a **:unab** abbreviation, and return to **vi**. Remove macros without the **Ctrl-M** by using **:ab** abbreviation. After removing or changing abbreviations created with **:ab**, enter **:ab** to list all currently defined abbreviations.

If you use an IBM 3161 ASCII Display Station, IBM 3163 ASCII Display or IBM 3101 ASCII Display Station, the default key mapping of **vi** can cause you to lose data. To see the default mapping, issue a :map command. Specific problems arise with the Esc-J or Shift-J sequence. This sequence deletes any information from the current position of the cursor to the end of the file. To avoid problems, change this sequence using a .exrc file.

Keeping a Customized Change

When you customize vi from the vi command line, the customization is in effect until you leave the editor. If you want to keep your assignments you must put the commands in the file .exrc. Each time you start the editor it reads this file. When you create the customization file, do not type the: (colon) before each command. The: is only required when entering commands on the command line. The following is an example of a .exrc file:

```
set ai aw
set wm=5
map @ dd
```

Flags

- -1 Enters vi in LISP mode. In this mode, vi indents appropriately for LISP code and the (,), {, }, [[, and]] subcommands are modified to act appropriately for LISP.
- -r [file] Recovers a file after an editor or system crash. If you do not specify file, vi displays a list of all saved files.

-R Sets the readonly option to protect the *file* against overwriting.
-t tag Edits the file containing the tag and positions the editor at its definition.
-wnum Sets the default window size to num. This is useful when you use the editor

over a low-speed line.

+[subcmd] Carries out the **ex** subcommand before editing begins. If you do not specify

subcmd, the cursor is placed on the last line of the file.

-y Overrides the maximum line setting of 1,048,560 with any value above 1024.

Subcommands

In the following lists, **Esc** stands for pressing the **ESCAPE** key instead of pressing the **Enter** key.

General Subcommand Syntax

[named_buffer] [operator] [number] object

Surrounding square brackets indicate optional items.

[named_buffer] A temporary text storage area in memory.

[operator] Specifies the subcommand or action; instructs vi.

[number] A whole decimal value that specifies either the extent of the action, or a

line address.

object Specifies what to act on. This can be a text object (a character, word,

sentence, paragraph, section, character string) or a text position (a line,

position in the current line, screen position).

Counts before Subcommands

You can prefix many subcommands with a number. The vi editor interprets this number in one of the following ways:

1. Go to line number:

5G 10z

2. Go to column number:

251

3. Scroll number lines:

10Ctrl-D 10Ctrl-U

Subcommands for Moving within the File

There are many commands that you can use to move within a file. They can be entered while vi is in the command state.

Movements within a Line

 \leftarrow or h or Ctrl-H

Moves the cursor one character to the left.

↓ or j or Ctrl-J or Ctrl-N

Moves the cursor down one line (but it remains in the same column).

↑ or k or Ctrl-P

Moves the cursor up one line (but it remains in the same column).

 \rightarrow or l

Moves the cursor one character to the right.

Character Positioning within a Line

- ^ Moves the cursor to the first nonblank character.
- Moves the cursor to the beginning of the line.
- \$ Moves the cursor to the end of the line.
- fx Moves the cursor to the next x character.
- $\mathbf{F}x$ Moves the cursor to the last x character.
- tx Moves the cursor to one column before the next x character.
- Tx Moves the cursor to one column after the last x character.
- ; Repeat the last f, F, t, or T subcommand.
- Repeat the last f, F, t, or T subcommand in the opposition direction.
- num! Moves the cursor to the specified column.

Words, Sentences, Paragraphs

- w Moves the cursor to the next small word.
- **b** Moves the cursor to the previous small word.
- e Moves the cursor to the end of the small word
- W Moves the cursor to the next big word.

- B Moves the cursor to the previous big word.
- E Moves the cursor to the end of a big word.

Line Positioning

- H Moves the cursor to the top line on the screen.
- L Moves the cursor to the last line on the screen.
- M Moves the cursor to the middle line on the screen.
- + Moves the cursor to the next line at its first nonblank character.
- Moves the cursor to the previous line at its first nonblank character.
- **Enter** Moves the cursor to the next line at its first nonblank character.

Scrolling

- Ctrl-U Scrolls up one half screen.
- Ctrl-D Scrolls down one half screen.
- Ctrl-F Scrolls forward one screen.
- Ctrl-B Scrolls backward one screen.

Searching for Patterns

- [num]G Places the cursor at line number num or to the last line if num is not specified.
- /pattern Places the cursor at the next line containing pattern.
- ?pattern Places the cursor at the next previous line containing pattern.
- n Repeats last search for pattern in the same direction.
- N Repeats last search for *pattern* in the opposite direction.

/pattern/+num

Places the cursor at the *num*th line after the line matching *pattern*.

?pattern?-num

Places the cursor at the *num*th line before the line matching *pattern*.

% Finds the parentheses or brace that matches the one at the current cursor position.

Moving to Sentences, Paragraphs, or Sections

- Places the cursor at next section (or function if you are in LISP mode).
- [[Places the cursor at previous section (or function if you are in LISP mode).
- Places the cursor at the beginning of the previous sentence (or the previous s-expression if you are in LISP mode).
- Places the cursor at the beginning of the next sentence (or the next s-expression if you are in LISP mode).
- Places the cursor at the beginning of the next paragraph (or at the next list if you are in LISP mode).
- Places the cursor at the beginning of the next paragraph, at the next section if you are in C mode, or at the next list if you are in LISP mode.

Marking and Returning

- " Moves the cursor to the previous location of the current line.
- " Moves cursor to the beginning of the line containing the pervious location off the current line.
- $\mathbf{m}x$ Marks the current position with letter x.
- 'x Moves cursor to mark x.
- 'x Moves cursor to the beginning of the line containing mark x.

Adjusting the Screen

- Ctrl-L Clears and redraws the screen.
- Ctrl-R Redraws the screen and eliminates blank lines marked with a @.
- z Redraws the screen with the current line at the top of the screen.
- **z-** Redraws the screen with the current line at the bottom of the screen.
- z. Redraws the screen with the current line at the center of the screen.

/pattern/z-

Redraws the screen with the line containing pattern at the bottom.

- znum Makes the window num lines long.
- z+ Page Up.
- z^ Page Down.

Ctrl-E Scrolls the window down one line.

Ctrl-Y Scrolls the window up one line.

Subcommands for Editing

Use the following subcommands to edit your text. Subcommands not followed by an * (asterisk) should be entered in the text input state. These subcommands affect the text relative to the current cursor position. You return to the command state by pressing the **Esc** key.

Editing the File

atext Inserts text after the cursor.

Atext Adds text to the end of the line.

C Changes rest of line (c\$).

cc Changes a line.

cw Changes a word.

cwtext Changes word to text.

D * Deletes the rest of the line (**d**\$).

dd * Deletes a line.

dw * Deletes a word.

itext Inserts text before the cursor.

Itext Inserts text before the first nonblank character in the line.

J * Joins lines.

• Adds an empty line below the current line.

O Adds an empty line above the current line.

 $\mathbf{r}x$ * Replaces the current character with x. (Commands followed by * do not enter the text input state.)

Rtext Overwrites characters with text.

s * Substitutes characters (cl).

S * Substitutes lines (cc).

u * Undoes the previous change.

x * Deletes a character.

- X * Deletes characters before cursor (dh).
- yw * Yanks a word into the undo buffer.
- yy * Yanks a line into the **undo** buffer.
- < < * Shifts one line to the left.
- <L * Shifts all lines from the cursor to the end of the screen to the left.
- >> * Shifts one line to the right.
- >L * Shifts all lines from the cursor to the end of the screen to the right.
- ~ * Changes letters at cursor to opposite case.
- ! * Indents for LISP.

Corrections during Insert

Use the following commands only while in text input state. They have different meanings in the command state.

- Ctrl-H Erases last character.
- Ctrl-W Erases last small word.

Note: For more information on small words see "Character Sets with vi" in this section.

- \ Quotes the erase and kill characters.
- Esc Ends insertion, back to command state.
- Ctrl-? Interrupts, terminates insert or Ctrl-D.
- Ctrl-D Goes back to previous autoindent stop.
- ^Ctrl-D Ends autoindent for this line only.
- **0Ctrl-D** Moves cursor back to left margin.
- Ctrl-V Enters nonprinting character.

Moving Text

- **p** Puts back text in the **undo** buffer after the cursor.
- P Puts back text in the undo buffer before the cursor.
- "xp Puts back text from the buffer x.

"xd Deletes text into the buffer x.

y Places the object that follows (for example, w for word) in the undo buffer.

"xy Places the object that follows in the x buffer, where x is any letter.

Y Places the line in the **undo** buffer.

Restoring and Repeating Changes

u Undoes the last change.

U Restores the current line if the cursor has not left the line since the last change.

. Repeats the last change or increments the "n p command.

Note: This subcommand is not meant for use with a macro. Enter @@ to repeat a macro.

"n p Retrieves the nth last delete of a complete line or block of lines.

Interrupting, Canceling, and Exiting vi

Q Enter ex editor in command state.

:sh Runs a shell. You can return to vi by pressing Ctrl-D.

:!cmd Runs cmd, then returns.

:!! Repeats the last :!cmd command.

n!!cmd Executes shell command cmd and replaces the number of lines specified by n with the output of cmd. If n is not specified, when the default is 1. If cmd expects standard input, the lines specified are used as input. Thus the command !sort can sort a paragraph.

nlobi cmd

Executes shell command cmd and replaces n with output of cmd. If n is not specified, the default is 1. If cmd expects standard input, the lines or obj specified is used as input.

ZZ Exits vi, saving changes.

:q Quits **vi**. If you have changed the contents of the editing buffer, **vi** displays a warning message and does not quit.

:q! Quits vi, discarding the editing buffer.

Esc Ends insert or ends an incomplete subcommand.

Ctrl-L Redisplays a screen.

Ctrl-R Redisplays the screen if Ctrl-L is the \rightarrow key.

Ctrl-? Interrupts a subcommand.

File Manipulation

:e file Edits file.

:e! Re-edits the current file and discards all changes.

:e + file

Edits file starting at the end.

:e + num

Edits file starting at line num.

:e # Edits the alternate file. The alternate file is usually the previous current file name. However, if changes are pending on the current file when a new file is called, the new file becomes the alternate file. This subcommand is the same as Ctrl-A.

Edits next file in the list entered on the command line.

:n files Specifies new list of files to edit.

:r file Reads the file into the editing buffer by adding new lines below the current cursor position.

:r!cmd Runs the shell command cmd and places its output in the file by adding new lines below the current cursor position.

:ta tag Edits a file containing tag at the location of tag.

:w Writes the editing buffer contents to the original file.

:w file Writes the editing buffer contents to the named file.

:w! file Overwrites file with the editing buffer contents.

Ctrl-G Shows current file name and line.

Ctrl-A. Edits the alternate file. The alternate file is usually the previous current file name. However, if changes are pending on the current file when a new file is called, the new file becomes the alternate file. This subcommand is the same as :e #.

vmh

Purpose

Invokes a visual interface for use with MH commands.

Syntax

vmh ---- -help ----- |

AJ2FL239

Description

The vmh command is used to invoke a visual interface for use with MH commands. vmh is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The vmh command implements the server side of the MH window management protocol and maintains a split-screen interface to any program that implements the client side of the protocol.

vmh prompts for commands and sends them to the client side of the protocol. If the command produces a window of more than one screen's worth of output, vmh prompts the user for a subcommand.

Subcommands

SPACE	Advances to the next screen.
[num] ENTER	Advances the specified number of lines. The default is one line.
[num] y	Goes back the specified number of lines. The default is one line.
[num] d	Advances ten times the specified number of lines. The default for <i>num</i> is 1, for a total of ten lines.

vmh

[num] u Goes back ten times the specified number of lines. The default for num

is 1, for a total of ten lines.

[num] g Goes to the specified line.

[num] G Goes to the end of the window. If num is specified, this command acts

like **g**.

CTRL-L Refreshes the screen.

h Displays a help message.

q Ends output.

Flags

-help Displays help information for the command.

-novmhproc Runs the default *vmproc* directly, without the window management

protocol.

-prompt string Uses the specified string as the prompt.

-vmhproc cmdstring Specifies the program which implements the client side of the

window management protocol. The default is msh.

Profile Entries

Path:

Specifies your mhpath.

mshproc:

Specifies the program used for the MH shell.

Files

 $HOME/.mh_profile$

The MH user profile.

Related Information

The MH command "msh" on page 677.

The mh-profile file in AIX Operating System Technical Reference.

The "Overview of the Message Handling Package" in Managing the AIX Operating System.

vrm2rtfont

Purpose

Converts a standard AIX font file to RT rtx font format.

Syntax

```
vrm2rtfont — aixfile — rtxfile —
```

AJ2FL125

Description

Before any of the standard fonts provided with the AIX Operating System can be used with the X-Windows program, they must be converted to the X-Windows' rtx font file-format. This command takes an AIX font file as input and converts the file to rtx format. This format can be used with X-Windows on RT displays.

Examples

To convert the AIX font file etc/vtm/itl1.9x20 to an rtx font file:

vrm2rtfont /etc/vtm/itl1.9x20 /usr/lpp/fonts/Itl14.500

Note how the output file name conforms to the rtx naming convention.

Files

/etc/vtm /usr/lpp/fonts Contains AIX fonts.

Contains fonts for other programs.

Related Information

The following command: "vrm2rtfont."

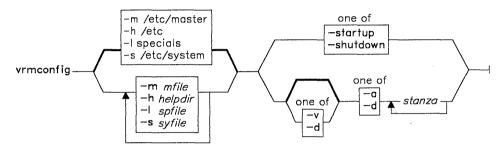

For more information on X-Windows, see X-Windows.

vrmconfig

Purpose

Installs peripheral devices.

Syntax

OL805400

Description

The **vrmconfig** command installs VRM device drivers. Normally, it runs automatically at each system startup. Its exit value is the number of errors it encountered. When auditing is on, an audit record of the type, **vrmconfig** is created.

Note: Most users will never need to run this command from the command line.

The vrmconfig command performs its operations through the /dev/config driver.

Flags

-a stanza	Adds devices to a running system. vrmconfig processes the specified <i>stanza</i> in /etc/system or the file specified with the -s flag.
-d stanza	Deletes a device from a running system. vrmconfig processes the specified stanza in /etc/system or the file specified with -s. The special file list produced includes commands to remove relevant special files, since vrmconfig assumes that the device has been removed from the configuration.
-h helpdir	Specifies the directory that contains the configuration helper programs. The default value is /etc.
-l spfile	Specifies the output special file list. The default value is specials.

-m mfile	Specifies the input master configuration file. The default value is /etc/master.
-s syfile	Specifies the input system configuration file. The default value is /etc/system.
-u	Causes only kernel-related configuration steps to be performed, that is, kernel driver installation calls. This flag may be used only with the -a or -d flags.
-v	Causes only VRM-related configuration steps to be performed, that is, definedevice calls. This flag may be used only with the -a or -d flags.
-shutdown	Causes all installed drives to be deleted for shutting down the system. Special files are not deleted, since the actual configuration is not considered changed.
-startup	Causes all defined devices to be configured in at system startup. (Any stanza that contains the attribute noipl=true is skipped.) For devices such as minidisks, which remain configured between system restarts, vrmconfig does not perform "once-only" configuration steps. It does not modify special files that already exist.

Files

/etc/confgstatus	Status file recording current configuration status.
/etc/system	Default system file.
/etc/master	Default master file.
specials	Default special file list.
/etc	Default directory containing configuration helper programs.
/etc/vrmdd	Directory containing VRM device driver modules.
/vrm/vrmdd	Directory containing VRM device driver modules.
/etc/ddi	Directory containing device specific information files.

Related Information

The master and system files in AIX Operating System Technical Reference.

Installing and Customizing the AIX Operating System.

wall

Purpose

Writes a message to all logged-in users.

Syntax

wall----

OL805017

Description

The wall command reads a message from standard input until it reaches an end-of-file character. It then sends the message to all logged-in users preceded by the following heading:

Broadcast Message from user

To override any protections other users have set up, you must be operating with superuser authority. Typically, **the superuser** uses **wall** to warn all users of an impending system shutdown.

Note: This command only sends messages to the local node.

Files

/dev/tty*

Related Information

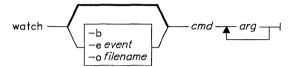

The following commands: "mesg" on page 642, "su" on page 1026, and "write" on page 1225.

watch

Purpose

Observes and reports security-relevant actions on the system.

Syntax

OL805487

Description

The watch command allows a user with superuser authority to observe the actions of an untrustworthy program.

The watch command creates a channel to the audit device on which the events specified by -e event are recorded. If no events are specified, a default set of events is audited and appears on this device. The watch command reads these audit records and writes them to standard output.

The watch command executes the command specified by cmd, (with the arguments specified by args). If the cmd or any of its descendants perform an action specified by the event, the action is audited.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-b Specifies that audit records should be written out as binary records. Normally, the watch command first processes audit records through auditpr.

-e event Specifies an event to be audited for the command. If no -e flag is specified, a list of events which contains all modifications of the trusted computing base is audited.

watch

-o filename Specifies a file name for output. If the -o flag is not specified, audit records are written to standard output.

Files

/dev/audit Used to monitor and enable the actions of descendent processes.

Related Information

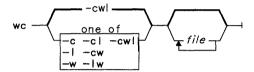

The discussion of trusted programs and the trusted computing base in $Managing\ the\ AIX\ Operating\ System.$

\mathbf{wc}

Purpose

Counts the number of lines, words, and characters in a file.

Syntax

OL805242

Description

The wc command counts the number of lines, words, or characters in *file* or in the standard input if you do not specify any *files*. It writes the results to standard output. It also keeps a total count for all named files. A word is defined as a string of characters delimited by spaces, tabs, or new-line characters. wc counts lines, words, and characters by default.

When you specify more than one file on the command line, wc displays the name of the file along with the counts.

Flags

- -c Counts bytes.
- -l Counts lines.
- -w Counts words.

Examples

1. To display the line, word, and character counts of a file:

wc chap1

This displays the number of lines, words, and characters in the file chap1.

2. To display only character and word counts:

wc -cw chap*

This displays the number of characters and words in each file whose name starts with chap, and displays the totals.

what

Purpose

Displays identifying information in files.

Syntax

OL805295

Description

The **what** command searches the named *files* for all occurrences of the pattern that **get** substitutes for the $%\mathbf{Z}%$ keyletter (see "Identification Keywords" on page 480). By convention, the value substituted is @(#).

what writes to standard output whatever follows the pattern up to but not including the first double quotation mark ("), greater than symbol (>), new-line character, backslash (\), or null character.

The **what** command is intended for use in conjunction with the **get** command, which automatically inserts the identifying information. You can also use **what** on files where the information is inserted manually.

Flags

-s Searches for only the first occurrence of Q(#).

Examples

Related Information

The following commands: "get" on page 477, and "help" on page 513.

The sccsfile file in AIX Operating System Technical Reference.

