Introduction	V
How to Use This Manual	v
Document Conventions	vi
Alphabetic Reference	. 1

Introduction

The Microsoft® Windows[™] 3.1 operating system is a single-user system for personal computers. Applications that run with this operating system use functions in the Windows applications programming interface (API). This manual describes the API functions in alphabetic order, including each function's purpose, the version of Windows in which it first appeared, and the function's syntax, parameters, and possible return values. Many function descriptions also contain additional information and simple code examples that illustrate how the function can be used to carry out simple tasks.

How to Use This Manual

For most of the functions described in this manual, the syntax is given in Clanguage format. In your C-language source files, the function name must be spelled exactly as given in syntax and the parameters must be used in the order given in syntax.

The Windows API uses many types, structures, and constants that are not part of standard C language. These items, designed for Windows, are defined in the Windows C-language header files. Although there are many Windows header files, the majority of API functions, structures, and messages are defined in the WINDOWS. H header file. You can use these items in your Windows application by placing an **#include** directive specifying WINDOWS. H at the beginning of your C-language source file.

In this manual, if a function is not defined in WINDOWS.H, its appropriate header file is included in the first line of syntax. If no header file is listed, you can assume the function is defined in WINDOWS.H.

Note You will find a list of the appropriate module and library for each Windows function in the *Microsoft Windows Programmer's Reference*, *Volume 1*. A list of the types used in the Windows API, with a brief description of each, is provided in the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Document Conventions

The following conventions are used throughout this manual to define syntax:

Convention	Meaning	
Bold text	Denotes a term or character to be typed literally, such as a resource- definition statement or function name (MENU or CreateWindow), a Microsoft MS-DOS® command, or a command-line option (/ nod). You must type these terms exactly as shown.	
Italic text	Denotes a placeholder or variable: You must provide the actual value. For example, the statement $SetCursorPos(X, Y)$ requires you to substitute values for the X and Y parameters.	
[]	Enclose optional parameters.	
1	Separates an either/or choice.	
	Specifies that the preceding item may be repeated.	
BEGIN •	Represents an omitted portion of a sample application.	
•		
END		

In addition, certain text conventions are used to help you understand this material:

Convention	Meaning
SMALL CAPITALS	Indicate the names of keys, key sequences, and key combinations—for example, ALT+SPACEBAR.
FULL CAPITALS	Indicate filenames and paths, most type and structure names (which are also bold), and constants.
monospace	Sets off code examples and shows syntax spacing.

3.1

AbortDoc

int AbortDoc(hdc) HDC hdc; /* h	andle of device context */
	The AbortDoc function terminates the current print job and erases everything drawn since the last call to the StartDoc function. This function replaces the ABORTDOC printer escape for Windows version 3.1.
Parameters	<i>hdc</i> Identifies the device context for the print job.
Return Value	The return value is greater than or equal to zero if the function is successful. Otherwise, it is less than zero.
Comments	Applications should call the AbortDoc function to terminate a print job because of an error or if the user chooses to cancel the job. To end a successful print job, an application should use the EndDoc function.
	If Print Manager was used to start the print job, calling the AbortDoc function erases the entire spool job—the printer receives nothing. If Print Manager was not used to start the print job, the data may have been sent to the printer before Abort- Doc was called. In this case, the printer driver would have reset the printer (when possible) and closed the print job.
See Also	EndDoc, SetAbortProc, StartDoc

AbortProc

3.1

HDC hdc;	/* handle of device context	*/
int error;	/* error value	*/

The **AbortProc** function is an application-defined callback function that is called when a print job is to be canceled during spooling.

Parameters

Identifies the device context.

error

hdc

BOOL CALLBACK AbortProc(hdc, error)

Specifies whether an error has occurred. This parameter is zero if no error has occurred; it is SP_OUTOFDISK if Print Manager is currently out of disk space

	and more disk space will become available if the application waits. If this parameter is SP_OUTOFDISK, the application need not cancel the print job. If it does not cancel the job, it must yield to Print Manager by calling the Peek-Message or GetMessage function.
Return Value	The callback function should return TRUE to continue the print job or FALSE to cancel the print job.
Comments	An application installs this callback function by calling the SetAbortProc func- tion. AbortProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the ap- plication's module-definition file.
See Also	GetMessage, PeekMessage, SetAbortProc

2.x

AccessResource

int AccessResource(HINSTANCE hinst; HRSRC hrsrc;	
	The AccessResource function opens the given executable file and moves the file pointer to the beginning of the given resource.
Parameters	<i>hinst</i> Identifies the instance of the module whose executable file contains the re- source.
	<i>hrsrc</i> Identifies the desired resource. This handle should be created by using the FindResource function.
Return Value	The return value is the handle of the resource file if the function is successful. Otherwise, it is -1 .
Comments	The AccessResource function supplies an MS-DOS file handle that can be used in subsequent file-read calls to load the resource. The file is opened for reading only.
	Applications that use this function must close the resource file by calling the _lclose function after reading the resource. AccessResource can exhaust available MS-DOS file handles and cause errors if the opened file is not closed after the resource is accessed.

See Also	FindResource, _lclose, LoadResource, LockResource
	You should not use AccessResource to access executable files that are installed in ROM on a ROM-based system, since there are no disk files associated with the executable file; in such a case, a file handle cannot be returned.
	In general, the LoadResource and LockResource functions are preferred. These functions will access the resource more quickly if several resources are being read, because Windows maintains a file-handle cache for accessing executable files. However, each call to AccessResource requires that a new handle be opened to the executable file.

AddAtom

ATOM AddAtom(lp LPCSTR lpszName;	<i>pszName</i>) ; /* address of string to add */
	The AddAtom function adds a character string to the local atom table and returns a unique value identifying the string.
Parameters	<i>lpszName</i> Points to the null-terminated character string to be added to the table.
Return Value	The return value specifies the newly created atom if the function is successful. Otherwise, it is zero.
Comments	The AddAtom function stores no more than one copy of a given string in the atom table. If the string is already in the table, the function returns the existing atom value and increments (increases by one) the string's reference count.
	The MAKEINTATOM macro can be used to convert a word value into a string that can be added to the atom table by using the AddAtom function.
	The atom values returned by AddAtom are in the range 0xC000 through 0xFFFF.
	Atoms are case-insensitive.
Example	The following example uses the AddAtom function to add the string "This is an atom" to the local atom table:

```
ATOM at;
char szMsg[80];
at = AddAtom("This is an atom");
if (at == 0)
    MessageBox(hwnd, "AddAtom failed", "", MB_ICONSTOP);
else {
    wsprintf(szMsg, "AddAtom returned %u", at);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

2.x

See Also

DeleteAtom, FindAtom, GetAtomName

AddFontResource

int AddFontResour LPCSTR lpszFilena	
	The AddFontResource function adds a font resource to the Windows font table. Any application can then use the font.
Parameters	<i>lpszFilename</i> Points to a character string that names the font resource file or that contains a handle of a loaded module. If this parameter points to a font resource filename, it must be a valid MS-DOS filename, including an extension, and the string must be null-terminated. The system passes this string to the LoadLibrary function if the font resource must be loaded.
Return Value	The return value specifies the number of fonts added if the function is successful. Otherwise, it is zero.
Comments	Any application that adds or removes fonts from the Windows font table should send a WM_FONTCHANGE message to all top-level windows in the system by using the SendMessage function with the <i>hwnd</i> parameter set to 0xFFFF.
	When font resources added by using AddFontResource are no longer needed, you should remove them by using the RemoveFontResource function.
Example	The following example uses the AddFontResource function to add a font resource from a file, notifies other applications by using the SendMessage function, then removes the font resource by using the RemoveFontResource function:

See Also

LoadLibrary, RemoveFontResource, SendMessage

AdjustWindowRect

void AdjustWindowRect(lprc, dwStyle, fMenu) **RECT FAR*** *lprc*; /* address of client-rectangle structure */ **DWORD** *dwStyle*: /* window styles */ */ **BOOL** *fMenu*; /* menu-present flag The **AdjustWindowRect** function computes the required size of the window rectangle based on the desired client-rectangle size. The window rectangle can then be passed to the CreateWindow function to create a window whose client area is the desired size. **Parameters** lprc Points to a **RECT** structure that contains the coordinates of the client rectangle. The **RECT** structure has the following form: typedef struct tagRECT { /* rc */ int left: int top; int right; int bottom; } RECT; For a full description of this structure, see the *Microsoft Windows Program*mer's Reference, Volume 3. dwStyle Specifies the window styles of the window whose client rectangle is to be converted. fMenu Specifies whether the window has a menu.

Return Value This function does not return a value.

CommentsA client rectangle is the smallest rectangle that completely encloses a client area.
A window rectangle is the smallest rectangle that completely encloses the window.AdjustWindowRect does not take titles and borders into account when computing the size of the client area. For window styles that include titles and borders, applications must add the title and border sizes after calling AdjustWindowRect.
This function also does not take the extra rows into account when a menu bar

See Also AdjustWindowRectEx, CreateWindowEx

wraps to two or more rows.

AdjustWindowRectEx

void AdjustWindowR	ectEx(lprc, dwStyle, fMenu, dwExStyle)	
RECT FAR* <i>lprc</i> ;	/* address of client-rectangle structure	*/
DWORD dwStyle;	/* window styles	*/
BOOL fMenu;	/* menu-present flag	*/
DWORD dwExStyle;	/* extended style	*/
oi w	he AdjustWindowRectEx function compute a window with extended style based on the indow rectangle can then be passed to the C window whose client area is the desired size	e desired client-rectangle size. The CreateWindowEx function to create
Parameters <i>lp</i>	rc	
_	Points to a RECT structure that contains the	he coordinates of the client rectangle.

Points to a **RECT** structure that contains the coordinates of the client rectangle. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

dwStyle

Specifies the window styles of the window whose client rectangle is to be converted.

3.1

	<i>fMenu</i> Specifies whether the window has a menu.
	<i>dwExStyle</i> Specifies the extended style of the window being created.
Return Value	This function does not return a value.
Comments	A client rectangle is the smallest rectangle that completely encloses a client area. A window rectangle is the smallest rectangle that completely encloses the window.
	AdjustWindowRectEx does not take titles and borders into account when com- puting the size of the client area. For window styles that include titles and borders, applications must add the title and border sizes after calling AdjustWindow- RectEx. This function also does not take the extra rows into account when a menu bar wraps to two or more rows.
See Also	AdjustWindowRect, CreateWindowEx

AllocDiskSpace

#include <stress.h>

int AllocDiskSpace(<i>lLeft</i> , <i>uDrive</i>)		
long <i>lLeft</i> ;	/* number of bytes left available	*/
UINT uDrive;	/* disk partition	*/
	specified amount of space or less is	tes a file that is large enough to ensure that the s available on the specified disk partition. The d in the root directory of the disk partition.
	If STRESS.EAT already exists wh letes it and creates a new one.	en AllocDiskSpace is called, the function de-
Parameters	<i>lLeft</i> Specifies the number of bytes to	leave available on the disk.
	<i>uDrive</i> Specifies the disk partition on w parameter must be one of the for	which to create the STRESS.EAT file. This llowing values:

	Value	Meaning
	EDS_WIN	Creates the file on the Windows partition.
	EDS_CUR	Creates the file on the current partition.
	EDS_TEMP	Creates the file on the partition that contains the TEMP directory.
Return Value	The return value is greater than zero if the function is successful; it is zero if the function could not create a file; or it is -1 if at least one of the parameters is invalid.	
Comments	In two situations, the amount of free space left on the disk may be less than the number of bytes specified in the <i>lLeft</i> parameter: when the amount of free space on the disk is less than the number in <i>lLeft</i> when an application calls Alloc-DiskSpace , or when the value of <i>lLeft</i> is not an exact multiple of the disk cluster size.	
	The UnAllocDisl	kSpace function deletes the file created by AllocDiskSpace .
See Also	UnAllocDiskSpa	nce

AllocDStoCSAlias

UINT AllocDStoC UINT uSelector;	SAlias(uSelector) /* data-segment selector */	
	The AllocDStoCSAlias function accepts a data-segment selector and returns a code-segment selector that can be used to execute code in the data segment.	
Parameters	<i>uSelector</i> Specifies the data-segment selector.	
Return Value	The return value is the code-segment selector corresponding to the data-segment selector if the function is successful. Otherwise, it is zero.	
Comments	The application should not free the new selector by calling the FreeSelector func- tion. Windows will free the selector when the application terminates.	
	In protected mode, attempting to execute code directly in a data segment will cause a general-protection violation. AllocDStoCSAlias allows an application to execute code that the application had created in its own stack segment.	

3.1

Windows does not track segment movements. Consequently, the data segment must be fixed and nondiscardable; otherwise, the data segment might move, invalidating the code-segment selector.

The **PrestoChangoSelector** function provides another method of obtaining a code selector corresponding to a data selector.

An application should not use this function unless it is absolutely necessary, since its use violates preferred Windows programming practices.

See Also FreeSelector, PrestoChangoSelector

AllocFileHandles

#include <stress.h>

int AllocFileHandles(<i>Left</i>) int <i>Left</i> ; /* number of file handles to leave available */		
	The AllocFileHandles function allocates file handles until only the specified number of file handles is available to the current instance of the application. If this or a smaller number of handles is available when an application calls AllocFile-Handles , the function returns immediately.	
	Before allocating new handles, this function frees any handles previously allocates by AllocFileHandles .	
Parameters	<i>Left</i> Specifies the number of file handles to leave available.	
Return Value	The return value is greater than zero if AllocFileHandles successfully allocates at least one file handle. The return value is zero if fewer than the specified number of file handles were available when the application called AllocFileHandles . The return value is -1 if the <i>Left</i> parameter is negative.	
Comments	AllocFileHandles will not allocate more than 256 file handles, regardless of the number available to the application.	
	The UnAllocFileHandles function frees all file handles previously allocated by AllocFileHandles .	
See Also	UnAllocFileHandles	

AllocGDIMem

#include <stress.h>

BOOL AllocGDIMem(uLeft)		
UINT uLeft;	/* number of bytes to leave available */	
	The AllocGDIMem function allocates memory in the graphics device interface (GDI) heap until only the specified number of bytes is available. Before making any new memory allocations, this function frees memory previously allocated by AllocGDIMem .	
Parameters	<i>uLeft</i> Specifies the amount of memory, in bytes, to leave available in the GDI heap.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The FreeAllGDIMem function frees all memory allocated by AllocGDIMem.	
See Also	FreeAllGDIMem	

AllocMem

#include <stress.h>

BOOL AllocMem(d		
DWORD dwLeft;	/*smallest memory allocation */	
	The AllocMem function allocates global memory until only the specified number of bytes is available in the global heap. Before making any new memory allocations, this function frees memory previously allocated by AllocMem .	
Parameters	<i>dwLeft</i> Specifies the smallest size, in bytes, of memory allocations to make.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The FreeAllMem function frees all memory allocated by AllocMem.	
See Also	FreeAllMem	

3.1

Anouncoun		2.8
HINSTANCE <i>hinst</i> ;	<pre>source(hinst, hrsrc, cbResource) /* handle of module containing resource /* handle of resource /* size to allocate, or zero</pre>	*/ */ */
	The AllocResource function allocates uninitialize	ed memory for the given resource.
Parameters	<i>hinst</i> Identifies the instance of the module whose exe source.	ecutable file contains the re-
	<i>hrsrc</i> Identifies the desired resource. This handle sho the FindResource function.	uld have been created by using
	<i>cbResource</i> Specifies the size, in bytes, of the memory objet this parameter is zero, Windows allocates enous source.	
Return Value	The return value is the handle of the global memory successful.	ry object if the function is
See Also	FindResource, LoadResource	

AllocSelector

AllocBosourco

UINT AllocSelector (uSelector)
UINT uSelector;/* selector to copy or zero*/The AllocSelector function allocates a new selector.
Do not use this function in an application unless it is absolutely necessary, since
its use violates preferred Windows programming practices.ParametersuSelector
Specifies the selector to return. If this parameter specifies a valid selector, the
function returns a new selector that is an exact copy of the one specified here. If
this parameter is zero, the function returns a new, uninitialized sector.

2.x

Return Value	The return value is a selector that is either a copy of an existing selector, or a new, uninitialized selector. Otherwise, the return value is zero.
Comments	The application must free the new selector by calling the FreeSelector function.
	An application can call AllocSelector to allocate a selector that it can pass to the PrestoChangoSelector function.
See Also	PrestoChangoSelector

AllocUserMem

#include <stress.h>

BOOL AllocUserMem(<i>uContig</i>) UINT <i>uContig</i> ; /* smallest memory allocation */	
	The AllocUserMem function allocates memory in the USER heap until only the specified number of bytes is available. Before making any new allocations, this function frees memory previously allocated by AllocUserMem .
Parameters	<i>uContig</i> Specifies the smallest size, in bytes, of memory allocations to make.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The FreeAllUserMem function frees all memory allocated by AllocUserMem.
See Also	FreeAllUserMem

AnimatePalette

void AnimatePalette(hpal, iStart, cEntries	s, lppe)	
HPALETTE hpal;	/* handle of palette	*/
UINT iStart;	/* first palette entry to animate	*/
UINT cEntries;	/* number of entries in palette	*/
<pre>const PALETTEENTRY FAR* lppe;</pre>	/* address of color structure	*/

3.0

	The AnimatePalette function replaces entries in the specified logical palette. An application does not have to update the client area when it calls AnimatePalette , because Windows maps the new entries into the system palette immediately.
Parameters	<i>hpal</i> Identifies the logical palette.
	<i>iStart</i> Specifies the first entry in the palette to be animated.
	<i>cEntries</i> Specifies the number of entries in the palette to be animated.
	<i>lppe</i> Points to the first member of an array of PALETTEENTRY structures. These palette entries will replace the palette entries identified by the <i>iStart</i> and <i>cEntries</i> parameters. The PALETTEENTRY structure has the following form:
	typedef struct tagPALETTEENTRY { /* pe */ BYTE peRed; BYTE peGreen; BYTE peBlue; BYTE peFlags; } PALETTEENTRY;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
Comments	The AnimatePalette function can change an entry in a logical palette only when the PC_RESERVED flag is set in the corresponding palPaletteEntry member of the LOGPALETTE structure that defines the current logical palette.
Example	The following example initializes a LOGPALETTE structure and an array of PALETTEENTRY structures, uses the CreatePalette function to retrieve a handle of a logical palette, and then uses the AnimatePalette function to map the entries into the system palette:
	#define NUMENTRIES 128 HPALETTE hpal; PALETTEENTRY ape[NUMENTRIES];
	plgpl = (LOGPALETTE*)
	plgpl->palNumEntries = cColors; plgpl->palVersion = 0x300;

2.x

See Also CreatePalette

AnsiLower

LPSTR AnsiLo	
LPSTR lpsz;	/* address of string, or specific character */
	The AnsiLower function converts a character string to lowercase.
Parameters	<i>lpsz</i> Points to a null-terminated string or specifies a single character. If the high- order word of this parameter is zero, the low-order byte of the low-order word must contain a single character to be converted.
Return Value	The return value points to a converted character string if the function is successful. Otherwise, the return value is a 32-bit value that contains the converted character in the low-order byte of the low-order word.
Comments	The conversion is made by the language driver for the current language (the one selected by the user at setup or by using Control Panel). If no language driver has been selected, Windows uses an internal function.
Example	The following example uses the AnsiLower function to convert two strings to lowercase for a non-case-sensitive comparison:
	/* * Convert the target string to lowercase, and then * convert the subject string one character at a time. */

See Also AnsiLowerBuff, AnsiNext, AnsiUpper

AnsiLowerBuff

LPSTR lpszString;		
UINT cbString;	/* length of string */The AnsiLowerBuff function converts a character string in a buffer to lowercase.	
Parameters	<i>lpszString</i> Points to a buffer containing one or more characters.	
	<i>cbString</i> Specifies the number of bytes in the buffer identified by the <i>lpszString</i> parameter. If <i>cbString</i> is zero, the length is 64K (65,536).	
Return Value	The return value specifies the length of the converted string if the function is successful. Otherwise, it is zero.	
Comments	The language driver makes the conversion for the current language (the one selected by the user at setup or by using Control Panel). If no language driver has been selected, Windows uses an internal function.	
Example	The following example uses the AnsiLowerBuff function to convert two strings to lowercase for a non–case-sensitive comparison:	
	AnsiLowerBuff(pszSubject, (UINT) lstrlen(pszSubject)); AnsiLowerBuff(pszTarget, (UINT) lstrlen(pszTarget));	

```
while (*pszTarget != '\0') {
    if (*pszTarget != *pszSubject)
        return FALSE;
    pszTarget = AnsiNext(pszTarget);
    pszSubject = AnsiNext(pszSubject);
}
```

See Also

AnsiLower, AnsiUpper

AnsiNext

LPSTR AnsiNext(*lpchCurrentChar*) */ **LPCSTR** *lpchCurrentChar*: /* address of current character The AnsiNext function moves to the next character in a string. **Parameters** *lpchCurrentChar* Points to a character in a null-terminated string. **Return Value** The return value points to the next character in the string or to the null character at the end of the string, if the function is successful. Comments The **AnsiNext** function can be used to move through strings where each character is a single byte, or through strings where each character is two or more bytes (such as strings that contain characters from a Japanese character set). Example The following example uses the **AnsiNext** function to step through the characters in a filename: /* Find the last backslash. */ for (lpszFile = lpszTemp; *lpszTemp != '\0'; lpszTemp = AnsiNext(lpszTemp)) { if (*lpszTemp == '\\') lpszFile = AnsiNext(lpszTemp); } See Also AnsiPrev

2.x

AnsiPrev

LPSTR AnsiPrev(lp LPCSTR lpchStart; LPCSTR lpchCurre	<i>achStart, lpchCurrentChar)</i> /* address of first character */ <i>ntChar;</i> /* address of current character */		
	The AnsiPrev function moves to the previous character in a string.		
Parameters	<i>lpchStart</i> Points to the beginning of the string. <i>lpchCurrentChar</i>		
	Points to a character in a null-terminated string.		
Return Value	The return value points to the previous character in the string, or to the first char- acter in the string if the <i>lpchCurrentChar</i> parameter is equal to the <i>lpchStart</i> parameter.		
Comments	The AnsiPrev function can be used to move through strings where each character is a single byte, or through strings where each character is two or more bytes (such as strings that contain characters from a Japanese character set).		
	This function can be very slow, because the string must be scanned from the begin- ning to determine the previous character. Wherever possible, the AnsiNext func- tion should be used instead of this function.		
Example	The following example uses the AnsiNext and AnsiPrev functions to change every occurrence of the characters '\&' in a string to a single newline character:		
	/* Find ampersands. */		
	for (lpsz = lpszTest; *lpsz != '\0'; lpsz = AnsiNext(lpsz)) {		
	/* Check the previous character. */		
	<pre>if (*lpsz == '&' &&</pre>		
	}		
See Also	AnsiNext		

AnsiToOem

void AnsiToOen const char _hug char _huge* hps		
	The AnsiToOem function translates a string from the Windows character set into the specified OEM character set.	
Parameters	<i>hpszWindows</i> Points to a null-terminated string of characters from the Windows character set.	
	<i>hpszOem</i> Points to the location where the translated string is to be copied. To translate the string in place, this parameter can be the same as <i>hpszWindows</i> .	
Return Value	This function does not return a value.	
Comments	The string to be translated can be greater than 64K in length.	
	Windows-to-OEM mappings are defined by the keyboard driver, where this func- tion is implemented. Some keyboard drivers may have different mappings than others, depending on the machine environment, and some keyboard driver support loading different OEM character sets; for example, the standard U.S. keyboard driver for an IBM keyboard supports loadable code pages, with the default being code page 437 and the most common alternative being code page 850. (The Win- dows character set is sometimes referred to as code page 1007.)	
	The OEM character set must always be used when accessing string data created by MS-DOS or MS-DOS applications. For example, a word processor should convert OEM characters to Windows characters when importing documents from an MS-DOS word processor. When an application makes an MS-DOS call, including a C run-time function call, filenames must be in the OEM character set, whereas they must be presented to the user in Windows characters (because the Windows fonts use Windows characters).	
Example	The following example is part of a dialog box in which a user would create a directory by typing a name in an edit control:	
	<pre>case IDOK: GetWindowText(GetDlgItem(hwndDlg, ID_EDITDIRNAME), szDirName, sizeof(szDirName)); AnsiToOem(szDirName, szDirName); mkdir(szDirName); EndDialog(hwndDlg, 1); return TRUE;</pre>	

See Also AnsiToOemBuff, OemToAnsi

Ans	iToO	em	Buff
-----	------	----	------

3.0

	The AnsiToOemBuff function translates a string from the Windows character set into the specified OEM character set.	
Parameters	<i>lpszWindowsStr</i> Points to a buffer containing one or more characters from the Windows charac- ter set.	
	<i>lpszOemStr</i> Points to the location where the translated string is to be copied. To translate the string in place, this parameter can be the same as <i>lpszWindowsStr</i> .	
	<i>cbWindowsStr</i> Specifies the number of bytes in the buffer identified by the <i>lpszWindowsStr</i> parameter. If <i>cbWindowsStr</i> is zero, the length is 64K (65,536).	
Return Value	This function does not return a value.	
See Also	AnsiToOem, OemToAnsi	

AnsiUpper

LPSTR AnsiUpper LPSTR lpszString;	(<i>lpszString</i>) /* address of string, or specific character */	
	The AnsiUpper function converts the given character string to uppercase.	
Parameters	<i>lpszString</i> Points to a null-terminated string or specifies a single character. If the high- order word of this parameter is zero, the low-order byte of the low-order word must contain a single character to be converted.	

Return Value	The return value points to a converted character string if the function parameter is a character string. Otherwise, the return value is a 32-bit value that contains the converted character in the low-order byte of the low-order word.		
Comments	The language driver makes the conversion for the current language (the one selected by the user at setup or by using Control Panel). If no language driver is selected, Windows uses an internal function.		
Example	<pre>The following example uses the AnsiUpper function to convert two strings to up- percase for a non-case-sensitive comparison: /* * Convert the target string to uppercase, and then * convert the subject string one character at a time. */ AnsiUpper(pszTarget); while (*pszTarget != '\0') { if (*pszTarget != '\0') { MAKELP(0, *pszSubject))) return FALSE; pszTarget = AnsiNext(pszTarget); pszSubject = AnsiNext(pszSubject); }</pre>		
See Also	AnsiLower, AnsiUpperBuff		

AnsiUpperBuff

UINT AnsiUpperBu	ff(lpszString, cbString)	
LPSTR lpszString;	/* address of string to convert	*/
UINT <i>cbString</i> ;	/* length of string	*/
	The Ancillonor Duff function con	varte a character string in

The AnsiUpperBuff function converts a character string in a buffer to uppercase.

3.0

Parameters

lpszString

Points to a buffer containing one or more characters.

cbString

Specifies the number of bytes in the buffer identified by the *lpszString* parameter. If *cbString* is zero, the length is 64K (65,536).

Return Value	The return value specifies the length of the converted string if the function is successful.		
Comments	The language driver makes the conversion for the current language (the one selected by the user at setup or by using Control Panel). If no language driver is selected, Windows uses an internal function.		
Example	The following example uses the AnsiUpperBuff function to convert two strings to lowercase for a non–case-sensitive comparison:		
	<pre>/* * Convert both the subject and target strings to uppercase before * comparing. */</pre>		
	AnsiUpperBuff(pszSubject, (UINT) lstrlen(pszSubject)); AnsiUpperBuff(pszTarget, (UINT) lstrlen(pszTarget));		
	<pre>while (*pszTarget != '\0') { if (*pszTarget != *pszSubject) return FALSE; pszTarget = AnsiNext(pszTarget); pszSubject = AnsiNext(pszSubject); }</pre>		

See Also AnsiLower, AnsiUpper

AnyPopup

BOOL AnyPopup(void)

The **AnyPopup** function indicates whether an unowned, visible, top-level pop-up, or overlapped window exists on the screen. The function searches the entire Windows screen, not just the caller's client area.

- **Parameters** This function has no parameters.
- **Return Value** The return value is nonzero if a pop-up window exists, even if the pop-up window is completely covered by other windows. The return value is zero if no pop-up window exists.

Comments	AnyPopup is a Windows 1. <i>x</i> function and remains for compatibility reasons. It is generally not useful.
	This function does not detect unowned pop-up windows or windows that do not have the WS_VISIBLE style bit set.
See Also	GetLastActivePopup, ShowOwnedPopups

3.0

AppendMenu

BOOL AppendMer HMENU hmenu; UINT fuFlags; UINT idNewItem; LPCSTR lpNewIten		*/ */ ier */	
		on appends a new item to the end of a menu. The appli- e of the menu item by setting values in the <i>fuFlags</i>	
Parameters	<i>hmenu</i> Identifies the menu to be changed.		
	<i>fuFlags</i> Specifies information about the state of the new menu item when it is added to the menu. This parameter consists of one or more of the values listed in the fol- lowing Comments section.		
	<i>idNewItem</i> Specifies either the command identifier of the new menu item or, if the <i>fuFlags</i> parameter is set to MF_POPUP, the menu handle of the pop-up menu.		
	<i>lpNewItem</i> Specifies the content of the new menu item. The interpretation of the <i>lpNewItem</i> parameter depends on the value of the <i>fuFlags</i> parameter.		
	Value	Menu-item content	
	MF_STRING	Contains a long pointer to a null-terminated string.	
	MF_BITMAP	Contains a bitmap handle in its low-order word.	

	Value	Menu-item content	
	MF_OWNERDRAW	Contains an application-supplied 32-bit value that the application can use to maintain additional data associated with the menu item. An application can find this value in the itemData member of the structure pointed to by the <i>lParam</i> parameter of the WM_MEASUREITEM and WM_DRAWITEM messages that are sent when the menu item is changed or initially displayed.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	 Whenever a menu changes (whether or not the menu is in a window that is displayed), the application should call the DrawMenuBar function. Each of the following groups lists flags that are mutually exclusive and cannot be used together: MF_DISABLED, MF_ENABLED, and MF_GRAYED MF_BITMAP, MF_STRING, and MF_OWNERDRAW 		
	MF_MENUBARBRE	AK and MF_MENUBREAK	
	 MF_CHECKED and MF_UNCHECKED 		

Following are the flags that can be set in the *fuFlags* parameter:

Value	Meaning
MF_BITMAP	Uses a bitmap as the item. The low-order word of the <i>lpNewItem</i> parameter contains the handle of the bitmap.
MF_CHECKED	Places a check mark next to the item. If the application has supplied check mark bitmaps (see the SetMenuItem-Bitmaps function), setting this flag displays the "check mark on" bitmap next to the menu item.
MF_DISABLED	Disables the menu item so that it cannot be selected, but does not gray it.
MF_ENABLED	Enables the menu item so that it can be selected, and re- stores it from its grayed state.
MF_GRAYED	Disables the menu item so that it cannot be selected, and grays it.
MF_MENUBARBREAK	Same as MF_MENUBREAK except that, for pop-up menus, separates the new column from the old column with a vertical line.
MF_MENUBREAK	Places the item on a new line for static menu-bar items. For pop-up menus, places the item in a new column, with no dividing line between the columns.

Example

See Also

Value	Meaning
MF_OWNERDRAW	Specifies that the item is an owner-drawn item. The wi dow that owns the menu receives a WM_MEASUREITEM message when the menu is dis played for the first time to retrieve the height and width of the menu item. The WM_DRAWITEM message is then sent whenever the owner window must update the visual appearance of the menu item. This option is not valid for a top-level menu item.
MF_POPUP	Specifies that the menu item has a pop-up menu as- sociated with it. The <i>idNewItem</i> parameter specifies a handle to a pop-up menu to be associated with the item This is used for adding either a top-level pop-up menu adding a hierarchical pop-up menu to a pop-up menu item.
MF_SEPARATOR	Draws a horizontal dividing line. Can be used only in a pop-up menu. This line cannot be grayed, disabled, or highlighted. The <i>lpNewItem</i> and <i>idNewItem</i> parameters are ignored.
MF_STRING	Specifies that the menu item is a character string; the <i>lpNewItem</i> parameter points to the string for the menu item.
MF_UNCHECKED	Does not place a check mark next to the item (default). the application has supplied check mark bitmaps (see SetMenuItemBitmaps), setting this flag displays the "check mark off" bitmap next to the menu item.
The following example floating pop-up menu:	uses the AppendMenu function to append three items
POINT ptCurrent; HMENU hmenu;	

Arc

BOOL Arc(hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nXStartArc, nYStartArc, nXEndArc, nYEndArc)

, , , , , , , , , , , , , , , , , , , 		
HDC hdc;	/* handle of device context	*/
int nLeftRect;	/* x-coordinate upper-left corner bounding rectangle	*/
int nTopRect;	/* y-coordinate upper-left corner bounding rectangle	*/
int nRightRect;	/* x-coordinate lower-right corner bounding rectangle	*/
int nBottomRect;	/* y-coordinate lower-right corner bounding rectangle	*/
int nXStartArc;	/* x-coordinate arc starting point	*/
int nYStartArc;	/* y-coordinate arc starting point	*/
int nXEndArc;	/* x-coordinate arc ending point	*/
int nYEndArc;	/* y-coordinate arc ending point	*/

The Arc function draws an elliptical arc.

Parameters

Identifies the device context.

nLeftRect

hdc

Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.

nTopRect

Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.

nRightRect

Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.

nBottomRect

Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.

nXStartArc

Specifies the logical x-coordinate of the point that defines the arc's starting point. This point need not lie exactly on the arc.

nYStartArc

Specifies the logical y-coordinate of the point that defines the arc's starting point. This point need not lie exactly on the arc.

nXEndArc

Specifies the logical x-coordinate of the point that defines the arc's endpoint. This point need not lie exactly on the arc.

nYEndArc

Specifies the logical y-coordinate of the point that defines the arc's endpoint. This point need not lie exactly on the arc.

Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The arc drawn by using the Arc function is a segment of the ellipse defined by the specified bounding rectangle. The starting point of the arc is the point at which a ray drawn from the center of the bounding rectangle through the specified starting point intersects the ellipse. The end point of the arc is the point at which a ray drawn from the center of the bounding rectangle through the specified end point intersects the ellipse. The arc is drawn in a counterclockwise direction. Since an arc is not a closed figure, it is not filled.
	Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.
Example	The following example uses a RECT structure to store the points defining the bounding rectangle and uses POINT structures to store the coordinates that specify the beginning and end of the arc:
	HDC hdc;
	RECT rc = { 10, 10, 180, 140 }; POINT ptStart = { 12, 12 }; POINT ptEnd = { 128, 135 };
	<pre>Arc(hdc, rc.left, rc.top, rc.right, rc.bottom,</pre>
See Also	Chord

ArrangelconicWindows

UINT ArrangeIconicWindows(*hwnd*)

HWND *hwnd*; /* handle of parent window */

The **ArrangeIconicWindows** function arranges all the minimized (iconic) child windows of a parent window.

Parametershwnd
Identifies the parent window.Return ValueThe return value is the height of one row of icons if the function is successful.
Otherwise, it is zero.

Comments	An application that maintains its own minimized child windows can call Arrange-IconicWindows to arrange icons in a client window. This function also arranges icons on the desktop window, which covers the entire screen. The GetDesktop-Window function retrieves the window handle of the desktop window.
	An application sends the WM_MDIICONARRANGE message to the MDI client window to prompt the client window to arrange its minimized MDI child windows.
See Also	GetDesktopWindow

BeginDeferWindowPos

HDWP BeginDe int cWindows;	eferWindowPos(cWindows) /* number of windows */
	The BeginDeferWindowPos function returns a handle of an internal structure. The DeferWindowPos function fills this structure with information about the tar- get position for a window that is about to be moved. The EndDeferWindowPos function accepts a handle of this structure and instantaneously repositions the win- dows by using the information stored in the structure.
Parameters	<i>cWindows</i> Specifies the initial number of windows for which to store position information in the structure. The DeferWindowPos function increases the size of the struc- ture if necessary.
Return Value	The return value identifies the internal structure if the function is successful. Otherwise, it is NULL.
Comments	If Windows must increase the size of the internal structure beyond the initial size specified by the <i>cWindows</i> parameter but cannot allocate enough memory to do so, Windows fails the entire begin/defer/end window-positioning sequence. By specifying the maximum size needed, an application can detect and handle failure early in the process.
See Also	DeferWindowPos, EndDeferWindowPos

BeginPaint

HDC BeginPaint(h HWND hwnd; PAINTSTRUCT FA		/* handle of window to paint /* address of structure with paint information	*/ */
		Paint function prepares the specified window for paint RUCT structure with information about the painting.	ing and fills a

BitBlt

BOOL BitBlt(hdcD	est, nXDest, nYDest, nWidth, nHeight, hdcSrc,	nXSrc, nYSrc, dwRop)
HDC hdcDest;	/* handle of destination device context	*/
int nXDest;	/* upper-left corner destination rectangle	*/
int nYDest;	/* upper-left corner destination rectangle	*/
int nWidth;	/* bitmap width	*/
int nHeight;	/* bitmap height	*/
HDC hdcSrc;	/* handle of source device context	*/
int <i>nXSrc</i> ;	/* upper-left corner source bitmap	*/
int nYSrc;	/* upper-left corner source bitmap	*/
DWORD dwRop;	/* raster operation for copy	*/
Devemetere	The BitBlt function copies a bitmap from a s tion device context.	peemed de tree context to a destina
Parameters	<i>hdcDest</i> Identifies the destination device context.	
	<i>nXDest</i> Specifies the logical x-coordinate of the up rectangle.	pper-left corner of the destination
	<i>nYDest</i> Specifies the logical y-coordinate of the upper-left corner of the destination rectangle.	
	<i>nWidth</i> Specifies the width, in logical units, of the map.	destination rectangle and source bit-

nHeight

Specifies the height, in logical units, of the destination rectangle and source bitmap.

hdcSrc

Identifies the device context from which the bitmap will be copied. This parameter must be NULL if the *dwRop* parameter specifies a raster operation that does not include a source. This parameter can specify a memory device context.

nXSrc

Specifies the logical x-coordinate of the upper-left corner of the source bitmap.

nYSrc

Specifies the logical y-coordinate of the upper-left corner of the source bitmap.

dwRop

Specifies the raster operation to be performed. Raster operation codes define how the graphics device interface (GDI) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. This parameter can be one of the following:

Code	Description
BLACKNESS	Turns all output black.
DSTINVERT	Inverts the destination bitmap.
MERGECOPY	Combines the pattern and the source bitmap by using the Boolean AND operator.
MERGEPAINT	Combines the inverted source bitmap with the destination bit- map by using the Boolean OR operator.
NOTSRCCOPY	Copies the inverted source bitmap to the destination.
NOTSRCERASE	Inverts the result of combining the destination and source bit- maps by using the Boolean OR operator.
PATCOPY	Copies the pattern to the destination bitmap.
PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
PATPAINT	Combines the inverted source bitmap with the pattern by using the Boolean OR operator. Combines the result of this operation with the destination bitmap by using the Boolean OR operator.
SRCAND	Combines pixels of the destination and source bitmaps by using the Boolean AND operator.
SRCCOPY	Copies the source bitmap to the destination bitmap.
SRCERASE	Inverts the destination bitmap and combines the result with the source bitmap by using the Boolean AND operator.
SRCINVERT	Combines pixels of the destination and source bitmaps by using the Boolean XOR operator.

BitBlt 31

.

	Code	Description
	SRCPAINT	Combines pixels of the destination and source bitmaps by using the Boolean OR operator.
	WHITENESS	Turns all output white.
Return Value	The return value is no	onzero if the function is successful. Otherwise, it is zero.
Comments	another window or fr the same window sho CS_BYTEALIGNCL the windows or client BitBlt operations occ	ses the BitBlt function to copy pixels from one window to om a source rectangle in a window into a target rectangle in buld set the CS_BYTEALIGNWINDOW or LIENT flag when registering the window classes. By aligning a areas on byte boundaries, the application can ensure that the our on byte-aligned rectangles. BitBlt operations on byte- e considerably faster than BitBlt operations on rectangles that

		is the current text color for the specified device context, and is the current background color for the specified device con-
		rt the BitBlt function. An application can determine whether Blt by calling the GetDeviceCaps function and specifying ndex.
	For a complete list of grammer's Reference	the raster-operation codes, see the <i>Microsoft Windows Pro-</i> <i>y, Volume 4</i> .
Example	The following examp a window:	le loads a bitmap, retrieves its dimensions, and displays it in

```
HDC hdc, hdcMemory;

HBITMAP hbmpMyBitmap, hbmpOld;

BITMAP bm;

hbmpMyBitmap = LoadBitmap(hinst, "MyBitmap");

GetObject(hbmpMyBitmap, sizeof(BITMAP), &bm);

hdc = GetDC(hwnd);

hdcMemory = CreateCompatibleDC(hdc);

hbmpOld = SelectObject(hdcMemory, hbmpMyBitmap);

BitBlt(hdc, 0, 0, bm.bmWidth, bm.bmHeight, hdcMemory, 0, 0, SRCCOPY);

SelectObject(hdcMemory, hbmpOld);

DeleteDC(hdcMemory);

ReleaseDC(hwnd, hdc);

See Also GetDeviceCaps, PatBlt, SetTextColor, StretchBlt, StretchDIBits
```

2.x

BringWindowToTop

BOOL BringWindowToTop(hwnd)

HWND hwnd;	/* handle of window */
	The BringWindowToTop function brings the given pop-up or child window (including an MDI child window) to the top of a stack of overlapping windows. In addition, it activates pop-up, top-level, and MDI child windows. The Bring-WindowToTop function should be used to uncover any window that is partially or completely obscured by any overlapping windows.
Parameters	<i>hwnd</i> Identifies the pop-up or child window to bring to the top.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Calling this function is similar to calling the SetWindowPos function to change a window's position in the Z-order. The BringWindowToTop function does not make a window a top-level window.
See Also	SetWindowPos

BuildCommDCB

int BuildCommDCB(lpszDef, lpdcb)

LPCSTR lpszDef;	/* address of device-control string	*/
DCB FAR* lpdcb;	/* address of device-control block	*/

The BuildCommDCB function translates a device-definition string into appropriate serial device control block (DCB) codes.

Parameters

lpszDef

Points to a null-terminated string that specifies device-control information. The string must have the same form as the parameters used in the MS-DOS mode command.

lpdcb

Points to a **DCB** structure that will receive the translated string. The structure defines the control settings for the serial-communications device. The DCB structure has the following form:

typedef struct tagDCB		/*	dcb	*/
{ BYTE Id; UINT BaudRate; BYTE ByteSize; BYTE Parity; BYTE StopBits; UINT R1sTimeout; UINT CtsTimeout; UINT DsrTimeout;		/* /* /* /* /*	<pre>internal device identifier baud rate number of bits/byte, 4-8 0-4=none,odd,even,mark,space 0,1,2 = 1, 1.5, 2 timeout for RLSD to be set timeout for CTS to be set timeout for DSR to be set</pre>	*/ */ */ */ */
UINT fBinary UINT fRtsDisable UINT fParity UINT fOutxCtsFlow UINT fOutxDsrFlow UINT fDummy UINT fDtrDisable	:1; :1; :1; :1; :1; :2;	/* /* /* /*	binary mode (skip EOF check) don't assert RTS at init time enable parity checking CTS handshaking on output DSR handshaking on output reserved don't assert DTR at init time	*/ */ */ */
UINT fOutX UINT fInX • UINT fPeChar UINT fNull UINT fChEvt UINT fDtrflow UINT fRtsflow UINT fDummy2	:1; :1; :1; :1; :1;	/* /* /* /*	enable output XON/XOFF enable input XON/XOFF enable parity err replacement enable null stripping enable Rx character event DTR handshake on input RTS handshake on input	*/ */ */ */ */

	char XonChar; char XoffChar; UINT XonLim; UINT XoffLim; char PeChar; char EofChar; char EvtChar; UINT TxDelay; } DCB; For a full description of this so mer's Reference, Volume 3.	<pre>/* Tx and Rx XON character /* Tx and Rx XOFF character /* transmit XON threshold /* transmit XOFF threshold /* parity error replacement char /* end of Input character /* received event character /* amount of time between chars tructure, see the Microsoft Windows Prog</pre>	*/ */ */ */ */ */
Return Value	The return value is zero if the fu	nction is successful. Otherwise, it is -1 .	
Comments	The BuildCommDCB function of port, an application should use the	only fills the buffer. To apply the settings e SetCommState function.	to a

See Also	SetCommState		

SetCommState

CallMsgFilte	2.x
BOOL CallMsgFilt MSG FAR* <i>lpmsg</i> ; int <i>nCode</i> ;	er(lpmsg, nCode) /* address of structure with message data */ /* processing code */
	The CallMsgFilter function passes the given message and code to the current mes- sage-filter function. The message-filter function is an application-specified func- tion that examines and modifies all messages. An application specifies the function by using the SetWindowsHook function.
Parameters	<i>lpmsg</i> Points to an MSG structure that contains the message to be filtered. The MSG structure has the following form:
	typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>nCode</i> Specifies a code used by the filter function to determine how to process the message.
Return Value	The return value specifies the state of message processing. It is zero if the message should be processed or nonzero if the message should not be processed further.
Comments	The CallMsgFilter function is usually called by Windows to let applications ex- amine and control the flow of messages during internal processing in menus and scroll bars or when moving or sizing a window.
	Values given for the <i>nCode</i> parameter must not conflict with any of the MSGF_ and HC_ values passed by Windows to the message-filter function.
See Also	SetWindowsHook

CallNextHookEx

LRESULT CallNex HHOOK hHook; int nCode; WPARAM wParam LPARAM lParam;	tHookEx(hHook, nCode, wParam, lParam) /* handle of hook function */ /* hook code */ ; /* first message parameter */ /* second message parameter */
	The CallNextHookEx function passes the hook information to the next hook function in the hook chain.
Parameters	 <i>hHook</i> Identifies the current hook function. <i>nCode</i> Specifies the hook code to pass to the next hook function. A hook function uses this code to determine how to process the message sent to the hook. <i>wParam</i> Specifies 16 bits of additional message-dependent information. <i>IParam</i> Specifies 32 bits of additional message-dependent information.
Return Value	The return value specifies the result of the message processing and depends on the value of the $nCode$ parameter.
Comments	Calling the CallNextHookEx function is optional. An application can call this function either before or after completing any processing in its own hook function. If an application does not call CallNextHookEx , Windows will not call the hook functions that were installed before the application's hook function was installed.
See Also	SetWindowsHookEx, UnhookWindowsHookEx

CallWindowProc

LRESULT CallWindowProc	(wndprcPrev, hwnd, uMsg, wParam, lParam)	
WNDPROC wndprcPrev;	/* instance address of previous procedure	*/
HWND hwnd;	/* handle of window	*/
UINT uMsg;	/* message	*/
WPARAM wParam;	/* first message parameter	*/
LPARAM lParam;	/* second message parameter	*/

	dow procedure.
Parameters	<i>wndprcPrev</i> Specifies the procedure-instance address of the previous window procedure.
	<i>hwnd</i> Identifies the window that will receive the message.
	<i>uMsg</i> Specifies the message.
	wParam Specifies 16 bits of additional message-dependent information.
	<i>lParam</i> Specifies 32 bits of additional message-dependent information.
Return Value	The return value specifies the result of the message processing and depends on the message sent.
Comments	The CallWindowProc function is used for window subclassing. Normally, all windows with the same class share the same window procedure. A subclass is a window or set of windows belonging to the same window class whose messages are intercepted and processed by another window procedure (or procedures) before being passed to the window procedure of that class.
	The SetWindowLong function creates the subclass by changing the window pro- cedure associated with a particular window, causing Windows to call the new win- dow procedure instead of the previous one. Any messages not processed by the new window procedure must be passed to the previous window procedure by calling CallWindowProc . This allows you to create a chain of window proce- dures.
See Also	SetWindowLong

The CallWindowProc function passes message information to the specified win-

CallWndProc

3.1

LRESULT CALLBAC	K CallWndProc(code, wParam, lParam)	
int code;	/* process-message flag	*/
WPARAM wParam;	/* current-task flag	*/
LPARAM lParam;	/* address of structure with message data	*/

The **CallWndProc** function is a library-defined callback function that the system calls whenever the **SendMessage** function is called. The system passes the

message to the callback function before passing the message to the destination window procedure.

Parameters

code

Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If the *code* parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.

wParam

Specifies whether the message is sent by the current task. This parameter is nonzero if the message is sent; otherwise, it is NULL.

lParam

Points to a structure that contains details about the message. The following shows the order, type, and description of each member of the structure:

Member	Description
lParam	Contains the <i>lParam</i> parameter of the message.
wParam	Contains the wParam parameter of the message.
uMsg	Specifies the message.
hWnd	Identifies the window that will receive the message.

Return Value The callback function should return zero.

Comments The **CallWndProc** callback function can examine or modify the message as necessary. Once the function returns control to the system, the message, with any modifications, is passed on to the window procedure.

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the WH_CALLWNDPROC filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

CallWndProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also CallNextHookEx, SendMessage, SetWindowsHookEx

Catch

int Catch(lpCatchB int FAR* lpCatchB		
	The Catch function captures the current execution environment and copies it to a buffer. The Throw function can use this buffer later to restore the execution environment. The execution environment includes the state of all system registers and the instruction counter.	
Parameters	<i>lpCatchBuf</i> Points to a memory buffer large enough to contain a CATCHBUF array.	
Return Value	The Catch function returns immediately with a return value of zero. When the Throw function is called, it returns again, this time with the return value specified in the <i>nErrorReturn</i> parameter of the Throw function.	
Comments	The Catch function is similar to the C run-time function setjmp .	
Example The following example calls the Catch function to save the current exect environment before calling a recursive sort function. The first return val from Catch is zero. If the doSort function calls the Throw function, exec will again return to the Catch function. This time, Catch will return the STACKOVERFLOW error passed by the doSort function. The doSort f recursive—that is, it calls itself. It maintains a variable, wStackCheck, the to check to see how much stack space has been used. If more then 3K of has been used, doSort calls Throw to drop out of all the nested function into the function that called Catch .		
	#define STACKOVERFLOW 1	
	UINT uStackCheck; CATCHBUF catchbuf;	
	{ int iReturn; char szBuf[80];	
	<pre>if ((iReturn = Catch((int FAR*) catchbuf)) != 0) { .</pre>	
	. /* Error processing goes here. */	
	}	