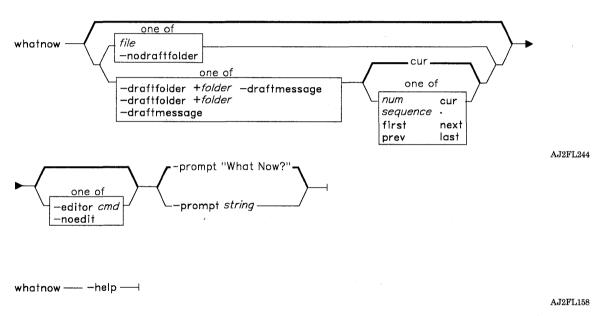

The discussion of SCCS in AIX Operating System Programming Tools and Interfaces.

whatnow

Purpose

Invokes a prompting interface for draft disposition.

Syntax

Description

The whatnow command is the default program used by comp, dist, forw, and repl to prompt you for the disposition of messages. whatnow is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

By default, whatnow invokes an editor and places the current draft message (or *file*) in the editing session. When you exit the editing session, whatnow prompts: What now? You can specify any of the whatnow subcommands, or you can press Enter to see a list of the subcommands. These subcommands enable you to re-edit the message, direct the disposition of the message, or end the processing of the whatnow command. The whatnow command continues to prompt you for subcommands until you specify quit.

Subcommands

Displays the message being acted upon (redistributed or replied display [flags] to). For flags, you can specify any flag that is valid for the command serving as the lproc. (You can set a default lproc: entry in \$HOME/.mh_profile.) If you specify any flags that are not valid for *lproc*, whatnow does not pass the path name of the draft to the lproc. edit [cmdstring] Re-edits the message using the specified editor. You can specify the editor and any valid flags to that editor. If you do not specify an editor, whatnow selects a default editor according to the information supplied in the MH profiles. You can define a default editor for re-editing in \$HOME/.mh_profile. If an editor is not defined for re-editing in your .mh_profile, whatnow invokes the editor used in the previous editing session. list [flags] Displays the draft. For flags, you can specify any flag that is valid for the command serving as the *lproc*. (You can set a default lproc: entry in \$HOME/.mh_profile.) If you specify any flags that are not valid for lproc, whatnow does not pass the path name of the draft to *lproc*. push [flags] Sends the message in the background. You can specify any valid flag for the send command. Ends the whatnow session. If you specify -delete, whatnow quit [-delete] deletes the draft. Otherwise, whatnow stores the draft. Files the draft in the specified folder and supplies a new draft refile [flags] + folder having the previously specified form. For flags, you can specify any flag that is valid for the command serving as the fileproc. (You can set a default fileproc: entry in \$HOME/.mh_profile.) send [flags] Sends the message. You can specify any valid flags for the send command. whom [flags] Displays the addresses to which the message would be sent. You can specify any valid flags for the whom command.

Flags

-draftfolder + folder Places the draft message in the specified folder. If you do not

specify this flag, whatnow selects a default draft folder according to the information supplied in the MH profiles. You can define a

default draft folder in \$HOME/.mh_profile. If

-draftfolder + folder is followed by msg, msg represents the

-draftmessage attribute.

-draftmessage msg Specifies the draft message. You can use one of the following

message references as msg:

num

sequence

first

prev next

cur last

The default draft message is cur.

-editor cmd Specifies that cmd is the initial editor for composing or revising the

message. If you do not specify this flag, whatnow selects a default editor or suppresses the initial edit, according to the information supplied in the MH profiles. You can define a default initial editor

in \$HOME/.mh_profile.

-help Displays help information for the command.

-nodraftfolder Places the draft in the file *user_mh_directory*/**draft**.

-noedit Suppresses the initial edit.

-prompt string Uses string as the prompt. The default string is What now?

Profile Entries

Draft-Folder:

Sets your default folder for drafts. Sets your default initial editor.

Editor: fileproc:

Specifies the program used to refile messages. Specifies the editor used after exiting *lasteditor*.

lasteditor-next:

Specifies the program used to list the contents of a message.

lproc: Path:

Specifies your *user_mh_directory*.

sendproc:

Specifies the program used to send messages.

whomproc:

Specifies the program used to determine the users to whom a message

would be sent.

Files

\$HOME/.mh_profile The MH user profile. user_mh_directory/draft The draft file.

Other MH commands: "comp" on page 185, "dist" on page 336, "forw" on page 438, "prompter" on page 778, "refile" on page 817, "repl" on page 821, "rmm" on page 841, "scan" on page 871, "send" on page 893, "whom" on page 1222.

The mh-alias, mh-format, mh-mail, and mh-profile files in AIX Operating System Technical Reference.

The "Overview of the Message Handling Package" in Managing the AIX Operating System.

who

Purpose

Identifies the users currently logged in.

Syntax

who am i ----

AJ2FL120

Description

The who command with no flags writes to standard output the login name, work station name, and date and time of login for all users currently on the system. Entering who am i displays your login name and work station name, and the date and time you logged on.

Note: The who am i command does not display the time of login when executed from a virtual terminal.

With flags, **who** can also display the elapsed time since line activity occurred, the process ID of the command interpreter (shell), logins, logoffs, restarts, and changes to the system clock, as well as other processes generated by the **init** process.

The general format of the output of **who** is as follows:

name [state] line time activity pid [location] [exit]

where:

- name is the user's login name.
- state indicates whether or not the line is readable by everyone (see the -T flag on page 1221).
- line is the name of the line as found in the directory /dev.
- time is the time the user logged in.

- activity is the hours and minutes since activity last occurred on that user's line. A dot (.) here indicates line activity within the last minute. If the line has been quiet more than 24 hours or has not been used since the last system startup, the entry is marked as old.
- pid is the process ID of the user's shell.
- location is the location associated with this line as found in file /etc/ports. This file can contain information about where the work station is located, the telephone number of the dataset, the type of a direct-connected work station, and other related information.
- exit is the exit status of ended processes (see the -d flag on page 1220).

To obtain information, **who** normally examines /**etc/utmp**. If you specify another *file*, **who** examines the named *file* instead. This *file* will usually be /**usr/adm/wtmp**, which contains the history of all logins since the file was last created or /**etc/.ilog**, which contains the history of invalid logins. Only someone operating with superuser authority or a member of the system group can examine /**etc/.ilog**

Note: This command only identifies users on the local node.

Flags

- -a Processes /etc/utmp or the named file with all flags on.
- -b Indicates the time and date of the most recent system startup. The NLTIME and NLLDATE environment variables control the format of the login time and date.
- -d Displays all processes that have expired without being regenerated by init. The exit field appears for dead processes and contains the termination and exit values (as returned by wait) of the dead process. (This flag is useful for determining why a process ended.)
- -l Lists only work stations not in use. The *name* field is **LOGIN** in such cases. Other fields are the same as for user entries except that the *state* field doesn't appear.
- -p Lists any active process that is currently active and has been previously generated by init.
- -r Indicates the current run-level of the process.
- -s Lists only the *name*, *line*, and *time* fields. (This is the default; thus, **who** and **who** -s are equivalent.) The **NLTIME** environment variable controls the format of the time.
- -t Indicates the last change to the system clock by the superuser using the date command. The NLTIME environment variable controls the format of the time.

- -T Displays the state of the work station line and indicates who can write to that work station as follows:
 - + writable by anyone
 - writable only by the superuser or its owner
 - bad line encountered.
- -u Displays the user name, work station name, login time, line activity, and process ID of each current user. The NLTIME environment variable controls the format of the login time.

Examples

1. To display information about who is using the system:

who

This lists the user name, work station name, and login time of all users currently using the system.

To display your user name:

who am i

This displays the user name you typed when you logged in, the name of the work station you are using, and the time you logged in. Your login user name may be different from your current user name if you have used the su command.

To display a history of logins, logoffs, system startups, and system shutdowns:

```
who /usr/adm/wtmp
```

Files

```
/etc/utmp
/usr/adm/wtmp
/etc/ports
```

The wait system call and the ports and utmp files in AIX Operating System Technical Reference.

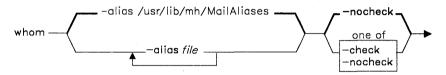

"Overview of International Character Support" in Managing the AIX Operating System.

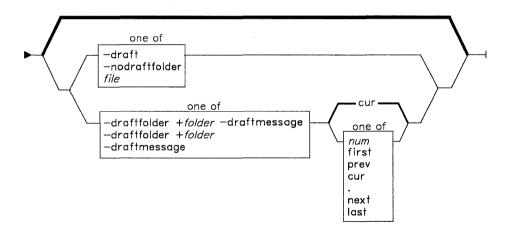

whom

Purpose

Lists the addresses of the proposed recipients of a message and verifies the addresses.

Syntax

AJ2FL172

Description

The **whom** command is used to expand the headers of a message into a set of addresses. **whom** is also used to verify that those addresses are valid. **whom** is part of the MH (Message Handling) package and can be used with other MH and AIX commands.

The message can reside in a draft folder or in a file. You can use one of the **-draft**, **-draftfolder**, **-draftmessage**, or **nodraftfolder** flags or the *file* argument to specify where the message resides.

If you want to verify the addresses, you must specify the -check flag.

Flags

-alias file Specifies that file is a mail alias file to be searched for aliases. The

default alias file is /usr/lib/mh/MailAliases.

-check Checks to see if the addresses are valid.

-draft Uses the header information in the file user_mh_directory/draft if

it exists.

-draftfolder + folder Uses the header information of the draft message in the specified

folder. If you do not specify this flag, **whom** selects a default draft folder according to the information supplied in the MH profiles. You can define a default draft folder in **\$HOME/.mh_profile**. If **-draftfolder** + folder is followed by msg, msg represents the

-draftmessage attribute.

-draftmessage msg Uses the header information in the specified draft message. You

can use one of the following message references when specifying

msg:

num sequence first

prev cur next last

The default draft message is cur.

-help Displays help information for the command.

-nocheck Does not check to see if the addresses are valid. This is the

default.

-nodraftfolder Undoes the last occurrence of **-draftfolder** + folder.

Profile Entries

Draft-Folder: Sets your default folder for drafts.

postproc: Specifies the program used to post messages.

Files

\$HOME/.mh_profile

The MH user profile.

Related Information

Other MH commands: "ali" on page 48, "post" on page 758, "whatnow" on page 1215.

The **mh-alias**, **mh-format**, **mh-mail**, and **mh-profile** files in AIX Operating System Technical Reference.

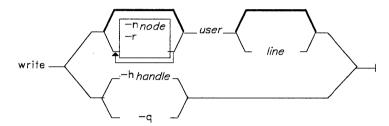

"Overview of the Message Handling Package" in Managing the AIX Operating System.

write

Purpose

Sends messages to other users on the system.

Syntax

AJ2FL121

Description

A common use of this command is to *converse* with another logged-in *user*. That is, each user alternately sends and receives short messages from the other work station. Long messages can be sent by first putting the complete message in a file and then redirecting that file as input to the **write** command.

For another *user* to receive your message, that user must be logged in and must not have refused message permission. When a person you are trying to reach is not logged in, you get the message user not logged in. When the person you are trying to reach has refused message permission, you get the message write: permission denied.

When you run the **write** command, it immediately sends the following message, along with an attention-getting sound (the ASCII BEL character) to the person whose login name you entered.

Message from yourid (ttynn) $\lceil date \rceil$. . .

After successful connection, **write** then sends two ASCII BEL characters to your work station to alert you that whatever you enter now is being sent to the other *user*. Sending continues until you press **Ctrl-D**, at which point **write** sends an end-of-text character to the other work station and exits.

At this point, the other *user* can respond by sending a **write** message back. For this type of exchange, the following convention is useful: When you first **write** to others, wait for them to **write** back before sending any text. End a message with a signal such as 0 (over) to alert the other person to reply. Use 00 (over and out) when the conversation is finished.

When you write to a *user* logged in at more than one work station, write uses the first login instance found in file /etc/utmp as the message delivery point, and you get the message:

userid is logged on more than one place.
You are connected to "work station".
Other locations are:
work station

You can contact this *user* at another location by specifying the *line*. *line* indicates to which work station (tty00, for example) the message should be sent.

Permission to write to another user is granted or denied by the other user with the mesg command. Some commands deny message permission while they are running to prevent interference with their output. A user with superuser authority can write to any work station regardless of the work station's message permission.

If Distributed Services is installed on your system, you can use the **write** command to converse with users on other nodes. You can identify a user on a remote node explicitly by using the **-n** flag or implicitly through entries in the file **/etc/wwwmachines**. This file contains a list of node IDs or nicknames of machines at which a user may be contacted. If you use the **-n** flag, **write** does not run through the list of machines named in **/etc/wwwmachines**.

The write command is also used by **qdaemon** to send messages to users on other nodes and to wait for replies. The contents of the message becomes the reply. Certain keywords in the reply message are recognized as having special meaning. If the user replies with the word Ok, then the original write exits with a status of 0. If the user replies with the word cancel, then the write exits with a status of 1. If the reply contains the word query, then the message associated with the handle given is displayed.

Flags

-n node Specifies a remote node. The node field may be a nickname or a node-ID.

-h handle Replies to a message sent by a utility or shell script using write with the reply option. The value to be used for handle is generated internally and supplied to the user in the text of the original message.

- Generates a message handle, places it in the message header, sends the message, and waits for a reply. This flag is used by **qdaemon** for operator messages and can be put in shell scripts. It is not used for interactive conversations. An exit status of 0 indicates that the reply was 0k, a status of 1 indicates that the reply was cancel, and an exit status of 2 indicates that the user could not be contacted.
- -q Queries all messages awaiting replies from users on a node and displays them with their handles.

Examples

1. To write a message to a user who is logged in:

```
write scottie
I need to see you! Meet me in the computer room at 12:30.
Ctrl-D
```

If your user ID is kirk and you are using work station tty3, scottie's work station displays:

```
Message from kirk tty3...
I need to see you! Meet me in the computer room at 12:30.
EOF
```

2. To hold a conversation:

```
write scottie
Meet me in the computer room at 12:30.
(o)
```

This starts the conversation. The (0) at the end stands for "over." It tells scottie that you are waiting for a response. Do not press Ctrl-D if you wish to continue.

Now Scottie replies by typing:

```
write kirk
I'm running tests at 12:30. Can we meet at 3?
(o)
```

And you might respond:

```
write scottie
OK--the computer room at 3.
(oo)
```

The (00) stands for "over and out," telling Scottie that you have nothing more to say. If Scottie is also finished (00), then you both press Ctrl-D to end the conversation.

3. To write someone a prepared message:

```
write jay <message.text
```

This writes the contents of the file message.text to fred's work station.

4. To write to the person using a certain work station:

```
write - console
The printer in building 998 has jammed.
Please send help.
Ctrl-D
```

This writes the message to the person logged in at the work station /dev/console.

5. To send a message to user spuds at node partya:

```
write -n partya spuds
Your new tape has just arrived,
come see me to pick it up.
Thanks!
Ctrl-D
```

6. Here is an example of a message sent by qdaemon:

```
Message from mary on node 10813661 [ Aug 17 10:03:34 ] ... [ Sent by qdaemon, use "write -h 6398492" to reply ]
```

Please insert tape number 5 into rmt0.

E0F

To reply in the affirmative enter:

```
write -h 6398492
ok
Ctrl-D
```

To reply in the negative enter:

```
write -h 6398492
cancel
Ctrl-D
```

Note: With the -h flag, there is no need to supply the node ID or user ID. This information is tracked with the handle.

Files

/etc/utmp

Contains user and accounting information for the who, write, and

login commands.

/etc/wwwmachines

Contains node IDs and nicknames of machines at which the users

may be contacted.

The following commands: "mesg" on page 642, "nroff, troff" on page 709, "pr" on page 761, "sh" on page 913, "wall" on page 1208, and "who" on page 1219.

writesry

Purpose

Allows Distributed Services users to send messages to and receive messages from a remote system.

Syntax

writesry ---

AJ2FL254

Description

The writesrv command is a daemon that allows users in a Distributed Services environment to send messages to users on a remote system and receive responses from users on a remote system with the write command.

The writesrv utility receives incoming requests from a write command and creates a server process to handle the request. This server process communicates with the client process (write) and provides whatever services are requested.

To perform these services, the **writesrv** command creates an IPC queue using the key 0x203fe. All requests for service are sent as messages to this queue. The server also creates an IPC queue profile named **IBMWRT**node where node is the node ID of the local system. This profile may be examined with the **ipctable** command but should not be modified.

Related Information

The commands: "write" on page 1225 and "ipctable" on page 544.

The msgget, msgctl, msgsnd, and msgrcv system calls in AIX Operating System Technical Reference.

wump

Purpose

Plays the game Hunt the Wumpus.

Syntax

/usr/games/wump —

OL805232

Description

A wumpus is a creature living in a cave with many rooms interconnected by tunnels. You move among the rooms trying to shoot the wumpus with an arrow and trying to avoid being eaten by the wumpus or falling into bottomless pits. There are also Super Bats that may pick you up and drop you in some randomly selected room. For moving among the rooms and shooting arrows, wump asks appropriate questions and follows your instructions.

After either you kill the wumpus, the wumpus eats you, or you fall into a Bottomless Pit, wump asks if you want a new game. To guit the game at any time, press INTERRUPT (Alt-Pause) or END OF FILE (Ctrl-D).

xargs

Purpose

Constructs argument lists and runs commands.

Syntax

OL805298

Description

The **xargs** command runs a command line. It constructs the command line by combining *cmdstring*, a string containing a command and its flags or parameters, with additional arguments read from standard input. It runs *cmdstring* as many times as necessary to process all input arguments. The default *cmdstring* is **echo**.

Arguments read from standard input are character strings delimited by one or more blanks, tabs, or new-line characters. You can embed a blank or a tab in arguments by preceding it with a \ (backslash) or by putting it in quotation marks. xargs reads characters enclosed in single or double quotation marks as literals and removes the delimiting quotes. It always discards empty lines.

Flags

-e[eofstr] Sets the logical end-of-file string to eofstr. xargs reads standard input until it encounters either an end-of-file character or the logical **EOF** string. If you do not specify the -e flag, the default eofstr is _ (the underline character). If you specify -e with no eofstr, xargs interprets the underline character as a literal character rather than as an end-of-file marker.

- -i[replstr] Takes an entire line as a single argument and inserts it in each instance of replstr found in cmdstring. A maximum of five arguments in cmdstring can each contain one or more instances of replstr. xargs discards blanks and tabs at the beginning of each line. The argument constructed cannot be larger than 255 bytes. The default replstr is {}. This flag also turns on the -x flag.
- -I[num] Runs cmdstring with the specified num of nonempty argument lines read from standard input. The last invocation of cmdstring can have fewer argument lines if fewer than num remain. A line ends with the first new-line character unless the last character of the line is a blank or a tab. A trailing blank or tab indicates a continuation through the next non-empty line. The default num is 1. This flag turns on the -x flag.
- -nnum Executes cmdstring using as many standard input arguments as possible, up to a maximum of num. The xargs command uses fewer arguments if their total size is greater than the number of bytes specified by the -ssize flag described below. It also uses fewer arguments for the last invocation if fewer than num arguments remain. When -x is present, each num argument must fit the size limitation specified by -x.
- -p Asks whether or not to run *cmdstring*. It displays the constructed command line, followed by a?... prompt. Press y to run the *cmdstring*. Any other response causes **xargs** to skip that particular invocation of *cmdstring*. You are asked about each invocation.
- -ssize Sets the maximum total size of each argument list. size must be a positive integer less than or equal to 470. The default size is 470 bytes. Note that the byte count for size includes one extra byte for each argument and the number of bytes in the command name.
- -t Echoes the *cmdstring* and each constructed argument list to file descriptor 2 (usually standard error).
- -x Stops running xargs if any argument list is greater than the number of bytes specified by the -ssize. This flag is turned on if you specify either the -i or -l flags. If you do not specify -i, -l, or -n, the total length of all arguments must be within the size limit.

Note: The xargs command ends if it cannot run *cmdstring* or if it receives a return code of -1. When *cmdstring* calls a shell procedure, the shell procedure should explicitly **exit** with an appropriate value to avoid accidentally returning -1. (See "sh" on page 913.)

Examples

1. To use a command on files whose names are listed in a file:

xarqs lint -a <cfiles1 *

If cfiles contains the text:

```
main.c readit.c
gettoken.c
putobj.c
```

then xargs constructs and runs the command:

```
lint -a main.c readit.c gettoken.c putobj.c
```

Each shell command line can be up to 470 bytes long. If cfiles contains more file names than fit on a single line, then **xargs** runs the **lint** command with the file names that fit. It then constructs and runs another **lint** command using the remaining file names. Depending on the names listed in cfiles, the commands might look like:

```
lint -a main.c readit.c gettoken.c . . .
lint -a getisx.c getprp.c getpid.c . . .
lint -a fltadd.c fltmult.c fltdiv.c . . .
```

This is not quite the same as running **lint** once with all the file names. The **lint** command checks cross-references between files. However, in this example it cannot check between main.c and fltadd.c, or between any two files listed on separate command lines.

For this reason you may want to run the command only if all the file names fit on one line. Tell **xargs** this by using the **-x** flag:

```
xargs -x lint -a <cfiles
```

If all the file names in Cfiles do not fit on one command line, then xargs displays an error message.

2. To construct commands that contain a certain number of file names:

```
xargs -t -n2 diff <<end
starting chap1 concepts chap2 writing
chap3
end</pre>
```

This constructs and runs diff commands that contain two file names each (-n2):

```
diff starting chap1
diff concepts chap2
diff writing chap3
```

The -t flag tells xargs to display each command before running it so that you can see what is happening. The <<end and end define a "Here Document," which uses the text entered before the end line as standard input for the xargs command. For more details, see "Inline Input Documents" on page 928.

3. To insert file names into the middle of commands:

ls
$$!$$
 xargs $-t$ $-i$ mv $\{\}$ $\{\}.old$

This renames all files in the current directory by adding .old to the end of each name. The -i tells xargs to insert each line of the ls directory listing where a {} appears. If the current directory contains the files chap1, chap2, and chap3, then this constructs the commands:

```
chap1 chap1.old
mν
mv chap2 chap2.old
my chap3 chap3.old
```

To run a command on files that you select individually:

```
ls | xarqs -p -nl ar r lib.a
```

This allows you to select files to add to the library lib.a. The -p flag tells xargs to display each ar command it constructs and ask if you want to run it. Type V and press Enter to run the command. Press Enter alone if you do not want to run it.

Related Information

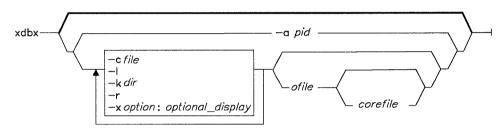

The following command: "sh" on page 913.

xdbx

Purpose

Provides an overlaying X-Window application for the dbx symbolic debugger.

Syntax

AJ2FL128

Description

The **xdbx** command is a user interface for the **dbx** source level debugger that provides a multi-window environment for interactive debugging of C, Pascal, and FORTRAN programs. All **dbx** flags, subcommands, and options can be used with **xdbx**.

Note: The -x flag is available with xdbx but not with dbx.

You must start X-Windows before using the **xdbx** command. The **xdbx** debugger displays up to three separate menu windows depending on the debugging mode. You select a debugging mode from **dbx** or **xdbx** using the **dbx** subcommand **set**.

Flags

-x option: (optional display) Runs the display portion of xdbx on a remote host. Where option is the name of the remote host, and the optional display is a small integer designating the display. The default is 0.

Related Information

The following command: "dbx" on page 284.

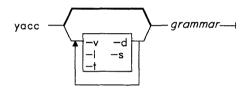

A discussion of how to debug programs in AIX Operating System Programming Tools and Interfaces.

yacc

Purpose

Generates a LR(1) parsing program from input consisting of a context-free grammar specification.

Syntax

OL805300

Description

The yacc command converts a context-free grammar into a set of tables for a simple automaton that executes an LR(1) parsing algorithm. The grammar can be ambiguous; specified precedence rules are used to break ambiguities.

You must compile the output file, y.tab.c, with a C Language compiler to produce a function yyparse. This function must be loaded with the lexical analyzer function yylex, as well as main and yyerror, an error-handling routine (you must provide these routines). The lex command is useful for creating lexical analyzers usable by yacc.

For more detailed discussion of yacc and its operations, see AIX Operating System Programming Tools and Interfaces.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

-d Produces the file y.tab.h. This contains the #define statements that associate the yacc-assigned token codes with your token names. This allows source files other than y.tab.c to access the token codes by including this header file.

- -l Does not include any #line constructs in y.tab.c. Use this only after the grammar and associated actions are fully debugged.
- -s Breaks the yyparse function into several smaller functions. Since its size is somewhat proportional to that of the grammar, it is possible for yyparse to become too large to compile, optimize, or execute efficiently.
- -t Compiles run-time debugging code. By default, this code is not included when y.tab.c is compiled. However, the run-time debugging code is under the control of YYDEBUG, a global variable for the cc command preprocessor. If YYDEBUG has a nonzero value, the C compiler (cc) includes the debugging code, whether or not the -t flag was used. Without compiling this code, yyparse will have a faster operating speed.
- -v Prepares the file **y.output**. It contains a readable description of the parsing tables and a report on conflicts generated by grammar ambiguities.

Files

y.output y.tab.c

y.tab.h

Definitions for token names.

yacc.tmp,

yacc.debug vacc.acts Temporary file. Temporary file.

/usr/lib/yaccpar

Parser prototype for C programs.

Related Information

The following command: "lex" on page 562.

The description of yacc in AIX Operating System Programming Tools and Interfaces.

ypbind

Purpose

Allows Yellow Pages client processes to communicate with the YP server.

Syntax

/etc/vpbind -----

A5AC5011

Description

The **vpbind** commands remembers information that allows client processes on a single node to communicate with some ypserv process. The ypbind daemon must run on all machines using YP services, both YP servers and clients. The ypbind daemon is typically activated at system startup time from /etc/rc.nfs, if that file contains the appropriate

The information handled by **ypbind** for a particular server is called a **binding**. A binding associates a domain name with both the Internet address of a YP server and the server's port at which the **ypserv** process is listening for service requests.

When a request for an unbound domain comes in, the **ypbind** process broadcasts on the network in order to find a vpserv process that serves maps within that domain. When a domain is bound by a particular **ypbind** process, that binding is given to every client process on the node. The ypwhich command can be used to guery the ypbind process on the local node or a remote node for the binding of a particular domain.

Bindings are verified before they are given out to a client process. If **ypbind** is unable to communicate with the ypserv process to which it is bound, it marks the domain as unbound. Then it informs the client process that the domain is unbound and tries again to bind the domain.

Requests for an unbound domain fail immediately. In general, a bound domain is marked as unbound when the node running vpserv crashes or is overloaded. Then vpbind attempts to bind to any YP server available on the network.

The **ypbind** daemon accepts requests to set its binding for a particular domain. Such requests are typically generated by the YP subsystem itself.

ypbind

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

File

/etc/rc.nfs

Related Information

The following commands: "ypcat" on page 1241, "ypmatch" on page 1245, "yppush" on page 1252, "ypserv" on page 1256, "ypset" on page 1254, and "ypwhich" on page 1258.

The section on Yellow Pages in Managing the AIX Operating System.

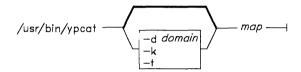

The Yellow Pages library section in AIX Operating System Technical Reference.

ypcat

Purpose

Displays values in a Yellow Pages data base.

Syntax

A5AC5016

Description

The ypcat command displays values in a Yellow Pages map specified by map, which can be either a map name or a map nickname. No YP server is specified since ypcat uses the YP network services.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a *domain* other than the default domain.
- -k Displays the keys for those maps in which the values are null or the key is not part of the value.
- -t Inhibits translation of map nickname to a map name. For example, the command sequence ypcat -t passwd fails because there is no map named passwd. However, the sequence ypcat passwd works because the map nickname passwd is translated to the map name passwd.byname.

-x Displays the map nickname table. The table lists valid nicknames and shows the map name associated with each nickname.

Related Information

The following commands: "ypmatch" on page 1245 and "domainname" on page 340.

ypinit

Purpose

Builds and installs a Yellow Pages (YP) data base on the YP master server and YP slave servers.

Syntax

```
/etc/yp/ypinit ——-s mastername ——
```

A5AC5003

Description

The **vpinit** command sets up a Yellow Pages data base on a YP master server or YP slave server. Only users with superuser authority can use **ypinit**.

With the -m option, ypinit initially sets up a YP master server which functions as the master for all maps in the data base. After initialization you can change the association of maps to masters. The **ypinit** -m command invokes the **make** procedure, which follows the instructions in /etc/yp/Makefile. By default, it uses the ASCII system files as input files to the data bases being created. See the Files section later in this discussion for a list of the default files vpinit uses to create the data base. The files used to build the data bases should be in their full-length form rather than in the abbreviated form used on client machines.

With the -s option, the YP data base on a YP slave server is set up by copying a data base from the YP server specified by the mastername parameter (the machine's host name). The YP server from which the data base is being copied can be the YP master server, or a YP slave server whose data base is up to date and stable.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

Specifies the local host as the YP master server, and installs the YP data -m base of maps.

-s mastername

Sets up a YP slave server by installing a copy of the master data base from the host specified by the *mastername* argument.

Files

```
/etc/passwd
/etc/group
/etc/hosts
/etc/networks
/etc/protocols
/etc/netgroup (if set up)
/etc/rpc
/etc/services
/etc/ethers (if set up)
/etc/networks (if set up)
/usr/lib/aliases (if set up)
```

Related Information

The following commands: "makedbm" on page 632 and "ypxfr" on page 1260.

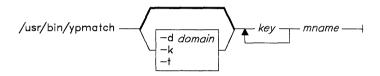

The Yellow Pages section in Managing the AIX Operating System.

ypmatch

Purpose

Displays the value of one or more keys from a Yellow Pages map.

Syntax

/usr/bin/vpmatch — -x —

A5AC5018

Description

The **vpmatch** command displays the values associated with one or more keys from the Yellow Pages (YP) map specified by mname. The mname parameter may be either a mapname or a map nickname.

When multiple keys are specified by the key parameter, the same map is searched for all the specified keys. Pattern matching is not done for keys, so the exact string, including capitalization, must be given.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a *domain* other than the default domain.
- -k Displays the key itself, followed by a colon, before displaying the value of the key. This flag is useful if the keys and their values are not identical, or if you specify so many keys that the output would be difficult to read.

ypmatch

- Inhibits translation of *mname* to a map name. For example, the command sequence ypmatch -t zippy passwd fails because there is no map named passwd. However, the sequence ypmatch zippy passwd works because passwd is translated to the mapname passwd.byname.
- -x Displays the map nickname table. The table lists valid nicknames and shows the mapname associated with each nickname.

Related Information

The following commands: "domainname" on page 340 and "ypcat" on page 1241.

yppasswd

Purpose

Establishes or changes your Yellow Pages password.

Syntax

A5AC5001

Description

The **yppasswd** command establishes or changes your Yellow Pages password entry. Your YP password may be different from the login password you use on your own machine.

When you enter the **yppasswd** command you are prompted for your old YP password. If you do not have an old password, press **Enter**. You then receive the prompt for your new password. If you do have an old YP password, you must type it in correctly in order to be prompted for a new password.

After entering your new password once, you are prompted for it a second time. The first and second entries must match in order for the new password to be validated.

Passwords should be at least four characters long, or six characters long if you use only upper case letters or only lower case letters. Superuser authority is required to change the YP password of another user.

Note: The YP password update protocol passes all the initial information to the server in a single RPC call. If you enter your old password incorrectly, you are not informed until after you enter your new password.

The **yppasswdd** daemon must be running on your YP server in order for your new password to take effect.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

yppasswd

Files

/etc/yp/Makefile /etc/passwd

Related Information

The following commands: "passwd" on page 735 and "yppasswdd" on page 1249.

The section on Yellow Pages in Managing the AIX Operating System.

The /etc/passwd file format in AIX Operating System Technical Reference.

yppasswdd

Purpose

Handles password change requests from the yppasswd command.

Syntax

OL805511

Description

The **yppasswdd** daemon handles password change requests from the **yppasswd** command. It changes a Yellow Pages password entry in a file, provided the file has the same format as the **/etc/passwd** file. An entry in a file is changed only if the password presented by **yppasswd** matches the encrypted password of that entry.

The -m flag runs the make command using Makefile in the /etc/yp directory in order to update the changed password in the YP password data base. Any arguments that follow the -m flag are passed to the make command.

For example, if the Yellow Pages password file is named /etc/yp/passwd, then to have password changes take effect immediately, yppasswdd should be invoked as follows:

```
/usr/etc/rpc.yppasswdd /etc/yp/passwd -m passwd \
   PASSWD=/etc/yp/passwd
```

The **yppasswdd** daemon must be run only on the YP master server for the YP password map. This daemon is not automatically invoked by **inetd** or by default like the other RPC daemons.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

yppasswdd

Flag

-m

Runs the **make** command using **Makefile** in the /etc/yp directory in order to update the changed password in the YP password data base. Any arguments that follow the flag are passed to the **make** command.

Files

/etc/yp/Makefile /etc/passwd

Related Information

The following command: "yppasswd" on page 1247.

The section on Yellow Pages in Managing the AIX Operating System.

The /etc/passwd file format in AIX Operating System Technical Reference.

yppoll

Purpose

Displays the version of a Yellow Pages map located at a Yellow Pages server.

Syntax

A5AC5013

Description

The **yppoll** command queries the **ypserv** process for the order number and name of the host that is the YP master server for the map named by *mapname*.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a domain other than the default domain.
- -h Queries the **ypserv** process at the specified *host* for the map parameters. If **host** is not specified, the YP server for the local host is used.

Related Information

The following command: "ypwhich" on page 1258.

yppush

Purpose

Forces the distribution of a changed Yellow Pages map.

Syntax

A5AC5012

Description

The **yppush** command copies a new version of a Yellow Pages map from the YP master server to YP slave servers. It is normally run only on the YP master server from **/etc/yp/Makefile** after the data bases on the YP master server are changed.

The **yppush** command constructs a list of the YP server hosts by reading the YP map **ypservers** within the specified *domain*. The **ypservers** map contains the names of the machines which maintain YP maps. A request to transfer a map is sent to each YP server, along with the information needed to call back the **yppush** process.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a domain other than the default domain.
- -v Verbose. Causes messages to be displayed when each server is called, and displays one message for each response. Only error messages are displayed if this flag is omitted.

Files

/etc/yp/domainname/ypservers.dir /etc/yp/domainname/ypservers.pag

Related Information

The following commands: "makedbm" on page 632 and "ypxfr" on page 1260.

ypset

Purpose

Directs the **ypbind** daemon to a particular server.

Syntax

A5AC5009

Description

The **ypset** command directs the **ypbind** daemon to get YP services for the specified *domain* from the **ypserv** daemon running on the specified *server*. The binding set by **ypset** is tested by **ypbind** when a client process tries to get a binding for the *domain*. If a binding is invalid (*server* is down or is not running **ypserv**), **ypbind** keeps trying to bind for the same domain.

The **ypset** command can be used to bind a client node that is not on a broadcast network, or to bind a client node on a broadcast network that is not running a YP host. The command can also be used for debugging Yellow Pages client applications, such as when a YP map only exists on a single YP server host.

If several hosts on the local network are supplying YP services, **ypbind** can rebind to another host while you are attempting to find out if the **ypset** operation succeeded. Then you might see the response host2 after typing ypset host1 and ypwhich. Such a response is simply a function of the the YP subsystem's attempt to balance its load among the available YP servers. The response occurs when *host1* is not running **ypserv** or is overloaded, and *host2* is running **ypserv** and is not overloaded.

The server parameter is the YP server to which a machine or node binds. It can be a name or an IP address. If a name is specified, **ypset** tries to use YP services to resolve the name to an IP address. The name can be resolved to an address only if the node has a current valid binding for the *domain*.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a domain other than the default domain.
- Sets **ypbind** on *host* instead of locally. -h
- -V1 Binds server for Version 1 YP protocol.

Related Information

The following commands: "domainname" on page 340, "ypwhich" on page 1258, "ypserv" on page 1256, and "ypbind" on page 1239.

ypserv

Purpose

Looks up information in the local data base of Yellow Pages maps.

Syntax

/usr/etc/ypserv ——

A5AC5010

Description

The **ypserv** daemon is typically activated at system startup time from **/etc/rc.nfs**, if that file contains the appropriate entry. The **ypserv** daemon runs only on Yellow Pages server machines that have a complete YP data base.

The ypserv daemon's primary function is to look up information in its local data base of YP maps. The operations performed by ypserv are defined for programmers by the rpcsvc/yp_prot.h header file, and for network implementors by the YP protocol specification. Communication with ypserv is by means of Remote Procedure Calls.

There are four YP lookup operations that are performed on a specified map within some YP domain: Match, Get_first, Get_next, and Get_all. The Match operation takes a key and returns the associated value. The Get_first operation returns the first key-value pair from the map, and Get_next returns a certain number of the remaining key-value pairs (as specified in the program). The Get_all operation ships the entire YP map to a requestor in response to a single RPC request. These lookup operations are supplied as the following C-callable functions in /lib/libc: yp_match, yp_first, yp_next, and yp_all.

There are two other operations, **Get_order_number** and **Get_master_name**, that supply information about a map instead of map entries. Both order number and master name actually exist in the map as key-value pairs, but the server does not return either of them through the normal lookup functions. However, they will be visible if you examine the map with the **makedbm** command. **Get_order_number** and **Get_master_name** are supplied as the following C-callable functions in /lib/libc: yp_order and yp_master.

Log information is written to the file /etc/yp/ypserv if it exists when ypserv starts running.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Files

/etc/rc.nfs /etc/yp/ypserv.log

Related Information

The following commands: "ypbind" on page 1239, "ypcat" on page 1241, "ypmatch" on page 1245, "yppush" on page 1252, "ypset" on page 1254, "ypwhich" on page 1258, and "ypxfr" on page 1260.

The section on the Yellow Pages in Managing the AIX Operating System.

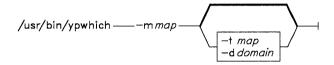

The Yellow Pages section in AIX Operating System Technical Reference.

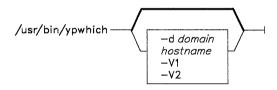

ypwhich

Purpose

Displays the name of the host machine acting as the Yellow Pages server or as a YP map server.