```
else {
       uStackCheck = 0;
                             /* initializes stack-usage count */
       doSort(1, 100);
                             /* calls sorting function
                                                               */
    }
   break:
}
void doSort(int sLeft, int sRight)
ſ
    int sLast;
    /*
    * Determine whether more than 3K of the stack has been
    * used, and if so, call Throw to drop back into the
    * original calling application.
    *
    * The stack is incremented by the size of the two parameters,
    * the two local variables, and the return value (2 for a near
    * function call).
    */
    uStackCheck += (sizeof(int) * 4) + 2;
    if (uStackCheck > (3 * 1024))
       Throw((int FAR*) catchbuf, STACKOVERFLOW);
    . /* A sorting algorithm goes here. */
    doSort(sLeft, sLast - 1); /* note recursive call
                                                                */
   uStackCheck -= 10;
                               /* updates stack-check variable */
}
```

CBTProc

3.1

LRESULT CALLBACK	CBTProc (code, wParam, lParam)	
int code;	/* CBT hook code	*/
WPARAM wParam;	/* depends on the code parameter	*/
LPARAM lParam;	/* depends on the code parameter	*/

The **CBTProc** function is a library-defined callback function that the system calls before activating, creating, destroying, minimizing, maximizing, moving, or sizing a window; before completing a system command; before removing a mouse or

keyboard event from the system message queue; before setting the input focus; or before synchronizing with the system message queue.

The value returned by the callback function determines whether to allow or prevent one of these operations.

Parameters

code

Specifies a computer-based-training (CBT) hook code that identifies the operation about to be carried out, or a value less than zero if the callback function should pass the *code*, *wParam*, and *lParam* parameters to the **CallNextHookEx** function. The *code* parameter can be one of the following:

Code	Meaning
HCBT_ACTIVATE	Indicates that the system is about to activate a win- dow.
HCBT_CLICKSKIPPED	Indicates that the system has removed a mouse mes- sage from the system message queue. A CBT applica- tion that must install a journaling playback filter in response to the mouse message should do so when it receives this hook code.
HCBT_CREATEWND	Indicates that a window is about to be created. The system calls the callback function before sending the WM_CREATE or WM_NCCREATE message to the window. If the callback function returns TRUE, the system destroys the window—the CreateWindow function returns NULL, but the WM_DESTROY message is not sent to the window. If the callback function returns FALSE, the window is created normally.
	At the time of the HCBT_CREATEWND notifica- tion, the window has been created, but its final size and position may not have been determined, nor has its parent window been established.
	It is possible to send messages to the newly created window, although the window has not yet received WM_NCCREATE or WM_CREATE messages.
	It is possible to change the Z-order of the newly created window by modifying the hwndInsertAfter member of the CBT_CREATEWND structure.
HCBT_DESTROYWND	Indicates that a window is about to be destroyed.
HCBT_KEYSKIPPED	Indicates that the system has removed a keyboard message from the system message queue. A CBT ap- plication that must install a journaling playback filter in response to the keyboard message should do so when it receives this hook code.
HCBT_MINMAX	Indicates that a window is about to be minimized or maximized.

	Code	Meaning
	HCBT_MOVESIZE	Indicates that a window is about to be moved or sized.
	HCBT_QS	Indicates that the system has retrieved a WM_QUEUESYNC message from the system message queue.
	HCBT_SETFOCUS	Indicates that a window is about to receive the input focus.
	HCBT_SYSCOMMAND	Indicates that a system command is about to be car- ried out. This allows a CBT application to prevent task switching by hot keys.
	<i>wParam</i> This parameter depends on the <i>code</i> parameter. See the followi section for details.	
	<i>lParam</i> This parameter depends or section for details.	n the <i>code</i> parameter. See the following Comments
		to the following CBT hook codes, the callback func- ow the operation, or 1 to prevent it:
	HCBT_ACTIVATE HCBT_CREATEWND HCBT_DESTROYWND HCBT_MINMAX HCBT_MOVESIZE HCBT_SYSCOMMAND	
	The return value is ignored for operations corresponding to the for hook codes:	
	HCBT_CLICKSKIPPED HCBT_KEYSKIPPED HCBT_QS	
Comments	The callback function should described in the preceding lis	not install a playback hook except in the situations t of hook codes.
	This callback function must b	be in a dynamic-link library.
		the callback function by specifying the WH_CBT filter nee address of the callback function in a call to the on.

CBTProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

The following table describes the *wParam* and *lParam* parameters for each HCBT_ constant.

Constant	wParam	lParam
HCBT_ACTIVATE	Specifies the handle of the win- dow about to be activated.	Specifies a long pointer to a CBT- ACTIVATESTRUCT structure that con- tains the handle of the currently active window and specifies whether the activation is changing because of a mouse click.
HCBT_CLICKSKIPPED	Identifies the mouse message re- moved from the system mes- sage queue.	Specifies a long pointer to a MOUSE- HOOKSTRUCT structure that contains the hit-test code and the handle of the window for which the mouse message is intended. For a list of hit-test codes, see the descrip- tion of the WM_NCHITTEST message.
HCBT_CREATEWND	Specifies the handle of the new window.	Specifies a long pointer to a CBT_CREATEWND data structure that contains initialization parameters for the window.
HCBT_DESTROYWND	Specifies the handle of the win- dow about to be destroyed.	This parameter is undefined and should be set to 0L.
HCBT_KEYSKIPPED	Identifies the virtual key code.	Specifies the repeat count, scan code, key- transition code, previous key state, and con- text code. For more information, see the description of the WM_KEYUP or WM_KEYDOWN message.
HCBT_MINMAX	Specifies the handle of the win- dow being minimized or maxi- mized.	The low-order word specifies a show- window value (SW_) that specifies the operation. For a list of show-window values, see the description of the ShowWindow function. The high-order word is undefined.
HCBT_MOVESIZE	Specifies the handle of the win- dow to be moved or sized.	Specifies a long pointer to a RECT structure that contains the coordinates of the window.
HCBT_QS	This parameter is undefined; it should be set to 0.	This parameter is undefined and should be set to 0L.
HCBT_SETFOCUS	Specifies the handle of the win- dow gaining the input focus.	The low-order word specifies the handle of the window losing the input focus. The high- order word is undefined.

Constant	wParam	lParam	
HCBT_SYSCOMMAND	Specifies a system-command value (SC_) that specifies the system command. For more information about system command values, see the description of the WM_SYSCOMMAND message.	If <i>wParam</i> is SC_HOTKEY, the low-order word of <i>lParam</i> contains the handle of the window that task switching will bring to the foreground. If <i>wParam</i> is not SC_HOTKEY and a System-menu command is chosen with the mouse, the low-order word of <i>lParam</i> contains the x-coordinate of the cur- sor and the high-order word contains the y-coordinate. If neither of these conditions is true, <i>lParam</i> is undefined.	

See Also CallNextHookEx, SetWindowsHookEx

ChangeClipboardChain

	boardChain(hwnd, hwndNext)
	/* handle of window to remove */ /* handle of next window */
nwind nwhaivexi;	/* handle of next window */
	The ChangeClipboardChain function removes the window identified by the hwnd parameter from the chain of clipboard viewers and makes the window identified by the <i>hwndNext</i> parameter the descendant of the <i>hwnd</i> parameter's ancestor in the chain.
Parameters	<i>hwnd</i> Identifies the window that is to be removed from the chain. The handle must have been passed to the SetClipboardViewer function.
	<i>hwndNext</i> Identifies the window that follows <i>hwnd</i> in the clipboard-viewer chain (this is the handle returned by the SetClipboardViewer function, unless the sequence was changed in response to a WM_CHANGECBCHAIN message).
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also	SetClipboardViewer

ChangeMenu

The Microsoft Windows 3.1 Software Development Kit (SDK) has replaced this function with five specialized functions, listed as follows:

	Function	Description	
	AppendMenu	Appends a menu item to the end of a menu.	
	DeleteMenu	Deletes a menu item from a menu, destroying the menu item. Inserts a menu item into a menu.	
	InsertMenu		
	ModifyMenu	Modifies a menu item in a menu.	
	RemoveMenu Removes a menu item from a menu but does not des item.		ienu
Example	ChangeMenu a and 3.1 should o	ritten for Windows versions earlier than 3.0 may continue to as previously documented. Applications written for Window call the new functions. example shows a call to ChangeMenu and how it would be endMenu:	ws 3.0
	_ AppendMenu(hMe	<pre>/* position parameter not used</pre>	*/ */ */ */ */ */
	"&White");	; /* menu-item string	*/
See Also	AppendMenu,	DeleteMenu, InsertMenu, ModifyMenu, RemoveMenu	

CheckDlgButton

void CheckDlgButton(hwndDlg, idButton, uCheck)		
HWND hwndĎlg;	/* handle of dialog box	*/
int idButton;	/* button-control identifier	*/
UINT uCheck;	/* check state	*/

2.x

	The CheckDlgButton function selects (places a check mark next to) or clears (removes a check mark from) a button control, or it changes the state of a three-state button.
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the button.
	<i>idButton</i> Identifies the button to be modified.
	 <i>uCheck</i> Specifies the check state of the button. If this parameter is nonzero, CheckDlgButton selects the button; if the parameter is zero, the function clears the button. For a three-state check box, if <i>uCheck</i> is 2, the button is grayed; if <i>uCheck</i> is 1, it is selected; if <i>uCheck</i> is 0, it is cleared.
Return Value	This function does not return a value.
Comments	The CheckDlgButton function sends a BM_SETCHECK message to the specified button control in the given dialog box.
See Also	CheckRadioButton, IsDlgButtonChecked

CheckMenuItem

BOOL CheckMenu	Item(hmenu, idCheckItem, uCheck)	
HMENU hmenu;	/* handle of menu	*/
UINT idCheckItem;	/* menu-item identifier	*/
UINT uCheck;	/* check state and position	*/
		lects (places a check mark next to) or clears (re- fied menu item in the given pop-up menu.
Parameters	<i>hmenu</i> Identifies the menu.	
	<i>idCheckItem</i> Identifies the menu item to be se	elected or cleared.
	should be selected or cleared (M parameter can be a combination	position of the menu item BYPOSITION) and whether the item IF_CHECKED or MF_UNCHECKED). This of these values, which can be combined by The values are described as follows:

2.x

	Value	Meaning
	MF_BYCOMMAND	Specifies that the <i>idCheckItem</i> parameter gives the menu- item identifier (MF_BYCOMMAND is the default).
	MF_BYPOSITION	Specifies that the <i>idCheckItem</i> parameter gives the position of the menu item (the first item is at position zero).
	MF_CHECKED	Selects the item (adds check mark).
	MF_UNCHECKED	Clears the item (removes check mark).
Return Value	The return value specifies the previous state of the item—MF_CHECKED or MF_UNCHECKED—if the function is successful. The return value is -1 if the menu item does not exist.	
Comments	The <i>idCheckItem</i> parameter may identify a pop-up menu item as well as a menu item. No special steps are required to select a pop-up menu item. Top-level menu items cannot have a check.	
	A pop-up menu item shou item identifier associated	ald be selected by position since it does not have a menu- with it.
See Also	GetMenuState, SetMen	uItemBitmaps

CheckRadioButton

void CheckRadioB HWND hwndDlg; int idFirstButton; int idLastButton; int idCheckButton;	utton(hwndDlg, idFirstButton, idLastButton, idCheckButton)/* handle of dialog box/* identifier of first radio button in group/* identifier of last radio button in group/* identifier of radio button to select
	The CheckRadioButton function selects (adds a check mark to) a given radio button in a group and clears (removes a check mark from) all other radio buttons in the group.
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the radio button.
	<i>idFirstButton</i> Specifies the identifier of the first radio button in the group.
	<i>idLastButton</i> Specifies the identifier of the last radio button in the group.

	<i>idCheckButton</i> Specifies the identifier of the radio button to select.
Return Value	This function does not return a value.
Comments	The CheckRadioButton function sends a BM_SETCHECK message to the specified radio button control in the given dialog box.
See Also	CheckDlgButton, IsDlgButtonChecked

ChildWindowFromPoint

HWND ChildWind HWND hwndParent POINT pt;	owFromPoint(hwndParent, pt) '* handle of parent window */ /* structure with point coordinates */
	The ChildWindowFromPoint function determines which, if any, of the child windows belonging to the given parent window contains the specified point.
Parameters	<pre>hwndParent Identifies the parent window. pt Specifies a POINT structure that defines the client coordinates of the point to be checked. The POINT structure has the following form:</pre>
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.</pre>
Return Value	The return value is the handle of the child window (hidden, disabled, or trans- parent) that contains the point, if the function is successful. If the given point lies outside the parent window, the return value is NULL. If the point is within the parent window but is not contained within any child window, the return value is the handle of the parent window.
Comments	More than one window may contain the given point, but Windows returns the handle only of the first window encountered that contains the point.

See Also WindowFromPoint

ChooseColor	3.1
#include <commdlg< th=""><th>.h></th></commdlg<>	.h>
BOOL ChooseColor CHOOSECOLOR	
	The ChooseColor function creates a system-defined dialog box from which the user can select a color.
Parameters	<i>lpcc</i> Points to a CHOOSECOLOR structure that initially contains information nec- essary to initialize the dialog box. When the ChooseColor function returns, this structure contains information about the user's color selection. The CHOOSE- COLOR structure has the following form:
	#include <commdlg.h></commdlg.h>
	<pre>typedef struct tagCHOOSECOLOR { /* cc */ DWORD lStructSize; HWND hwndOwner; HWND hInstance; COLORREF rgbResult; COLORREF FAR* lpCustColors; DWORD Flags; LPARAM lCustData; UINT (CALLBACK* lpfnHook)(HWND, UINT, WPARAM, LPARAM); LPCSTR lpTemplateName; } CHOOSECOLOR;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. It is zero if an error oc- curs, if the user chooses the Cancel button, or if the user chooses the Close com- mand on the System menu (often called the Control menu) to close the dialog box.
Errors	Use the CommDlgExtendedError function to retrieve the error value, which may be one of the following:
	CDERR_FINDRESFAILURE CDERR_INITIALIZATION CDERR_LOCKRESFAILURE

	CDERR_LOADRESFAILURE CDERR_LOADSTRFAILURE CDERR_MEMALLOCFAILURE CDERR_MEMLOCKFAILURE CDERR_NOHINSTANCE CDERR_NOHOOK CDERR_NOTEMPLATE CDERR_STRUCTSIZE
Comments	The dialog box does not support color palettes. The color choices offered by the dialog box are limited to the system colors and dithered versions of those colors.
	If the hook function (to which the lpfnHook member of the CHOOSECOLOR structure points) processes the WM_CTLCOLOR message, this function must return a handle for the brush that should be used to paint the control background.
Example	The following example initializes a CHOOSECOLOR structure and then creates a color-selection dialog box:
	/* Color variables */
	CHOOSECOLOR cc; COLORREF clr; COLORREF aclrCust[16]; int i;
	/* Set the custom-color controls to white. */
	for (i = 0; i < 16; i++) aclrCust[i] = RGB(255, 255, 255);
	/* Initialize clr to black. */
	clr = RGB(0, 0, 0);
	/* Set all structure fields to zero. */
	<pre>memset(&cc, 0, sizeof(CH00SEC0L0R));</pre>
	/* Initialize the necessary CHOOSECOLOR members. */
	<pre>cc.lStructSize = sizeof(CHOOSECOLOR); cc.hwndOwner = hwnd; cc.rgbResult = clr; cc.lpCustColors = aclrCust; cc.Flags = CC_PREVENTFULLOPEN;</pre>

3.1

```
if (ChooseColor(&cc))
.
. /* Use cc.rgbResult to select the user-requested color. */
.
```

ChooseFont

#include <commdlg.h>

BOOL ChooseFont(*lpcf*) **CHOOSEFONT FAR****lpcf*; /* address of structure with initialization data

*/

The **ChooseFont** function creates a system-defined dialog box from which the user can select a font, a font style (such as bold or italic), a point size, an effect (such as strikeout or underline), and a color.

Parameters

lpcf

Points to a **CHOOSEFONT** structure that initially contains information necessary to initialize the dialog box. When the **ChooseFont** function returns, this structure contains information about the user's font selection. The **CHOOSEFONT** structure has the following form:

#include <commdlg.h>

typedef struct tagCH DWORD	HOOSEFONT { /* cf */ lStructSize:
HWND	hwndOwner:
HDC	hDC;
LOGFONT FAR*	lpLogFont;
int	iPointSize;
DWORD	Flags;
COLORREF	rgbColors;
LPARAM	lCustData;
UINT (CALLBACK*	<pre>lpfnHook)(HWND, UINT, WPARAM, LPARAM);</pre>
LPCSTR	<pre>lpTemplateName;</pre>
HINSTANCE	hInstance;
LPSTR	lpszStyle;
UINT	nFontType;
int	nSizeMin;
int	nSizeMax;

} CHOOSEFONT;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero. Frrors Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following: CDERR FINDRESFAILURE CDERR INITIALIZATION CDERR LOCKRESFAILURE CDERR LOADRESFAILURE CDERR LOADSTRFAILURE CDERR_MEMALLOCFAILURE CDERR MEMLOCKFAILURE CDERR NOHINSTANCE CDERR NOHOOK CDERR NOTEMPLATE CDERR STRUCTSIZE CFERR MAXLESSTHANMIN CFERR NOFONTS Example The following example initializes a **CHOOSEFONT** structure and then displays a font dialog box: LOGFONT 1f; CHOOSEFONT cf: /* Set all structure fields to zero. */ memset(&cf, 0, sizeof(CHOOSEFONT)); cf.lStructSize = sizeof(CHOOSEFONT): cf.hwndOwner = hwnd; cf.lpLogFont = &lf; cf.Flags = CF_SCREENFONTS | CF_EFFECTS; cf.rgbColors = RGB(0, 255, 255); /* light blue */ cf.nFontType = SCREEN FONTTYPE; ChooseFont(&cf):

Chord

BOOL Chord(*hdc*, *nLeftRect*, *nTopRect*, *nRightRect*, *nBottomRect*, *nXStartLine*, *nYStartLine*, *nXEndLine*, *nYEndLine*)

nationaline, ni Lindline)		
HDC hdc;	/* handle of device context	*/
int nLeftRect;	/* x-coordinate upper-left corner bounding rectangle	*/
int nTopRect;	/* y-coordinate upper-left corner bounding rectangle	*/
int nRightRect;	/* x-coordinate lower-right corner bounding rectangle	*/
int nBottomRect;	/* y-coordinate lower-right corner bounding rectangle	*/
<pre>int nXStartLine;</pre>	/* x-coordinate line-segment starting point	*/
int nYStartLine;	/* y-coordinate line-segment starting point	*/
int nXEndLine;	/* x-coordinate line-segment ending point	*/
int nYEndLine;	/* y-coordinate line-segment ending point	*/

The **Chord** function draws a chord (a closed figure bounded by the intersection of an ellipse and a line segment).

Parameters

Identifies the device context.

nLeftRect

hdc

Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.

nTopRect

Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.

nRightRect

Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.

nBottomRect

Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.

nXStartLine

Specifies the logical x-coordinate of the starting point of the line segment.

nYStartLine

Specifies the logical y-coordinate of the starting point of the line segment.

nXEndLine

Specifies the logical x-coordinate of the ending point of the line segment.

nYEndLine

Specifies the logical y-coordinate of the ending point of the line segment.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments	The (<i>nLeftRect</i> , <i>nTopRect</i>) and (<i>nRightRect</i> , <i>nBottomRect</i>) parameter combina- tions specify the upper-left and lower-right corners, respectively, of a rectangle bounding the ellipse that is part of the chord. The (<i>nXStartLine</i> , <i>nYStartLine</i>) and (<i>nXEndLine</i> , <i>nYEndLine</i>) parameter combinations specify the endpoints of a line that intersects the ellipse. The chord is drawn by using the selected pen and is filled by using the selected brush.
	The figure the Chord function draws extends up to but does not include the right and bottom coordinates. This means that the height of the figure is determined as follows:
	nBottomRect – nTopRect
	The width of the figure is determined similarly:
	nRightRect – nLeftRect
Example	The following example uses a RECT structure to store the points defining the bounding rectangle and uses POINT structures to store the coordinates that specify the beginning and end of the chord:
	HDC hdc;
	RECT rc = { 10, 10, 180, 140 }; POINT ptStart = { 12, 12 }; POINT ptEnd = { 128, 135 };
	Chord(hdc, rc.left, rc.top, rc.right, rc.bottom, ptStart.x, ptStart.y, ptEnd.x, ptEnd.y);
See Also	Arc

ClassFirst

#include <toolhelp.h>

BOOL ClassFirst(*lpce*) **CLASSENTRY FAR*** *lpce*;

/* address of structure for class info */

The **ClassFirst** function fills the specified structure with general information about the first class in the Windows class list.

3.1

Parameters	<i>lpce</i> Points to a CLASSENTRY structure that will receive the class information. The CLASSENTRY structure has the following form:
	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagCLASSENTRY { /* ce */ DWORD dwSize; HMODULE hInst; char szClassName[MAX_CLASSNAME + 1]; WORD wNext; } CLASSENTRY;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The ClassFirst function can be used to begin a walk through the Windows class list. To examine subsequent items in the class list, an application can use the ClassNext function.
	Before calling ClassFirst , an application must initialize the CLASSENTRY struc- ture and specify its size, in bytes, in the dwSize member. An application can ex- amine subsequent entries in the Windows class list by using the ClassNext function.
	For more specific information about an individual class, use the GetClassInfo function, specifying the name of the class and instance handle from the CLASSENTRY structure.
See Also	ClassNext, GetClassInfo

ClassNext

3.1

#include <toolhelp.h>

BOOL ClassNext(*lpce*) **CLASSENTRY FAR*** *lpce*; /* address of structure for class info

*/

The **ClassNext** function fills the specified structure with general information about the next class in the Windows class list.

Parameters	<i>lpce</i> Points to a CLASSENTRY structure that will receive the class information. The CLASSENTRY structure has the following form:
	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagCLASSENTRY { /* ce */ DWORD dwSize; HMODULE hInst; char szClassName[MAX_CLASSNAME + 1]; WORD wNext; } CLASSENTRY; For a full description of this structure, see the Microsoft Windows Program-</pre>
	mer's Reference, Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The ClassNext function can be used to continue a walk through the Windows class list started by the ClassFirst function.
	For more specific information about an individual class, use the GetClassInfo function with the name of the class and instance handle from the CLASSENTRY structure.
See Also	ClassFirst

ClearCommBreak

int ClearCommBreak(idComDev)
int idComDev; /* device to be restored */

The **ClearCommBreak** function restores character transmission and places the communications device in a nonbreak state.

Parameters

idComDev

Identifies the communications device to be restored. The **OpenComm** function returns this value.

Return Value	The return value is zero if the function is successful, or -1 if the <i>idComDev</i> parameter does not identify a valid device.
Comments	This function clears the communications-device break state set by the SetComm-Break function.
See Also	OpenComm, SetCommBreak

ClientToScreen

<pre>void ClientToScreen HWND hwnd; POINT FAR* lppt;</pre>	/* window handle for source coordinates */
	The ClientToScreen function converts the client coordinates of a given point on the screen to screen coordinates.
Parameters	 hwnd Identifies the window whose client area is used for the conversion. <i>lppt</i> Points to a POINT structure that contains the client coordinates to be converted. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.</pre>
Return Value	This function does not return a value.
Comments	The ClientToScreen function replaces the coordinates in the POINT structure with the screen coordinates. The screen coordinates are relative to the upper-left corner of the screen.

Example	The following example uses the LOWORD and HIWORD macros and the ClientToScreen function to convert the mouse position to screen coordinates:
	POINT pt;
	pt.x = LOWORD(1Param); pt.y = HIWORD(1Param); ClientToScreen(hwnd, &pt);
See Also	MapWindowPoints, ScreenToClient

ClipCursor	2.x
void ClipCursor(<i>lpre</i> const RECT FAR* <i>l</i>	
	The ClipCursor function confines the cursor to a rectangle on the screen. If a sub- sequent cursor position (set by the SetCursorPos function or by the mouse) lies outside the rectangle, Windows automatically adjusts the position to keep the cur- sor inside.
Parameters	<i>lprc</i> Points to a RECT structure that contains the screen coordinates of the upper- left and lower-right corners of the confining rectangle. If this parameter is NULL, the cursor is free to move anywhere on the screen. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
Comments	The cursor is a shared resource. An application that has confined the cursor to a given rectangle must free it before relinquishing control to another application.
See Also	GetClipCursor, GetCursorPos, SetCursorPos

CloseClipboard

BOOL CloseClipboard(void)

	The CloseClipboard function closes the clipboard.
Parameters	This function has no parameters.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The CloseClipboard function should be called when a window has finished ex- amining or changing the clipboard. This lets other applications access the clip- board.
See Also	GetOpenClipboardWindow, OpenClipboard

CloseComm

<pre>int CloseComm(idComDev) int idComDev; /* device to close */</pre>		
	The CloseComm function closes the specified communications device and frees any memory allocated for the device's transmission and receiving queues. All char- acters in the output queue are sent before the communications device is closed.	
Parameters	<i>idComDev</i> Specifies the device to be closed. The OpenComm function returns this value.	
Return Value	The return value is zero if the function is successful. Otherwise, it is less than zero.	
See Also	OpenComm	

2.x

CloseDriver

HDRVR hdrvr;	iver(hdrvr, lParam1, lParam2) /* handle of installable driver */ /* driver-specific data */ /* driver-specific data */	
	The CloseDriver function closes an installable driver.	
Parameters	<i>hdrvr</i> Identifies the installable driver to be closed. This parameter must have been ob- tained by a previous call to the OpenDriver function.	
	<i>lParam1</i> Specifies driver-specific data.	
	<i>lParam2</i> Specifies driver-specific data.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	When an application calls CloseDriver and the driver identified by <i>hdrvr</i> is the last instance of the driver, Windows calls the DriverProc function three times. On the first call, Windows sets the third DriverProc parameter, <i>wMessage</i> , to DRV_CLOSE; on the second call, Windows sets <i>wMessage</i> to DRV_DISABLE; and on the third call, Windows sets <i>wMessage</i> to DRV_FREE. When the driver identified by <i>hdrvr</i> is not the last instance of the driver, only DRV_CLOSE is sent. The values specified in the <i>lParam1</i> and <i>lParam2</i> parameters are passed to the <i>lParam1</i> and <i>lParam2</i> parameters of the DriverProc function.	
See Also	DriverProc, OpenDriver	

CloseMetaFile

HMETAFILE CloseMetaFile(hdc)HDC hdc;/* handle of device context*/

The **CloseMetaFile** function closes a metafile device context and creates a handle of a metafile. An application can use this handle to play the metafile.

Parameters

hdc

Identifies the metafile device context to be closed.

3.1

2.x

Return Value	The return value is the handle of the metafile if the function is successful. Other wise, it is NULL.
Comments	If a metafile handle created by using the CloseMetaFile function is no longer needed, you should remove it (using the DeleteMetaFile function).
Example	The following example creates a device-context handle of a memory metafile, draws a line in the device context, retrieves a handle of the metafile, plays the metafile, and finally deletes the metafile.
	HDC hdcMeta; HMETAFILE hmf;
	<pre>hdcMeta = CreateMetaFile(NULL); MoveTo(hdcMeta, 10, 10); LineTo(hdcMeta, 100, 100); hmf = CloseMetaFile(hdcMeta); PlayMetaFile(hdc, hmf); DeleteMetaFile(hmf);</pre>
See Also	CreateMetaFile, DeleteMetaFile, PlayMetaFile

CloseSound

void CloseSound(void)

This function is obsolete. Use the multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

CloseWindow		2. x
void CloseWind HWND hwnd;	ow (<i>hwnd</i>) /* handle of window to minimize */	
	The CloseWindow function minimizes (but does To destroy a window, an application must use the	
Parameters	<i>hwnd</i> Identifies the window to be minimized.	

Return Value	This function does not return a value.
Comments	This function has no effect if the <i>hwnd</i> parameter identifies a pop-up or child win- dow.
See Also	DestroyWindow, IsIconic, OpenIcon

CombineRgn

int CombineRgn(hrgnDest, hrgnSrc1, hrgnSrc2, fCombineMode)

HRGN hrgnDest;	/* handle of region to receive combined regions	*/
HRGN hrgnSrc1;	/* handle of first source region	*/
HRGN hrgnSrc2;	/* handle of second source region	*/
<pre>int fCombineMode;</pre>	/* mode for combining regions	*/

The **CombineRgn** function creates a new region by combining two existing regions.

Parameters

hrgnDest

Identifies an existing region that will be replaced by the new region.

hrgnSrc1

Identifies an existing region.

hrgnSrc2

Identifies an existing region.

fCombineMode

Specifies the operation to use when combining the two source regions. This parameter can be any one of the following values:

Value	Meaning
RGN_AND	Uses overlapping areas of both regions (intersection).
RGN_COPY	Creates a copy of region 1 (identified by the <i>hrgnSrc1</i> parameter).
RGN_DIFF	Creates a region consisting of the areas of region 1 (identified by <i>hrgnSrc1</i>) that are not part of region 2 (identified by the <i>hrgnSrc2</i> parameter).
RGN_OR	Combines all of both regions (union).
RGN_XOR	Combines both regions but removes overlapping areas.

Return Value The return value specifies that the resulting region has overlapping borders (COMPLEXREGION), is empty (NULLREGION), or has no overlapping borders

3.1

	(SIMPLEREGION), if the function is successful. Otherwise, the return value is ERROR.
Comments	The size of a region is limited to 32,000 by 32,000 logical units or 64K of memory, whichever is smaller.
	The CombineRgn function replaces the region identified by the <i>hrgnDest</i> parameter with the combined region. To use CombineRgn most efficiently, <i>hrgnDest</i> should be a trivial region, as shown in the following example.
Example	The following example creates two source regions and an empty destination re- gion, uses the CombineRgn function to create a complex region, selects the re- gion into a device context, and then uses the PaintRgn function to display the region:
	HDC hdc; HRGN hrgnDest, hrgnSrc1, hrgnSrc2;
	hrgnDest = CreateRectRgn(0, 0, 0, 0); hrgnSrc1 = CreateRectRgn(10, 10, 110, 110); hrgnSrc2 = CreateRectRgn(90, 90, 200, 150);
	CombineRgn(hrgnDest, hrgnSrc1, hrgnSrc2, RGN_OR); SelectObject(hdc, hrgnDest); PaintRgn(hdc, hrgnDest);
0	

See Also CreateRectRgn, PaintRgn

CommDlgExtendedError

#include <commdlg.h>

DWORD CommDlgExtendedError(void)

The **CommDlgExtendedError** function identifies the cause of the most recent error to have occurred during the execution of one of the following common dialog box procedures:

- ChooseColor
- ChooseFont
- FindText
- GetFileTitle
- GetOpenFileName

	GetSaveFileName
--	-----------------

- PrintDlg
- ReplaceText

Parameters This function has no parameters.

Return Value The return value is zero if the prior call to a common dialog box procedure was successful. The return value is CDERR_DIALOGFAILURE if the dialog box could not be created. Otherwise, the return value is a nonzero integer that identifies an error condition.

Comments Following are the possible **CommDlgExtendedError** return values and the meaning of each:

Value	Meaning
CDERR_FINDRESFAILURE	Specifies that the common dialog box proce- dure failed to find a specified resource.
CDERR_INITIALIZATION	Specifies that the common dialog box proce- dure failed during initialization. This error often occurs when insufficient memory is available.
CDERR_LOADRESFAILURE	Specifies that the common dialog box proce- dure failed to load a specified resource.
CDERR_LOCKRESFAILURE	Specifies that the common dialog box proce- dure failed to lock a specified resource.
CDERR_LOADSTRFAILURE	Specifies that the common dialog box proce- dure failed to load a specified string.
CDERR_MEMALLOCFAILURE	Specifies that the common dialog box proce- dure was unable to allocate memory for internal structures.
CDERR_MEMLOCKFAILURE	Specifies that the common dialog box proce- dure was unable to lock the memory associated with a handle.
CDERR_NOHINSTANCE	Specifies that the ENABLETEMPLATE flag was set in the Flags member of a structure for the corresponding common dialog box but that the application failed to provide a correspond- ing instance handle.
CDERR_NOHOOK	Specifies that the ENABLEHOOK flag was set in the Flags member of a structure for the corre- sponding common dialog box but that the appli- cation failed to provide a pointer to a corresponding hook function.

Value	Meaning
CDERR_NOTEMPLATE	Specifies that the ENABLETEMPLATE flag was set in the Flags member of a structure for the corresponding common dialog box but that the application failed to provide a correspond- ing template.
CDERR_REGISTERMSGFAIL	Specifies that the RegisterWindowMessage function returned an error value when it was called by the common dialog box procedure.
CDERR_STRUCTSIZE	Specifies as invalid the IStructSize member of a structure for the corresponding common dialog box.
CFERR_NOFONTS	Specifies that no fonts exist.
CFERR_MAXLESSTHANMIN	Specifies that the size given in the nSizeMax member of the CHOOSEFONT structure is less than the size given in the nSizeMin mem- ber.
FNERR_BUFFERTOOSMALL	Specifies that the filename buffer is too small. (This buffer is pointed to by the lpstrFile mem- ber of the structure for a common dialog box.)
FNERR_INVALIDFILENAME	Specifies that a filename is invalid.
FNERR_SUBCLASSFAILURE	Specifies that an attempt to subclass a list box failed due to insufficient memory.
FRERR_BUFFERLENGTHZERO	Specifies that a member in a structure for the corresponding common dialog box points to an invalid buffer.
PDERR_CREATEICFAILURE	Specifies that the PrintDlg function failed when it attempted to create an information context.
PDERR_DEFAULTDIFFERENT	Specifies that an application has called the PrintDlg function with the DN_DEFAULTPRN flag set in the wDefault member of the DEVNAMES structure, but the printer described by the other structure mem- bers does not match the current default printer. (This happens when an application stores the DEVNAMES structure and the user changes the default printer by using Control Panel.)
	To use the printer described by the DEV - NAMES structure, the application should clear the DN_DEFAULTPRN flag and call the PrintDlg function again. To use the default printer, the application should replace the DEV - NAMES structure (and the DEVMODE struc- ture, if one exists) with NULL; this selects the default printer automatically.

Value	Meaning
PDERR_DNDMMISMATCH	Specifies that the data in the DEVMODE and DEVNAMES structures describes two different printers.
PDERR_GETDEVMODEFAIL	Specifies that the printer driver failed to initial ize a DEVMODE structure. (This error value applies only to printer drivers written for Windows versions 3.0 and later.)
PDERR_INITFAILURE	Specifies that the PrintDlg function failed during initialization.
PDERR_LOADDRVFAILURE	Specifies that the PrintDlg function failed to load the device driver for the specified printer.
PDERR_NODEFAULTPRN	Specifies that a default printer does not exist.
PDERR_NODEVICES	Specifies that no printer drivers were found.
PDERR_PARSEFAILURE	Specifies that the PrintDlg function failed to parse the strings in the [devices] section of the WIN.INI file.
PDERR_PRINTERNOTFOUND	Specifies that the [devices] section of the WIN.INI file did not contain an entry for the r quested printer.
PDERR_RETDEFFAILURE	Specifies that the PD_RETURNDEFAULT flag was set in the Flags member of the PRINTDLG structure but that either the hDe Mode or hDevNames member was nonzero.
PDERR_SETUPFAILURE	Specifies that the PrintDlg function failed to load the required resources.

CopyCursor

3.1

HCURSOR CopyCursor(hinst, hcur) HINSTANCE hinst; /* handle of a HCURSOR hcur; /* handle of a

/* handle of application instance */ /* handle of cursor to copy */

The **CopyCursor** function copies a cursor.

3.1

Parameters	<i>hinst</i> Identifies the instance of the module that will copy the cursor.
	<i>hcur</i> Identifies the cursor to be copied.
Return Value	The return value is the handle of the duplicate cursor if the function is successful. Otherwise, it is NULL.
Comments	When it no longer requires a cursor, an application must destroy the cursor, using the DestroyCursor function.
	The CopyCursor function allows an application or dynamic-link library to accept a cursor from another module. Because all resources are owned by the module in which they originate, a resource cannot be shared after the module is freed. Copy- Cursor allows an application to create a copy that the application then owns.
See Also	CopyIcon, DestroyCursor, GetCursor, SetCursor, ShowCursor

Copylcon

HICON CopyIcon(*hinst*, *hicon*) HINSTANCE hinst; /* handle of application instance */ /* handle of icon to copy HICON hicon; */ The CopyIcon function copies an icon. **Parameters** hinst Identifies the instance of the module that will copy the icon. hicon Identifies the icon to be copied. **Return Value** The return value is the handle of the duplicate icon if the function is successful. Otherwise, it is NULL. Comments When it no longer requires an icon, an application should destroy the icon, using the **DestroyIcon** function.

The **CopyIcon** function allows an application or dynamic-link library to accept an icon from another module. Because all resources are owned by the module in which they originate, a resource cannot be shared after the module is freed. **Copy-Icon** allows an application to create a copy that the application then owns.

CopyLZFile

#include <lzexpand.h>

LONG CopyLZFile HFILE hfSource; HFILE hfDest;	e(<i>hfSource</i> , <i>hfDest</i>) /* handle of source file /* handle of destination file	*/ */
	file is compressed, this function c	a source file to a destination file. If the source reates a decompressed destination file. If the s function duplicates the original file.
Parameters	<i>hfSource</i> Identifies the source file.	
	hfDest Identifies the destination file.	
Return Value	The return value specifies the size, in bytes, of the destination file if the function is successful. Otherwise, it is an error value less than zero; it may be one of the following:	
	Value	Meaning
	LZERROR_BADINHANDLE	The handle identifying the source file was not valid.
	LZERROR_BADOUTHANDLE	The handle identifying the destination file was not valid.
	LZERROR_READ	The source file format was not valid.
	LZERROR_WRITE	There is insufficient space for the output file.
	LZERROR_GLOBALLOC	There is insufficient memory for the required buffers.
	LZERROR_UNKNOWNALG	The file was compressed with an unrecognized compression algorithm.

Comments	This function is identical to the LZCopy function.
	The CopyLZFile function is designed for copying or decompressing multiple files, or both. To allocate required buffers, an application should call the LZStart function prior to calling CopyLZFile . To free these buffers, an application should call the LZDone function after copying the files.
	If the function is successful, the file identified by <i>hfDest</i> is decompressed.
	If the source or destination file is opened by using a C run-time function (rather than by using the _lopen or OpenFile function), it must be opened in binary mode.
Example	The following example uses the CopyLZFile function to create copies of four text files:
	#define STRICT
	#include <windows.h> #include <lzexpand.h></lzexpand.h></windows.h>
	#define NUM_FILES 4
	<pre>char *szSrc[NUM_FILES] = {"readme.txt", "data.txt", "update.txt", "list.txt"}; char *szDest[NUM_FILES] = {"readme.bak", "data.bak", "update.bak", "list.bak"}; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest; HFILE hfSrcFile, hfDstFile; int i;</pre>
	/* Allocate internal buffers for the CopyLZFile function. */
	LZStart();
	/* Open, copy, and then close the files. */
	<pre>for (i = 0; i < NUM_FILES; i++) { hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ); hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE); CopyLZFile(hfSrcFile, hfDstFile); LZClose(hfSrcFile); }</pre>
	LZDone(); /* free the internal buffers */

CopyMetaFile

HMETAFILE Copy HMETAFILE hmfSr LPCSTR lpszFile;	MetaFile(<i>hmfSrc</i> , <i>lpszFile</i>) c; /* handle of metafile to copy /* address of name of copied metafile	*/ */
	The CopyMetaFile function copies a source me turns a handle of the new metafile.	etafile to a specified file and re-
Parameters	<i>hmfSrc</i> Identifies the source metafile to be copied.	
	<i>lpszFile</i> Points to a null-terminated string that specific file. If this value is NULL, the source metafil	
Return Value	The return value is the handle of the new metafic Otherwise, it is NULL.	le if the function is successful.
Example	The following example copies a metafile to a sp file, retrieves a handle of the copied metafile, ch metafile is played 200 logical units to the right, a new location:	anges the position at which the
	HANDLE hmf, hmfSource, hmfOld; LPSTR lpszFile1 = "MFTest";	
	<pre>hmf = CopyMetaFile(hmfSource, lpszFile1); PlayMetaFile(hdc, hmf); DeleteMetaFile(hmf);</pre>	
	hmfOld = GetMetaFile(lpszFile1); SetWindowOrg(hdc, -200, 0); PlayMetaFile(hdc, hmfOld);	
	DeleteMetaFile(hmfSource); DeleteMetaFile(hmfOld);	
See Also	GetMetaFile, PlayMetaFile, SetWindowOrg	

oopyricor	2.8
void CopyRect(lph RECT FAR* lprcl const RECT FAR*	Dst;/* address of struct. for destination rect.*/* lprcSrc;/* address of struct. with source rect.*/
	The CopyRect function copies the dimensions of one rectangle to another.
Parameters	<i>lprcDst</i> Points to the RECT structure that will receive the dimensions of the source rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lprcSrc</i> Points to the RECT structure whose dimensions are to be copied.
Return Value	This function does not return a value.
See Also	SetRect

CountClipboardFormats

int CountClipboardFormats(void)

ConvRect

The CountClipboardFormats function retrieves the number of different data for-
mats currently in the clipboard.ParametersThis function has no parameters.Return ValueThe return value specifies the number of different data formats in the clipboard, if
the function is successful.See AlsoEnumClipboardFormats

2.x

CountVoiceNotes

int CountVoiceNotes(nvoice)

int *nvoice*; /* sound queue to be counted

This function is obsolete. Use the multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

*/

CPIApplet

LONG CALLBACH	X* CPlApplet(hwndCPl, iMessage, lParam1,	lParam2)
HWND hwndCPl;	/* handle of Control Panel window	*/
UINT iMessage;	/* message	*/
LPARAM lParam1;	/* first message parameter	*/
LPARAM lParam2;		*/
	The CPIApplet function serves as the entry plink library (DLL). This function is supplied	
Parameters	<i>hwndCPl</i> Identifies the main Control Panel window	
	<i>iMessage</i> Specifies the message being sent to the D	LL.
	<i>lParam1</i> Specifies 32 bits of additional message-de	ependent information.
	<i>lParam2</i> Specifies 32 bits of additional message-de	ependent information.
Return Value	The return value depends on the message. For tions of the individual Control Panel messag <i>mer's Reference</i> , <i>Volume 3</i> .	
Comments	Use the <i>hwndCPl</i> parameter for dialog boxes handle of a parent window.	s or other windows that require a

CreateBitmap

HBITMAP Create	Bitmap(nWidth, nHeight, cbPlanes, cbBits, lpvBits)	
int nWidth;	•	/* bitmap width	*/
int nHeight;		/* bitmap height	*/
UINT <i>cbPlanes</i> ;		/* number of color planes	*/
UINT cbBits;		/* number of bits per pixel	*/
const void FAR* lp	ovBits;	/* address of array with bitmap bits	*/
		reateBitmap function creates a device-depe cified width, height, and bit pattern.	ndent memory bitmap that has
Parameters	<i>nWidtl</i> Spe	n cifies the width, in pixels, of the bitmap.	
	nHeig	ht	
	0	cifies the height, in pixels, of the bitmap.	
	<i>cbPlanes</i> Specifies the number of color planes in the bitmap. The number of bits per plane is the product of the plane's width, height, and bits per pixel (<i>nWidth</i> × <i>nHeight</i> × <i>cbBits</i>).		
	<i>cbBits</i> Spe	cifies the number of color bits per display p	ixel.
	this tior BI T	s nts to an array of short integers that contains parameter is NULL, the new bitmap is left is about these bit values, see the description of MAP structure in the <i>Microsoft Windows Pume 3</i> .	uninitialized. For more informa- f the bmBits member of the
Return Value		turn value is the handle of the bitmap if the t t is NULL.	function is successful. Other-
Comments		tmap created by the CreateBitmap function of for a memory device context by using the S	
	For a color bitmap, either the <i>cbPlanes</i> or <i>cbBits</i> parameter should be set to 1. If both of these parameters are set to 1, CreateBitmap creates a monochrome bitmap.		
	tion ca	igh a bitmap cannot be copied directly to a d in copy it from a memory device context (in compatible device context, including a scree	which it is the current bitmap)

When it has finished using a bitmap created by **CreateBitmap**, an application should select the bitmap out of the device context and then remove the bitmap by using the **DeleteObject** function.

Example

The following example uses the **CreateBitmap** function to create a bitmap with a zigzag pattern and then uses the **PatBlt** function to fill the client area with that pattern:

```
HDC hdc;
HBITMAP hbmp:
HBRUSH hbr, hbrPrevious;
RECT rc:
int aZigzag[] = \{ 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF \};
hbmp = CreateBitmap(8, 8, 1, 1, aZigzag);
hbr = CreatePatternBrush(hbmp);
hdc = GetDC(hwnd);
UnrealizeObject(hbr):
hbrPrevious = SelectObject(hdc, hbr);
GetClientRect(hwnd, &rc);
PatBlt(hdc, rc.left, rc.top,
    rc.right - rc.left, rc.bottom - rc.top, PATCOPY);
SelectObject(hdc, hbrPrevious);
ReleaseDC(hwnd, hdc);
DeleteObject(hbr);
DeleteObject(hbmp);
```

See Also

BitBlt, CreateBitmapIndirect, CreateCompatibleBitmap, CreateDIBitmap, CreateDiscardableBitmap, DeleteObject, SelectObject

CreateBitmapIndirect

2.x

*/

HBITMAP CreateBitmapIndirect(*lpbm*) BITMAP FAR* *lpbm*; /* address of structure with bitmap information

The **CreateBitmapIndirect** function creates a bitmap that has the width, height, and bit pattern specified in a **BITMAP** structure.

Parameters	<i>lpbm</i> Points to a BITMAP structure that contains information about the bitmap. The BITMAP structure has the following form:
	<pre>typedef struct tagBITMAP { /* bm */ int bmType; int bmWidth; int bmHeight; int bmWidthBytes; BYTE bmPlanes; BYTE bmBitsPixel; void FAR* bmBits; } BITMAP;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.
Comments	Large bitmaps cannot be displayed on a display device by copying them directly to the device context for that device. Instead, applications should create a memory device context that is compatible with the display device, select the bitmap as the current bitmap for the memory device context, and then use a function such as BitBlt or StretchBlt to copy it from the memory device context to the display device context. (The PatBlt function can copy the bitmap for the current brush directly to the display device context.)
	When an application has finished using the bitmap created by the Create-BitmapIndirect function, it should select the bitmap out of the device context and then delete the bitmap by using the DeleteObject function.
	If the BITMAP structure pointed to by the <i>lpbm</i> parameter has been filled in by using the GetObject function, the bits of the bitmap are not specified, and the bitmap is uninitialized. To initialize the bitmap, an application can use a function such as BitBlt or SetDIBits to copy the bits from the bitmap identified by the first parameter of GetObject to the bitmap created by CreateBitmapIndirect .
Example	The following example assigns values to the members of a BITMAP structure and then calls the CreateBitmapIndirect function to create a bitmap handle:
	BITMAP bm; HBITMAP hbm;
	int aZigzag[] = { 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF };

See Also	BitBlt, CreateBitmap, CreateCompatibleBitmap, CreateDIBitmap, CreateDiscardableBitmap, DeleteObject, GetObject
	<pre>hbm = CreateBitmapIndirect(&bm);</pre>
	bm.bmBits = aZigzag;
	<pre>bm.bmBitsPixel = 1;</pre>
	<pre>bm.bmPlanes = 1;</pre>
	<pre>bm.bmWidthBytes = 2;</pre>
	bm.bmHeight = 8;
	<pre>bm.bmWidth = 8;</pre>
	<pre>bm.bmType = 0;</pre>

CreateBrushIndirect

HBRUSH CreateBrushIndirect(lplb)LOGBRUSH FAR* lplb;/* address of structure with brush attributes*/		
	The CreateBrushIndirect function creates a brush that has the style, color, and pattern specified in a LOGBRUSH structure. The brush can subsequently be selected as the current brush for any device.	
Parameters	<i>lplb</i> Points to a LOGBRUSH structure that contains information about the brush. The LOGBRUSH structure has the following form:	
	<pre>typedef struct tagLOGBRUSH { /* lb */ UINT lbStyle; COLORREF lbColor; int lbHatch; } LOGBRUSH;</pre>	
	For a full description of this structure, see the <i>Microsoft Windows Program-</i> mer's Reference, Volume 3.	
Return Value	The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.	
Comments	A brush created by using a monochrome (one plane, one bit per pixel) bitmap is drawn by using the current text and background colors. Pixels represented by a bit set to 0 are drawn with the current text color, and pixels represented by a bit set to 1 are drawn with the current background color.	

2.x

	When it has finished using a brush created by CreateBrushIndirect , an applica- tion should select the brush out of the device context in which it was used and then remove the brush by using the DeleteObject function.
Example	The following example creates a hatched brush with red diagonal hatch marks and uses that brush to fill a rectangle:
	LOGBRUSH 1b; HBRUSH hbr, hbr01d;
	lb.lbStyle = BS_HATCHED; lb.lbColor = RGB(255, 0, 0); lb.lbHatch = HS_BDIAGONAL;
	hbr = CreateBrushIndirect(&lb); hbrOld = SelectObject(hdc, hbr); Rectangle(hdc, 0, 0, 100, 100);
See Also	CreateDIBPatternBrush, CreatePatternBrush, CreateSolidBrush, Delete- Object, GetStockObject, SelectObject

CreateCaret

void CreateCaret(h	wnd, hbmp, nWidth, nHeight)	
· · · · · · · · · · · · · · · · · · ·	/* handle of owner window	*/
HBITMAP hbmp;	/* handle of bitmap for caret shape	*/
int nWidth;	/* caret width	*/
int nHeight;	/* caret height	*/
	The CreateCaret function creates a new ownership of the caret to the given wind or bitmap.	v shape for the system caret and assigns low. The caret shape can be a line, block,
Parameters	<i>hwnd</i> Identifies the window that owns the n	iew caret.
<i>hbmp</i> Identifies the bitmap that defines the caret shape. If this parame caret is solid; if the parameter is 1, the caret is gray.		. .
	<i>nWidth</i> Specifies the width of the caret in log width is set to the system-defined wir	ical units. If this parameter is NULL, the ndow-border width.

	<i>nHeight</i> Specifies the height of the caret, in logical units. If this parameter is NULL, the height is set to the system-defined window-border height.
Return Value	This function does not return a value.
Comments	If the <i>hbmp</i> parameter contains a bitmap handle, the <i>nWidth</i> and <i>nHeight</i> parameters are ignored; the bitmap defines its own width and height. (The bitmap handle must have been created by using the CreateBitmap , CreateDIBitmap , or Load-Bitmap function.) If <i>hbmp</i> is NULL or 1, <i>nWidth</i> and <i>nHeight</i> give the caret's width and height, in logical units; the exact width and height (in pixels) depend on the window's mapping mode.
	The CreateCaret function automatically destroys the previous caret shape, if any, regardless of which window owns the caret. Once created, the caret is initially hidden. To show the caret, use the ShowCaret function.
	The system caret is a shared resource. A window should create a caret only when it has the input focus or is active. It should destroy the caret before losing the input focus or becoming inactive.
	The system's window-border width or height can be retrieved by using the GetSystemMetrics function, specifying the SM_CXBORDER and SM_CYBORDER indices. Using the window-border width or height guarantees that the caret will be visible on a high-resolution screen.
Example	The following example creates a caret, sets its initial position, and then displays the caret:
	<pre>case WM_SETFOCUS: CreateCaret(hwndParent, NULL, CARET_WIDTH, CARET_HEIGHT); SetCaretPos(CARET_XPOS, CARET_YPOS); ShowCaret(hwndParent); break;</pre>
See Also	CreateBitmap, CreateDIBitmap, DestroyCaret, GetSystemMetrics, LoadBitmap, ShowCaret

CreateCompatibleBitmap

HBITMAP Cre HDC hdc; int nWidth; int nHeight;	eateCompatibleBitmap(hdc, nWidth, nHeight) /* handle of device context */ /* bitmap width */ /* bitmap height */
	The CreateCompatibleBitmap function creates a bitmap that is compatible with the given device.
Parameters	 hdc Identifies the device context. <i>nWidth</i> Specifies the width, in bits, of the bitmap. <i>nHeight</i> Specifies the height, in bits, of the bitmap.
Return Value	The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL.
Comments	The bitmap created by the CreateCompatibleBitmap function has the same number of color planes or the same bits-per-pixel format as the given device. It can be selected as the current bitmap for any memory device that is compatible with the one identified by <i>hdc</i> .
	If <i>hdc</i> identifies a memory device context, the bitmap returned has the same for- mat as the currently selected bitmap in that device context. A memory device con- text is a memory object that represents a screen surface. It can be used to prepare images in memory before copying them to the screen surface of the compatible device.
	When a memory device context is created, the graphics device interface (GDI) automatically selects a monochrome stock bitmap for it.
	Since a color memory device context can have either color or monochrome bit- maps selected, the format of the bitmap returned by the CreateCompatible- Bitmap function is not always the same; however, the format of a compatible bitmap for a non-memory device context is always in the format of the device.
	When it has finished using a bitmap created by CreateCompatibleBitmap , an application should select the bitmap out of the device context and then remove the bitmap by using the DeleteObject function.

ſ

}

Example

The following example shows a function named DuplicateBitmap that accepts the handle of a bitmap, duplicates the bitmap, and returns a handle of the duplicate. This function uses the **CreateCompatibleDC** function to create source and destination device contexts and then uses the **GetObject** function to retrieve the dimensions of the source bitmap. The **CreateCompatibleBitmap** function uses these dimensions to create a new bitmap. When each bitmap has been selected into a device context, the **BitBlt** function copies the bits from the source bitmap to the new bitmap. (Although an application could use the GetDIBits and SetDIBits functions to duplicate a bitmap, the method illustrated in this example is much faster.)