Syntax

A5AC5008

Description

The **ypwhich** command shows which YP server supplies Yellow Pages services to a YP client, or shows which server is the YP master server for a map. With no flags or arguments specified, the **ypwhich** command displays the name of the YP server for the local machine. When a particular machine is specified by **hostname**, that machine is queried for the name of the YP server it is using.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- -d Specifies a domain other than the default domain.
- Finds the master YP server for a map. No hostname can be specified if -m is -m selected. The map parameter can be a mapname or a nickname for a map. A list of available maps is displayed when map is omitted.
- Inhibits nickname translation. This flag is used if map is identical to a -t nickname.
- -V1 Displays name of server using Version 1 YP protocol.
- -V2 Displays name of server using Version 2 YP protocol.
- Displays the map nickname table. The table lists valid nicknames and shows -x the mapname associated with each nickname.

Related Information

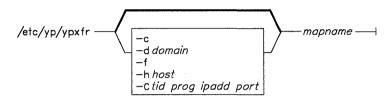

The following commands: "ypset" on page 1254 and "yppoll" on page 1251.

ypxfr

Purpose

Transfers a Yellow Pages map to the local host machine.

Syntax

A5AC5006

Description

The ypxfr command moves a Yellow Pages map to the local host by:

- Creating a temporary map in /etc/yp/domain (which must already exist)
- Filling the map by enumerating its entries
- Fetching and loading the map parameters (order number and server)
- Deleting any old versions of the map
- Assigning mapname to the temporary map, making it the new map.

If used interactively, **ypxfr** sends output to the user's terminal. If invoked without a controlling terminal, **ypxfr** appends its output to the file **/etc/yp/ypxfr.log** (if the file exists). The **ypxfr** command is most often invoked from **crontab** or by the **ypserv** daemon.

To maintain consistent information between servers, **ypxfr** should be used periodically for every map in the YP data base. Some maps change more frequently than others, and therefore should be updated more often. For example, the services name map can change once every few months, whereas the mail aliases and password name maps can change several times a day.

You can use a **crontab** entry to perform periodic updates automatically. You can also group commands together in a shell script to update several maps at once. For useful examples, refer to **ypxfr_1perd**, **ypxfr_2perd**, and **ypxfr_1perh** in the **/etc/yp** directory.

Japanese Language Support Information

If Japanese Language Support is installed on your system, this command is not available.

Flags

- Prevents a "clear current map request" from being sent to the local ypserv -c process. Use this flag if ypserv is not running locally at the time you are running vpxfr.
- -C This option is only for use by **vpsery**. The parameters tid, prog. ipadd, and port (see syntax diagram) must be specified. The ypserv command specifies that **vpxfr** should call back a **vppush** process at the host with IP address ipadd. registered as program number prog, listening on port, and waiting for a response to transaction tid.
- -d Specifies a domain other than the default domain.
- -f Forces the transfer to occur even though the version at the server is not more recent than the local version.
- -h Gets the map from host regardless of the server specified by the map. If host is not specified, vpxfr asks the YP service for the name of the server, and tries to get the map from there. The host parameter may be a name or an IP address of the form a.b.c.d.

Files

/etc/yp/ypxfr.log

Related Information

300

Purpose

Handles special line-motion functions for DASI 300/300s work stations.

Syntax

OL805193

Description

Note: If your work station has a **PLOT** switch, make sure this switch is turned on before using this command.

The **300** command reads standard input, processes its input for printing on the DASI 300, GSI 300, or DTC 300 work stations, and writes to standard output. The **300**s command performs the same functions for the DASI 300s, GSI 300s, and DTC 300s. They convert the input files' motion control characters for half-line forward, half-line reverse, and full-line reverse into motion commands recognized by these work stations.

You can use the 300 and 300s commands to draw Greek characters and other special symbols that require more than one vertical line, and it allows you to use 12-pitch text. For a discussion of special symbols and Greek characters supported by 300, see "greek" on page 499.

The **nroff** command can be used with the **300** command to format text. **300** must be used if you use special delays or formatting options. You can either pipe from **nroff** to **300** or use the **-T300** flag with **nroff** to specify the printing device. The movement control of the **300** command usually produces better aligned output than **nroff -T300**.

When using **nroff**, the -s flag or .rd requests are required for inserting paper manually or changing fonts in the middle of a document. In these cases, you must press the line feed key to continue printing.

Using the 300 command with the neqn command will give you the best display of your equations. You can use the following sequence to display equations:

neqn
$$file$$
 . . . I nroff I 300

Note: Some special characters cannot be correctly printed in column 1 because the print head cannot be moved to the left from that position.

If your output contains Greek characters or reverse line feeds, use a friction-feed platen instead of a forms tractor. A forms tractor slips when reversing direction.

Flags

-dt,len,c Controls output delay factors. The default setting is -d3,90,30. DASI 300 is too slow to handle very long lines, too many tab characters, or long strings with no blanks and no identical characters. One null character is inserted in a line for every set of t tabs, and for every contiguous string of c nonblank, nontab characters. When a line is longer than len bytes, several nulls (the line length divided by 20, plus one) are inserted at the end of that line. In all three cases, the nulls delay the output enough to avoid a problem. Items can be omitted from the end of the list, implying the default values. Entering zero for t results in insertion of two null bytes per tab, while entering zero for c results in insertion of two null bytes per character.

When printing C Language programs, using -d0,1 will help adjust for the many indentation levels. When printing files like /etc/passwd, using -d3,30,5 will help print it properly.

This flag affects carriage return and line feed delays. The stty parameters nl0 cr2 or nl0 cr3 are recommended for most uses.

-num Controls the size of half-line spacing. The default half-line values (which are exact half-lines) of num are:

10-pitch, 6 lines-per-inch, num = 4 12-pitch, 8 lines-per-inch, num = 3 12-pitch, 6 lines-per-inch, num = 4

You can use other values for *num* to change the appearance of subscripts and superscripts. For example, -2 makes **nroff** half-lines act like quarter-lines.

+12 Uses 12-pitch, 6 lines-per-inch text. The DASI 300 normally allows only two combinations: 10-pitch, 6 lines per inch, or 12-pitch, 8 lines per inch. To use the 12-pitch, 6 lines-per-inch combination, set the PITCH switch to 12 and use the +12 flag on the command line.

The greek miscellaneous facility in AIX Operating System Technical Reference.

4014

Purpose

Formats a full page 66-line screen display for a Tektronix 4014 work station.

Syntax

OL805195

Description

The 4014 command reads a *file* (standard input by default) and writes a 66-line page display to standard output. It also divides the screen into a specified number of columns, adding an eight-space page offset when it uses the default single-column format. It interprets tabs, spaces, backspaces, and TELETYPE Model 37 half-line and reverse-line sequences correctly. At the end of each page, 4014 waits for a line feed from the keyboard before continuing. While 4014 is waiting, you can send commands to the shell by entering !AIX-cmd, where AIX-cmd is a AIX command.

Flags

-cnum Divides the screen into num columns and waits after the last column. The default is a single, full page-width column.

-n Starts displaying at the current cursor position and does not erase the screen.

-pnuml

-pnumi Sets page length to num lines (l, the default) or to num inches (i).

-t Does not wait between pages.

Related Information

The following commands: "pr" on page 761, "tc" on page 1056, and "troff" on page 710.

450

Purpose

Handles special line-motion functions for the DASI 450 work station

Syntax

OL805194

Description

The 450 command reads standard input, processes its data for output on a DASI 450 or an equivalent work station (such as the DIABLO 1620 or XEROX 1700). It converts half-line forward, half-line reverse, and full-line reverse motions to the correct vertical motions on standard output. It attempts to draw Greek characters and other special symbols in the same manner as the 300 command vertical line space. See "greek" on page 499 for a list of symbols supported by 450.

Use 450 with the nroff -s flag or .rd requests when you need to insert paper manually or change fonts in the middle of a document. Instead of using the Return key in these cases, you must use the LINE FEED character to get any response. In many cases you can use nroff -T450 instead of the 450 command. However, you must use 450 if you require special delays or options. In a few cases, using 450 may produce better aligned output. You can pipe the output of the neqn command to 450 to print equations neatly.

Notes:

- 1. Make sure the **PLOT** switch is turned on before using this command. Also, the **SPACING** switch should be in the desired position, either 10- or 12-pitch. For either setting, vertical spacing is 6 lines per inch unless changed to 8 lines per inch by an escape sequence.
- 2. Some special characters cannot be correctly printed in column 1 because the print head cannot be moved to the left from that position.
- 3. If your output contains Greek characters or reverse line feeds, use a friction-feed platen instead of a forms tractor. A forms tractor tends to slip when reversing direction.

Flag

-f Permits the use of ETX/ACK protocol with 1200 bps printers. You cannot use 450 with this flag in a pipeline or if you redirect its output. Instead it must drive the printer directly.

Appendix A. AIX Device Table

AIX standard devices are special files. The following table lists and describes some special files. For more detailed information on special files, see AIX Operating System Technical Reference.

Special File	Description
appltrace	Application trace pseudo-device driver
config	Configuration pseudo-device driver
console	Console device
error	Error-logging interface
$\mathbf{fd}[num]$	Diskette drive; block device
fp	Floating-point function
hd[num]	Fixed disk drive; block device
hft	High function terminal
kmem	Kernel memory image
lp[num]	Line printer
mem	Memory image
null	The null device
nvram	Non-volatile memory image
osm	System message interface
prf	AIX Operating System profiler
$\mathbf{rfd}[num]$	Diskette drive; raw device
rhd[num]	Fixed disk drive; raw device
rmt[num]	Streaming tape
termio	General terminal interface
tty[num]	Controlling terminal interface
unixtrace	Kernel trace event pseudo-device driver
vrmtrace	VRM trace event pseudo-device driver

Appendix C. Syntax Diagram Guide

Syntax Diagrams

Syntax diagrams are read from left to right. A single path is followed until the end mark is encountered. An end mark indicates nothing more can be entered with that command.

Within syntax diagrams, the following conventions are used:

- Diagram items that must be entered literally on the command line are in **bold**. These items include the command name, flags, and literal characters.
- Variable diagram items for which you determine the name to enter are in *italics*. These items include parameters that follow flags and parameters that the command reads, such as *files* and *directories*.
- Default values that do not have to be entered are in the normal font on a **bold** path.

Command Only

The simplest syntax diagram illustrates a command that is entered on the command line with nothing else. For example:

logname —

OL805145

The bold command name means **logname** should be entered literally. As you follow the line away from the command name to the right, you reach the end mark and must stop. To enter this command, you would enter:

logname

Commands with Required Parameters

Many diagrams have parameters to represent specific values that you must enter on the command line. When you encounter a parameter, read the command description to determine what to enter in place of the parameter. The following diagram requires a parameter:

unlink — file —

OL805227

The bold command name means **unlink** should be entered literally. As you follow the line away from the command name to the right, the next item that you encounter is the parameter *file*. Since the only path goes through this parameter, you must supply a file name. As you move further to the right, you reach the end mark and must stop. To enter this command, enter:

unlink report

Suppose you want to unlink two files, report and memo. Since this command accepts one and only one file, you would have to enter the command twice:

unlink report unlink memo

Some commands allow you to enter more than one parameter on the command line. If you are allowed to do so, the diagrams show it with a **repeat arrow**, an arrow that provides a path back to an earlier part of the diagram. For example:

OL805063

The bold command name indicates sact should be entered literally. As you follow the line away from the command name to the right, the next item that you encounter is the parameter file. Since the only path goes through this parameter, you must enter a file name. As you move further to the right, you reach a repeat arrow. Here you can choose to remain on the main path and proceed to the end mark or follow the repeat arrow around to the point between the command name and the parameter. Following the repeat arrow allows you to select the parameter again. If there is a maximum number of parameters that you can enter, the diagram tells you that number. If no maximum is specified (as in this diagram), then you can choose the repeat arrow again and again until you reach the limit of the length of a command line. Here are some examples:

sact s.letter sact s.letter s.memo s.report

Commands with an Optional Flag or Parameter

Many commands have optional flags or parameters. If something is optional, you have a choice of paths in the diagram. One takes you around the item, and the other takes you through it. For example:

OT-805049

With this diagram, as you move to the right from the command name, you reach a branch. You can either take the upper branch (nothing is entered) or you can take the lower branch (enter the flag). The bold line above the flag is the default line. This is the most commonly used path. After the branch, you encounter a parameter. Since the only path goes through the parameter you must enter it. After the parameter is entered once you can choose to proceed to the end mark or use the repeat arrow to select the parameter again.

For example:

```
del file1
del file1 file2 file3
del - file1 file2
```

As the command syntax becomes more complicated, the features of the diagrams are combined to help you enter commands properly. The next diagram shows a command that accepts an optional flag and an optional parameter that can be repeated.

OL805052

In this diagram, as you move to the right from the command name, you reach a branch. You can either take the upper branch (nothing is entered) or the lower branch (enter the flag). Next you encounter another branch. Here you can either take the upper branch (nothing is entered) or the lower branch (enter the parameter). If you choose to enter the parameter, you can enter the parameter once and proceed to the end mark or you can use the repeat arrow to select the parameter again. For example:

```
df
df -s
df system1
df -s system1
df system1 system2
df -s system1 system2 system3
```

Commands That Take More Than One Flag

With many commands, you can enter as many items from a group of flags or parameters as you want within the limits of the length of the command line. If this is the case, the items are in a box that has a repeat arrow around it. Follow the arrow around and through the box as many times as necessary to select all of the items you want to use. Note that most commands do not work properly if you choose the same flags more than once. Therefore, once you have chosen an item from the box, you should not choose it again unless a footnote indicates a flag may be used more than once.

¹ The default action is to provide information for each file system in /etc/filesystems with the attribute free=true.

For example:

OL805086

With this command you can enter only the command name by following the default line over the box, enter one flag and then continue to the end mark, or follow the arrow around and choose both flags. The following are examples of valid command lines:

cat cat cat **-** S cat -u -s

Commands with an Exclusive Flag or Parameter

Many commands have flags or parameters that should not be entered together on the command line. Mutually exclusive items are enclosed in a single-choice box (a box with the words one of above it). You can choose only one item from this type of box. The following diagram contains a single-choice box.

$$\frac{\text{one of}}{\binom{n}{y}}$$

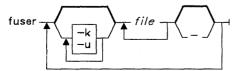

OL805036

Valid ways to enter this command are:

mesq mesg n mesq y

Commands that Can Repeat Part of a Sequence

Some commands allow you to choose flags for each parameter that they read. When this is the case, more than one repeat arrow allows you to go back to earlier parts of the diagram. For example:

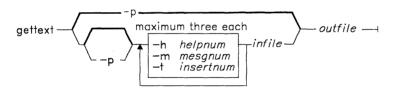

In this diagram, there are three repeat arrows. The first allows you to choose one or both flags. The second allows you to have **fuser** read more than one file. The third allows you to repeat the complete sequence from the beginning of the diagram to the end. The following are all correct ways to enter **fuser**:

```
fuser memo
fuser memo -
fuser -k memo
fuser -k -u memo
fuser -k -u memo letter
fuser -k -u memo -
fuser -k memo - -u -k letter -u report -
```

The third arrow allows you to enter the same flag repeatedly, but only *after* at least one file name has been entered. If you follow the diagram, you cannot repeat a flag without entering at least one file name after it.

Commands with Default Values

The default line can show more than just an alternate path around flags and parameters. Sometimes, a flag is set automatically (by default) or a sometimes a parameter has a default value. When this is the case, the default value is shown in the normal font on the default line. For example:

OL805130

If you do not enter any flags with **gettext**, the -**p** flag is set by default. If you choose the path that contains the -**h**, -**m**, and -**t** flags, you must choose whether or not to use the -**p** flag also. The following command lines are equivalent ways of entering **gettext**:

```
gettext -p report
gettext report
```

The following are valid command lines that do not use the default flag for gettext:

```
gettext -h2 report
gettext -m3 memo report
```

To select both the -p and -m flag, you must explicitly enter the -p flag. For example:

```
gettext -p -m3 memo
```

You can also have default parameter values.

OL805279

In this case you can choose to specify a *profile* or to use the default value /etc/trcprofile. Since the bold path indicates that this is a default, you do not have to enter this file name. The system does this for you. If a *profile* is not supplied, **trace** reads the file /etc/trcprofile.

The following are equivalent command lines:

trace
trace /etc/trcprofile

Diagrams That Are Continued on the Next Line

Some of the more complex diagrams cannot fit on one line. They are marked with an arrowhead where they break, and they continue with the arrowhead on the next line. For example:

OL805437

¹ Do not put a blank between these items.

Follow the diagram making choices until you reach the arrowhead. Then go down to the arrowhead on the next line. Continue until you reach the end mark. Following the diagram will seem to impose a specific order to the flags; however, you do not need to strictly follow that order when entering the command. If strict order is important, it is stated under "Description" in the commands discussion.

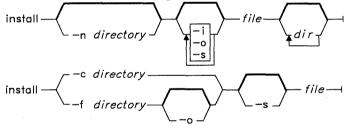

The following are some of the ways you can enter **pr** on the command line:

```
pr
pr -d
pr -o4 -r -m -sX memo letter
pr -r -m -t -n4 -iX3 memo letter report
pr -m -n4 -r -iX3 -t memo report letter
pr -130 5 -3 -a -nX -iX3 -eY memo report
```

Notice that this diagram has a footnote. Footnotes are used to show information that cannot be diagramed. In this case, it tells you that you cannot put a space between the -e or -i flags and their parameters.

Commands With More Than One Diagram

Some commands require more than one diagram to indicate the different ways a command can be entered. For example:

OL805022

Because some flags and parameters cannot be combined with others, two diagrams are required to indicate the ways the command can be entered. For example, the following are ways you can enter this command:

```
install -o fixit /etc /games
install -n /usr/bin fixit
install -c /usr/bin fixit
install -f /usr/bin -o -s fixit
```

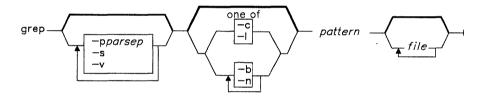

File Input and Output in Diagrams

Some commands must read a file as their input, some must read standard input, and some can read both. The syntax diagrams help you to determine which case applies to each particular command. If a command must read a file as its input, the diagram shows a path through a parameter representing the file and the "Description" section tells you this file is an input file. The path in the diagram will not have a branch around it. The following is an example of a command that must read an input file:

OT-805258

When there is no place in a diagram to supply an input file, the command reads standard input for this information. To supply input through standard input, you can supply it through a pipeline, through redirection of the output from another command, or directly from the keyboard (if it is standard input).

Most commands can either read standard input or files for their input. The diagrams show this by branching and giving you a choice of entering a file name or nothing. For example:

OL805375

If you specify an input file, the command reads that file for its input. If you do not specify a file, the command reads standard input. The following are valid command lines for this command:

```
grep
     AAA
grep
     -sAAA
     AAA memo
grep
     -s -v AAA memo
grep
grep
     AAA memo
                letter report
```

In the first two cases, the grep command reads standard input. In the last three cases, the grep command uses the specified input files.

Note: Some commands require that you enter a - (minus) when you want the command to read standard input. If this is the case, it is explained under "Description", not in the diagram. Usually this is done so that you can read several files as input and you can include standard input as one of the files.

Appendix D. Japanese Language Support

The following table lists the commands that have not been modified to support Japanese characters.				
	dist	ipcrm		
. Ide	dos	ipcs		
acct/*	dosdel	ipctable		
acctems	dp	istat		
acctcom	dsipc	keyboard		
acctcon1, acctcon2	dsldxprof	lint

Glossary

access. To obtain data from or put data in storage.

access permission. A group of designations that determine who can access a particular AIX file and how the user may access the file.

account. The login directory and other information that give a user access to the system.

active service. A code service relationship between a client and a server where the client is dependent on accessing overmounted server directories to get execution access to required programs and functions. Contrast with passive service. See also client and server.

activity manager. A collection of system-supplied tasks allowing users to manage their activities. Provides the ability to list current activities (Activity List) and to begin, cancel, hide, and activate activities.

All Points Addressable (APA) display. A display that allows each pel to be individually addressed. An APA display allows for images to be displayed that are not made up of images predefined in character boxes. Contrast with character display.

allocate. To assign a resource, such as a disk file or a diskette file, to perform a specific task.

alphabetic. Pertaining to a set of letters a through z.

alphanumeric character. Consisting of letters, numbers and often other symbols, such as punctuation marks and mathematical symbols.

American National Standard Code for Information Interchange (ASCII). The code developed by ANSI for information interchange among data processing systems, data communications systems, and associated equipment. The ASCII character set consists of 7-bit control characters and symbolic characters.

American National Standards Institute (ANSI). An organization sponsored by the Computer and Business Equipment Manufacturers Association for establishing voluntary industry standards.

application. A program or group of programs that apply to a particular business area, such as the Inventory Control or the Accounts Receivable application.

application program. A program used to perform an application or part of an application.

argument. Numbers, letters, or words that change the way a command works.

ASCII. See American National Standard Code for Information Interchange.

attribute. A characteristic. For example, the attribute for a displayed field could be blinking.

audit. To review and examine the activities of a data processing system mainly to test the adequacy and effectiveness of procedures for data privacy and data integrity.

audit bin. A file containing unprocessed audit records

audit class. A list of events that define which actions taken on a system are recorded. They

are defined by the administrator of the system in the user data base.

audit event. An action (such as a command or access) taken on a system, which can be recorded by the system.

audit trail. A collection of events that could compromise system security recorded in the order in which they occurred.

auto carrier return. The system function that places carrier returns automatically within the text and on the display. This is accomplished by moving whole words that exceed the line end zone to the next line.

backend. The program that sends output to a particular device. There are two types of backends: friendly and unfriendly.

background process. (1) A process that does not require operator intervention that can be run by the computer while the work station is used to do other work. (2) A mode of program execution in which the shell does not wait for program completion before prompting the user for another command.

backup copy. A copy, usually of a file or group of files, that is kept in case the original file or files are unintentionally changed or destroyed.

backup diskette. A diskette containing information copied from a fixed disk or from another diskette. It is used in case the original information becomes unusable.

backup format. A compressed file format. When the backup command makes a copy of a file, it writes the file in this format. A file in this format must be restored by the restore command before it can be used.

backup format file. (1) A file in backup format. (2) In a code-server environment, a file in backup format that contains a copy of an install or update distribution media for a program.

bad block. A portion of a disk that can never be used reliably.

base address. The beginning address for resolving symbolic references to locations in storage.

base name. The last element to the right of a full path name. A filename specified without its parent directories.

batch printing. Queueing one or more documents to print as a separate job. The operator can type or revise additional documents at the same time. This is a background process.

batch processing. A processing method in which a program or programs process records with little or no operator action. This is a background process. Contrast with *interactive processing*.

big word. A collection of alphanumerics defined by the collation table and bounded by blanks, tabs, or new-line indicators.

binary. (1) Pertaining to a system of numbers to the base two; the binary digits are 0 and 1. (2) Involving a choice of two conditions, such as on-off or yes-no.

bit. Either of the binary digits 0 or 1 used in computers to store information. See also byte.

block. (1) A group of records that is recorded or processed as a unit. Same as *physical record*. (2) In data communications, a group of records that is recorded, processed, or sent as a unit. (3) A block is 512 bytes long. (4) A logical block is 2048 bytes long.

block file. A file listing the usage of blocks on a disk.

block special file. A special file that provides access to an input or output device is capable of supporting a file system. See also *character* special file.

bootstrap. A small program that loads larger programs during system initialization.

branch. In a computer program an instruction that selects one of two or more alternative sets of instructions. A conditional branch occurs only when a specified condition is met.

breakpoint. A place in a computer program, usually specified by an instruction, where execution may be interrupted by external intervention or by a monitor program.

buffer. (1) A temporary storage unit, especially one that accepts information at one rate and delivers it at another rate. (2) An area of storage, temporarily reserved for performing input or output, into which data is read, or from which data is written.

burst pages. On continuous-form paper, pages of output that can be separated at the perforations.

byte. The amount of storage required to represent one character; a byte is 8 bits.

call. (1) To activate a program or procedure at its entry point. Compare with *load*.

callouts. An AIX kernel parameter establishing the maximum number of scheduled activities that can be pending simultaneously.

cancel. To end a task before it is completed.

carrier return. (1) In text data, the action causing line ending formatting to be performed at the current cursor location followed by a line advance of the cursor. Equivalent to the carriage return of a typewriter. (2) A keystroke generally indicating the end of a command line.

case sensitive. Able to distinguish between uppercase and lowercase letters.

character. A letter, digit, or other symbol.

character display. A display that uses a character generator to display predefined character boxes of images (characters) on the screen. This kind of display cannot address the screen any less than one character box at a time. Contrast with *All Points Addressable display*.

character key. A keyboard key that allows the user to enter the character shown on the key. Compare with *function keys*.

character position. On a display, each location that a character or symbol can occupy.

character set. A group of characters used for a specific reason; for example, the set of characters a printer can print or a keyboard can support.

character special file. A special file that provides access to an input or output device. The character interface is used for devices that do not use block I/O. See also block special file.

character string. A sequence of consecutive characters.

character variable. The name of a character data item whose value may be assigned or changed while the program is running.

child. (1) Pertaining to a secured resource, either a file or library, that uses the user list of a parent resource. A child resource can have only one parent resource. (2) In the AIX Operating System, child is a process spawned by a parent process that shares resources of parent process. Contrast with parent.

C language. A general-purpose programming language that is the primary language of the AIX Operating System.

class. Pertaining to the I/O characteristics of a device. AIX devices are classified as block or character.

client. In a code service environment, a system that is dependent on a server to provide it with programs or access to programs.

client partial. The subset of control information or files in a program install or

update distribution that is node unique. That is, those files that must be locally installed on a client for it to successfully run the program in an active-service environment. See also *client*.

close. (1) To end an activity and remove that window from the display.

code. (1) Instructions for the computer. (2) To write instructions for the computer; to program. (3) A representation of a condition, such as an error code.

code page. In AIX, arrays of code points representing characters that establish ordinal sequence (numeric order) of characters. AIX uses 256-character code pages. Code page P0 consists of 1-byte characters that represent the ASCII, ISO, and EBCDIC character sets and additional characters and symbols. Lower code page P0 (0-127 ordinal) is the ASCII character set. Additional code pages consist of code points for 2-byte character representations.

code point. A 1- or 2-byte representation of a character. A byte can contain a single-shifted bit that indicates that the second byte is a part of the same code. In AIX (but not in Japanese Language Support), a byte can contain a single-shifted bit that indicates the code page of the character. Again in AIX, the second byte (only byte in the case of a 1-byte character) places the character in the code page array.

code segment. See segment.

code server. A system that is providing a code service for other computers on a network. See also *code service*.

code service. An integrated process where one or more server systems provide access via a Distributed Services network for any number of client systems to the code and functions of AIX and other programs. See also *server* and Distributed Services *network*.

collating sequence. The sequence in which characters are ordered within the computer for sorting, combining, or comparing.

collation. The process of character and string sorting based on alphabetical order, and, in AIX, on equivalence class. Japanese Language Support uses character class rather than equivalence class.

color display. A display device capable of displaying more than two colors and the shades produced via the two colors, as opposed to a monochrome display.

column. A vertical arrangement of text or numbers.

column headings. Text appearing near the top of columns of data for the purpose of identifying or titling.

command. A request to perform an operation or run a program. When parameters, arguments, flags, or other operands are associated with a command, the resulting character string is a single command.

command interpreter. A program that sends instructions to the kernel; also called an interface.

command line. The area of the screen where commands are displayed as they are typed.

command line editing keys. Keys for editing the command line.

command programming language. Facility that allows programming by the combination of commands rather than by writing statements in a conventional programming language.

compile. (1) To translate a program written in a high-level programming language into a machine language program. (2) The computer actions required to transform a source file into an executable object file.

compress. (1) To move files and libraries together on disk to create one continuous area of unused space. (2) In data communications, to delete a series of duplicate characters in a character string.

concatenate. (1) To link together. (2) To join two character strings.

condition. An expression in a program or procedure that can be evaluated to a value of either true or false when the program or procedure is running.

configuration. The group of machines, devices, and programs that make up a computer system. See also *system customization*.

configuration file. A file that specifies the characteristics of a system or subsystem, for example, the AIX queueing system.

consistent. Pertaining to a file system, without internal discrepancies.

console. (1) The main AIX display station. (2) A device name associated with the main AIX display station.

constant. A data item with a value that does not change. Contrast with *variable*.

context search. A search through a file whose target is a character string.

control block. A storage area used by a program to hold control information.

control commands. Commands that allow conditional or looping logic flow in shell procedures.

control program. Part of the AIX Operating System system that determines the order in which basic functions should be performed.

controlled cancel. The system action that ends the job step being run, and saves any new data already created. The job that is running can continue with the next job step.

copy. The action by which the user makes a whole or partial duplicate of already existing data.

crash. An unexpected interruption of computer service, usually due to a serious hardware or software malfunction.

current directory. The directory that is active, and can be displayed with the **pwd** command.

current line. The line on which the cursor is located.

current working directory. See current directory.

cursor. (1) A movable symbol (such as an underline) on a display, used to indicate to the operator where the next typed character will be placed or where the next action will be directed. (2) A marker that indicates the current data access location within a file.

cursor movement keys. The directional keys used to move the cursor.

customize. To describe (to the system) the devices, programs, users, and user defaults for a particular data processing system.

cylinder. All fixed disk or diskette tracks that can be read or written without moving the disk drive or diskette drive read/write mechanism.

daemon. See daemon process.

daemon process. A process begun by the root or the root shell that can be stopped only by the root. Daemon processes generally provide services that must be available at all times such as sending data to a printer.

data block. See block.

data communications. The transmission of data between computers, or remote devices or both (usually over long distance).

data stream. All information (data and control information) transmitted over a data link.

dbos. The minimum set of AIX programs that must be present to provide code service.

debug. (1) To detect, locate, and correct mistakes in a program. (2) To find the cause of problems detected in software.

default. A value that is used when no alternative is specified by the operator.

default directory. The directory name supplied by the operating system if none is specified.

default drive. The drive name supplied by the operating system if none is specified.

default value. A value stored in the system that is used when no other value is specified.

delete. To remove. For example, to delete a file.

dependent work station. A work station having little or no stand alone capability, that must be connected to a host or server in order to provide any meaningful capability to the user.

device. An electrical or electronic machine that is designed for a specific purpose and that attaches to your computer, for example, a printer, plotter, disk drive, and so forth.

device driver. A program that operates a specific device, such as a printer, disk drive, or display.

device name. A name reserved by the system that refers to a specific device.

diagnostic. Pertaining to the detection and isolation of an error.

diagnostic aid. A tool (procedure, program, reference manual) used to detect and isolate a device or program malfunction or error.

diagnostic routine. A computer program that recognizes, locates, and explains either a fault in equipment or a mistake in a computer program.

digit. Any of the numerals from 0 through 9.

directory. A type of file containing the names and controlling information for other files or other directories.

disable. To make nonfunctional.

discipline. Pertaining to the order in which requests are serviced, for example, first-come-first-served (fcfs) or shortest job next (sjn).

disk I/O. Fixed-disk input and output.

diskette. A thin, flexible magnetic plate that is permanently sealed in a protective cover. It can be used to store information copies from the disk or another diskette.

diskette drive. The mechanism used to read and write information on diskettes.

display device. An output unit that gives a visual representation of data.

display screen. The part of the display device that displays information visually.

display station. A device that includes a keyboard from which an operator can send information to the system and a display screen on which an operator can see the information sent to or received from the computer.

Distributed Services. A licensed program that allows you to use both local and remote directories and files to build file trees.

Distributed Services network. A network that is running Distributed Services. See also Distributed Services.

dump. (1) To copy the contents of all or part of storage, usually to an output device.(2) Data that has been dumped.

dump diskette. A diskette that contains a dump or is prepared to receive a dump.

dump formatter. Program for analyzing a dump.

EBCDIC. See extended binary-coded decimal interchange code.

EBCDIC character. Any one of the symbols included in the 8-bit EBCDIC set.

edit. To modify the form or format of data.

edit buffer. A temporary storage area used by an editor.

editor. A program used to enter and modify programs, text, and other types of documents and data.

emulation. Imitation; for example, when one computer imitates the characteristics of another computer.

enable. To make functional.

enter. To send information to the computer by pressing the Enter key.

entry. A single input operation on a work station.

environment. The settings for shell variables and paths set associated with each process. These variables can be modified later by the user.

equivalence class. In AIX, a grouping of characters (or character strings) that are considered equal for purposes of collation. For example, many languages place an uppercase character in the same equivalence class as its lowercase form, but other languages distinguish between accented and unaccented character forms for the purpose of collation.

error-correct backspace. An editing key that performs editing based on a cursor position; the cursor is moved one position toward the beginning of the line, the character at the new cursor location is deleted, and all characters following the cursor are moved one position toward the beginning of the line (to fill the vacancy left by the deleted element).

escape character. A character that suppresses the special meaning of one or more characters that follow.

exit value. A numeric value that a command returns to indicate whether or not the command completed successfully. Some commands return exit values that give other information, such as whether a file exists. Shell programs can test exit values to control branching and looping.

expression. A representation of a value. For example, variables and constants appearing alone or in combination with operators.

extended binary-coded decimal interchange code (EBCDIC). A set of 256 eight-bit characters.

feature. A programming or hardware option, usually available at an extra cost.

field. (1) An area in a record or panel used to contain a particular category of data. (2) The smallest component of a record that can be referred to by a name.

FIFO. See first-in-first-out.

file. A collection of related data that is stored and retrieved by an assigned name.

file name. The name used by a program to identify a file. See also *label*.

filename. In DOS, that portion of the file name that precedes the extension.

file specification (filespec). The name and location of a file. A file specification consists of a drive specifier, a path name, and a file name.

file system. The complete structure of directories and files contained on a physical or logical mass storage device, such as a diskette or minidisk.

filetab. An AIX kernel parameter establishing the maximum number of files that can be open simultaneously. file tree. The complete directory and file structure of a particular node, starting at the root directory. A file tree contains all local and remote mounts performed on minidisks, directories, and files.

filter. A command that reads standard input data, modifies the data, and sends it to standard output.

first-in-first-out (FIFO). A named permanent pipe. A FIFO allows two unrelated processes to exchange information using a pipe connection.

first level interrrupt handler (FLIH). A routine that receives control of the system as a result of a hardware interrupt. One FLIH is assigned to each of the six interrupt levels.

fixed disk. A flat, circular, nonremoveable plate with a magnetic surface layer on which data can be stored by magnetic recording.

fixed-disk drive. The mechanism used to read and write information on fixed disk.

flag. A modifier that appears on a command line with the command name that defines the action of the command. Flags in the AIX Operating System almost always are preceded by a dash.

flattened character. In AIX, an ASCII character created by translating an extended character to its ASCII equivalent in appearance. Code point information is lost; the character cannot be retranslated to an extended character.

font. A family or assortment of characters of a given size and style.

foreground. A mode of program execution in which the shell waits for the program specified on the command line to complete before returning your prompt.

format. (1) A defined arrangement of such things as characters, fields, and lines, usually used for displays, printouts, or files. (2) The pattern which determines how data is recorded.

formatted diskette. A diskette on which control information for a particular computer system has been written but which may or may not contain any data.

free list. A list of available space on each file system. This is sometimes called the free-block list.

free-block list. See free list.

full install. A complete installation of AIX or other programs.

full path name. The name of any directory or file expressed as a string of directories and files beginning with the root directory.

function. A synonym for procedure. The C language treats a function as a data type that contains executable code and returns a single value to the calling function.

function keys. Keys that request actions but do not display or print characters. Included are the keys that normally produce a printed character, but when used with the code key produce a function instead. Compare with character key.

generation. For some remote systems, the translation of configuration information into machine language.

Gid. See group number.

global. Pertains to information available to more than one program or subroutine.

global action. An action having general applicability, independent of the context established by any task.

global character. The special characters * and? that can be used in a file specification to match one or more characters. For example, placing a? in a file specification means any character can be in that position.

global search. The process of having the system look through a document for specific characters, words, or groups of characters.

global variable. A symbol defined in one program module, but used in other independently assembled program modules.

graphic character. A character that can be displayed or printed.

group name. A name that uniquely identifies a group of users to the system.

group number (Gid). A unique number assigned to a group of related users. The group number can often be substituted in commands that take a group name as an argument.

hardware. The equipment, as opposed to the programming, of a computer system.

header. Constant text that is formatted to be in the top margin of one or more pages.

header label. A special set of records on a diskette describing the contents of the diskette.

here document. Data contained within a shell program or procedure (also called *inline input*).

highlight. To emphasize an area on the display by any of several methods, such as brightening the area or reversing the color of characters within the area.

history file. A file containing a log of system actions and operator responses.

hog factor. In system accounting, an analysis of how many times each command was run, how much processor time and memory it used, and how intensive that use was.

home directory. (1) A directory associated with an individual user. (2) The user's current directory on login or after issuing the **cd** command with no argument.

I/O. See input/output.

ID. Identification.

IF expressions. Expressions within a procedure, used to test for a condition.

indirect block. A block containing pointers to other blocks. Indirect blocks can be single-indirect, double-indirect, or triple-indirect.

informational message. A message providing information to the operator, that does not require a response.

initial program load (IPL). The process of loading the system programs and preparing the system to run jobs. See *initialize*.

initialize. To set counters, switches, addresses, or contents of storage to zero or other starting values at the beginning of, or at prescribed points in, the operation of a computer routine.

inline input. See here document.

i-node. The internal structure for managing files in the system. I-nodes contain all of the information pertaining to the node, type, owner, and location of a file. A table of i-nodes is stored near the beginning of a file system.

i-number. A number specifying a particular i-node on a file system.

inodetab. A kernel parameter that establishes a table in memory for storing copies of i-nodes for all active files.

input. Data to be processed.

input device. Physical devices used to provide data to a computer.

input file. A file opened by a program so that the program can read from that file.

input list. A list of variables to which values are assigned from input data.

input redirection. The specification of an input source other than the standard one.

input-output file. A file opened for input and output use.

input-output device number. A value assigned to a device by the virtual machine or to a virtual device by the virtual resource manager. This number uniquely identifies the device regardless of whether it is real or virtual.

input/output (I/O). Pertaining to either input, output, or both between a computer and a device.

input/output subsystem. That part of the VRM comprised of processes and device managers that provides the mechanism for data transfer and I/O device management and control.

interactive processing. A processing method in which each system user action causes response from the program or the system. Contrast with *batch processing*.

interface. A shared boundary between two or more entities. An interface might be a hardware component to link two devices together or it might be a portion of storage or registers accessed by two or more computer programs.

interleave factor. Specification of the ratio between contiguous physical blocks (on a fixed disk) and logically contiguous blocks (as in a file).

interrupt. (1) To temporarily stop a process. (2) In data communications, to take an action at a receiving station that causes the sending station to end a transmission. (3) A signal sent by an I/O device to the processor when an error has occurred or when assistance is needed to complete I/O. An interrupt usually suspends execution of the currently executing program.