```
HBITMAP PASCAL DuplicateBitmap(HBITMAP hbmpSrc)
   HBITMAP hbmpOldSrc, hbmpOldDest, hbmpNew;
   HDC
            hdcSrc, hdcDest;
   BITMAP bmp:
   hdcSrc = CreateCompatibleDC(NULL):
   hdcDest = CreateCompatibleDC(hdcSrc);
   GetObject(hbmpSrc, sizeof(BITMAP), &bmp);
   hbmpOldSrc = SelectObject(hdcSrc, hbmpSrc);
   hbmpNew = CreateCompatibleBitmap(hdcSrc, bmp.bmWidth,
       bmp.bmHeight);
   hbmpOldDest = SelectObject(hdcDest, hbmpNew);
   BitBlt(hdcDest, 0, 0, bmp.bmWidth, bmp.bmHeight, hdcSrc, 0, 0,
       SRCCOPY):
   SelectObject(hdcDest, hbmpOldDest);
   SelectObject(hdcSrc, hbmpOldSrc);
   DeleteDC(hdcDest):
   DeleteDC(hdcSrc):
   return hbmpNew;
```

CreateBitmap, CreateBitmapIndirect, CreateDIBitmap, DeleteObject

CreateCompatibleDC

HDC CreateCompatibleDC(*hdc*) HDC hdc; /* handle of device context */ The **CreateCompatibleDC** function creates a memory device context that is compatible with the given device. An application must select a bitmap into a memory device context to represent a screen surface. The device context can then be used to prepare images in memory before copying them to the screen surface of the compatible device. **Parameters** hdc Identifies the device context. If this parameter is NULL, the function creates a memory device context that is compatible with the system screen. **Return Value** The return value is the handle of the new memory device context if the function is successful. Otherwise, it is NULL. Comments The **CreateCompatibleDC** function can be used only to create compatible device contexts for devices that support raster operations. To determine whether a device supports raster operations, an application can call the GetDeviceCaps function with the RC BITBLT index. GDI output functions can be used with a memory device context only if a bitmap has been created and selected into that context. When it has finished using a device context created by **CreateCompatibleDC**, an application should free the device context by calling the **DeleteDC** function. All objects selected into the device context after it was created should be selected out and replaced with the original objects before the device context is removed. Example The following example loads a bitmap named Dog, uses the Create-**CompatibleDC** function to create a memory device context that is compatible with the screen, selects the bitmap into the memory device context, and then uses the **BitBlt** function to move the bitmap from the memory device context to the screen device context: HDC hdc, hdcMemory; HBITMAP hbmpMyBitmap, hbmpOld; BITMAP bm; hbmpMyBitmap = LoadBitmap(hinst. "MyBitmap"): GetObject(hbmpMyBitmap, sizeof(BITMAP), &bm);

See Also	DeleteDC. GetDeviceCaps
	ReleaseDC(hwnd, hdc);
	<pre>DeleteDC(hdcMemory);</pre>
	BitBlt(hdc, 0, 0, bm.bmWidth, bm.bmHeight, hdcMemory, 0, 0, SRCCOPY); SelectObject(hdcMemory, hbmpOld);
	hdc = GetDC(hwnd); hdcMemory = CreateCompatibleDC(hdc); hbmpOld = SelectObject(hdcMemory, hbmpMyBitmap);

CreateCursor

HCURSOR CreateCursor(*hinst*, *xHotSpot*, *yHotSpot*, *nWidth*, *nHeight*, *lpvANDplane*, *lpvXORplane*)

HINSTANCE hinst;	/* handle of application instance	*/
int xHotSpot;	/* horizontal position of hot spot	*/
int yHotSpot;	/* vertical position of hot spot	*/
int <i>nWidth</i> ;	/* cursor width	*/
int nHeight;	/* cursor height	*/
<pre>const void FAR* lpvANDplane;</pre>	/* address of AND mask array	*/
<pre>const void FAR* lpvXORplane;</pre>	/* address of XOR mask array	*/

The **CreateCursor** function creates a cursor that has the specified width, height, and bit patterns.

3.0

Parameters

hinst

Identifies the instance of the module that will create the cursor.

xHotSpot

Specifies the horizontal position of the cursor hot spot.

yHotSpot

Specifies the vertical position of the cursor hot spot.

nWidth

Specifies the width, in pixels, of the cursor.

nHeight

Specifies the height, in pixels, of the cursor.

lpvANDplane

Points to an array of bytes that contains the bit values for the AND mask of the cursor. These can be the bits of a device-dependent monochrome bitmap.

	<i>lpvXORplane</i> Points to an array of bytes that contains the bit values for the XOR mask of the cursor. These can be the bits of a device-dependent monochrome bitmap.
Return Value	The return value is the handle of the cursor if the function is successful. Otherwise, it is NULL.
Comments	The <i>nWidth</i> and <i>nHeight</i> parameters must specify a width and height supported by the current display driver, since the system cannot create cursors of other sizes. An application can determine the width and height supported by the display driver by calling the GetSystemMetrics function and specifying the SM_CXCURSOR or SM_CYCURSOR value.
	Before terminating, an application must call the DestroyCursor function to free any system resources associated with the cursor.
See Also	CreateIcon, DestroyCursor, GetSystemMetrics, SetCursor

CreateDC

#include <print.h>

HDC CreateDC(lpszDriver, lpsz.	Device, lpszOutput, lpvInitData)	
LPCSTR lpszDriver;	/* address of driver name	*/
LPCSTR lpszDevice;	/* address of device name	*/
LPCSTR lpszOutput;	/* address of filename or port name	*/
const void FAR* lpvInitData;	/* address of initialization data	*/

The **CreateDC** function creates a device context for the given device.

Parameters

lpszDriver

Points to a null-terminated string that specifies the MS-DOS filename (without extension) of the device driver (for example, Epson).

lpszDevice

Points to a null-terminated string that specifies the name of the specific device to be supported (for example, Epson FX-80). This parameter is used if the module supports more than one device.

lpszOutput

Points to a null-terminated string that specifies the MS-DOS filename or device name for the physical output medium (file or output port).

lpvInitData

Points to a **DEVMODE** structure that contains device-specific initialization information for the device driver. The **ExtDeviceMode** function retrieves this structure already filled in for a given device. The *lpvInitData* parameter must be NULL if the device driver is to use the default initialization (if any) specified by the user through Windows Control Panel.

The **DEVMODE** structure has the following form:

#include <print.h>

typedef st	<pre>:ruct tagDEVMODE { /* dm */</pre>
char	<pre>dmDeviceName[CCHDEVICENAME];</pre>
UINT	dmSpecVersion;
UINT	dmDriverVersion;
UINT	dmSize;
UINT	dmDriverExtra;
DWORD	dmFields;
int	dmOrientation;
int	dmPaperSize;
int	dmPaperLength;
int	dmPaperWidth;
int	dmScale;
int	dmCopies;
int	dmDefaultSource;
int	dmPrintQuality;
int	dmColor;
int	dmDuplex;
int	dmYResolution;
int	dmTTOption;

} DEVMODE;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

Return Value The return value is the handle of the device context for the specified device if the function is successful. Otherwise, it is NULL.

Comments

The PRINT.H header file is required if the **DEVMODE** structure is used.

Device contexts created by using the **CreateDC** function must be deleted by using the **DeleteDC** function. All objects selected into the device context after it was created should be selected out and replaced with the original objects before the device context is deleted.

MS-DOS device names follow MS-DOS conventions; an ending colon (:) is recommended, but optional. Windows strips the terminating colon so that a device name ending with a colon is mapped to the same port as the same name without a colon. The driver and port names must not contain leading or trailing spaces. **Example** The following example uses the **CreateDC** function to create a device context for a printer, using information returned by the **PrintDlg** function in a **PRINTDLG** structure:

PRINTDLG HDC LPDEVNAMES LPSTR LPSTR LPSTR	pd; hdc; lpDevNames; lpszDriverName; lpszDeviceName; lpszPortName;
	g displays the common dialog box for printing. The G structure should be initialized with appropriate values.
lpszDriver lpszDevice lpszPortNar GlobalUnloc	<pre>bd); = (LPDEVNAMES) GlobalLock(pd.hDevNames); Name = (LPSTR) lpDevNames + lpDevNames->wDriverOffset; Name = (LPSTR) lpDevNames + lpDevNames->wDeviceOffset; ne = (LPSTR) lpDevNames + lpDevNames->wOutputOffset; ck(pd.hDevNames); teDC(lpszDriverName, lpszDeviceName, lpszPortName, NULL);</pre>

CreateDialog

HWND CreateDialog(hinst	, lpszDlgTemp, hwndOwner, dlgprc)	
HINSTANCE hinst;	/* handle of application instance	*/
LPCSTR lpszDlgTemp;	/* address of dialog box template name	*/
HWND hwndOwner;	/* handle of owner window	*/
DLGPROC <i>dlgprc</i> ;	/* instance address of dialog box procedure	*/

The **CreateDialog** function creates a modeless dialog box from a dialog box template resource.

Parameters

hinst

Identifies an instance of the module whose executable file contains the dialog box template.

lpszDlgTemp

Points to a null-terminated string that names the dialog box template.

hwndOwner

Identifies the window that owns the dialog box.

	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation about the dialog box procedure, see the description of the Dialog- Proc callback function.
Return Value	The return value is the handle of the dialog box that was created, if the function is successful. Otherwise, it is NULL.
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if the DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The CreateDialog function returns immediately after creating the dialog box.
	To make the dialog box appear in the owner window upon being created, use the WS_VISIBLE style in the dialog box template.
	Use the DestroyWindow function to destroy a dialog box created by the Create-Dialog function.
	A dialog box can contain up to 255 controls.
Example	The following example creates a modeless dialog box:
	HWND hwndDlgFindBox; DLGPROC dlgprc = (DLGPROC) MakeProcInstance(FindDlgProc, hinst);
	hwndDlgFindBox = CreateDialog(hinst, "dlgFindBox", hwndParent, dlgprc);
See Also	CreateDialogIndirect, CreateDialogIndirectParam, CreateDialogParam, DestroyWindow, MakeProcInstance

CreateDialogIndirect 2.x		
HWND CreateDial HINSTANCE hinst const void FAR* lp HWND hwndOwner DLGPROC dlgprc;	<i>DlgTmp</i> ; /* address of dialog box template */	
	The CreateDialogIndirect function creates a modeless dialog box from a dialog box template in memory.	
Parameters	 <i>hinst</i> Identifies the instance of the module that will create the dialog box. <i>lpvDlgTmp</i> Points to a global memory object that contains a dialog box template used to create the dialog box. This template is in the form of a DialogBoxHeader structure. For more information about this structure, see Chapter 7, "Resource Formats Within Executable Files," in the <i>Microsoft Windows Programmer's Reference, Volume 4.</i> 	
	 hwndOwner Identifies the window that owns the dialog box. dlgprc Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation, see the description of the DialogProc callback function. 	
Return Value	The return value is the window handle of the dialog box if the function is successful. Otherwise, it is NULL.	
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if the DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.	
	The CreateDialogIndirect function returns immediately after creating the dialog box.	
	To make the dialog box appear in the owner window upon being created, use the WS_VISIBLE style in the dialog box template.	
	Use the DestroyWindow function to destroy a dialog box created by the Create-DialogIndirect function.	
	A dialog box can contain up to 255 controls.

	. /* Allocate global memory and build a dialog box template. */ · hdlg = CreateDialogIndirect(hinst, lpbDlgTemp, hwndParent, dlgprc);		
	DLGPROC dlgprc = (DLGPROC) MakeProcInstance(DialogProc, hinst); HWND hdlg; BYTE FAR* lpbDlgTemp;		
Example	The following example uses the CreateDialogIndirect function to create a dialog box from a dialog box template in memory:		

CreateDialogIndirectParam

HWND CreateDialogIndirectParam(hinst, lpvDlgTmp, hwndOwner, dlgprc, lParamInit) HINSTANCE hinst; /* handle of application instance */ const void FAR* *lpvDlgTmp*; /* address of dialog box template */ HWND hwndOwner; /* handle of owner window */ **DLGPROC** *dlgprc*: /* instance address of dialog box procedure */ LPARAM lParamInit: */ /* initialization value The **CreateDialogIndirectParam** function creates a modeless dialog box from a dialog box template in memory. Before displaying the dialog box, the function passes an application-defined value to the dialog box procedure as the *lParam* parameter of the WM_INITDIALOG message. An application can use this value to initialize dialog box controls. **Parameters** hinst Identifies the instance of the module that will create the dialog box. *lpvDlgTmp* Points to a global memory object that contains a dialog box template used to create the dialog box. This template is in the form of a DialogBoxHeader structure. For more information about this structure, see Chapter 7, "Resource Formats Within Executable Files," in the Microsoft Windows Programmer's Reference, Volume 4.

	<i>hwndOwner</i> Identifies the window that owns the dialog box.
	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation, see the description of the DialogProc callback function.
	<i>lParamInit</i> Specifies the value to pass to the dialog box when processing the WM_INITDIALOG message.
Return Value	The return value is the window handle of the dialog box if the function is successful. Otherwise, it is NULL.
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if the DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The CreateDialogIndirectParam function returns immediately after creating the dialog box.
	To make the dialog box appear in the owner window upon being created, use the WS_VISIBLE style in the dialog box template.
	Use the DestroyWindow function to destroy a dialog box created by the Create-DialogIndirectParam function.
	A dialog box can contain up to 255 controls.
Example	The following example calls the CreateDialogIndirectParam function to create a modeless dialog box from a dialog box template in memory. The example uses the <i>lParamInit</i> parameter to send two initialization parameters, wInitParm1 and wInitParm2, to the dialog box procedure when the WM_INITDIALOG message is being processed.
	#define MEM_LENGTH 100 HGLOBAL hglbDlgTemp; BYTE FAR* lpbDlgTemp; DLGPROC dlgprc = (DLGPROC) MakeProcInstance(DialogProc, hinst); HWND hwndDlg;

CreateDialogParam

HWND CreateDialo	gParam(hinst, lpszDlgTemp, hwndOwner, dlgprc, lParamInit)
HINSTANCE hinst;	
LPCSTR lpszDlgTer	<i>np</i> ; /* address of name of dialog box template */
HWND hwndOwner	
DLGPROC <i>dlgprc</i> ;	/* instance address of dialog box procedure */
LPARAM lParamín	
	The CreateDialogParam function creates a modeless dialog box from a dialog box template resource. Before displaying the dialog box, the function passes an application-defined value to the dialog box procedure as the <i>lParam</i> parameter of the WM_INITDIALOG message. An application can use this value to initialize dialog box controls.
Parameters	<i>hinst</i> Identifies an instance of the module whose executable file contains the dialog box template.
	<i>lpszDlgTemp</i> Points to a null-terminated string that names the dialog box template.
	<i>hwndOwner</i> Identifies the window that owns the dialog box.
	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation about the dialog box procedure, see the description of the Dialog- Proc callback function.

	<i>lParamInit</i> Specifies the value to pass to the dialog box when processing the WM_INITDIALOG message.		
Return Value	The return value is the handle of the dialog box that was created, if the function successful. Otherwise, it is NULL.		
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if the DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.		
	The CreateDialogParam function returns immediately after creating the dialog box.		
	To make the dialog box appear in the owner window upon being created, use the WS_VISIBLE style in the dialog box template.		
	A dialog box can contain up to 255 controls.		
Example	The following example uses the CreateDialogParam function to create a mode- less dialog box. The function passes the application-defined flags MIXEDCASE and WHOLEWORD, which will be received by the dialog box as the <i>lParam</i> pa- rameter of the WM_INITDIALOG message.		
	HWND hwndChangeBox; DLGPROC dlgprc = (DLGPROC) MakeProcInstance(ChangeDlgProc, hinst);		
	hwndChangeBox = CreateDialogParam(hinst, "dlgFindBox", hwndParent, dlgprc, MIXEDCASE WHOLEWORD);

CreateDIBitmap

HBITMAP CreateDIBitmap(hdc, lpbmih, dwInit, lpvBits, lpbmi, fnColorUse)			
HDC hdc;	/* handle of device context	*/	
BITMAPINFOHEADER FAR* lpbmih;	/* address of structure with header	*/	
DWORD dwInit;	/* CBM_INIT to initialize bitmap	*/	
const void FAR* lpvBits;	/* address of array with bitmap values	*/	
BITMAPINFO FAR* lpbmi;	/* address of structure with bitmap data	*/	
UINT fnColorUse;	/* RGB or palette indices	*/	

The **CreateDIBitmap** function creates a device-specific memory bitmap from a device-independent bitmap (DIB) specification and optionally sets bits in the bitmap.

Parameters

Identifies the device context.

lpbmih

hdc

Points to a **BITMAPINFOHEADER** structure that describes the size and format of the device-independent bitmap. The **BITMAPINFOHEADER** structure has the following form:

```
typedef struct tagBITMAPINFOHEADER {
                                          /* bmih */
    DWORD
            biSize:
    LONG
            biWidth;
    LONG
            biHeight;
    WORD
            biPlanes:
            biBitCount;
    WORD
    DWORD
            biCompression;
    DWORD
            biSizeImage:
    LONG
            biXPelsPerMeter;
    LONG
            biYPelsPerMeter;
    DWORD
            biClrUsed:
    DWORD
            biClrImportant;
```

} BITMAPINFOHEADER;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

dwInit

Specifies whether the memory bitmap is initialized. If this value is CBM_INIT, the function initializes the bitmap with the bits specified by the *lpvBits* and *lpbmi* parameters.

lpvBits

Points to a byte array that contains the initial bitmap values. The format of the bitmap values depends on the **biBitCount** member of the **BITMAPINFO-HEADER** structure identified by the *lpbmi* parameter.

lpbmi

Points to a **BITMAPINFO** structure that describes the dimensions and color format of the *lpvBits* parameter. The **BITMAPINFO** structure contains a **BIT-MAPINFOHEADER** structure and an array of **RGBQUAD** structures specifying the colors in the bitmap. The **BITMAPINFO** structure has the following form:

typedef struct tagBITMAPINFO { /* bmi */ BITMAPINFOHEADER bmiHeader; RGBQUAD bmiColors[1]; } BITMAPINFO;

	 For a full description of the BITMAPINFO and RGBQUAD structures, see the <i>Microsoft Windows Programmer's Reference</i>, <i>Volume 3</i>. <i>fnColorUse</i> Specifies whether the bmiColors member of the BITMAPINFO structure contains explicit red, green, blue (RGB) values or indices into the currently realized logical palette. The <i>fnColorUse</i> parameter must be one of the following values: 			
	Value	Meaning		
	DIB_PAL_COLORS	The color table consists the currently realized lo		bit indices into
	DIB_RGB_COLORS	The color table contains	literal RGB value	s.
Return Value	The return value is the ha wise, it is NULL.	ndle of the bitmap if the	e function is succ	essful. Other-
	When it has finished usin should select the bitmap or using the DeleteObject from the select the bitmap of the select from t	out of the device contex		
Example	The following example initializes an array of bits and an array of RGBQUAD structures, allocates memory for the bitmap header and color table, fills in the r quired members of a BITMAPINFOHEADER structure, and calls the Create Bitmap function to create a handle of the bitmap:		e, fills in the re-	
	HANDLE hloc; PBITMAPINFO pbmi; HBITMAP hbm;			
	0×01, 0×02, 0×02, 0×02, 0×02,	0x00, 0x00, 0x00, 0x12, 0x22, 0x11, 0x12, 0x22, 0x11, 0x20, 0x00, 0x22, 0x20, 0x20, 0x22, 0x20, 0x00, 0x22, 0x20, 0x00, 0x22, 0x12, 0x22, 0x11,	/* bottom row	*/
		<pre>0x12, 0x22, 0x11 };</pre>	/* top row	*/
		55, 0, 0, 0 }, , 255, 0, 0 }, , 0, 255, 0 }};	/* blue /* green /* red	*/ */ */
	hloc = LocalAlloc(LMEM sizeof(BITMAPINFOH pbmi = (PBITMAPINFO) L	EADER) + (sizeof(RGBC		

```
pbmi->bmiHeader.biSize = sizeof(BITMAPINFOHEADER);
pbmi->bmiHeader.biWidth = 8;
pbmi->bmiHeader.biPlanes = 1;
pbmi->bmiHeader.biBitCount = 4;
pbmi->bmiHeader.biCompression = BI_RGB;
memcpy(pbmi->bmiColors, argbq, sizeof(RGBQUAD) * 3);
hbm = CreateDIBitmap(hdcLocal, (BITMAPINFOHEADER FAR*) pbmi, CBM_INIT,
aBits, pbmi, DIB_RGB_COLORS);
LocalFree(hloc);
.

CreateDIBPatternBrush

HBRUSH CreateDI HGLOBAL hglbDII UINT fnColorSpec;			ice-independent bitmap	*/ */
	specified by	a device-indepen	h function creates a brush th dent bitmap (DIB). The bru apports raster operations.	
ParametershglbDIBPackedIdentifies a global memory object containing a packed device-independent I map. A packed DIB consists of a BITMAPINFO structure immediately fol lowed by the array of bytes that define the pixels of the bitmap. The BITMAPINFO structure has the following form:			cture immediately fol-	
		APINFOHEADER JAD	PINFO { /* bmi */ bmiHeader; bmiColors[1];	
For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.				

fnColorSpec

Specifies whether the **bmiColors** member(s) of the **BITMAPINFO** structure contain explicit red, green, blue (RGB) values or indices into the currently realized logical palette. This parameter must be one of the following values:

	Value	Meaning		
	DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.		
	DIB_RGB_COLORS	The color table contains literal RGB values.		
Return Value	The return value is the ha it is NULL.	ndle of the brush if the function is successful. Otherwise,		
Comments	To retrieve the handle identified by the <i>hglbDIBPacked</i> parameter, an application calls the GlobalAlloc function to allocate a global memory object and then fills the memory with the packed DIB.			
	larger, Windows creates a	rns should be 8 pixels by 8 pixels. If such a bitmap is a fill pattern using only the bits corresponding to the first pixels in the upper-left corner of the bitmap.		
	When an application selects a two-color DIB pattern brush into a monochrome device context, Windows ignores the colors specified in the DIB and instead displays the pattern brush, using the current text and background colors of the device context. Pixels mapped to the first color (at offset 0 in the DIB color table) of the DIB are displayed using the text color, and pixels mapped to the second color (at offset 1 in the color table) are displayed using the background color.			
	When it has finished using a brush created by CreateDIBPatternBrush , an appli cation should remove the brush by using the DeleteObject function.			
Example	source file, uses the bitma	etrieves a bitmap named DIBit from the application's re- up to create a pattern brush in a call to the CreateDIB - elects the brush into a device context, and fills a w brush:		
	HRSRC hrsrc; HGLOBAL hglbl; HBRUSH hbr, hbrOld;			
	hrsrc = FindResource(h hglbl = LoadResource(h LockResource(hglbl);	inst, "DIBit", RT_BITMAP); inst, hrsrc);		

<pre>hbr = CreateDIBPatternBrush(hglbl,</pre>	<pre>DIB_RGB_COLORS);</pre>
<pre>hbr0ld = SelectObject(hdc, hbr);</pre>	
Rectangle(hdc, 10, 10, 100, 100);	
UnlockResource(hglbl);

CreateDiscardableBitmap

bitmap.

HBITMAP CreateDiscardableBitmap(hdc, nWidth, nHeight) HDC hdc: /* handle of device context */ */ int nWidth; /* bitmap width int *nHeight*: /* bitmap height */ The CreateDiscardableBitmap function creates a discardable bitmap that is compatible with the given device. The bitmap has the same number of color planes or the same bits-per-pixel format as the device. An application can select this bitmap as the current bitmap for a memory device that is compatible with the one identified by the *hdc* parameter. **Parameters** hdc Identifies the device context. nWidth Specifies the width, in bits, of the bitmap. nHeight Specifies the height, in bits, of the bitmap. Return Value The return value is the handle of the bitmap if the function is successful. Otherwise, it is NULL. Comments Windows can discard a bitmap created by this function only if an application has not selected it into a device context. If Windows discards the bitmap when it is not selected and the application later attempts to select it, the SelectObject function will return zero. Applications should use the **DeleteObject** function to delete the handle returned by the **CreateDiscardableBitmap** function, even if Windows has discarded the

CreateEllipticRgn

	icRgn(nLeftRect, nTopRect, nRightRect, nBottomRect) /* x-coordinate upper-left corner bounding rectangle */
<pre>int nLeftRect; int nTopRect;</pre>	/* x-coordinate upper-left corner bounding rectangle */ /* y-coordinate upper-left corner bounding rectangle */
int nRightRect;	/* x-coordinate lower-right corner bounding rectangle */
int nBottomRect;	/* y-coordinate lower-right corner bounding rectangle */
	The CreateEllipticRgn function creates an elliptical region.
Parameters	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle of the ellipse.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle of the ellipse.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle of the ellipse.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle of the ellipse.
Return Value	The return value is the handle of the region if the function is successful. Otherwise, it is NULL.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
	When it has finished using a region created by using the CreateEllipticRgn func- tion, an application should remove it by using the DeleteObject function.
See Also	CreateEllipticRgnIndirect, DeleteObject, PaintRgn

CreateEllipticRgnIndirect

2.x

HRGN CreateEllipticRgnIndirect(*lprc*) const RECT FAR* *lprc*; /* address of structure with bounding rectangle

*/

The CreateEllipticRgnIndirect function creates an elliptical region.

Parameters	<pre>lprc Points to a RECT structure that contains the logical coordinates of the upper- left and lower-right corners of the bounding rectangle of the ellipse. The RECT structure has the following form: typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom;</pre>
	<pre>} RECT; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.</pre>
Return Value	The return value is the handle of the region if the function is successful. Otherwise, it is NULL.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
	When it has finished using a region created by CreateEllipticRgnIndirect , an application should remove the region by using the DeleteObject function.
Example	The following example assigns values to the members of a RECT structure, uses the CreateEllipticRgnIndirect function to create an elliptical region, selects the region into a device context, and then uses the PaintRgn function to display the re- gion:
	HDC hdc; RECT rc; HRGN hrgn;
	SetRect(&rc, 10, 10, 200, 50);
	hrgn = CreateEllipticRgnIndirect(&rc); SelectObject(hdc, hrgn); PaintRgn(hdc, hrgn);
See Also	CreateEllipticRgn, DeleteObject, PaintRgn

The **CreateFont** function creates a logical font that has the specified characteristics. The logical font can subsequently be selected as the font for any device.

Parameters

nHeight

Specifies the requested height, in logical units, for the font. If this parameter is greater than zero, it specifies the cell height of the font. If it is less than zero, it specifies the character height of the font. (Character height is the cell height minus the internal leading. Applications that specify font height in points typically use a negative number for this member.) If this parameter is zero, the font mapper uses a default height. The font mapper chooses the largest physical font that does not exceed the requested size (or the smallest font, if all the fonts exceed the requested size). The absolute value of the *nHeight* parameter must not exceed 16,384 after it is converted to device units.

nWidth

Specifies the average width, in logical units, of characters in the font. If this parameter is zero, the font mapper chooses a "closest match" default width for the specified font height. (The default width is chosen by matching the aspect ratio of the device against the digitization aspect ratio of the available fonts. The closest match is determined by the absolute value of the difference.)

nEscapement

Specifies the angle, in tenths of degrees, between the escapement vector and the x-axis of the screen surface. The escapement vector is the line through the origins of the first and last characters on a line. The angle is measured counter-clockwise from the x-axis.

nOrientation

Specifies the angle, in tenths of degrees, between the base line of a character and the x-axis. The angle is measured in a counterclockwise direction from the x-axis for left-handed coordinate systems (that is, MM_TEXT, in which the y-direction is down) and in a clockwise direction from the x-axis for righthanded coordinate systems (in which the y-direction is up).

fnWeight

Specifies the font weight. This parameter can be one of the following values:

Constant	Value
FW_DONTCARE	0
FW_THIN	100
FW_EXTRALIGHT	200
FW_ULTRALIGHT	200
FW_LIGHT	300
FW_NORMAL	400
FW_REGULAR	400
FW_MEDIUM	500
FW_SEMIBOLD	600
FW_DEMIBOLD	600
FW_BOLD	700
FW_EXTRABOLD	800
FW_ULTRABOLD	800
FW_BLACK	900
FW_HEAVY	900

The appearance of the font depends on the typeface. Some fonts have only FW_NORMAL, FW_REGULAR, and FW_BOLD weights. If FW_DONTCARE is specified, a default weight is used.

fbItalic

Specifies an italic font if set to nonzero.

fbUnderline

Specifies an underlined font if set to nonzero.

fbStrikeOut

Specifies a strikeout font if set to nonzero.

fbCharSet

Specifies the character set of the font. The following values are predefined:

Constant	Value
ANSI_CHARSET	0
DEFAULT_CHARSET	1
SYMBOL_CHARSET	2
SHIFTJIS_CHARSET	128
OEM_CHARSET	255

The DEFAULT_CHARSET value is not used by the font mapper. An application can use this value to allow the name and size of a font to fully describe the logical font. If the specified font name does not exist, a font from any character set can be substituted for the specified font; to avoid unexpected results, applications should use the DEFAULT_CHARSET value sparingly.

The OEM character set is system-dependent.

Fonts with other character sets may exist in the system. If an application uses a font with an unknown character set, it should not attempt to translate or interpret strings that are to be rendered with that font.

fbOutputPrecision

Specifies the requested output precision. The output precision defines how closely the output must match the requested font's height, width, character orientation, escapement, and pitch. This parameter can be one of the following values:

OUT_CHARACTER_PRECIS OUT_DEFAULT_PRECIS OUT_DEVICE_PRECIS OUT_RASTER_PRECIS OUT_STRING_PRECIS OUT_STROKE_PRECIS OUT_TT_PRECIS

Applications can use the OUT_DEVICE_PRECIS, OUT_RASTER_PRECIS, and OUT_TT_PRECIS values to control how the font mapper chooses a font when the system contains more than one font with a given name. For example, if a system contained a font named Symbol in raster and TrueType form, specifying OUT_TT_PRECIS would force the font mapper to choose the TrueType version. (Specifying OUT_TT_PRECIS forces the font mapper to choose a TrueType font whenever the specified font name matches a device or raster font, even when there is no TrueType font of the same name.)

fbClipPrecision

Specifies the requested clipping precision. The clipping precision defines how to clip characters that are partially outside the clipping region. This parameter can be one of the following values:

CLIP_CHARACTER_PRECIS CLIP_DEFAULT_PRECIS CLIP_ENCAPSULATE

CLIP_LH_ANGLES CLIP_MASK CLIP_STROKE_PRECIS CLIP_TT_ALWAYS

To use an embedded read-only font, applications must specify CLIP_ENCAPSULATE.

To achieve consistent rotation of device, TrueType, and vector fonts, an application can use the OR operator to combine the CLIP_LH_ANGLES value with any of the other *fbClipPrecision* values. If the CLIP_LH_ANGLES bit is set, the rotation for all fonts is dependent on whether the orientation of the coordinate system is left-handed or right-handed. If CLIP_LH_ANGLES is not set, device fonts always rotate counterclockwise, but the rotation of other fonts is dependent on the orientation of the coordinate system. (For more information about the orientation of coordinate systems, see the description of the *nOrientation* parameter.)

fbQuality

Specifies the output quality of the font, which defines how carefully the graphics device interface (GDI) must attempt to match the attributes of a logical font to those of a physical font. This parameter can be one of the following values:

Value	Meaning
DEFAULT_QUALITY	Appearance of the font does not matter.
DRAFT_QUALITY	Appearance of the font is less important than when the PROOF_QUALITY value is used. For GDI raster fonts, scaling is enabled. Bold, italic, underline, and strikeout fonts are synthesized if necessary.
PROOF_QUALITY	Character quality of the font is more important than exact matching of the logical-font attributes. For GDI raster fonts, scaling is disabled and the font closest in size is chosen. Bold, italic, underline, and strikeout fonts are synthesized if necessary.

fbPitchAndFamily

Specifies the pitch and family of the font. The two low-order bits specify the pitch of the font and can be one of the following values:

DEFAULT_PITCH FIXED_PITCH VARIABLE_PITCH

Applications can set bit 2 (0x04) of the **lfPitchAndFamily** member to choose a TrueType font.

The four high-order bits specify the font family and can be one of the following values:

	Value	Meaning
	FF_DECORATIVE	Novelty fonts. Old English is an example.
	FF_DONTCARE	Don't care or don't know.
	FF_MODERN	Fonts with constant stroke width, with or without serifs. Pica, Elite, and Courier New® are examples.
	FF_ROMAN	Fonts with variable stroke width and with serifs. Times New Roman® and New Century Schoolbook® are ex- amples.
	FF_SCRIPT	Fonts designed to look like handwriting. Script and Cursive are examples.
	FF_SWISS	Fonts with variable stroke width and without serifs. MS® Sans Serif is an example.
		pecify a value for the <i>fbPitchAndFamily</i> parameter by R operator to join a pitch constant with a family constant.
		be the look of a font in a general way. They are intended for n the exact typeface requested is not available.
	The length of this str Families function ca	inated string that specifies the typeface name of the font. ing must not exceed LF_FACESIZE – 1. The EnumFont - n be used to enumerate the typeface names of all currently s parameter is NULL, GDI uses a device-dependent type-

CreateFontIndirect, DeleteObject, EnumFontFamilies

CreateFontIndirect

```
HFONT CreateFontIndirect(lplf)
```

const LOGFONT FAR* *lplf*; /* address of struct. with font attributes */

The **CreateFontIndirect** function creates a logical font that has the characteristics given in the specified structure. The font can subsequently be selected as the current font for any device.