IPL. See initial program load.

job. (1) A unit of work to be done by a system. (2) One or more related procedures or programs grouped into a procedure.

job queue. A list, on disk, of jobs waiting to be processed by the system.

justify. To print a document with even right and left margins.

kbuffers. An AIX kernel parameter establishing the number of buffers that can be used by the kernel.

K-byte. See kilobyte.

kernel. A part of the AIX Operating System which participates in the control of computer functions such as input/output, management and control of hardware and software, and scheduling of user processes.

kernel parameters. Variables that specify how the kernel allocates certain system resources.

key pad. A physical grouping of keys on a keyboard (for example, numeric key pad, and cursor key pad).

keyboard. An input device consisting of various keys allowing the user to input data, control cursor and pointer locations, and to control the dialog between the user and the display station

keylock feature. A security feature in which a lock and key can be used to restrict the use of the display station.

keyword. One of the predefined words of a programming language; a reserved word.

keyword argument. One type of variable assignment that can be made on the command line.

kill. An AIX Operating System command that stops a process.

kill character. The character that is used to delete a line of characters entered after the user's prompt.

kilobyte. 1024 bytes.

kprocs. A kernel parameter establishing the maximum number of processes that the kernel can run simultaneously.

label. (1) The name in the disk or diskette volume table of contents that identifies a file. See also *file name*. (2) The field of an instruction that assigns a symbolic name to the location at which the instruction begins, or such a symbolic name.

left margin. The area on a page between the left paper edge and the leftmost character position on the page.

left-adjust. The process of aligning lines of text at the left margin or at a tab setting such that the leftmost character in the line or filed is in the leftmost position. Contrast with right-adjust.

library. A collection of functions, calls, subroutines, or other data.

licensed program product (LPP). Software programs that remain the property of the manufacturer, for which customers pay a license fee.

line editor. An editor that modifies the contents of a file one line at a time.

linefeed. An ASCII character that causes an output device to move forward one line.

link. A connection between an i-node and one or more file names associated with it.

literal. A symbol or a quantity in a source program that is itself data, rather than a reference to data.

load. (1) To move data or programs into storage. (2) To place a diskette into a diskette

drive, or a magazine into a diskette magazine drive. (3) To insert paper into a printer.

loader. A program that reads run files into main storage, thus preparing them for execution.

local. Pertaining to a device directly connected to your system without the use of a communications line. Contrast with *remote*.

log. To record; for example, to log all messages on the system printer. A list of this type is called a log, such as an error log.

log in. To begin a session at a display station.

login shell. The program, or command interpreter, started for a user at login.

log off. To end a session at a display station.

log out. To end a session at a display station.

logical device. A file for conducting input or output with a physical device.

login user ID. The ID set by the system for a user at login.

loop. A sequence of instructions performed repeatedly until an ending condition is reached.

main program. A primary or control program. See also program.

main storage. The part of the processing unit where programs are run.

maintenance system. A special version of the AIX Operating System which is loaded from diskette and used to perform system management tasks.

major device number. A system identification number for each device or type of device.

mapped files. Files on the fixed disk that are accessed as if they are in memory.

mask. A pattern of characters that controls the keeping, deleting, or testing of portions of another pattern of characters.

matrix. An array arranged in rows and columns.

maxprocs. A kernel parameter establishing the maximum number of processes that can be run simultaneously by a user.

memory. Storage on electronic chips. Examples of memory are random access memory, read only memory, or registers. See *storage*.

menu. A displayed list of items from which an operator can make a selection.

message. (1) A response from the system to inform the operator of a condition which may affect further processing of a current program. (2) Information sent from one user in a multiuser operating system to another.

minidisk. A logical division of a fixed disk.

minor device number. A number used to specify various types of information about a particular device, for example, to distinguish among several printers of the same type.

mode word. An i-node field that describes the type and state of the i-node.

modem. See modulator-demodulator.

modulation. Changing the frequency or size of one signal by using the frequency or size of another signal.

modulator-demodulator (modem). A device that converts data from the computer to a signal that can be transmitted on a communications line, and converts the signal received to data for the computer.

module. (1) A discrete programming unit that usually performs a specific task or set of tasks. Modules are subroutines and calling programs

that are assembled separately, then linked to make a complete program. (2) See *load module*.

mount. To make accessible to a file system or file tree. AIX allows local file and directory mounts. Distributed Services permits those file mounts to occur for a remote node.

mountab. A kernel parameter establishing the maximum number of file systems that can be mounted simultaneously.

multiprogramming. The processing of two or more programs at the same time.

multivolume file. A diskette file occupying more than one diskette.

nest. To incorporate a structure or structures of some kind into a structure of the same kind. For example, to nest one loop (the nested loop) within another loop (the nesting loop); to nest one subroutine (the nested subroutine) within another subroutine (the nesting subroutine).

network. A collection of products connected by communication lines for information exchange between locations.

new-line character. A control character that causes the print or display position to move to the first position on the next line.

node. An individual system connected to a network.

null. Having no value, containing nothing.

null character (NUL). The character hex 00, used to represent the absence of a printed or displayed character.

numeric. Pertaining to any of the digits 0 through 9.

object code. Machine-executable instruction, usually generated by a compiler from source code written in a higher level language. Consists of directly executable machine code. For programs that must be linked, object code consists of relocatable machine code.

octal. A base eight numbering system.

open. To make a file available to a program for processing.

operating system. Software that directs and controls the hardware and software in the computer system in which the operating system resides, by providing services such as resource allocation, scheduling, input/output control, and data management.

operation. A specific action (such as move, add, multiply, load) that the computer performs when requested.

operator. A symbol representing an operation to be done.

output. The result of processing data.

output devices. Physical devices used by a computer to present data to a user.

output file. A file that is opened by a program so that the program can write to that file.

output redirection. The specification of an output destination other than the standard one.

overmount. A mount in which the path to the mount point and the path to the mounted object are the same. For example in a code server environment you might mount a server's /usr/lib over a client's /usr/lib.

override. (1) A parameter or value that replaces a previous parameter or value. (2) To replace a parameter or value.

overwrite. To write output into a storage or file space that is already occupied by data.

owner. The user who has the highest level of access authority to a data object or action, as defined by the object or action.

pad. To fill unused positions in a field with dummy data, usually zeros or blanks.

page. A block of instructions, data, or both.

page space minidisk. The area on a fixed disk that temporarily stores instructions or data currently being run. See also *minidisk*.

pagination. The process of adjusting text to fit within margins and/or page boundaries.

paging. The action of transferring instructions, data, or both between real storage and external page storage.

parallel processing. The condition in which multiple tasks are being performed simultaneously within the same activity.

parameter. Information that the user supplies to a panel, command, or function.

parent. Pertaining to a secured resource, either a file or library, whose user list is shared with one or more other files or libraries. Contrast with *child*.

parent directory. The directory one level above the current directory.

partition. See minidisk.

passive service. A code service relationship between a client and a server where the client accesses a server, installs one or more programs from files on the server then disconnects and runs as a stand-alone system. Contrast with active service. See also client and server.

password. A string of characters that, when entered along with a user identification, allows an operator to sign on to the system.

password security. A program product option that helps prevent the unauthorized use of a display station, by checking the password entered by each operator at sign-on.

path name. See full path name and relative path name.

pattern-matching character. Special characters such as * or ? that can be used in search patterns. Some used in a file specification to match one or more characters.

For example, placing a? in a file specification means any character can be in that position. Pattern-matching characters are also called wildcards.

permission code. A three-digit octal code, or a nine-letter alphabetic code, indicating the access permissions. The access permissions are read, write, and execute.

permission field. One of the three-character fields within the permissions column of a directory listing indicating the read, write, and run permissions for the file or directory owner, group, and all others.

phase. One of several stages file system checking and repair performed by the fsck command.

physical device. See device.

physical file. An indexed file containing data for which one or more alternative indexes have been created.

physical record. (1) A group of records recorded or processed as a unit. Same as block.
(2) A unit of data moved into or out of the computer.

PID. See process ID.

pipe. To direct the data so that the output from one process becomes the input to another process.

pipeline. A direct, one-way connection between two or more processes.

pitch. A unit of width of typewriter type, based on the number of times a letter can be set in a linear inch. For example, 10-pitch type has 10 characters per inch.

platen. The support mechanism for paper on a printer, commonly cylindrical, against which printing mechanisms strike to produce an impression.

pointer. A logical connection between physical blocks.

port. (1) To make the programming changes necessary to allow a program that runs on one type of computer to run on another type of computer. (2) An access point for data input to or data output from a computer system. See connector.

position. The location of a character in a series, as in a record, a displayed message, or a computer printout.

positional parameter. A shell facility for assigning values from the command line to variables in a program.

print queue. A file containing a list of the names of files waiting to be printed.

printout. Information from the computer produced by a printer.

priority. The relative ranking of items. For example, a job with high priority in the job queue will be run before one with medium or low priority.

priority number. A number that establishes the relative priority of printer requests.

privileged instructions. System control instructions that can only run in the processor's privileged state (VRM mode). Privileged instructions generally manipulate virtual machines or the memory manager; they typically are not used by application programmers. See privileged state.

privileged state. A hardware protection state in which the processor can run privileged instructions.

privileged user. The account with superuser authority.

problem determination. The process of identifying why the system is not working. Often this process identifies programs,

equipment, data communications facilities, or user errors as the source of the problem.

problem determination procedure. A prescribed sequence of steps aimed at recovery from, or circumvention of, problem conditions.

procedure. See shell procedure.

process. (1) A sequence of actions required to produce a desired result. (2) An entity receiving a portion of the processor's time for executing a program. (3) An activity within the system begun by entering a command, running a shell program, or being started by another process.

process accounting. An analysis of the use each process makes of the processing unit, memory, and I/O resources.

process ID (PID). A unique number assigned to a process that is running.

profile. (1) A file containing customized settings for a system or user (2) Data describing the significant features of a user, program, or device.

program. A file containing a set of instructions conforming to a particular programming language syntax.

prompt. A displayed request for information or operator action.

propagation time. The time necessary for a signal to travel from one point on a communications line to another.

qdaemon. The daemon process that maintains a list of outstanding jobs and sends them to the specified device at the appropriate time.

queue. A line or list formed by items waiting to be processed.

queued message. A message from the system that is added to a list of messages stored in a file for viewing by the user at a later time. This

is in contrast to a message that is sent directly to the screen for the user to see immediately.

quit. A key, command, or action that tells the system to return to a previous state or stop a process.

quote. To mask the special meaning of certain characters; to cause them to be taken literally.

random access. An access mode in which records can be read from, written to, or removed from a file in any order.

readonly. Pertaining to file system mounting, a condition that allows data to be read, but not modified.

recovery procedure. (1) An action performed by the operator when an error message appears on the display screen. Usually, this action permits the program to continue or permits the operator to run the next job. (2) The method of returning the system to the point where a major system error occurred and running the recent critical jobs again.

redirect. To divert data from a process to a file or device to which it would not normally go.

reference count. In an i-node, a record of the total number of directory entries that refer to the i-node.

relational expression. A logical statement describing the relationship (such as greater than or equal) of two arithmetic expressions or data items.

relational operator. The reserved words or symbols used to express a relational condition or a relational expression.

relative address. An address specified relative to the address of a symbol. When a program is relocated, the addresses themselves will change, but the specification of relative addresses remains the same.

relative addressing. A means of addressing instructions and data areas by designating their locations relative to some symbol.

relative path name. The name of a directory or file expressed as a sequence of directories followed by a file name, beginning from the current directory.

remote. Pertaining to a system or device that is connected to your system through a communications line. Contrast with *local*.

reserved character. A character or symbol that has a special (nonliteral) meaning unless quoted.

reserved word. A word that is defined in a programming language for a special purpose, and that must not appear as a user-declared identifier.

reset. To return a device or circuit to a clear state.

restore. To return to an original value or image. For example, to restore a library from diskette.

right adjust. The process of aligning lines of text at the right margin or tab setting such that the rightmost character in the line or file is in the rightmost position.

right justify. See right align.

right margin. The area on a page between the last text character and the right upper edge.

right-adjust. To place or move an entry in a field so that the rightmost character of the field is in the rightmost position. Contrast with *left-adjust*.

root. Another name sometimes used for superuser.

root directory. The top level of a tree-structured directory system.

root file system. The basic AIX Operating System file system, which contains operating

system files and onto which other file systems can be mounted. The root file system is the file system that contains the files that are run to start the system running.

routine. A set of statements in a program causing the system to perform an operation or a series of related operations.

run. To cause a program, utility, or other machine function to be performed.

run-time environment. A collection of subroutines and shell variables that provide commonly used functions and information for system components.

scratch file. A file, usually used as a work file, that exists until the program that uses it ends.

screen. See display screen.

scroll. To move information vertically or horizontally to bring into view information that is outside the display screen boundaries.

second level interrupt handler (SLIH). A routine that handles the processing of an interrupt from a specific adapter. An SLIH is called by the first level interrupt handler associated with that interrupt level.

sector. (1) An area on a disk track or a diskette track reserved to record information. (2) The smallest amount of information that can be written to or read from a disk or diskette during a single read or write operation.

security. The protection of data, system operations, and devices from accidental or intentional ruin, damage, or exposure.

segment. A contiguous area of virtual storage allocated to a job or system task. A program segment can be run by itself, even if the whole program is not in main storage.

separator. A character used to separate parts of a command or file.

sequential access. An access method in which records are read from, written to, or removed from a file based on the logical order of the records in the file.

server. (1) On a network, the computer that contains programs, data, or provides the facilities to be accessed by other computers on the network. (2) A program that handles protocol, queueing, routing, and other tasks necessary for data transfer between devices in a computer system. (3) An application program that usually runs in the background (daemon) and is controlled by the System Program Controller.

session records. In the accounting system, a record of time connected and line usage for connected display stations, produced from login and logoff records.

set flags. Flags that can be put into effect with the shell set command.

shared printer. A printer that is used by more than one work station.

shell. A program that accepts and interprets commands for the operating system, such as sh, csh, and the DOS shell program. Also called a *shell program*.

shell procedure. A series of commands contained in a file that carry out a particular function when the file is run or when the file is specified as an argument to the sh command. Also called a *shell script*.

shell program. See shell.

shell prompt. The character string on the command line indicating that the system can accept a command (typically the \$ character).

shell script. See shell procedure.

shell variables. Facilities of the shell program for assigning variable values to constant names.

shutdown. The process of ending the operation of a system or a subsystem by following a defined procedure.

size field. In an i-node, a field that indicates the size, in bytes, of the file associated with the i-node.

software. Programs.

sort. To rearrange some or all of a group of items based upon the contents or characteristics of those items.

source diskette. The diskette containing data to be copied, compared, restored, or backed up.

source program. A set of instructions written in a programming language, that must be translated to machine language compiled before the program can be run.

special character. A character other than an alphabetic or numeric character. For example; *, +, and % are special characters.

special file. Used in the AIX Operating System to provide an interface to input/output devices. There is at least one special file for each device connected to the computer. Contrast with directory and file. See also block special file and character special file.

spool files. Files used in the transmission of data among devices.

standalone shell. A limited version of the shell program used for system maintenance.

stand-alone system. See *stand-alone work station*.

stand-alone work station. (1) A work station that can be used to perform tasks independent of (without being connected to) other resources such as servers or host systems. (2) A node that either does not have Distributed Services installed or is acting in ways that do not use the function provided by Distributed Services.

standard error (STDERR). The place where many programs place error messages.

standard input (STDIN). The primary source of data going into a command. Standard input comes from the keyboard unless redirection or piping is used, in which case standard input can be from a file or the output from another command.

standard output (STDOUT). The primary destination of data coming from a command. Standard output goes to the display unless redirection or piping is used, in which case standard output can be to a file or another command.

stanza. A group of lines in a file that together have a common function. Stanzas are usually separated by blank lines, and each stanza has a name.

statement. An instruction in a program or procedure.

status. (1) The current condition or state of a program or device. For example, the status of a printer. (2) The condition of the hardware or software, usually represented in a status code.

STDERR. See standard error.

STDIN. See standard input.

STDOUT. See standard output.

storage. (1) The location of saved information. (2) In contrast to memory, the saving of information on physical devices such as disk or tape. See *memory*.

storage device. A device for storing and/or retrieving data.

string. A linear sequence of entities such as characters or physical elements. Examples of strings are alphabetic string, binary element string, bit string, character string, search string, and symbol string.

su. See superuser.

subdirectory. A directory contained within another directory in the file system hierarchy.

subprogram. A program invoked by another program. Contrast with *main program*.

subroutine. (1) A sequenced set of statements that may be used in one or more computer programs and at one or more points in a computer program. (2) A routine that can be part of another routine. See also *routine*.

subscript. An integer or variable whose value refers to a particular element in a table or an array.

subshell. An instance of the shell program started from an existing shell program.

substring. A part of a character string.

subsystem. A secondary or subordinate system, usually capable of operating independently of, or synchronously with, a controlling system.

superblock. The most critical part of the file system containing information about every allocation or deallocation of a block in the file system.

superuser (su). The user who can operate without the restrictions designed to prevent data loss or damage to the system (user ID 0).

superuser authority. The unrestricted ability to access and modify any part of the operating system that is associated with the user who manages the system. The authority obtained when one logs in as **root**.

system. The computer and its associated devices and programs.

system call. A request by an active process for a service by the system kernel.

system customization. A process of specifying the devices, programs, and users for a particular data processing system.

system date. The date assigned by the system user during setup and maintained by the system.

system dump. A copy of memory made whenever an error stops the system. Contrast with *task dump*.

system management. The tasks involved in maintaining the system in good working order and modifying the system to meet changing requirements.

system parameters. See kernel parameters.

system profile. A file containing the default values used in system operations.

system unit. The part of the system that contains the processing unit, the disk drives, and the diskette drives.

system user. A person who uses a computer system.

target diskette. The diskette to be used to receive data from a source diskette.

task. A basic unit of work to be performed. Examples are a user task, a server task, and a processor task.

task dump. A copy of memory associated program that failed (and its data). Contrast with system dump.

terminal. An input/output device containing a keyboard and either a display device or a printer. Terminals usually are connected to a computer and allow a person to interact with the computer.

text. A type of data consisting of a set of linguistic characters (for example, alphabet, numbers, and symbols) and formatting controls.

text application. A program defined for the purpose of processing text data (for example, memos, reports, and letters).

text editing program. See editor and text application.

texttab. A kernel parameter establishing the size of the text table, in memory, that contains one entry each active shared program text segment.

trace. To record data that provides a history of events occurring in the system.

trace table. A storage area into which a record of the performance of computer program instructions is stored.

track. A circular path on the surface of a fixed disk or diskette on which information is magnetically recorded and from which recorded information is read.

trap. An unprogrammed, hardware-initiated jump to a specific address. Occurs as a result of an error or certain other conditions.

tree-structured directories. A method for connecting directories such that each directory is listed in another directory except for the root directory, which is at the top of the tree.

truncate. To shorten a field or statement to a specified length.

trusted communications path. A secure path to the system, invoked with a key sequence and used when entering or changing security-relevant information in the system. Used, for example, when changing passwords or logging in to the system.

trusted computing base. The total of all system components, both hardware and software, that protect data in the system.

trusted program. A program which assures proper function and is known to be free of programs that can compromise security.

trusted shell. A modified command interpreter that provides a restricted environment to perform administrative tasks in a secure manner.

typematic key. A key that repeats its function multiple times when held down.

typestyle. Characters of a given size, style and design.

Uid. See user number.

update. An improvement for some part of the system.

user. The name associated with an account.

user account. See account.

user ID. See user number.

user name. A name that uniquely identifies a user to the system.

user number (Uid). (1) A unique number identifying an operator to the system. This string of characters limits the functions and information the operator is allowed to use. The Uid can often be substituted in commands that take a user's name as an argument.

user profile. A file containing a description of user characteristics and defaults (for example, printer assignment, formats, group ID) to be conveyed to the system while the user is signed on.

utility. A service; in programming, a program that performs a common service function.

valid. (1) Allowed. (2) True, in conforming to an appropriate standard or authority.

value. (1) In Usability Services, information selected or typed into a pop-up. (2) A set of characters or a quantity associated with a parameter or name. (3) In programming, the contents of a storage location.

variable. A name used to represent a data item whose value can change while the program is running. Contrast with *constant*.

verify. To confirm the correctness of something.

version. Information in addition to an object's name that identifies different modification levels of the same logical object.

virtual device. A device that appears to the user as a separate entity but is actually a shared portion of a real device. For example, several virtual terminals may exist simultaneously, but only one is active at any given time.

virtual machine. The hardware-independent portion (kernel, shells, libraries, and other subsystems) of the AIX Operating System and user applications.

virtual machine interface (VMI). A standard software interface between the kernel and the Virtual Resource Manager.

virtual resource manager (VRM). A portion of the AIX Operating System that provides various services, interfaces and run-time routines, through which AIX controls the IBM RT hardware and peripherals.

virtual resources. See virtual resource manager.

virtual storage. Addressable space that appears to be real storage. From virtual storage, instructions and data are mapped into real storage locations.

virtual terminal. Any of several logical equivalents of a display station available at a single physical display station.

Volume ID (Vol ID). A series of characters recorded on the diskette used to identify the diskette to the user and to the system.

VRM. See virtual resource manager.

wildcard. See pattern-matching characters.

word. A contiguous series of 32 bits (4 bytes) in storage, addressable as a unit. The address of the first byte of a word is evenly divisible by four.

work file. A file used for temporary storage of data being processed.

work station. A device at which an individual may transmit information to, or receive information from, a computer for the purpose of performing a task, for example, a display

station or printer. See programmable work station and dependent work station.

working directory. See current directory.

wrap around. Movement of the point of reference in a file from the end of one line to the beginning of the next, or from one end of a file to the other.

Task Index

This index groups commands by task. Each command listing includes a command, a page reference, and a description of the command. Commands are grouped under the following tasks:

Managing the System	
Installing and Maintaining Programs	TASK-3
Configuring the System	TASK-3
Backing Up and Restoring System Files	TASK-4
Managing File Systems	TASK-4
Analyzing System Activity	TASK-5
Performing System Accounting Functions	TASK-6
Controlling System Security	TASK-6
Managing System Auditing	TASK-6
Managing the Secure System	TASK-6
Managing the Trusted Path	TASK-7
Managing Access Permissions and Ownerships	TASK-7
Using the System	TASK-8
Starting and Stopping the System	TASK-8
Using Shells and Interfaces	TASK-8
Displaying System Statistics and Information	TASK-8
Controlling System Processes	TASK-9
Using Disks and Diskettes	TASK-10
Using Tape	TASK-10
Working with Work Stations	TASK-10
Working with Files and Directories	TASK-11
Working with Directories	TASK-11
Creating and Editing Files	TASK-12
Printing and Displaying Files	TASK-12
Copying and Moving Files	TASK-12
Deleting Files	TASK-13
Comparing Files	TASK-13
Scanning Files	TASK-13
Sorting Files	TASK-14
Merging and Splitting Files	TASK-14
Working with Remote Files	TASK-14
Formatting Text	TASK-15
Working with Graphics	TASK-15
Protecting Files with File Permissions	TASK-16
Backing Up and Restoring Files	TASK-16
Working with Data	TASK-16
Using Data Tools	TASK-16

Performing Calculator Functions	TASK-17
Communicating on the System	TASK-17
Sending Messages and Notices	TASK-17
Using Mailboxes	TASK-17
Using the MH (Message Handling) Package	TASK-17
Communicating with Other Systems	TASK-19
Developing Programs	TASK-19
Programming in Assembler	TASK-19
Programming in C	TASK-19
Programming in Miscellaneous Languages	TASK-20
Programming in Shell	TASK-20
Working with Messages	TASK-21
Debugging Programs	TASK-21
Managing Source Programs Using the Source Code Control System (SCCS)	TASK-21
Managing Object Files	TASK-22
Playing Games	TASK-22

Managing the System

The following groups of commands are important for managing various aspects of the system.

Installing and Maintaining Programs

cvid	272	Creates a VRM install diskette for backup purposes.
install	524	Installs a command.
installp	529	Installs a licensed program.
make	625	Maintains up-to-date versions of programs.
mdrc	640	Allows you to reinstall a user-created minidisk after you have reinstalled AIX.
ndtable	685	Accesses the Distributed Services Node Table.
pwtable	801	Accesses the Distributed Services Node Security Table.
updatep	1122	Updates one or more programs.

Configuring the System

bffcreate	108	Creates files in backup format for complete or subset programs in a code service environment.
$\mathbf{biodd}_{-}\mathbf{cfg}$	115	Configures the block I/O AIX device driver.
chkcomp	158	Checks compatibility between a code server and an active-service client.
chngstate	164	Changes the state of a code service client to either active-service or stand-alone.
chparm	171	Changes or examines system parameters.
config	194	Extracts configuration information from configuration files.
devices	315	Adds, deletes, changes, and displays device information.
defkey	306	Defines keyboard key assignments.
display	332	Selects the physical display that an existing or new virtual terminal uses and sets colors and fonts.
dsipc	354	Installs the Interprocess Communication key mapping in the kernel.
dsldxprof	355	Loads translate information into the UID/GID translate profiles.
dsxlate	363	Installs Distributed Services UID/GID translate tables into the kernel.
\mathbf{env}	393	Sets the environment for execution of a command.
getty	490	Sets the characteristics of ports.
init	521	Initializes the system.
ipctable	544	Creates, displays, or changes the Distributed Services IPC Queues Table.
keyboard	551	Controls the delay and repetition rates of the keyboard.
locator	583	Controls the sample rate of the locator.
minidisks	650	Adds, deletes, changes, and displays minidisks.

mknod pdisable, phold	661 741	Creates a special file. Kills the logger running on the specified port.
pstart, penable, pshare, pdelay	791	Enables or reports the availability of login ports.
rc	806	Performs normal startup initialization.
setdma	910	Sets the DMA channel of the specified adapter.
sound	967	Controls the volume and click of the keyboard speaker.
splp	975	Changes or displays printer driver settings.
stty	1018	Sets, resets, or reports work station operating parameters.
termdef	1062	Queries terminal characteristics.
trdiag	1097	Starts diagnostics on the Token-Ring Network.
ugtable	1109	Creates, displays, and changes the Distributed Services Network Users/Groups Table.
users, adduser	1129	Adds, deletes, and changes user and group information.
varyon	1180	Makes an external disk drive and any minidisks or file systems defined on it available for use.
varyoff	1177	Removes an external disk drive from the operating system configuration.
verify	1186	Turns write verification on or off for a particular minidisk.
vrmconfig	1206	Installs peripheral devices.

Backing Up and Restoring System Files

backup	88	Backs up files.
pack	730	Compresses files.
restore	826	Copies back files created by the backup command.
tapechk	1047	Performs consistency checking of the streaming tape device.
tar	1048	Manipulates archives.
tetl	1058	Gives commands to streaming tape.

Managing File Systems

basename	95	Returns the base name of a string parameter.
chroot	172	Changes the root directory of a command.
clri	175	Clears the specified i-node.
cpio	205	Copies files into and out of archive storage and directories.
crash	215	Examines system images.

dcopy	299	Copies file systems for the best access time.
devnm	316	Names a device.
df	318	Reports number of available disk blocks.
env	393	Sets the environment for execution of a command.
\mathbf{ff}	417	Lists the file names and statistics for a file system.
\mathbf{fsck}	445	Checks file system consistency and interactively repairs the file system.
fsdb	450	Debugs file systems.
istat	545	Examines i-nodes.
link	575	Performs a link or unlink system call.
mkfs	658	Makes a file system.
mknod	661	Creates a special file.
mount	669	Makes a file system available for use.
ncheck	683	Generates path names from i-numbers.
proto	780	Constructs a prototype file for a file system.
setmnt	911	Creates mount table.
skulker	951	Cleans up file systems by removing unwanted files.
sync	1030	Updates the superblock and writes buffered files to the fixed disk.
umount,	1112	Unmounts a previously mounted file system, directory, or file.
unmount		
varyon	1180	Makes an external disk drive and any minidisks or file systems defined on it available for use.
varyoff	1177	Removes an external disk drive from the operating system configuration.

Analyzing System Activity

du dumpfmt errdead errdemon errpt errstop errupdate fuser	364 368 397 398 400 404 405 455	Summarizes disk usage. Formats the VRM dump file. Extracts error records from dump. Starts the error-logging daemon. Processes a report of logged errors. Terminates the error-logging daemon. Updates an error report template. Identifies processes using a file or file structure.
profiler time trace trcrpt trcstop trcupdate	775 1068 1086 1091 1093 1094	Profiles the operating system. Times the execution of a command. Starts the trace function. Formats a report from the trace log file. Stops the trace function. Updates trace format templates.

Performing System Accounting Functions

acct/*	13	Provides accounting shell procedures.
acctcms	18	Produces command usage summaries from accounting records.
acctcom	20	Displays selected process accounting record summaries.
acctcon	24	Performs connect-time accounting.
acctdisk,	26	Performs disk-usage accounting.
acctdusg		
acctmerg	28	Merges total accounting files.
acctprc	30	Performs process accounting.
diskusg	330	Generates disk accounting data by user ID.
fwtmp	457	Manipulates connect accounting records.
runacct	848	Runs daily accounting.
sadc	863	Provides a system activity report package.

Controlling System Security

The following groups of commands are important to ensure the security of the system.

Managing System Auditing

67	Controls system auditing.
69	Adds an audit bin file to the end of the audit trail file.
71	Manages bins of audit information.
73	Displays audit trail files.
76	Selects audit records.
78	Creates a channel for the reading of audit records.
80	Generates an audit record at the command level.
	69 71 73 76 78

Managing the Secure System

init	521	Initializes the system.
login	584	Allows you to sign on to the system and performs user identification and authentication.
loginx	587	Sets up a user's execution environment.
passwd	735	Changes login password.
print	767	Enqueues a file.
secure	885	Establishes a more secure system configuration
shell	938	Executes a shell in a user's login environment.

\mathbf{sysck}	1031	Verifies the secure system state.
tsh	1100	Interprets commands in a trusted shell.
tvi	1108	Acts as trusted editor for system administration.
watch	1209	Observes and reports security-relevant actions on the system.

Managing the Trusted Path

actman	32	Permits interaction with multiple virtual terminals.
getty	490	Sets the characteristics of ports.
init	521	Initializes the system.
login	584	Allows you to sign on to the system and performs user identification and authentication.
loginx	587	Sets up a user's execution environment.
logout	590	Stops all processes on a port, returning it to a dead state.
shell	938	Executes a shell in a user's login environment.
tsh	1100	Interprets commands in a trusted shell.
tvi	1108	Acts as trusted editor for system administration

Managing Access Permissions and Ownerships

chgrp	156	Changes the group ownership of a file or directory.
chmod	160	Changes permission codes.
chown	169	Changes the owner of files or directories.
chtcb	174	Sets or queries the tcb attribute of a file.
groups	506	Displays your group membership.
id	517	Displays the system identity of the user issuing the command.
logname	589	Displays your login name.
login	584	Allows you to sign on to the system and performs user identification and
_		authentication.
makekey	634	Generates an encryption key.
newgrp	689	Changes your primary group identification.
passwd	735	Changes login password.
pwck	798	Checks the password and group files for inconsistencies.
su	1026	Obtains the privileges of another user, including superuser authority.
umask	1110	Displays and sets file-creation permission code mask.
users,	1129	Adds, deletes, and changes user and group information.
adduser		

Using the System

The following groups of commands help you use the various functions of the system.

Starting and Stopping the System

actman	32	Permits interaction with multiple virtual terminals.
login	584	Allows you to sign on to the system and performs user identification and
_		authentication.
open	728	Opens a virtual terminal.
passwd	735	Cĥanges login password.
shutdown	946	Ends system operation.

Using Shells and Interfaces

actman	32	Permits interaction with multiple virtual terminals.
\mathbf{csh}	225	Interprets commands read from a file or entered from the keyboard.
dos	341	Starts shell.
\mathbf{sh}	913	Interprets commands read from a file or entered at the keyboard.
\mathbf{tsh}	1100	Interprets commands in a trusted shell.

Displaying System Statistics and Information

date	281	Displays or sets the date.
devices	315	Adds, deletes, changes, and displays device information.
diskusg	330	Generates disk accounting data by user ID.
dsstate	361	Sets the state of the Distributed Services kernel logic.
errpt	400	Processes a report of logged errors.
errupdate	405	Updates an error report template.
file	420	Determines file type.
fptype	444	Displays the floating point configuration of the system.
fuser	455	Identifies processes using a file or file structure.
groups	506	Displays your group membership.
help	513	Provides information about a Source Code Control System (SCCS) message or command or about certain non-SCCS commands.
id	517	Displays the system identity of the user issuing the command.
ipcs	539	Reports interprocess communication facility status.
ipctable	544	Creates, displays, or changes the Distributed Services IPC Queues Table.
istat	545	Examines i-nodes.

logname man minidisks ncheck ndtable news od profiler PostScript pstart,	589 635 650 683 685 691 723 775 786 791	Displays your login name. Displays manual entries online. Adds, deletes, changes, and displays minidisks. Generates path names from i-numbers. Accesses the Distributed Services Node Table. Writes system news items to standard output. Writes the contents of storage to the standard output. Profiles the operating system. Reports process status. Enables or reports the availability of login ports.
penable,		
pshare,		
pdelay pwck	798	Checks the password and group files for inconsistencies.
pwd	800	Displays the path name of the working directory.
pwtable	801	Accesses the Distributed Services Node Security Table.
rstatd	847	Returns NFS performance statistics from the kernel.
rup	854	Displays the host status of local machines.
rusers	856	Identifies users logged in on network hosts.
sact	862	Displays current Source Code Control System (SCCS) file editing status.
sadc	863	Provides a system activity report package.
sag	865	Displays a graph of system activity.
sar	867	Collects, reports, or saves system activity information.
splp	975	Changes or displays printer driver settings.
\mathbf{stty}	1018	Sets, resets, or reports work station operating parameters.
sum	1029	Displays the checksum and block count of a file.
time	1068	Times the execution of a command.
timex	1069	Times a command, and reports process data and system activity.
tty	1105	Writes to standard output the full path name of your work station.
ugtable	1109	Creates, displays, and changes the Distributed Services Network Users/Groups Table.
uname	1114	Displays the name of the current operating system.
uustat	1158	Reports the status of and provides rudimentary job control for BNU commands.
who	1219	Identifies the users currently logged in.

Controlling System Processes

at	63	Runs commands at a later time.
cron	220	Runs commands automatically.
crontab	222	Submits a schedule of commands to cron .

errdemon errstop	398 404	Starts the error-logging daemon. Terminates the error-logging daemon.
kill	552	Sends a signal to a running process.
killall	555	Cancels all processes except the calling process.
nice	699	Runs a command at a different priority.
nohup	707	Runs a command without hangups and quits.
open	728	Opens a virtual terminal.
qdaemon	802	Schedules jobs enqueued by the print command.
sleep	952	Suspends execution for an interval.
syslogd	1037	Reads and logs messages.
tlog	1071	Stops or restarts sending of terminal I/O to a daemon.
${f tlogger}$	1072	Gathers I/O from a terminal and writes it to a log file.
writesrv	1230	Allows Distributed Services users to send messages to and receive messages from a remote system.

Using Disks and Diskettes

format	436	Formats diskettes.
mdrc	640	Allows you to reinstall a user-created minidisk after you have reinstalled AIX.
minidisks	650	Adds, deletes, changes, and displays minidisks.
mount	669	Makes a file system available for use.
umount,	1112	Unmounts a previously mounted file system, directory, or file.
unmount		
varyon	1180	Makes an external disk drive and any minidisks or file systems defined on it available for use.
varyoff	1177	Removes an external disk drive from the operating system configuration.
verify	1186	Turns write verification on or off for a particular minidisk.

Using Tape

tapechk	1047	Performs consistency checking of the streaming tape device.
tar	1048	Manipulates archives.
tetl	1058	Gives commands to streaming tape.

Working with Work Stations

defkey	306	Defines keyboard key assignments.
display	332	Selects the physical display that an existing or new virtual terminal uses and
		sets colors and fonts.

echo hp keyboard locator pdisable, phold	369 514 551 583 741	Writes its arguments to standard output. Handles special functions for the HP2640- and HP2621-series terminals. Controls the delay and repetition rates of the keyboard. Controls the sample rate of the locator. Kills the logger running on the specified port.
pstart, penable, pshare, pdelay	791	Enables or reports the availability of login ports.
stty	1018	Sets, resets, or reports work station operating parameters.
tabs	1041	Sets tab stops on work stations.
termdef	1062	Queries terminal characteristics.
\mathbf{tic}	1067	Translates terminfo files from source to compiled format.
tput	1081	Queries the terminfo file.
\mathbf{tty}	1105	Writes to standard output the full path name of your work station.
300	1262	Handles special line-motion functions for DASI 300/300s work stations.
4014	1264	Formats a full page 66-line screen display for a Tektronix 4014 work station.
450	1265	Handles special line-motion functions for the DASI 450 work station.

Working with Files and Directories

The following groups of commands allow you to create and manipulate files and directories.