Parameters

lplf

Points to a **LOGFONT** structure that defines the characteristics of the logical font. The **LOGFONT** structure has the following form:

```
typedef struct tagLOGFONT {
                               /* ]f */
   int
         lfHeight:
   int
         lfWidth:
   int
         lfEscapement;
   int
         lfOrientation:
   int
         lfWeight:
   BYTE lfItalic;
   BYTE lfUnderline;
   BYTE lfStrikeOut:
   BYTE lfCharSet:
   BYTE
         lfOutPrecision:
   BYTE
        lfClipPrecision;
   BYTE lfQuality:
         lfPitchAndFamily;
   BYTE
   BYTE lfFaceName[LF FACESIZE];
} LOGFONT:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

Return Value The return value is the handle of the logical font if the function is successful. Otherwise, it is NULL.

Comments The **CreateFontIndirect** function creates a logical font that has the characteristics specified in the **LOGFONT** structure. When the font is selected by using the **SelectObject** function, the graphics device interface (GDI) font mapper attempts to match the logical font with an existing physical font. If it cannot find an exact match for the logical font, the font mapper provides an alternative whose characteristics match as many of the requested characteristics as possible.

Fonts created by using the **CreateFontIndirect** function must be selected out of any device context in which they were used and then removed by using the **DeleteObject** function.

Example The following example uses the **CreateFontIndirect** function to retrieve the handle of a logical font. The nPtSize and pszFace parameters are passed to the function containing this code. The **MulDiv** and **GetDeviceCaps** functions are used to convert the specified point size into the correct point size for the MM TEXT mapping mode on the current device.

HFONT hfont, hfont01d;

PLOGFONT plf = (PLOGFONT) LocalAlloc(LPTR, sizeof(LOGFONT));

plf->lfHeight = -MulDiv(nPtSize, GetDeviceCaps(hdc, LOGPIXELSY), 72); strcpy(plf->lfFaceName, pszFace);

hfont = CreateFontIndirect(plf);

hfontOld = SelectObject(hdc, hfont);

TextOut(hdc, 10, 50, pszFace, strlen(pszFace));

LocalFree((HLOCAL) plf); SelectObject(hdc, hfontOld); DeleteObject(hfont);

See Also CreateFont, DeleteObject

CreateHatchBrush

HBRUSH CreateHa int fnStyle; COLORREF clrref;	atchBrush(fnStyle, clrref) /* hatch style of brus ; /* color of brush	sh */ */	
		function creates a brush rush can then be selected	that has the specified hatched for any device.
Parameters	<i>fnStyle</i> Specifies one of the fo	ollowing hatch styles for	the brush:
	Value	Meaning	
	HS_BDIAGONAL	45-degree upward hatch (left to right)
	HS_CROSS	Horizontal and vertical cr	osshatch
	HS_DIAGCROSS	45-degree crosshatch	
	HS_FDIAGONAL	45-degree downward hatc	ch (left to right)
	HS_HORIZONTAL	Horizontal hatch	
	HS_VERTICAL	Vertical hatch	
	<i>clrref</i> Specifies the foregrou	and color of the brush (the	e color of the hatches).
Return Value	The return value is the has it is NULL.	andle of the brush if the f	unction is successful. Otherwise,
Comments		d select the brush out of the	created by the CreateHatch - he device context and then delete
	The following illustratio to fill a rectangle:	n shows how the various	hatch brushes appear when used
	HS_HORIZONTAL	HS_BDIAGONAL	HS_FDIAGONAL
	HS_VERTICAL	HS_CROSS	HS_DIAGCROSS

Example The following example creates a hatched brush with green diagonal hatch marks and uses that brush to fill a rectangle:

HBRUSH hbr, hbr01d;

hbr = CreateHatchBrush(HS_FDIAGONAL, RGB(0, 255, 0)); hbrOld = SelectObject(hdc, hbr); Rectangle(hdc, 0, 0, 100, 100);

CreateIC

HDC CreateIC(lpszi	zDriver, lpszDevice, lpszOutput, lpvInitData)	
LPCSTR lpszDriver	r; /* address of driver name	*/
LPCSTR lpszDevice		*/
LPCSTR lpszOutput		e */
const void FAR* lpv	<i>vInitData</i> ; /* address of initialization data	*/
	The CreateIC function creates an information co The information context provides a fast way to g without creating a device context.	
Parameters	<i>lpszDriver</i> Points to a null-terminated string that specifie extension) of the device driver (for example, I	
	<i>lpszDevice</i> Points to a null-terminated string that specifie to be supported (for example, EPSON FX-80) module supports more than one device.	
	<i>lpszOutput</i> Points to a null-terminated string that specifie name for the physical output medium (file or p	
	<i>lpvInitData</i> Points to a DEVMODE structure that contain mation necessary to initialize the device drive retrieves this structure filled in for a given dev must be NULL if the device driver is to use th tion (if any) specified by the user through Win	r. The ExtDeviceMode function vice. The <i>lpvInitData</i> parameter the default initialization informa-

The **DEVMODE** structure has the following form:

	e
	<pre>#include <print.h></print.h></pre>
	<pre>typedef struct tagDEVMODE { /* dm */ char dmDeviceName[CCHDEVICENAME]; UINT dmSpecVersion; UINT dmDriverVersion; UINT dmDriverExtra; DWORD dmFields; int dmOrientation; int dmPaperSize; int dmPaperLength; int dmPaperWidth; int dmScale; int dmCopies; int dmDefaultSource; int dmDefaultSource; int dmDuplex; int dmDuplex; int dmUplex; int dmTOption; } DEVMODE;</pre>
Return Value	The return value is the handle of an information context for the given device if the function is successful. Otherwise, it is NULL.
Comments	The PRINT.H header file is required if the DEVMODE structure is used.
	MS-DOS device names follow MS-DOS conventions; an ending colon (:) is rec- ommended, but optional. Windows strips the terminating colon so that a device name ending with a colon is mapped to the same port as would be the same name without a colon.
	The driver and port names must not contain leading or trailing spaces.
	GDI output functions cannot be used with information contexts.
	When it has finished using an information context created by CreateIC , an application should remove the information context by using the DeleteDC function.
Example	The following example uses the CreateIC function to create an information con- text for the display and then uses the GetDCOrg function to retrieve the origin for the information context:
	DWORD dwOrigin;

hdcIC = CreateIC("DISPLAY", NULL, NULL, NULL); dwOrigin = GetDCOrg(hdcIC);

DeleteDC(hdcIC);

Return Value	The return vit is NULL.	value is the handle of the icon if the function is	successful. Otherwise,

Comments	The <i>nWidth</i> and <i>nHeight</i> parameters must specify a width and height supported by the current display driver, since the system cannot create icons of other sizes. An application can determine the width and height supported by the display driver by calling the GetSystemMetrics function, specifying the SM_CXICON or SM_CYICON constant.
	Before terminating, an application must call the DestroyIcon function to free system resources associated with the icon.
See Also	DestroyIcon, GetSystemMetrics

Create	Menu
--------	------

HMENU CreateMenu(void)

The CreateMenu function creates a menu. The menu is initially empty but can be
filled with menu items by using the AppendMenu or InsertMenu function.ParametersThis function has no parameters.Return ValueThe return value is the handle of the newly created menu if the function is successful. Otherwise, it is NULL.CommentsIf the menu is not assigned to a window, an application must free system resources associated with the menu before exiting. An application frees menu resources by calling the DestroyMenu function. Windows automatically frees resources as-

2.x

Example The following example creates a main menu and a pop-up menu and associates the pop-up menu with an item in the main menu:

HMENU hmenu; HMENU hmenuPopup; /* Create the main and pop-up menu handles. */ hmenu = CreateMenu(); hmenuPopup = CreatePopupMenu();

sociated with a menu that is assigned to a window.

AppendMenu, DestroyMenu, InsertMenu, SetMenu

CreateMetaFile

```
HDC CreateMetaFile(lpszFile)
LPCSTR lpszFile:
                      /* address of metafile name
                                                         */
                     The CreateMetaFile function creates a metafile device context.
Parameters
                     lpsz.File
                        Points to a null-terminated string that specifies the MS-DOS filename of the
                        metafile to create. If this parameter is NULL, a device context for a memory
                        metafile is returned.
Return Value
                     The return value is the handle of the metafile device context if the function is
                     successful. Otherwise, it is NULL.
Comments
                     When it has finished using a metafile device context created by CreateMetaFile,
                     an application should close it by using the CloseMetaFile function.
Example
                     The following example uses the CreateMetaFile function to create the handle of a
                     device context for a memory metafile, draws a line in that device context, retrieves
                     a handle of the metafile by calling the CloseMetaFile function, plays the metafile
                     by using the PlayMetaFile function, and finally deletes the metafile by using the
                     DeleteMetaFile function:
```

HDC hdcMeta; HMETAFILE hmf;

```
hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

DeleteMetaFile

CreatePalette

3.0

 HPALETTE CreatePalette(lplgpl)

 const LOGPALETTE FAR* lplgpl;
 /* address of LOGPALETTE structure
 */

The CreatePalette function creates a logical color palette.

Parameters	<i>lplgpl</i> Points to a LOGPALETTE structure that contains information about the colors in the logical palette. The LOGPALETTE structure has the following form:
	<pre>typedef struct tagLOGPALETTE { /* lgpl */ WORD</pre>
	For a full description of this structure, see the <i>Microsoft Windows Program-</i> mer's Reference, Volume 3.
Return Value	The return value is the handle of the logical palette if the function is successful. Otherwise, it is NULL.
Comments	When it has finished using a palette created by CreatePalette , an application should remove the palette by using the DeleteObject function.
Example	The following example initializes a LOGPALETTE structure and an array of PALETTEENTRY structures, and then uses the CreatePalette function to re- trieve a handle of a logical palette:
	#define NUMENTRIES 128 HPALETTE hpal; PALETTEENTRY ape[NUMENTRIES];

2.x

```
plgpl = (LOGPALETTE*) LocalAlloc(LPTR,
    sizeof(LOGPALETTE) + cColors * sizeof(PALETTEENTRY));
plgpl->palNumEntries = cColors:
plgpl \rightarrow palVersion = 0x300;
for (i = 0, red = 0, green = 127, blue = 127; i < NUMENTRIES;
        i++, red += 1, green += 1, blue += 1) {
    ape[i].peRed =
        plgpl->palPalEntry[i].peRed = LOBYTE(red);
    ape[i].peGreen =
        plgpl->palPalEntry[i].peGreen = LOBYTE(green);
    ape[i].peBlue =
        plgpl->palPalEntry[i].peBlue = LOBYTE(blue);
    ape[i].peFlags =
        plgpl->palPalEntry[i].peFlags = PC_RESERVED;
}
hpal = CreatePalette(plgpl);
LocalFree((HLOCAL) plgpl);
. /* Use the palette handle. */
DeleteObject(hpal);
```

See Also DeleteObject

CreatePatternBrush

HBRUSH CreatePa	atternBrush(hbmp)
HBITMAP hbmp;	/* handle of bitmap */
	The CreatePatternBrush function creates a brush whose pattern is specified by a bitmap. The brush can subsequently be selected for any device that supports raster operations.
Parameters	<i>hbmp</i> Identifies the bitmap.
Return Value	The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.
Comments	The bitmap identified by the <i>hbmp</i> parameter is typically created by using the CreateBitmap , CreateBitmapIndirect , CreateCompatibleBitmap , or Load-Bitmap function.

	Bitmaps used as fill patterns should be 8 pixels by 8 pixels. If the bitmap is larger, Windows will use the bits corresponding to only the first 8 rows and 8 columns of pixels in the upper-left corner of the bitmap.
	An application can use the DeleteObject function to remove a pattern brush. This does not affect the associated bitmap, which means the bitmap can be used to create any number of pattern brushes. In any case, when the brush is no longer needed, the application should remove it by using DeleteObject .
	A brush created by using a monochrome bitmap (one color plane, one bit per pixel) is drawn using the current text and background colors. Pixels represented by a bit set to 0 are drawn with the current text color, and pixels represented by a bit set to 1 are drawn with the current background color.
Example	The following example loads a bitmap named Pattern, uses the bitmap to create a pattern brush in a call to the CreatePatternBrush function, selects the brush into a device context, and fills a rectangle by using the new brush:
	HBITMAP hbmp; HBRUSH hbr, hbrOld;
	<pre>hbmp = LoadBitmap(hinst, "Pattern"); hbr = CreatePatternBrush(hbmp); hbr0ld = SelectObject(hdc, hbr); Rectangle(hdc, 10, 10, 100, 100);</pre>

CreatePen

HPEN CreatePen(fnPen	Style nWidth	clrrof	

int fnPenStyle;	/* style of pen	· */
int nWidth;	/* width of pen	*/
COLORREF clrref;	/* color of pen	*/

The CreatePen function creates a pen having the specified style, width, and color. The pen can subsequently be selected as the current pen for any device.

Parameters

Return Value

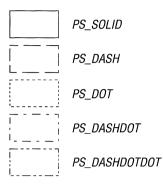

Comments

fnPenStyle

Specifies the pen style. This parameter can be one of the following values:

Meaning Creates a solid pen. Creates a dashed pen. (Valid only when the pen width is 1.) Creates a dotted pen. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.) Creates a null pen.
Creates a dashed pen. (Valid only when the pen width is 1.) Creates a dotted pen. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.) Creates a null pen.
Creates a dotted pen. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.) Creates a null pen.
Creates a pen with alternating dashes and dots. (Valid only when the pen width is 1.) Creates a pen with alternating dashes and double dots. (Valid only when the pen width is 1.) Creates a null pen.
when the pen width is 1.)Creates a pen with alternating dashes and double dots.(Valid only when the pen width is 1.)Creates a null pen.
(Valid only when the pen width is 1.) Creates a null pen.
Construction of the transmission of the former of the d
Creates a pen that draws a line inside the frame of closed shapes produced by graphics device interface (GDI) out- put functions that specify a bounding rectangle (for ex- ample, the Ellipse , Rectangle , RoundRect , Pie , and Chord functions). When this style is used with GDI out- put functions that do not specify a bounding rectangle (for example, the LineTo function), the drawing area of the pen is not limited by a frame.
the pen.
ndle of the pen if the function is successful. Otherwise, it
ter than one pixel always have the PS_NULL, DEFRAME style.
DEFRAME style and a color that does not match a color the pen is drawn with a dithered color. The PS_SOLID to create a pen with a dithered color. The e is identical to PS_SOLID if the pen width is less than

The following illustration shows how the various system pens appear when used to draw a rectangle.

Example The following example uses the **CreatePen** function to create a solid blue pen 6 units wide, selects the pen into a device context, and then uses the pen to draw a rectangle:

HPEN hpen, hpenOld;

hpen = CreatePen(PS_SOLID, 6, RGB(0, 0, 255)); hpenOld = SelectObject(hdc, hpen);

Rectangle(hdc, 10, 10, 100, 100);

SelectObject(hdc, hpenOld); DeleteObject(hpen);

See Also CreatePenIndirect, DeleteObject, Ellipse, Rectangle, RoundRect

CreatePenIndirect

 HPEN CreatePenIndirect(lplgpn)
 /* address of structure with pen data
 */

 LOGPEN FAR* lplgpn;
 /* address of structure with pen data
 */

 The CreatePenIndirect function creates a pen that has the style, width, and color given in the specified structure.
 Parameters
 lplgpn

 Points to the LOGPEN structure that contains information about the pen. The LOGPEN structure has the following form:
 Parameters

	<pre>typedef struct tagLOGPEN { /* lgpn */ UINT lopnStyle; POINT lopnWidth; COLORREF lopnColor; } LOGPEN; For a full description of this structure, see the Missensoft Windows Breasant</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is the handle of the pen if the function is successful. Otherwise, it is NULL.
Comments	Pens whose width is greater than 1 pixel always have the PS_NULL, PS_SOLID, or PS_INSIDEFRAME style.
	If a pen has the PS_INSIDEFRAME style and a color that does not match a color in the logical color table, the pen is drawn with a dithered color. The PS_INSIDEFRAME style is identical to PS_SOLID if the pen width is less than or equal to 1.
	When it has finished using a pen created by CreatePenIndirect , an application should remove the pen by using the DeleteObject function.
Example	The following example fills a LOGPEN structure with values defining a solid red pen 10 logical units wide, uses the CreatePenIndirect function to create this pen, selects the pen into a device context, and then uses the pen to draw a rectangle:
	LOGPEN lp; HPEN hpen, hpenOld;
	<pre>lp.lopnStyle = PS_SOLID; lp.lopnWidth.x = 10; lp.lopnWidth.y = 0;</pre>
	hpen = CreatePenIndirect(& p); hpenOld = SelectObject(hdc, hpen); Rectangle(hdc, 10, 10, 100, 100);
See Also	CreatePen, DeleteObject

CreatePolygonRgn

HRGN CreatePolygonRgn(lppt, cPoints, fnPolyFillMode)		
const POINT FAR* <i>lppt</i> ;	/* address of array of points	*/
int cPoints;	/* number of points in array	*/
int fnPolyFillMode;	/* polygon-filling mode	*/

The **CreatePolygonRgn** function creates a polygonal region. The system closes the polygon automatically, if necessary, by drawing a line from the last vertex to the first.

Parameters

lppt

Points to an array of **POINT** structures. Each structure specifies the x-coordinate and y-coordinate of one vertex of the polygon. The **POINT** structure has the following form:

```
typedef struct tagPOINT { /* pt */
   int x:
  int y:
} POINT;
```

For a full description of this structure, see the *Microsoft Windows Program*mer's Reference, Volume 3.

cPoints

Specifies the number of **POINT** structures in the array pointed to by the *lppt* parameter.

fnPolyFillMode

Specifies the polygon-filling mode. This value may be either ALTERNATE or WINDING

Return Value The return value is the handle of the region if the function is successful. Otherwise, it is NULL.

Comments The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.

> When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

> When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, the system increments a count (increases

it by one); when the line passes through a counterclockwise line segment, the system decrements the count. The area is filled if the count is nonzero when the line reaches the outside of the figure.

When it has finished using a region created by **CreatePolygonRgn**, an application should remove the region by using the **DeleteObject** function.

Example The following example fills an array of **POINT** structures with the coordinates of a five-pointed star, uses this array in a call to the **CreatePolygonRgn** function, selects the region into a device context, and then uses the **PaintRgn** function to display the region:

CreatePolyPolygonRgn

HRGN CreatePolyPolygonRgn(l	ppt, lpnPolyCount, cIntegers, fnPolyF	illMode)
const POINT FAR* <i>lppt</i> ;	/* address of structure of points	*/
const int FAR* <i>lpnPolyCount</i> ;	/* address of array of vertex data	*/
int cIntegers;	/* number of integers in array	*/
int fnPolyFillMode;	/* polygon-filling mode	*/
	PolyPolygonRgn function creates a regons. The polygons may be disjoint, or	2 0

Parameters

lppt

Points to an array of **POINT** structures that define the vertices of the polygons. Each polygon must be explicitly closed, because the system does not close them automatically. The polygons are specified consecutively. The **POINT** structure has the following form:

3.0

series of

	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lpnPolyCount</i> Points to an array of integers. The first integer specifies the number of vertices in the first polygon in the array pointed to by the <i>lppt</i> parameter, the second in- teger specifies the number of vertices in the second polygon, and so on.
	<i>cIntegers</i> Specifies the total number of integers in the array pointed to by the <i>lpnPoly</i> - <i>Count</i> parameter.
	<i>fnPolyFillMode</i> Specifies the polygon-filling mode. This value may be either ALTERNATE or WINDING.
Return Value	The return value is the handle of the region if the function is successful. Otherwise, it is NULL.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
	When the polygon-filling mode is ALTERNATE, the system fills the area be- tween odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.
	When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. When- ever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, the system increments a count (increases it by one); when the line passes through a counterclockwise line segment, the sys- tem decrements the count. The area is filled if the count is nonzero when the line reaches the outside of the figure.
	When it has finished using a region created by CreatePolyPolygonRgn , an application should remove the region by using the DeleteObject function.
Example	The following example fills an array of POINT structures with the coordinates of a five-pointed star and a rectangle, uses this array in a call to the CreatePoly- PolygonRgn function, selects the region into a device context, and then uses the PaintRgn function to display the region:

```
HDC hdc:
HRGN hrgn;
int aVertices[2] = \{ 6, 5 \};
POINT apts[11] = \{\{200, 10\}\}
                  { 300, 200 }.
                  { 100, 100 }, /* Star figure, manually closed */
                  { 300, 100 }.
                  { 100, 200 },
                  { 200, 10 },
                  { 10, 150 },
                  { 350, 150 },
                  { 350, 170 }, /* Rectangle, manually closed */
                  { 10, 170 }.
                  { 10, 150 }};
hrgn = CreatePolyPolygonRgn(apts,
                                                                  */
                                    /* array of points
                                                                  */
    aVertices,
                                     /* array of vertices
    sizeof(aVertices) / sizeof(int), /* integers in vertex array */
                                     /* alternate mode
                                                                  */
    ALTERNATE);
SelectObject(hdc, hrgn);
PaintRgn(hdc, hrgn);
```

See Also CreatePolygonRgn, DeleteObject, PolyPolygon, SetPolyFillMode

CreatePopupMenu

84

HMENU CreatePopupMenu(void)

	The CreatePopupMenu function creates an empty pop-up menu.
Parameters	This function has no parameters.
Return Value	The return value is the handle of the newly created menu if the function is successful. Otherwise, it is NULL.
Comments	An application adds items to the pop-up menu by calling the InsertMenu and AppendMenu functions. The application can add the pop-up menu to an existing menu or pop-up menu, or it can display and track selections on the pop-up menu by calling the TrackPopupMenu function. Before exiting, an application must free system resources associated with a pop-up menu if the menu is not assigned to a window. An application frees a menu by calling the DestroyMenu function.

3.0

Example The following example creates a main menu and a pop-up menu, and associates the pop-up menu with an item in the main menu:

> HMENU hmenu; HMENU hmenuPopup; /* Create the main and pop-up menu handles. */ hmenu = CreateMenu(): hmenuPopup = CreatePopupMenu(); /* Create the pop-up menu items. *./ AppendMenu(hmenuPopup, MF_ENABLED | MF_STRING, IDM_NEW, "&New"): AppendMenu(hmenuPopup, MF_ENABLED | MF_STRING, IDM_SAVE, "&Save"); AppendMenu(hmenuPopup, MF_ENABLED | MF_STRING, IDM_SAVE_AS, "&Save As"); /* Add the pop-up menu to the main menu. */ AppendMenu(hmenu, MF_ENABLED | MF_POPUP, (UINT) hmenuPopup, "&File"):

CreateRectRgn

HRGN CreateRect	Rgn (nLeftRect, nTopRect, nRightRect, nBottomRect)
<pre>int nLeftRect;</pre>	/* x-coordinate upper-left corner of region */
int nTopRect;	/* y-coordinate upper-left corner of region */
int nRightRect;	/* x-coordinate lower-right corner of region */
int nBottomRect;	/* y-coordinate lower-right corner of region */
	The CreateRectRgn function creates a rectangular region.
Parameters	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the region.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the region.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the region.
	6

See Also	CreateRectRgnIndirect, CreateRoundRectRgn, DeleteObject, PaintRgn
	hrgn = CreateRectRgn(10, 10, 110, 110); SelectObject(hdc, hrgn); PaintRgn(hdc, hrgn);
	HDC hdc; HRGN hrgn;
Example	The following example uses the CreateRectRgn function to create a rectangular region, selects the region into a device context, and then uses the PaintRgn function to display the region:
	When it has finished using a region created by CreateRectRgn , an application should remove the region by using the DeleteObject function.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
Return Value	The return value is the handle of a rectangular region if the function is successful. Otherwise, it is NULL.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the region.

CreateRectRgnIndirect

2.x

```
HRGN CreateRectRgnIndirect(lprc)
const RECT FAR* lprc; /* address of structure with region
```

The **CreateRectRgnIndirect** function creates a rectangular region by using a **RECT** structure.

Parameters

lprc

Points to a **RECT** structure that contains the logical coordinates of the upperleft and lower-right corners of the region. The **RECT** structure has the following form:

*/

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

	For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.
Return Value	The return value is the handle of the rectangular region if the function is success- ful. Otherwise, it is NULL.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
	When it has finished using a region created by CreateRectRgnIndirect , an application should remove the region by using the DeleteObject function.
Example	The following example assigns values to the members of a RECT structure, uses the CreateRectRgnIndirect function to create a rectangular region, selects the re- gion into a device context, and then uses the PaintRgn function to display the re- gion:
	RECT rc; HRGN hrgn;
	SetRect(&rc, 10, 10, 200, 50);
	hrgn = CreateRectRgnIndirect(&rc); SelectObject(hdc, hrgn); PaintRgn(hdc, hrgn);
See Also	CreateRectRgn, CreateRoundRectRgn, DeleteObject, PaintRgn

CreateRoundRectRgn

HRGN CreateRoundRectRgn(*nLeftRect*, *nTopRect*, *nRightRect*, *nBottomRect*, *nWidthEllipse*,

nHeightEllipse)		
int nLeftRect;	/* x-coordinate upper-left corner of region	*/
int nTopRect;	/* y-coordinate upper-left corner of region	*/
int nRightRect;	/* x-coordinate lower-right corner of region	*/
int nBottomRect;	/* y-coordinate lower-right corner of region	*/
int nWidthEllipse;	/* height of ellipse for rounded corners	*/
int nHeightEllipse;	/* width of ellipse for rounded corners	*/

The **CreateRoundRectRgn** function creates a rectangular region with rounded corners.

3.0

See Also	CreateRectRgn, CreateRectRgnIndirect, DeleteObject, PaintRgn
	<pre>hrgn = CreateRoundRectRgn(10, 10, 110, 110,</pre>
	HRGN hrgn; int nEllipWidth = 10; int nEllipHeight = 30;
Example	The following example uses the CreateRoundRectRgn function to create a re- gion, selects the region into a device context, and then uses the PaintRgn function to display the region:
	When it has finished using a region created by CreateRoundRectRgn , an application should remove the region by using the DeleteObject function.
Comments	The size of a region is limited to 32,767 by 32,767 logical units or 64K of memory, whichever is smaller.
Return Value	The return value is the handle of the region if the function is successful. Otherwise, it is NULL.
	<i>nHeightEllipse</i> Specifies the height of the ellipse used to create the rounded corners.
	<i>nWidthEllipse</i> Specifies the width of the ellipse used to create the rounded corners.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the region.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the region.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the region.
Parameters	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the region.

CreateScalableFontResource

BOOL CreateScalableFontResource(*fHidden*, *lpszResourceFile*, *lpszFontFile*, *lpszCurrentPath*)

UINT fHidden;	/* flag for read-only embedded font	*/
LPCSTR lpszResourceFile;	/* address of filename of font resource	*/
LPCSTR lpszFontFile;	/* address of filename of scalable font	*/
LPCSTR lpszCurrentPath;	/* address of path to font file	*/

The **CreateScalableFontResource** function creates a font resource file for the specified scalable font file.

Parameters

fHidden

Specifies whether the font is a read-only embedded font. This parameter can be one of the following values:

Value	Meaning
0	The font has read-write permission.
1	The font has read-only permission and should be hidden from other applications in the system. When this flag is set, the font is not enumerated by the EnumFonts or EnumFontFamilies function.

lpszResourceFile

Points to a null-terminated string specifying the name of the font resource file that this function creates.

lpszFontFile

Points to a null-terminated string specifying the scalable font file this function uses to create the font resource file. This parameter must specify either the filename and extension or a full path and filename, including drive and filename extension.

lpszCurrentPath

Points to a null-terminated string specifying either the path to the scalable font file specified in the *lpszFontFile* parameter or NULL, if *lpszFontFile* specifies a full path.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments

An application must use the **CreateScalableFontResource** function to create a font resource file before installing an embedded font. Font resource files for fonts with read-write permission should use the .FOT filename extension. Font resource files for read-only fonts should use a different extension (for example, .FOR) and should be hidden from other applications in the system by specifying 1 for the *fHidden* parameter. The font resource files can be installed by using the **Add-FontResource** function.

3.1

When the *lpszFontFile* parameter specifies only a filename and extension, the *lpszCurrentPath* parameter must specify a path. When the *lpszFontFile* parameter specifies a full path, the *lpszCurrentPath* parameter must be NULL or a pointer to NULL.

When only a filename and extension is specified in the *lpszFontFile* parameter and a path is specified in the *lpszCurrentPath* parameter, the string in *lpszFontFile* is copied into the .FOT file as the .TTF file that belongs to this resource. When the **AddFontResource** function is called, the system assumes that the .TTF file has been copied into the SYSTEM directory (or into the main Windows directory in the case of a network installation). The .TTF file need not be in this directory when the **CreateScalableFontResource** function is called, because the *lpszCurrentPath* parameter contains the directory information. A resource created in this manner does not contain absolute path information and can be used in any Windows installation.

When a path is specified in the *lpszFontFile* parameter and NULL is specified in the *lpszCurrentPath* parameter, the string in *lpszFontFile* is copied into the .FOT file. In this case, when the **AddFontResource** function is called, the .TTF file must be at the location specified in the *lpszFontFile* parameter when the **Create-ScalableFontResource** function was called; the *lpszCurrentPath* parameter is not needed. A resource created in this manner contains absolute references to paths and drives and will not work if the .TTF file is moved to a different location.

The **CreateScalableFontResource** function supports only TrueType scalable fonts.

The following example shows how to create a TrueType font file in the SYSTEM directory of the Windows startup directory:

CreateScalableFontResource(0, "c:\\windows\\system\\font.fot", "font.ttr", "c:\\windows\\system");

AddFontResource("c:\\windows\\system\\font.fot");

Example

The following example shows how to create a TrueType font file in a specified directory:

CreateScalableFontResource(0, "c:\\windows\\system\\font.fot", "c:\\fontdir\\font.ttr", NULL);

AddFontResource("c:\\windows\\system\\font.fot");

The following example shows how to work with a standard embedded font: HFONT hfont;

The following example shows how to work with a read-only embedded font: HFONT hfont;

AddFontResource

CreateSolidBrush

HBRUSH CreateSolidBrush(*clrref*) COLORREF *clrref*; /* brush color

> The **CreateSolidBrush** function creates a brush that has a specified solid color. The brush can subsequently be selected as the current brush for any device.