Working with Directories

cd	150	Changes the current directory.
chroot	172	Changes the root directory of a command.
dircmp	328	Compares two directories and the contents of their common files.
dosdir	346	Lists the directory for DOS files.
find	422	Finds files matching expression.
li	567	Lists the contents of a directory.
ls	595	Displays the contents of a directory.
mkdir	657	Makes a directory.
mvdir	682	Moves (renames) a directory.
pwd	800	Displays the path name of the working directory.
rm	833	Removes files or directories.
rmdir	838	Removes a directory.

Creating and Editing Files

admin	41	Creates and initializes SCCS files.
cdc	152	Changes the comments in a Source Code Control System (SCCS) delta.
ed	371	Edits text by line.
edit	387	Provides a simple line editor for the new user.
ex	407	Edits lines interactively, with screen display.
\mathbf{get}	477	Creates a specified version of a Source Code Control System (SCCS) file.
mknod	661	Creates a special file.
\mathbf{sed}	887	Provides a stream editor.
spell	969	Finds spelling errors.
tab	1040	Changes spaces into tabs or tabs into spaces.
uniq	1118	Deletes repeated lines in a file.
vi	1187	Edits files with a full screen display.

Printing and Displaying Files

cat	137	Concatenates or displays files.
cut	269	Writes out selected fields from each line of a file.
lp	593	Prints a file in a format suitable for sending to a line printer.
nl	701	Numbers lines in a file.
od	723	Writes the contents of storage to the standard output.
pg	744	Formats files to the work station.
piobe	753	Writes a file to standard output in a format suitable for sending to a line printer.
pr	761	Writes a file to standard output.
prs	781	Displays a Source Code Control System (SCCS) file.
print	767	Enqueues a file.
qdaemon	802	Schedules jobs enqueued by the print command.
$\overline{\mathbf{splp}}$	975	Changes or displays printer driver settings.
tail	1044	Writes a file to standard output, beginning at a specified point.
vc	1182	Substitutes assigned values in place of keywords.

Copying and Moving Files

cat	137	Concatenates or displays files.
ср	202	Copies files.
$\tilde{\mathbf{Cvt}}$	274	Moves old UUCP files into new BNU directories.
dd	301	Converts and copies a file.
dosread	348	Copies a DOS file.

doswrite	350	Copies AIX files to DOS files.
ln	581	Links files.
mv	679	Moves files.
uucp	1144	Copies files from one AIX system to another AIX system.
uuto	1162	Copies public files from one AIX system to another AIX system, with local
		system control of file access.

Deleting Files

del	308	Deletes files if the request is confirmed.
dosdel	345	Deletes DOS files.
\mathbf{rm}	833	Removes files or directories.
uniq	1118	Deletes repeated lines in a file.
uucleanup	1141	Deletes selected files older than a specified number of hours from the BNU
		spool directory or a named directory.

Comparing Files

bdiff	102	Uses diff to find differences in very large files.
cmp	177	Compares two files.
comm	183	Selects or rejects lines common to two sorted files.
diff	320	Compares text files.
diff3	323	Compares three files.
diffmk	326	Marks differences between files.
dircmp	328	Compares two directories and the contents of their common files.
sdiff	883	Compares two files and displays the differences in a side by side format.
sccsdiff	874	Compares two versions of a Source Code Control System (SCCS) file.

Scanning Files

awk	81	Finds lines in files matching specified patterns and performs specified actions on them.
\mathbf{bfs}	110	Scans files.
file	420	Determines file type.
find	422	Finds files matching expression.
grep	501	Searches a file for a pattern.
hyphen	516	Finds hyphenated words.
wc	1211	Counts the number of lines, words, and characters in a file.
what	1213	Displays identifying information in files.

Sorting Files

lorder	591	Finds the best order for member files in an object library.
sort	958	Sorts or merges files.
tsort	1102	Sorts an unordered list of ordered pairs (a topological sort).

Merging and Splitting Files

csplit	252	Splits files by context.
join	547	Joins data fields of two files.
paste	736	Merges the lines of several files or subsequent lines in one file.
sort	958	Sorts or merges files.
split	974	Splits a file into pieces.

Working with Remote Files

biod	114	Starts daemons that handle NFS block I/O requests.
domainname	340	Displays or sets YP domain name.
makedbm	632	Makes a Yellow Pages dbm map.
mountd	674	Answers NFS mount requests.
\mathbf{nfsd}	696	Starts NFS client request daemons.
nfsstat	697	Displays NFS statistics.
on	726	Executes a command remotely via NFS.
penfs	739	Serves PC-NFS client requests.
portmap	757	Maps RPC programs to the servicing ports on RPC servers.
rexd	832	Executes remote programs.
rpcgen	843	Compiles a Remote Procedure Call program.
rpcinfo	845	Reports Remote Procedure Call status information.
rstatd	847	Returns NFS performance statistics from the kernel.
rup	854	Displays the host status of local machines.
rusers	856	Identifies users logged in on network hosts.
rusersd	858	Displays list of active NFS users.
rwall	859	Writes to all network users.
rwalld	861	NFS daemon for rwall and shutdown .
${f showmount}$	945	Displays list of remotely mounted file systems.
spray	981	Sprays packets to host when NFS is installed.
sprayd	983	Receives packets sent by the spray command.
ypbind	1239	Allows Yellow Pages client processes to communicate with the YP server.
ypcat	1241	Displays values in a Yellow Pages data base.
ypinit	1243	Builds and installs the Yellow Pages data base.

ypmatch yppasswd yppasswdd	$1245 \\ 1247 \\ 1249$	Displays the values of one or more keys from a Yellow Pages map. Changes Yellow Pages passwords Handles Yellow Pages password change requests
yppoll	1251	Displays the version of a Yellow Pages map located at a Yellow Pages host.
yppush	1252	yppush.
ypserv	1256	Looks up information in a local Yellow Pages data base.
ypset	1254	Directs the ypbind daemon to a particular server.
ypwhich	1258	Displays the name of the host machine acting as the Yellow Pages server or
ypxfr	1260	as a map YP master server. Transfers a Yellow Pages map to the local host machine.

Formatting Text

col	179	Processes text having reverse linefeeds and forward/reverse half-linefeeds for output to standard output.		
cw	275	Prepares constant-width text for troff .		
deroff	313	Removes nroff , troff , troff , tbl , and eqn constructs from files.		
	395	Formats mathematical text for the nroff , troff and troff commands.		
eqn				
fmt	428	Formats mail messages prior to sending.		
greek	499	Converts output for a Teletype Model 37 work station to output for other		
_		work stations.		
hp	514	Handles special functions for the HP2640- and HP2621-series terminals.		
$\mathbf{m}\mathbf{m}$	663	Displays or checks documents formatted with Memorandum Macros.		
mmt	666	Typesets documents, manual pages, view graphs, and slides.		
${f newform}$	686	Changes the format of a text file.		
nl	701	Numbers lines in a file.		
nroff, troff	709	Formats text for printing devices.		
ptx	794	Generates a permuted index.		
tbl	1053	Formats tables for the nroff , troff and troff commands.		
\mathbf{tc}	1056	Simulates phototypesetter output for a Tektronix 4014 work station.		
${f vrm2rtfont}$	1205	Converts a standard AIX font file to RT rtx font format.		
300	1262	Handles special line-motion functions for DASI 300/300s work stations.		
4014	1264	Formats a full page 66-line screen display for a Tektronix 4014 work station.		
450	1265	Handles special line-motion functions for the DASI 450 work station.		

Working with Graphics

gdev	460	Provides graphical device routines and filters.
ged	463	Displays, makes, and edits graphical files on Tektronix 4010 terminals.
gend	475	Provides a general graphics device backend.

graph	494	Draws a graph.
graphics	497	Accesses graphical and numerical commands.
gutil	508	Provides graphical utility programs.
spline	972	Interpolates smooth curve.
stat	984	Provides tools for analyzing numerical data.
\mathbf{toc}	1074	Provides graphical table of contents routines.
tplot	1079	Produces plotting instructions for a particular work station.

Protecting Files with File Permissions

chgrp	156	Changes the group ownership of a file or directory.
chmod	160	Changes permission codes.
chown	169	Changes the owner of files or directories.
groups	506	Displays your group membership.
li	567	Lists the contents of a directory.
ls	595	Displays the contents of a directory.
umask	1110	Displays and sets file-creation permission code mask.

Backing Up and Restoring Files

ar	55	Maintains portable libraries used by the linkage editor.
backup	88	Backs up files.
cpio	205	Copies files into and out of archive storage and directories.
lorder	591	Finds the best order for member files in an object library.
pack	730	Compresses files.
restore	826	Copies back files created by the backup command.
shlib	939	Creates a shared library.
tar	1048	Manipulates archives.

Working with Data

The following groups of commands allow you to use various data tools.

Using Data Tools

banner	94	Writes character strings in large letters to standard output.
cal	132	Displays a calendar.
calendar	134	Writes reminder messages to standard output.
ctab	257	Produces a collating table.
		-

echo	369	Writes its arguments to standard output.
tr	1083	Translates characters.
units	1119	Converts units in one measure to equivalent units in another measure.

Performing Calculator Functions

\mathbf{bc}	97	Provides an interpreter for arbitrary-precision arithmetic language.
\mathbf{dc}	295	Provides an interactive desk calculator for doing arbitrary-precision integer
		arithmetic.
factor	416	Factors a number.

Communicating on the System

The following groups of commands allow you to use mail and message facilities on the system.

Sending Messages and Notices

confer	189	Provides an online conferencing system.
mesg	642	Permits or refuses write messages.
news	691	Writes system news items to standard output.
wall	1208	Writes a message to all logged-in users.
write	1225	Sends messages to other users on the system.

Using Mailboxes

bellmail	104	Sends messages to system users and displays messages from system users.
\mathbf{fmt}	428	Formats mail messages prior to sending.
mail, Mail	608	Sends and receives mail.
mailstats	623	Displays statistics regarding mail traffic.
sendmail	897	Routes mail for local or network delivery.

Using the MH (Message Handling) Package

ali	48	Lists mail aliases and their addresses.
anno	50	Annotates messages.
ар	53	Parses and reformats addresses.
burst	129	Explodes digests into messages.
comp	185	Composes a message.

conflict196Searches for alias and password conflicts.dist336Redistributes a message to additional addresses.	
uist 550 henstributes a message to additional addresses.	
dp 352 Parses and reformats dates.	
folder 429 Selects and lists folders and messages.	
folders 433 Lists folders and messages.	
forw 438 Forwards messages.	
inc 518 Incorporates new mail.	
install-mh 527 Initializes the MH environment.	
mark 637 Creates, modifies, and displays message sequences.	
mhl 643 Produces formatted listings of messages.	
mhmail 646 Sends or receives mail.	
mhpath 648 Prints full path names of messages and folders.	
msgchk 675 Checks for messages.	
msh 677 Creates an MH shell.	
next 694 Shows the next message.	
packf 733 Compresses the contents of a folder into a file.	
pick 748 Selects messages by content, and creates and modifies sequences.	
post 758 Delivers a message.	
prev 765 Shows the previous message.	
prompter 778 Invokes a prompting editor.	
rcvdist 808 Sends a copy of incoming messages to additional recipients.	
rcvpack 810 Saves incoming messages in a packed file.	
rcvstore 812 Incorporates new mail from standard input into a folder.	
rcvtty 815 Notifies the user of incoming messages.	
refile 817 Files messages in other folders.	
repl 821 Replies to a message.	
rmf 839 Removes a folder.	
rmm 841 Removes messages.	
scan 871 Produces a one line per message scan listing.	
send 893 Sends a message.	
show 942 Shows messages.	
slocal 954 Processes incoming mail.	
sortm 965 Sorts messages.	
spost 978 Delivers a message.	
vmh 1203 Invokes a visual interface for use with MH commands.	
whatnow 1215 Invokes a prompting interface for draft disposition.	41
whom 1222 Lists the addresses of the proposed recipients of a message and verification addresses.	es tne

Communicating with Other Systems

connect	198	Establishes a connection to a remote system.
\mathbf{ct}	254	Dials an attached terminal and issues a login process.
cu	263	Connects directly or indirectly to another UNIX system.
\mathbf{Cvt}	274	Moves old UUCP files into new BNU directories.
sum	1029	Displays the checksum and block count of a file.
uucheck	1137	Checks for files and directories required by BNU.
uucheck	1137	Checks for files and directories required by BNU.
uucico	1139	File transport program for the BNU facility.
uucleanup	1141	Deletes selected files older than a specified number of hours from the BNU spool directory or a named directory.
uucp	1144	Copies files from one AIX system to another AIX system.
uulog	1149	Provides information about uucp and uux activities on a system.
uuname	1151	Provides information about other systems accessible to the local system.
uucpadm	1133	Enters basic uucp configuration information.
uusched	1156	Schedules work for the BNU file transport program.
uustat	1158	Reports the status of and provides rudimentary job control for BNU commands.
uuto	1162	Copies public files from one AIX system to another AIX system, with local system control of file access.
uutry,	1164	Contacts a remote system with debugging turned on.
Uutry, uukick		
uux	1166	Runs a command on another AIX system.
uuxqt	1172	Executes remote command requests.

Developing Programs

The following groups of commands are for use in programming.

Programming in Assembler

as	61	Assembles a source file.
sdb	875	Provides a symbolic debugger for C and assembler programs.

Programming in C

cb Puts C source code into a form that is easily read.

cc cflow	$140 \\ 154$	Compiles C programs. Generates a C flow graph of external references.
срр	210	Performs file inclusion and macro substitution on C Language source files.
cxref	279	Creates a C program cross-reference listing.
factor	416	Factors a number.
ipcrm	537	Removes message queue, semaphore set or shared memory identifiers.
m4	603	Preprocesses files, expanding macro definitions.
lex	562	Generates a C Language program that matches patterns for simple lexical analysis of an input stream.
lint	577	Checks C programs for potential problems.
regcmp	820	Compiles patterns.
sdb	875	Provides a symbolic debugger for C and assembler programs.
tic	1067	Translates terminfo files from source to compiled format.
yacc	1237	Generates a LR(1) parsing program from input consisting of a context-free grammar specification.

Programming in Miscellaneous Languages

bc	97	Provides an interpreter for arbitrary-precision arithmetic language.
bs	118	Compiles and interprets modest-sized programs.
ctags	261	Makes a file of tags to help locate objects in source files.
m4	603	Preprocesses files, expanding macro definitions.
\mathbf{sno}	956	Provides a SNOBOL interpreter.

Programming in Shell

basename	95	Returns the base name of a string parameter.
cron	220	Runs commands automatically.
crontab	222	Submits a schedule of commands to cron.
$\operatorname{\mathbf{csh}}$	225	Interprets commands read from a file or entered from the keyboard.
echo	369	Writes its arguments to standard output.
env	393	Sets the environment for execution of a command.
expr	412	Evaluates arguments as expressions.
find	422	Finds files matching expression.
getopt	485	Parses command line flags and parameters.
line	574	Reads one line from the standard input.
nice	699	Runs a command at a different priority.
nohup	707	Runs a command without hangups and quits.
open	728	Opens a virtual terminal.
$\hat{\mathbf{sh}}$	913	Interprets commands read from a file or entered at the keyboard.

sleep	952	Suspends execution for an interval.
tee	1060	Displays the output of a program and copies it into a file.
test	1064	Evaluates conditional expressions.
\mathbf{time}	1068	Times the execution of a command.
true	1099	Returns an exit value of zero.
xargs	1232	Constructs argument lists and runs commands.

Working with Messages

dspcat	357	Displays all or part of a message catalog.
dspmsg	359	Displays a selected message from a message catalog.
gencat	470	Creates and modifies a message catalog.
gettext	488	Extracts message/insert/help descriptions.
mkcatdefs	651	Preprocesses a message source file.
puttext	796	Updates an output file that contains message/insert/help descriptions.
runcat	852	Pipes data from mkcatdefs to runcat.

Debugging Programs

crash	215	Examines system images.
dbx	284	Provides a tool to debug and run programs under AIX.
dump	366	Dumps selected parts of an object file.
dumpfmt	368	Formats the VRM dump file.
od	723	Writes the contents of storage to the standard output.
prof	773	Displays program profile data.
adb	33	Provides a general purpose debugger.
sdb	875	Provides a symbolic debugger for C and assembler programs.
${f time}$	1068	Times the execution of a command.
\mathbf{timex}	1069	Times a command, and reports process data and system activity.
xdbx	1236	Provides an overlaying X-Window application for the dbx symbolic debugger.

Managing Source Programs Using the Source Code Control System (SCCS)

admin	41	Creates and initializes SCCS files.
\mathbf{cdc}	152	Changes the comments in a Source Code Control System (SCCS) delta.
comb	181	Combines SCCS deltas.
delta	310	Creates a delta in a Source Code Control System file.
get	477	Creates a specified version of a Source Code Control System (SCCS) file.
help	513	Provides information about a Source Code Control System (SCCS) message
_		or command or about certain non-SCCS commands.

prs	781	Displays a Source Code Control System (SCCS) file.
rmdel	837	Removes a delta from a Source Code Control System (SCCS) file.
sact	862	Displays current Source Code Control System (SCCS) file editing status.
sccsdiff	874	Compares two versions of a Source Code Control System (SCCS) file.
unget	1116	Cancels a previous get command.
val	1175	Validates Source Code Control System (SCCS) files.
what	1213	Displays identifying information in files.

Managing Object Files

ar	55	Maintains portable libraries used by the linkage editor.
as	61	Assembles a source file.
dump	366	Dumps selected parts of an object file.
ld	557	Links object files.
lorder	591	Finds the best order for member files in an object library.
make	625	Maintains up-to-date versions of programs.
nm	705	Displays the symbol table of an object file.
prof	773	Displays program profile data.
size	949	Displays the section sizes of common object files.
strip	1017	Removes symbol and line number information from a common object file.
touch	1077	Updates the access and modification times of a file.
tsort	1102	Sorts an unordered list of ordered pairs (a topological sort).

Playing Games

The following groups of commands allow you to play games on the system.

ing game.
umber.
games.
us.

Book Evaluation Form

Your comments can help us produce better books. You may use this form to communicate your comments about this book, its organization, or subject matter, with the understanding that IBM may use or distribute whatever information you supply in any way it believes appropriate without incurring any obligation to you. Please take a few minutes to evaluate this book as soon as you become familiar with it. Circle Y (Yes) or N (No) for each question that applies and give us any information that may improve this book.

IN .	is the purpose of this book clear?	Y	N	Are the abbreviations and acronyms understandable?
N	Is the table of contents helpful?	Y	N	Are the examples clear?
N	Is the index complete?	Y	N	Are examples provided where they are needed?
N	Are the chapter titles and other headings meaningful?	Y	N	Are the illustrations clear?
N	Is the information organized appropriately?	Y	N	Is the format of the book (shape, size, color) effective?
N	Is the information accurate?			
N	Is the information complete?	Other Comments What could we do to make this book or the entire set of books for this system easier to use?		
N	Is only necessary information included?			
N	Does the book refer you to the appropriate places for more information?			Optional Information
N	Are terms defined clearly?	Con	npany r	name
N	Are terms used consistently?			
	N N N N N N N N	N Is the table of contents helpful? N Is the index complete? N Are the chapter titles and other headings meaningful? N Is the information organized appropriately?