Parameters	<i>clrref</i> Specifies the color of the brush.
Return Value	The return value is the handle of the brush if the function is successful. Otherwise, it is NULL.
Comments	When an application has finished using the brush created by CreateSolidBrush , it should select the brush out of the device context and then remove it by using the DeleteObject function.
Example	The following example uses the CreateSolidBrush function to create a green brush, selects the brush into a device context, and then uses the brush to fill a rectangle:
	HBRUSH hbr0ld; HBRUSH hbr;
	hbr = CreateSolidBrush(RGB(0, 255, 0)); hbrOld = SelectObject(hdc, hbr); Rectangle(hdc, 10, 10, 100, 100);
See Also	CreateBrushIndirect, CreateDIBPatternBrush, CreateHatchBrush, CreatePatternBrush, DeleteObject

*/

CreateWindow

HWND CreateWindow(*lpszClassName*, *lpszWindowName*, *dwStyle*, *x*, *y*, *nWidth*, *nHeight*, *hwndParent*, *hmenu*, *hinst*, *lpvParam*)

LPCSTR lpszClassName;	/* address of registered class name	*/
LPCSTR lpszWindowName;	/* address of window text	*/
DWORD <i>dwStyle</i> ;	/* window style	*/
int x;	/* horizontal position of window	*/
int y;	/* vertical position of window	*/
int nWidth;	/* window width	*/
int nHeight;	/* window height	*/
HWND hwndParent;	/* handle of parent window	*/
HMENU hmenu;	/* handle of menu or child-window identifier	*/
HINSTANCE hinst;	/* handle of application instance	*/
void FAR* lpvParam;	/* address of window-creation data	*/

The **CreateWindow** function creates an overlapped, pop-up, or child window. The **CreateWindow** function specifies the window class, window title, window style, and (optionally) the initial position and size of the window. The **Create-Window** function also specifies the window's parent (if any) and menu.

Parameters

lpszClassName

Points to a null-terminated string specifying the window class. The class name can be any name registered with the **RegisterClass** function or any of the predefined control-class names. (See the following Comments section for a complete list.)

lpszWindowName

Points to a null-terminated string that represents the window name.

dwStyle

Specifies the style of window being created. This parameter can be a combination of the window styles and control styles given in the following Comments section.

х

Specifies the initial x-position of the window. For an overlapped or pop-up window, the *x* parameter is the initial x-coordinate of the window's upper-left corner, in screen coordinates. For a child window, *x* is the x-coordinate of the upper-left corner of the window in the client area of its parent window.

If this value is CW_USEDEFAULT, Windows selects the default position for the window's upper-left corner and ignores the *y* parameter. CW_USEDEFAULT is valid only for overlapped windows. If CW_USEDEFAULT is specified for a non-overlapped window, the *x* and *y* parameters are set to 0.

Specifies the initial y-position of the window. For an overlapped window, the *y* parameter is the initial y-coordinate of the window's upper-left corner. For a pop-up window, *y* is the y-coordinate, in screen coordinates, of the upper-left corner of the pop-up window. For list-box controls, *y* is the y-coordinate of the upper-left corner of the control's client area. For a child window, *y* is the y-coordinate of the upper-left corner of the upper-left corner of the control sclient area. For a child window. All of these coordinates are for the window, not the window's client area.

If an overlapped window is created with the WS_VISIBLE style and the *x* parameter set to CW_USEDEFAULT, Windows ignores the *y* parameter.

nWidth

Specifies the width, in device units, of the window. For overlapped windows, the *nWidth* parameter is either the window's width (in screen coordinates) or CW_USEDEFAULT. If *nWidth* is CW_USEDEFAULT, Windows selects a default width and height for the window (the default width extends from the initial x-position to the right edge of the screen, and the default height extends from the initial y-position to the top of the icon area). CW_USEDEFAULT is valid only for overlapped windows. If CW_USEDEFAULT is specified in *nWidth* for a non-overlapped window, *nWidth* and *nHeight* are set to 0.

nHeight

Specifies the height, in device units, of the window. For overlapped windows, the *nHeight* parameter is the window's height in screen coordinates. If the *nWidth* parameter is CW_USEDEFAULT, Windows ignores *nHeight*.

hwndParent

Identifies the parent or owner window of the window being created. A valid window handle must be supplied when creating a child window or an owned window. An owned window is an overlapped window that is destroyed when its owner window is destroyed, hidden when its owner is minimized, and that is always displayed on top of its owner window. For pop-up windows, a handle can be supplied but is not required. If the window does not have a parent window or is not owned by another window, the *hwndParent* parameter must be set to HWND_DESKTOP.

hmenu

Identifies a menu or a child window. This parameter's meaning depends on the window style. For overlapped or pop-up windows, the *hmenu* parameter identifies the menu to be used with the window. It can be NULL, if the class menu is to be used. For child windows, *hmenu* identifies the child window and is an integer value that is used by a dialog box control to notify its parent of events (such as the EN_HSCROLL message). The child window identifier is determined by the application and should be unique for all child windows with the same parent window.

hinst

Identifies the instance of the module to be associated with the window.

y

lpvParam

Points to a value that is passed to the window through the **CREATESTRUCT** structure referenced by the *lParam* parameter of the WM_CREATE message. If an application is calling **CreateWindow** to create a multiple document interface (MDI) client window, *lpvParam* must point to a **CLIENTCREATE-STRUCT** structure. The **CREATESTRUCT** structure has the following form:

```
typedef struct tagCREATESTRUCT {
                                                             /* cs */
                           void FAR* lpCreateParams:
                          HINSTANCE hInstance:
                          HMENU
                                     hMenu:
                          HWND
                                     hwndParent:
                           int
                                     сy;
                           int
                                     cx;
                           int
                                     у:
                           int
                                     x:
                           LONG
                                     style:
                           LPCSTR
                                     lpszName;
                           LPCSTR
                                     lpszClass;
                           DWORD
                                     dwExStyle;
                      } CREATESTRUCT;
                      The CLIENTCREATESTRUCT structure has the following form:
                      typedef struct tagCLIENTCREATESTRUCT { /* ccs */
                          HANDLE hWindowMenu:
                          UINT
                                   idFirstChild:
                      } CLIENTCREATESTRUCT;
                      For a full description of these two structures, see the Microsoft Windows Pro-
                      grammer's Reference, Volume 3.
Return Value
                    The return value is the handle of the new window if the function is successful.
                    Otherwise, it is NULL.
Comments
                    For overlapped, pop-up, and child windows, the CreateWindow function sends
                    WM CREATE, WM GETMINMAXINFO, and WM NCCREATE messages to
                    the window. If the WS_VISIBLE style is specified, CreateWindow sends the win-
                    dow all the messages required to activate and show the window.
                    If the window style specifies a title bar, the window title pointed to by the
                    lpszWindowName parameter is displayed in the title bar. When using Create-
                    Window to create controls such as buttons, check boxes, and edit controls, use the
                    lpszWindowName parameter to specify the text of the control.
                    Before returning, the CreateWindow function sends a WM CREATE message to
                    the window procedure.
```

Following are the predefined control classes an application can specify in the *lpszClassName* parameter:

Class	Meaning
BUTTON	Designates a small rectangular child window that represents a but- ton the user can turn on or off by clicking. Button controls can be used alone or in groups, and can either be labeled or appear without text. Button controls typically change appearance when the user clicks them.
COMBOBOX	Designates a control consisting of a list box and a selection field similar to an edit control. The list box may be displayed at all times or may be dropped down when the user selects a pop-up list box next to the selection field.
	Depending on the style of the combo box, the user can or cannot edit the contents of the selection field. If the list box is visible, typing characters into the selection box will cause the first list box entry that matches the characters typed to be highlighted. Con- versely, selecting an item in the list box displays the selected text in the selection field.
EDIT	Designates a rectangular child window in which the user can type text from the keyboard. The user selects the control, and gives it the input focus by clicking it or moving to it by pressing the TAB key. The user can type text when the control displays a flashing caret. The mouse can be used to move the cursor and select characters to be replaced, or to position the cursor for inserting characters. The BACKSPACE key can be used to delete characters.
	Edit controls use the variable-pitch System font and display charac- ters from the Windows character set. Applications compiled to run with earlier versions of Windows display text with a fixed-pitch Sys- tem font unless they have been marked by the Windows 3.0 MARK utility (with the MEMORY FONT option specified). An applica- tion can also send the WM_SETFONT message to the edit control to change the default font.
	Edit controls expand tab characters into as many space characters as are required to move the cursor to the next tab stop. Tab stops are as- sumed to be at every eighth character position.
LISTBOX	Designates a list of character strings. This control is used whenever an application must present a list of names, such as filenames, from which the user can choose. The user can select a string by pointing to it and clicking. When a string is selected, it is highlighted and a notification message is passed to the parent window. A vertical or horizontal scroll bar can be used with a list box control to scroll lists that are too long for the control window. The list box automatically hides or shows the scroll bar as needed.

Class	Meaning
MDICLIENT	Designates an MDI client window. The MDI client window receives messages that control the MDI application's child windows. The rec- ommended style bits are WS_CLIPCHILDREN and WS_CHILD. To create a scrollable MDI client window that allows the user to scroll MDI child windows into view, an application can also use the WS_HSCROLL and WS_VSCROLL styles.
SCROLLBAR	Designates a rectangle that contains a scroll box (also called a "thumb") and has direction arrows at both ends. The scroll bar sends a notification message to its parent window whenever the user clicks the control. The parent window is responsible for updating the position, if necessary. Scroll bar controls have the same appearance and function as scroll bars used in ordinary windows. Unlike scroll bars, however, scroll bar controls can be positioned anywhere in a window and used whenever needed to provide scrolling input for a window.
	The scroll bar class also includes size box controls (Maximize and Minimize buttons). These controls are small rectangles that the user can click to change the size of the window.
STATIC	Designates a simple text field, box, or rectangle that can be used to label, box, or separate other controls. Static controls take no input and provide no output.

Following are the window styles an application can specify in the *dwStyle* parameter.

Style	Meaning
MDIS_ALLCHILDSTYLES	Creates an MDI child window that can have any combination of window styles. When this style is not specified, an MDI child window has the WS_MINIMIZE, WS_MAXIMIZE, WS_HSCROLL, and WS_VSCROLL styles as default settings.
WS_BORDER	Creates a window that has a border.
WS_CAPTION	Creates a window that has a title bar (implies the WS_BORDER style). This style cannot be used with the WS_DLGFRAME style.
WS_CHILD	Creates a child window. Cannot be used with the WS_POPUP style.
WS_CHILDWINDOW	Same as the WS_CHILD style.
WS_CLIPCHILDREN	Excludes the area occupied by child windows when drawing within the parent window. Used when creating the parent window.

Style	Meaning
WS_CLIPSIBLINGS	Clips child windows relative to each other; that is, when a particular child window receives a paint message, the WS_CLIPSIBLINGS style clips all other overlapped child windows out of the region of the child window to be updated. (If WS_CLIPSIBLINGS is not specified and child windows overlap, it is possible, when drawing within the client area of a child window, to draw within the client area of a neighboring child win- dow.) For use with the WS_CHILD style only.
WS_DISABLED	Creates a window that is initially disabled.
WS_DLGFRAME	Creates a window with a double border but no title.
WS_GROUP	Specifies the first control of a group of controls in which the user can move from one control to the next by using the arrow keys. All controls defined with the WS_GROUP style after the first control belong to the same group. The next control with the WS_GROUP style ends the style group and starts the next group (that is, one group ends where the next begins). Only dialog boxes use this style.
WS_HSCROLL	Creates a window that has a horizontal scroll bar.
WS_MAXIMIZE	Creates a window of maximum size.
WS_MAXIMIZEBOX	Creates a window that has a Maximize button.
WS_MINIMIZE	Creates a window that is initially minimized. For use with the WS_OVERLAPPED style only.
WS_MINIMIZEBOX	Creates a window that has a Minimize button.
WS_OVERLAPPED	Creates an overlapped window. An overlapped window has a title and a border.
WS_OVERLAPPEDWINDOW	Creates an overlapped window having the WS_OVERLAPPED, WS_CAPTION, WS_SYSMENU, WS_THICKFRAME, WS_MINIMIZEBOX, and WS_MAXIMIZEBOX styles.
WS_POPUP	Creates a pop-up window. Cannot be used with the WS_CHILD style.
WS_POPUPWINDOW	Creates a pop-up window that has the WS_BORDER, WS_POPUP, and WS_SYSMENU styles. The WS_CAPTION style must be combined with the WS_POPUPWINDOW style to make the System menu visible.
WS_SYSMENU	Creates a window that has a System-menu box in its title bar. Used only for windows with title bars.

Style	Meaning
WS_TABSTOP	Specifies one of any number of controls through which the user can move by using the TAB key. The TAB key moves the user to the next control specified by the WS_TABSTOP style. Only dialog boxes use this style.
WS_THICKFRAME	Creates a window with a thick frame that can be used to size the window.
WS_VISIBLE	Creates a window that is initially visible. This applies to overlapped, child, and pop-up windows. For overlapped windows, the <i>y</i> parameter is used as a ShowWindow function parameter.
WS_VSCROLL	Creates a window that has a vertical scroll bar.

Following are the button styles (in the BUTTON class) that an application can specify in the *dwStyle* parameter:

Value	Meaning
BS_3STATE	Creates a button that is the same as a check box, ex- cept that the box can be grayed (dimmed) as well as checked. The grayed state is used to show that the state of a check box is not determined.
BS_AUTO3STATE	Creates a button that is the same as a three-state check box, except that the box changes its state when the user selects it. The state cycles through checked, grayed, and normal.
BS_AUTOCHECKBOX	Creates a button that is the same as a check box, except that an X appears in the check box when the user selects the box; the X disappears (is cleared) the next time the user selects the box.
BS_AUTORADIOBUTTON	Creates a button that is the same as a radio button, ex- cept that when the user selects it, the button automat- ically highlights itself and clears (removes the selection from) any other buttons in the same group.
BS_CHECKBOX	Creates a small square that has text displayed to its right (unless this style is combined with the BS_LEFTTEXT style).
BS_DEFPUSHBUTTON	Creates a button that has a heavy black border. The user can select this button by pressing the ENTER key. This style is useful for enabling the user to quickly select the most likely option (the default option).
BS_GROUPBOX	Creates a rectangle in which other controls can be grouped. Any text associated with this style is dis- played in the rectangle's upper-left corner.

Value	Meaning
BS_LEFTTEXT	Places text on the left side of the radio button or check box when combined with a radio button or check box style.
BS_OWNERDRAW	Creates an owner-drawn button. The owner window receives a WM_MEASUREITEM message when the button is created, and it receives a WM_DRAWITEM message when a visual aspect of the button has changed. The BS_OWNERDRAW style cannot be combined with any other button styles.
BS_PUSHBUTTON	Creates a push button that posts a WM_COMMAND message to the owner window when the user selects the button.
BS_RADIOBUTTON	Creates a small circle that has text displayed to its right (unless this style is combined with the BS_LEFTTEXT style). Radio buttons are usually used in groups of related but mutually exclusive choices.

Following are the combo box styles (in the COMBOBOX class) that an application can specify in the *dwStyle* parameter:

Style	Description
CBS_AUTOHSCROLL	Automatically scrolls the text in the edit con- trol to the right when the user types a character at the end of the line. If this style is not set, only text that fits within the rectangular bound- ary is allowed.
CBS_DISABLENOSCROLL	Shows a disabled vertical scroll bar in the list box when the box does not contain enough items to scroll. Without this style, the scroll bar is hidden when the list box does not contain enough items.
CBS_DROPDOWN	Similar to CBS_SIMPLE, except that the list box is not displayed unless the user selects an icon next to the edit control.
CBS_DROPDOWNLIST	Similar to CBS_DROPDOWN, except that the edit control is replaced by a static text item that displays the current selection in the list box.
CBS_HASSTRINGS	Specifies that an owner-drawn combo box con- tains items consisting of strings. The combo box maintains the memory and pointers for the strings so the application can use the CB_GETLBTEXT message to retrieve the text for a particular item.

Style	Description
CBS_NOINTEGRALHEIGHT	Specifies that the size of the combo box is ex- actly the size specified by the application when it created the combo box. Normally, Windows sizes a combo box so that the combo box does not display partial items.
CBS_OEMCONVERT	Converts text entered in the combo-box edit control from the Windows character set to the OEM character set and then back to the Win- dows set. This ensures proper character conver- sion when the application calls the AnsiToOem function to convert a Windows string in the combo box to OEM characters. This style is most useful for combo boxes that contain filenames and applies only to combo boxes created with the CBS_SIMPLE or CBS_DROPDOWN styles.
CBS_OWNERDRAWFIXED	Specifies that the owner of the list box is re- sponsible for drawing its contents and that the items in the list box are all the same height. The owner window receives a WM_MEASUREITEM message when the combo box is created and a WM_DRAWITEM message when a visual aspect of the combo box changes.
CBS_OWNERDRAWVARIABLE	Specifies that the owner of the list box is re- sponsible for drawing its contents and that the items in the list box are variable in height. The owner window receives a WM_MEASURE- ITEM message for each item in the combo box when the combo box is created and a WM_DRAWITEM message when a visual aspect of the combo box changes.
CBS_SIMPLE	Displays the list box at all times. The current selection in the list box is displayed in the edit control.

Following are the edit control styles (in the EDIT class) that an application can specify in the *dwStyle* parameter:

Style	Meaning
ES_AUTOHSCROLL	Automatically scrolls text to the right by 10 characters when the user types a character at the end of the line. When the user presses the ENTER key, the control scrolls all text back to position zero.

Style	Meaning
ES_AUTOVSCROLL	Automatically scrolls text up one page when the user presses ENTER on the last line.
ES_CENTER	Centers text in a multiline edit control.
ES_LEFT	Left aligns text.
ES_LOWERCASE	Converts all characters to lowercase as they are typed into the edit control.
ES_MULTILINE	Designates a multiline edit control. (The default is single- line edit control.)
	When a multiline edit control is in a dialog box, the default response to pressing the ENTER key is to activate the default button. To use the ENTER key as a carriage return, an appli- cation should use the ES_WANTRETURN style.
	When the multiline edit control is not in a dialog box and the ES_AUTOVSCROLL style is specified, the edit control shows as many lines as possible and scrolls vertically when the user presses the ENTER key. If ES_AUTOVSCROLL is not specified, the edit control shows as many lines as possible and beeps if the user presses ENTER when no more lines can be displayed.
	If the ES_AUTOHSCROLL style is specified, the multiline edit control automatically scrolls horizontally when the caret goes past the right edge of the control. To start a new line, the user must press ENTER. If ES_AUTOHSCROLL is not specified, the control automatically wraps words to the beginning of the next line when necessary. A new line is also started if the user presses ENTER. The position of the wordwrap is determined by the window size. If the window size changes, the wordwrap position changes and the text is redisplayed.
	Multiline edit controls can have scroll bars. An edit control with scroll bars processes its own scroll bar messages. Edit controls without scroll bars scroll as described in the pre- vious two paragraphs and process any scroll messages sent by the parent window.
ES_NOHIDESEL	Negates the default behavior for an edit control. The default behavior is to hide the selection when the control loses the input focus and invert the selection when the control re- ceives the input focus.
ES_OEMCONVERT	Converts text entered in the edit control from the Windows character set to the OEM character set and then back to the Windows set. This ensures proper character conversion when the application calls the AnsiToOem function to con- vert a Windows string in the edit control to OEM characters. This style is most useful for edit controls that contain filenames.

Style	Meaning
ES_PASSWORD	Displays all characters as an asterisk (*) as they are typed into the edit control. An application can use the EM_SETPASSWORDCHAR message to change the charac- ter that is displayed.
ES_READONLY	Prevents the user from typing or editing text in the edit con- trol.
ES_RIGHT	Right aligns text in a multiline edit control.
ES_UPPERCASE	Converts all characters to uppercase as they are typed into the edit control.
ES_WANTRETURN	Specifies that a carriage return be inserted when the user presses the ENTER key while entering text into a multiline edit control in a dialog box. If this style is not specified, pressing the ENTER key has the same effect as pressing the dialog box's default push button. This style has no effect on a single-line edit control.

Following are the list box styles (in the LISTBOX class) that an application can specify in the *dwStyle* parameter:

Style	Meaning
LBS_DISABLENOSCROLL	Shows a disabled vertical scroll bar for the list box when the box does not contain enough items to scroll. If this style is not specified, the scroll bar is hidden when the list box does not contain enough items.
LBS_EXTENDEDSEL	Allows multiple items to be selected by using the SHIFT key and the mouse or special key combinations.
LBS_HASSTRINGS	Specifies that a list box contains items con- sisting of strings. The list box maintains the memory and pointers for the strings so the ap- plication can use the LB_GETTEXT message to retrieve the text for a particular item. By de- fault, all list boxes except owner-drawn list boxes have this style. An application can create an owner-drawn list box either with or without this style.
LBS_MULTICOLUMN	Specifies a multicolumn list box that is scrolled horizontally. The LB_SETCOLUMNWIDTH message sets the width of the columns.
LBS_MULTIPLESEL	Turns string selection on or off each time the user clicks or double-clicks the string. Any number of strings can be selected.

Style	Meaning
LBS_NOINTEGRALHEIGHT	Specifies that the size of the list box is exactly the size specified by the application when it created the list box. Normally, Windows sizes a list box so that the list box does not display par- tial items.
LBS_NOREDRAW	Specifies that the list box's appearance is not updated when changes are made. This style can be changed at any time by sending a WM_SETREDRAW message.
LBS_NOTIFY	Notifies the parent window with an input mes- sage whenever the user clicks or double-clicks a string.
LBS_OWNERDRAWFIXED	Specifies that the owner of the list box is re- sponsible for drawing its contents and that the items in the list box are the same height. The owner window receives a WM_MEASURE- ITEM message when the list box is created and a WM_DRAWITEM message when a visual aspect of the list box changes.
LBS_OWNERDRAWVARIABLE	Specifies that the owner of the list box is responsible for drawing its contents and that the items in the list box are variable in height. The owner window receives a WM_MEASUREITEM message for each item in the list box when the list box is created and a WM_DRAWITEM message whenever the visual aspect of the list box changes.
LBS_SORT	Sorts strings in the list box alphabetically.
LBS_STANDARD	Sorts strings in the list box alphabetically. The parent window receives an input message whenever the user clicks or double-clicks a string. The list box has borders on all sides.
LBS_USETABSTOPS	Allows a list box to recognize and expand tab characters when drawing its strings. The de- fault tab positions are 32 dialog box units. (A dialog box unit is a horizontal or vertical dis- tance. One horizontal dialog box unit is equal to one-fourth of the current dialog box base width unit. The dialog box base units are com- puted based on the height and width of the cur- rent system font. The GetDialogBaseUnits function returns the current dialog box base units in pixels.)

Style	Meaning
LBS_WANTKEYBOARDINPUT	Specifies that the owner of the list box receives WM_VKEYTOITEM or WM_CHARTOITEM messages whenever the user presses a key and the list box has the input focus. This allows an application to perform special processing on the keyboard input. If a list box has the LBS_HASSTRINGS style, the list box can re- ceive WM_VKEYTOITEM messages but not WM_CHARTOITEM messages. If a list box does not have the LBS_HASSTRINGS style, the list box can receive WM_CHARTOITEM messages but not WM_VKEYTOITEM mes- sages.

Following are the scroll bar styles (in the SCROLLBAR class) that an application can specify in the *dwStyle* parameter:

Style	Meaning
SBS_BOTTOMALIGN	Aligns the bottom edge of the scroll bar with the bottom edge of the rectangle de- fined by the following CreateWindow parameters: <i>x</i> , <i>y</i> , <i>nWidth</i> , and <i>nHeight</i> . The scroll bar has the default height for system scroll bars. Used with the SBS_HORZ style.
SBS_HORZ	Designates a horizontal scroll bar. If neither the SBS_BOTTOMALIGN nor SBS_TOPALIGN style is specified, the scroll bar has the height, width, and posi- tion specified by the CreateWindow pa- rameters.
SBS_LEFTALIGN	Aligns the left edge of the scroll bar with the left edge of the rectangle de- fined by the CreateWindow parameters. The scroll bar has the default width for system scroll bars. Used with the SBS_VERT style.

Style	Meaning
SBS_RIGHTALIGN	Aligns the right edge of the scroll bar with the right edge of the rectangle de- fined by the CreateWindow parameters. The scroll bar has the default width for system scroll bars. Used with the SBS_VERT style.
SBS_SIZEBOX	Designates a size box. If neither the SBS_SIZEBOXBOTTOMRIGHTALIGN nor SBS_SIZEBOXTOPLEFTALIGN style is specified, the size box has the height, width, and position specified by the CreateWindow parameters.
SBS_SIZEBOXBOTTOMRIGHTALIGN	Aligns the lower-right corner of the size box with the lower-right corner of the rectangle specified by the Create- Window parameters. The size box has the default size for system size boxes. Used with the SBS_SIZEBOX style.
SBS_SIZEBOXTOPLEFTALIGN	Aligns the upper-left corner of the size box with the upper-left corner of the rectangle specified by the following CreateWindow parameters: <i>x</i> , <i>y</i> , <i>nWidth</i> , and <i>nHeight</i> . The size box has the default size for system size boxes. Used with the SBS_SIZEBOX style.
SBS_TOPALIGN	Aligns the top edge of the scroll bar with the top edge of the rectangle de- fined by the CreateWindow parameters. The scroll bar has the default height for system scroll bars. Used with the SBS_HORZ style.
SBS_VERT	Designates a vertical scroll bar. If neither the SBS_RIGHTALIGN nor SBS_LEFTALIGN style is specified, the scroll bar has the height, width, and posi- tion specified by the CreateWindow pa- rameters.

Following are the static control styles (in the STATIC class) that an application can specify in the *dwStyle* parameter. A static control can have only one of these styles.

Style	Meaning
SS_BLACKFRAME	Specifies a box with a frame drawn in the same color as window frames. This color is black in the default Windows color scheme.
SS_BLACKRECT	Specifies a rectangle filled with the color used to draw window frames. This color is black in the default Win- dows color scheme.
SS_CENTER	Designates a simple rectangle and displays the given text centered in the rectangle. The text is formatted before it is displayed. Words that would extend past the end of a line are automatically wrapped to the beginning of the next centered line.
SS_GRAYFRAME	Specifies a box with a frame drawn with the same color as the screen background (desktop). This color is gray in the default Windows color scheme.
SS_GRAYRECT	Specifies a rectangle filled with the color used to fill the screen background. This color is gray in the de- fault Windows color scheme.
SS_ICON	Designates an icon displayed in the dialog box. The given text is the name of an icon (not a filename) defined elsewhere in the resource file. The <i>nWidth</i> and <i>nHeight</i> parameters are ignored; the icon automatically sizes itself.
SS_LEFT	Designates a simple rectangle and displays the given text left-aligned in the rectangle. The text is formatted before it is displayed. Words that would extend past the end of a line are automatically wrapped to the beginning of the next left-aligned line.
SS_LEFTNOWORDWRAP	Designates a simple rectangle and displays the given text left-aligned in the rectangle. Tabs are expanded but words are not wrapped. Text that extends past the end of a line is clipped.
SS_NOPREFIX	Prevents interpretation of any & characters in the con- trol's text as accelerator prefix characters (which are displayed with the & removed and the next character in the string underlined). This static control style may be included with any of the defined static controls. You can combine SS_NOPREFIX with other styles by using the bitwise OR operator. This is most often used when filenames or other strings that may contain an & need to be displayed in a static control in a dialog box.

Style	Meaning
SS_RIGHT	Designates a simple rectangle and displays the given text right-aligned in the rectangle. The text is for- matted before it is displayed. Words that would extend past the end of a line are automatically wrapped to the beginning of the next right-aligned line.
SS_SIMPLE	Designates a simple rectangle and displays a single line of text left-aligned in the rectangle. The line of text cannot be shortened or altered in any way. (The control's parent window or dialog box must not process the WM_CTLCOLOR message.)
SS_WHITEFRAME	Specifies a box with a frame drawn in the same color as window backgrounds. This color is white in the de- fault Windows color scheme.
SS_WHITERECT	Specifies a rectangle filled with the color used to fill window backgrounds. This color is white in the de- fault Windows color scheme.

Following are the dialog box styles an application can specify in the *dwStyle* parameter:

Style	Meaning
DS_LOCALEDIT	Specifies that edit controls in the dialog box will use memory in the application's data segment. By default, all edit controls in dialog boxes use memory outside the applica- tion's data segment. This feature may be suppressed by adding the DS_LOCALEDIT flag to the Style command for the dialog box. If this flag is not used, EM_GETHANDLE and EM_SETHANDLE messages must not be used, because the storage for the control is not in the application's data seg- ment. This feature does not affect edit controls created out- side of dialog boxes.
DS_MODALFRAME	Creates a dialog box with a modal dialog box frame that can be combined with a title bar and System menu by specifying the WS_CAPTION and WS_SYSMENU styles.
DS_NOIDLEMSG	Suppresses WM_ENTERIDLE messages that Windows would otherwise send to the owner of the dialog box while the dialog box is displayed.
DS_SYSMODAL	Creates a system-modal dialog box.

CreateWindowEx

HWND CreateWindowEx(*dwExStyle*, *lpszClassName*, *lpszWindowName*, *dwStyle*, *x*, *y*, *nWidth*, *nHeight*, *hwndParent*, *hmenu*, *hinst*, *lpvCreateParams*)

miergni, nivnui ureni, ninenu,	(ninsi, ipvCreater arams)	
DWORD dwExStyle;	/* extended window style	*/
LPCSTR lpszClassName;	/* address of registered class name	*/
LPCSTR lpszWindowName;	/* address of window text	*/
DWORD <i>dwStyle</i> ;	/* window style	*/
int x;	/* horizontal position of the window	*/
int y;	/* vertical position of the window	*/
int nWidth;	/* window width	*/
int nHeight;	/* window height	*/
HWND hwndParent;	/* handle of parent window	*/
HMENU hmenu;	/* handle of menu or child-window identifier	*/
HINSTANCE hinst;	/* handle of application instance	*/
<pre>void FAR* lpvCreateParams;</pre>	/* address of window-creation data	*/

The **CreateWindowEx** function creates an overlapped, pop-up, or child window with an extended style; otherwise, this function is identical to the **CreateWindow** function. For more information about creating a window and for full descriptions of the other parameters of **CreateWindowEx**, see the preceding description of the **CreateWindow** function.

Parameters

dwExStyle

Specifies the extended style of the window. This parameter can be one of the following values:

Style	Meaning
WS_EX_ACCEPTFILES	Specifies that a window created with this style accepts drag-drop files.
WS_EX_DLGMODALFRAME	Designates a window with a double border that may (optionally) be created with a title bar by specifying the WS_CAPTION style flag in the <i>dwStyle</i> parameter.
WS_EX_NOPARENTNOTIFY	Specifies that a child window created by using this style will not send the WM_PARENTNOTIFY message to its parent window when the child window is created or destroyed.
WS_EX_TOPMOST	Specifies that a window created with this style should be placed above all non-topmost win- dows and stay above them even when the win- dow is deactivated. An application can use the SetWindowPos function to add or remove this attribute.

Style	Meaning
WS_EX_TRANSPARENT	Specifies that a window created with this style is to be transparent. That is, any windows that are beneath the window are not obscured by the window. A window created with this style receives WM_PAINT messages only after all sibling windows beneath it have been updated.

lpszClassName

Points to a null-terminated string containing the name of the window class.

lpszWindowName

Points to a null-terminated string containing the name of the window.

dwStyle

Specifies the style of the window. For a list of the window styles that can be specified in this parameter, see the preceding description of the **CreateWindow** function.

х

Specifies the initial left-side position of the window.

y

Specifies the initial top position of the window.

nWidth

Specifies the width, in device units, of the window.

nHeight

Specifies the height, in device units, of the window.

hwndParent

Identifies the parent or owner window of the window to be created.

hmenu

Identifies a menu or a child window. The meaning depends on the window style.

hinst

Identifies the instance of the module to be associated with the window.

lpvCreateParams

Contains any application-specific creation parameters. The window being created may access this data when the **CREATESTRUCT** structure is passed to the window by the WM_NCCREATE and WM_CREATE messages.

The **CREATESTRUCT** structure has the following form:

	<pre>typedef struct tagCREATESTRUCT { /* cs */ void FAR* lpCreateParams; HINSTANCE hInstance; HMENU hMenu; HWND hwndParent; int cy; int cx; int y; int x; LONG style; LPCSTR lpszName; LPCSTR lpszClass; DWORD dwExStyle; CREATESTRUCT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>	
Return Value	The return value identifies the new window if the function is successful. Otherwise, it is NULL.	
Comments	The CreateWindowEx function sends the following messages to the window being created:	
	WM_NCCREATE WM_NCCALCSIZE WM_CREATE	
Example	The following example creates a main window that has the WS_EX_TOPMOST extended style, makes the window visible, and updates the window's client area:	
	char szClassName[] = "MyClass";	
	/* Create the main window. */	
	<pre>hwnd = CreateWindowEx(WS_EX_TOPMOST, szClassName, "Grouper", WS_OVERLAPPEDWINDOW, CW_USEDEFAULT, CW_USEDEFAULT, CW_USEDEFAULT, CW_USEDEFAULT, NULL, NULL, hinst, NULL);</pre>	
	/* Make the window visible and update its client area. */	
	ShowWindow(hwnd, SW_SHOW);	
See Also	CreateWindow, SetWindowPos	

DdeAbandonTransaction

#include <ddeml.h>

BOOL DdeAbando DWORD idInst; HCONV hConv; DWORD idTransac	nTransaction(<i>idInst</i> , <i>hConv</i> , <i>idTransaction</i>) /* instance identifier */ /* handle of conversation */ <i>tion</i> ; /* transaction identifier */
	The DdeAbandonTransaction function abandons the specified asynchronous transaction and releases all resources associated with the transaction.
Parameters	<i>idInst</i> Specifies the application-instance identifier obtained by a previous call to the DdeInitialize function.
	<i>hConv</i> Identifies the conversation in which the transaction was initiated. If this parameter is NULL, all transactions are abandoned (the <i>idTransaction</i> parameter is ignored).
	<i>idTransaction</i> Identifies the transaction to terminate. If this parameter is NULL, all active transactions in the specified conversation are abandoned.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR DMLERR_UNFOUND_QUEUE_ID
Comments	Only a dynamic data exchange (DDE) client application should call the Dde- AbandonTransaction function. If the server application responds to the transac- tion after the client has called DdeAbandonTransaction , the system discards the transaction results. This function has no effect on synchronous transactions.
See Also	DdeClientTransaction, DdeGetLastError, DdeInitialize, DdeQueryConvInfo

DdeAccessData

#include <ddeml.h>

BYTE FAR* DdeAd HDDEDATA hData DWORD FAR* lpcl		
	The DdeAccessData function provides access to the data in the given global memory object. An application must call the DdeUnaccessData function when it is finished accessing the data in the object.	
Parameters	hData Identifies the global memory object to access.	
	<i>lpcbData</i> Points to a variable that receives the size, in bytes, of the global memory object identified by the <i>hData</i> parameter. If this parameter is NULL, no size informa- tion is returned.	
Return Value	The return value points to the first byte of data in the global memory object if the function is successful. Otherwise, the return value is NULL.	
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:	
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR	
Comments	If the <i>hData</i> parameter has not been passed to a Dynamic Data Exchange Management Library (DDEML) function, an application can use the pointer returned by DdeAccessData for read-write access to the global memory object. If <i>hData</i> has already been passed to a DDEML function, the pointer can only be used for read-only access to the memory object.	
Example	The following example uses the DdeAccessData function to obtain a pointer to a global memory object, uses the pointer to copy data from the object to a local buffer, then frees the pointer:	
	HDDEDATA hData; LPBYTE lpszAdviseData; DWORD cbDataLen; DWORD i; char szData[128];	
	lpszAdviseData = DdeAccessData(hData, &cbDataLen);	

for (i = 0; i < cbDataLen; i++)
 szData[i] = *lpszAdviseData++;
DdeUnaccessData(hData);</pre>

DdeAddData

3.1

HDDEDATA DdeA HDDEDATA hData void FAR* lpvSrcBi DWORD cbAddDat DWORD offObj;	<i>if</i> ; /* address of source buffer */
	The DdeAddData function adds data to the given global memory object. An appli- cation can add data beginning at any offset from the beginning of the object. If new data overlaps data already in the object, the new data overwrites the old data in the bytes where the overlap occurs. The contents of locations in the object that have not been written to are undefined.
Parameters	<i>hData</i> Identifies the global memory object that receives additional data. <i>lpvSrcBuf</i>
	Points to a buffer containing the data to add to the global memory object.
	<i>cbAddData</i> Specifies the length, in bytes, of the data to be added to the global memory object.
	<i>offObj</i> Specifies an offset, in bytes, from the beginning of the global memory object. The additional data is copied to the object beginning at this offset.
Return Value	The return value is a new handle of the global memory object if the function is successful. The new handle should be used in all references to the object. The return value is zero if an error occurs.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:

	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_MEMORY_ERROR DMLERR_NO_ERROR
Comments	After a data handle has been used as a parameter in another Dynamic Data Ex- change Management Library (DDEML) function or returned by a DDE callback function, the handle may only be used for read access to the global memory object identified by the handle.
	If the amount of global memory originally allocated is not large enough to hold the added data, the DdeAddData function will reallocate a global memory object of the appropriate size.
Example	The following example creates a global memory object, uses the DdeAddData function to add data to the object, and then passes the data to a client with an XTYP_POKE transaction:
	DWORD idInst; /* instance identifier */ HDDEDATA hddeStrings; /* data handle */ HSZ hszMyItem; /* item-name string handle */ DWORD offObj = 0; /* offset in global object */ char szMyBuf[16]; /* temporary string buffer */ HCONV hconv; /* conversation handle */ DWORD dwResult; /* transaction results */ BOOL fAddAString; /* TRUE if strings to add */
	<pre>/* Create a global memory object. */ hddeStrings = DdeCreateDataHandle(idInst, NULL, 0, 0, hszMyItem, CF_TEXT, 0);</pre>
	/* * If a string is available, the application-defined function * IsThereAString() copies it to szMyBuf and returns TRUE. Otherwise, * it returns FALSE. */
	<pre>while ((fAddAString = IsThereAString())) {</pre>
	/* Add the string to the global memory object. */
	DdeAddData(hddeStrings, /* data handle */ &szMyBuf, /* string buffer */ (DWORD) strlen(szMyBuf) + 1, /* character count */ offObj); /* offset in object */
	offObj = (DWORD) strlen(szMyBuf) + 1; /* adjust offset */ }

3.1

/* No more data to add, so poke it to the server. */

HSZ hsz2;	/* handle of string	*/
HDDEDATA hData;	/* handle of global memory object	*/
DWORD dwData1;	/* transaction-specific data	*/
DWORD dwData2;	/* transaction-specific data	*/
()	he DdeCallback function is an application DDE) callback function that processes DI esult of DDE Management Library (DDE	DE transactions sent to the function as a
Parameters ty	<i>spe</i> Specifies the type of the current transac nation of transaction-class flags and tran describes each of the transaction classes	

Specifies the type of the current transaction. This parameter consists of a combination of transaction-class flags and transaction-type flags. The following table describes each of the transaction classes and provides a list of the transaction types in each class. For information about a specific transaction type, see the individual description of that type in the *Microsoft Windows Programmer's Reference, Volume 3.*

Value	Meaning
XCLASS_BOOL	A DDE callback function should return TRUE or FALSE when it finishes processing a transaction that belongs to this class. Following are the XCLASS_BOOL transaction types:
	XTYP_ADVSTART XTYP_CONNECT

Value	Meaning
XCLASS_DATA	A DDE callback function should return a DDE data handle, CBR_BLOCK, or NULL when it finishes processing a transaction that belongs to this class. Following are the XCLASS_DATA transaction types: XTYP_ADVREQ XTYP_REQUEST XTYP_WILDCONNECT
XCLASS_FLAGS	A DDE callback function should return DDE_FACK, DDE_FBUSY, or DDE_FNOTPROCESSED when it finishes processing a transaction that belongs to this class. Following are the XCLASS_FLAGS transaction types: XTYP_ADVDATA XTYP_EXECUTE XTYP_POKE
XCLASS_NOTIFICATION	The transaction types that belong to this class are for notification purposes only. The return value from the callback function is ignored. Following are the XCLASS_NOTIFICATION transaction types: XTYP_ADVSTOP XTYP_CONNECT_CONFIRM XTYP_DISCONNECT XTYP_ERROR XTYP_MONITOR XTYP_REGISTER XTYP_XACT_COMPLETE XTYP_UNREGISTER

fmt

Specifies the format in which data is to be sent or received.

hconv

Identifies the conversation associated with the current transaction.

hsz1

Identifies a string. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type.

hsz2

Identifies a string. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type.

	 <i>hData</i> Identifies DDE data. The meaning of this parameter depends on the type of the current transaction. For more information, see the description of the transaction type. <i>dwData1</i> Specifies transaction-specific data. For more information, see the description of the transaction of the transaction type.
	<i>dwData2</i> Specifies transaction-specific data. For more information, see the description of the transaction type.
Return Value	The return value depends on the transaction class. For more information about return values, see the descriptions of the individual DDE transactions in the <i>Microsoft Windows Programmer's Reference</i> , <i>Volume 3</i> .
Comments	The callback function is called asynchronously for transactions that do not involve creating or terminating conversations. An application that does not frequently accept incoming messages will have reduced DDE performance because DDEML uses messages to initiate transactions.
	An application must register the callback function by specifying its address in a call to the DdeInitialize function. DdeCallback is a placeholder for the application- or library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition file.

DdeClientTransaction

#include <ddeml.h>

HDDEDATA DdeClientTransaction(lpvData, cbData, hConv, hszItem, uFmt, uType, uTimeout,

lpuResult)		
void FAR* lpvData;	/* address of data to pass to server	*/
DWORD <i>cbData</i> ;	/* length of data	*/
HCONV hConv;	/* handle of conversation	*/
HSZ hszItem;	/* handle of item-name string	*/
UINT <i>uFmt</i> ;	/* clipboard data format	*/
UINT <i>uType</i> ;	/* transaction type	*/
DWORD uTimeout;	/* timeout duration	*/
DWORD FAR* <i>lpuResult</i> ;	/* points to transaction result	*/

The **DdeClientTransaction** function begins a data transaction between a client and a server. Only a dynamic data exchange (DDE) client application can call this function, and only after establishing a conversation with the server.

Parameters

lpvData

Points to the beginning of the data that the client needs to pass to the server.

Optionally, an application can specify the data handle (HDDEDATA) to pass to the server, in which case the *cbData* parameter should be set to -1. This parameter is required only if the *uType* parameter is XTYP_EXECUTE or XTYP_POKE. Otherwise, this parameter should be NULL.

cbData

Specifies the length, in bytes, of the data pointed to by the *lpvData* parameter. A value of -1 indicates that *lpvData* is a data handle that identifies the data being sent.

hConv

Identifies the conversation in which the transaction is to take place.

hszItem

Identifies the data item for which data is being exchanged during the transaction. This handle must have been created by a previous call to the **DdeCreate-StringHandle** function. This parameter is ignored (and should be set to NULL) if the *uType* parameter is XTYP_EXECUTE.

uFmt

Specifies the standard clipboard format in which the data item is being submitted or requested. For more information about standard clipboard formats, see the *Microsoft Windows Guide to Programming*.

иТуре

Specifies the transaction type. This parameter can be one of the following values:

Value	Meaning		
XTYP_ADVSTART	RT Begins an advise loop. Any number of distinct advise loops can exist within a conversation. An application can alter the advise loop type by combining the XTYP_ADVSTART transaction type with one or more of the following flags:		
	Value	Meaning	
	XTYPF_NODATA	Instructs the server to notify the client of any data changes without actually sending the data. This flag gives the client the option of ignoring the notification or re- questing the changed data from the server.	

	Meaning	
	Value	Meaning
	XTYPF_ACKREQ	Instructs the server to wait until the client acknowledges that it re- ceived the previous data item before sending the next data item This flag prevents a fast server from sending data faster than the client can process it.
XTYP_ADVSTOP	Ends an advise loop.	
XTYP_EXECUTE	Begins an execute tra	nsaction.
XTYP_POKE	Begins a poke transac	tion.
XTYP_REQUEST	Begins a request trans	action.
Points to a variable that does not check the	he result can set this va	of the transaction. An application lue to NULL. For synchronous iable will contain any applicable

Errors

	DMLERR_EXECACKTIMEOUT
	DMLERR_INVALIDPARAMETER
	DMLERR_MEMORY_ERROR
	DMLERR_NO_CONV_ESTABLISHED
	DMLERR_NO_ERROR
	DMLERR_NOTPROCESSED
	DMLERR_POKEACKTIMEOUT
	DMLERR_POSTMSG_FAILED
	DMLERR_REENTRANCY
	DMLERR_SERVER_DIED
	DMLERR_UNADVACKTIMEOUT
Comments	When the application is finished using the data handle returned by the DdeClient-Transaction function, the application should free the handle by calling the Dde-FreeDataHandle function.
	Transactions can be synchronous or asynchronous. During a synchronous transac- tion, the DdeClientTransaction function does not return until the transaction completes successfully or fails. Synchronous transactions cause the client to enter a modal loop while waiting for various asynchronous events. Because of this, the client application can still respond to user input while waiting on a synchronous transaction but cannot begin a second synchronous transaction because of the ac- tivity associated with the first. The DdeClientTransaction function fails if any in- stance of the same task has a synchronous transaction already in progress.
	During an asynchronous transaction, the DdeClientTransaction function returns after the transaction is begun, passing a transaction identifier for reference. When the server's DDE callback function finishes processing an asynchronous transaction, the system sends an XTYP_XACT_COMPLETE transaction to the client. This transaction provides the client with the results of the asynchronous transaction that it initiated by calling the DdeClientTransaction function. A client application can choose to abandon an asynchronous transaction by calling the DdeAbandonTransaction function.
Example	The following example requests an advise loop with a DDE server application:
	HCONV hconv; HSZ hszNow;

HSZ hszNow; HDDEDATA hData; DWORD dwResult;

3.1

```
hData = DdeClientTransaction(
   (LPBYTE) NULL. /* pass no data to server */
   0,
                /* no data
                                          */
                /* conversation handle
   hconv.
                                          */
   hszNow,
                /* item name
                                          */
   CF_TEXT,
                /* clipboard format
                                        */
   XTYP_ADVSTART, /* start an advise loop */
   1000. /* time-out in one second */
   &dwResult); /* points to result flags */
```

DdeCmpStringHandles

	StringHandles(<i>h</i> /* handle of fir /* handle of see	st string *	•	
			les function compares the values o e is not related to the case of the as	
Parameters	hsz2	fies the first string		
Return Value	The retur	n value can be on	e of the following:	
	Value	Meaning		
	-1	The value of hszl	' is either 0 or less than the value of hs	5z2.
	0	The values of hsz	I and hsz^2 are equal (both can be 0).	
	1	The value of hsz2	is either 0 or less than the value of hs	<i>sz1</i> .
Comments	should co StringH	ompare the string l	o do a case-sensitive comparison on nandles directly. An application sh r comparisons to preserve the case DE).	ould use DdeComp-

The **DdeCompStringHandles** function cannot be used to sort string handles alphabetically.

Example

This example compares two service-name string handles and, if the handles are the same, requests a conversation with the server, then issues an XTYP_ADVSTART transaction:

```
HSZ hszClock: /* service name */
HSZ hszTime; /* topic name
                               */
HSZ hsz1;
              /∗ unknown server
                                           */
             /* conversation handle
HCONV hConv:
                                           */
DWORD dwResult; /* result flags
                                           */
DWORD idInst: /* instance identifier
                                           */
/*
* Compare unknown service name handle with the string handle
* for the clock application.
*/
if (!DdeCmpStringHandles(hsz1, hszClock)) {
    /*
     * If this is the clock application, start a conversation
     * with it and request an advise loop.
     */
    hConv = DdeConnect(idInst, hszClock, hszTime, NULL);
    if (hConv != (HCONV) NULL)
       DdeClientTransaction(NULL, 0, hConv, hszNow,
            CF_TEXT, XTYP_ADVSTART, 1000, &dwResult);
}
```

DdeConnect

HCONV DdeConnect(idInst, hszSe	ervice, hszTopic, pCC)	
DWORD <i>idInst</i> ;	/* instance identifier	*/
HSZ hszService;	/* handle of service-name string	*/
HSZ hszTopic;	/* handle of topic-name string	*/
CONVCONTEXT FAR* <i>pCC</i> ;	/* address of structure with context data	*/

*/

The **DdeConnect** function establishes a conversation with a server application that supports the specified service name and topic name pair. If more than one such server exists, the system selects only one.

Parameters

Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.

hszService

idInst

Identifies the string that specifies the service name of the server application with which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, a conversation will be established with any available server.

hszTopic

Identifies the string that specifies the name of the topic on which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, a conversation on any topic supported by the selected server will be established.

pCC

Points to the **CONVCONTEXT** structure that contains conversation-context information. If this parameter is NULL, the server receives the default **CONV-CONTEXT** structure during the XTYP_CONNECT or XTYP_WILDCONNECT transaction.

The **CONVCONTEXT** structure has the following form:

```
#include <ddeml.h>
typedef struct tagCONVCONTEXT { /* cc
UINT cb;
UINT wFlags;
UINT wCountryID;
int iCodePage;
DWORD dwLangID;
DWORD dwSecurity;
} CONVCONTEXT:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Return Value The return value is the handle of the established conversation if the function is successful. Otherwise, it is NULL.

Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:		
	DMLERR_DLL_NOT_INITIAI DMLERR_INVALIDPARAME DMLERR_NO_CONV_ESTAB DMLERR_NO_ERROR	TER	
Comments	be selected. If an instance-specific conversation will be established a service names are passed to an approximation during the XTYP_REGISTER All members of the default CON	make assumptions regarding which server w ic name is specified in the <i>hszService</i> parameter only with the specified instance. VCONTEXT structure are set to zero except fucture, and iCodePage , which specifies page).	ter, a cific func-
Example	The following example creates a service-name string handle and a topic-name string handle, then attempts to establish a conversation with a server that supports the service name and topic name. If the attempt fails, the example retrieves an error value identifying the reason for the failure.		
	DWORD idInst = 0L; HSZ hszClock; HSZ hszTime; HCONV hconv; UINT uError;		
	hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI); hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI);		
	<pre>if ((hconv = DdeConnect(idInst, hszClock, hszTime, NULL)) == NULL) { uError = DdeGetLastError(}</pre>	/* server's service name * /* topic name * /* use default CONVCONTEXT *	< / < / < /
See Also	DdeConnectList, DdeCreateSt	ringHandle, DdeDisconnect,	

DdeDisconnectList, DdeInitialize

DdeConnectList

#include <ddeml.h>

HCONVLIST DdeConnectList (<i>idInst</i> , <i>hszService</i> , <i>hszTopic</i> , <i>hConvList</i> , <i>pCC</i>)			
DWORD <i>idInst</i> ;	/* instance identifier	*/	
HSZ hszService;	/* handle of service-name string	*/	
HSZ hszTopic;	/* handle of topic-name string	*/	
HCONVLIST hConvList;	/* handle of conversation list	*/	
CONVCONTEXT FAR* <i>pCC</i> ;	/* address of structure with context data	*/	

The **DdeConnectList** function establishes a conversation with all server applications that support the specified service/topic name pair. An application can also use this function to enumerate a list of conversation handles by passing the function an existing conversation handle. During enumeration, the Dynamic Data Exchange Management Library (DDEML) removes the handles of any terminated conversations from the conversation list. The resulting conversation list contains the handles of all conversations currently established that support the specified service name and topic name.

Parameters

idInst

Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.

hszService

Identifies the string that specifies the service name of the server application with which a conversation is to be established. If this parameter is NULL, the system will attempt to establish conversations with all available servers that support the specified topic name.

hszTopic

Identifies the string that specifies the name of the topic on which a conversation is to be established. This handle must have been created by a previous call to the **DdeCreateStringHandle** function. If this parameter is NULL, the system will attempt to establish conversations on all topics supported by the selected server (or servers).

hConvList

Identifies the conversation list to be enumerated. This parameter should be set to NULL if a new conversation list is to be established.

pCC

Points to the **CONVCONTEXT** structure that contains conversation-context information. If this parameter is NULL, the server receives the default **CONVCONTEXT** structure during the XTYP_CONNECT or XTYP_WILDCONNECT transaction.

The **CONVCONTEXT** structure has the following form:

	<pre>#include <ddeml.h></ddeml.h></pre>
	<pre>typedef struct tagCONVCONTEXT { /* cc */ UINT cb; UINT wFlags; UINT wCountryID; int iCodePage; DWORD dwLangID; DWORD dwSecurity; } CONVCONTEXT; For a full description of this structure, see the Microsoft Windows Program-</pre>
	mer's Reference, Volume 3.
Return Value	The return value is the handle of a new conversation list if the function is success- ful. Otherwise, it is NULL. The handle of the old conversation list is no longer valid.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALID_PARAMETER DMLERR_NO_CONV_ESTABLISHED DMLERR_NO_ERROR DMLERR_SYS_ERROR
Comments	An application must free the conversation-list handle returned by this function, re- gardless of whether any conversation handles within the list are active. To free the handle, an application can call the DdeDisconnectList function.
	All members of the default CONVCONTEXT structure are set to zero except cb , which specifies the size of the structure, and iCodePage , which specifies CP_WINANSI (the default code page).
Example	The following example uses the DdeConnectList function to establish a conversa- tion with all servers that support the System topic, counts the servers, allocates a buffer for storing the server's service-name string handles, and then copies the han- dles to the buffer:

```
HCONVLIST hconvList: /* conversation list
                                                */
DWORD idInst:
                    /* instance identifier
                                                */
                    /* System topic
HSZ hszSystem;
                                                */
HCONV hconv = NULL: /* conversation handle
                                                */
CONVINFO ci:
                    /* holds conversation data */
UINT cConv = 0;
                    /* count of conv. handles */
HSZ *pHsz. *aHsz:
                    /* point to string handles */
/* Connect to all servers that support the System topic. */
hconvList = DdeConnectList(idInst, (HSZ) NULL, hszSystem,
    (HCONV) NULL, (LPVOID) NULL);
/* Count the number of handles in the conversation list. */
while ((hconv = DdeQueryNextServer(hconvList. hconv)) != (HCONV) NULL)
    cConv++:
/* Allocate a buffer for the string handles. */
hconv = (HCONV) NULL;
aHsz = (HSZ *) LocalAlloc(LMEM FIXED, cConv * sizeof(HSZ));
/* Copy the string handles to the buffer. */
pHsz = aHsz:
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != (HCONV) NULL) {
    DdeQueryConvInfo(hconv, QID_SYNC, (PCONVINFO) &ci);
    DdeKeepStringHandle(idInst, ci.hszSvcPartner);
    *pHsz++ = ci.hszSvcPartner:
}
. /* Use the handles; converse with servers. */
/* Free the memory and terminate conversations. */
LocalFree((HANDLE) aHsz):
DdeDisconnectList(hconvList);
```

DdeCreateDataHandle

#include <ddeml.h>

HDDEDATA DdeCreateDataHandle(idInst, lpvSrcBuf, cbInitData, offSrcBuf, hszItem, uFmt, afCmd)			
DWORD idInst;	/* instance identifier	*/	
<pre>void FAR* lpvSrcBuf;</pre>	/* address of source buffer	*/	
DWORD <i>cbInitData</i> ;	/* length of global memory object	*/	
DWORD offSrcBuf;	/* offset from beginning of source buffer	*/	
HSZ hszItem;	/* handle of item-name string	*/	
UINT <i>uFmt</i> ;	/* clipboard data format	*/	
UINT afCmd;	/* creation flags	*/	

The **DdeCreateDataHandle** function creates a global memory object and fills the object with the data pointed to by the *lpvSrcBuf* parameter. A dynamic data exchange (DDE) application uses this function during transactions that involve passing data to the partner application.

Parameters

idInst

Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function

lpvSrcBuf

Points to a buffer that contains data to be copied to the global memory object. If this parameter is NULL, no data is copied to the object.

chInitData

Specifies the amount, in bytes, of memory to allocate for the global memory object. If this parameter is zero, the *lpvSrcBuf* parameter is ignored.

offSrcBuf

Specifies an offset, in bytes, from the beginning of the buffer pointed to by the *lpvSrcBuf* parameter. The data beginning at this offset is copied from the buffer to the global memory object.

hszItem

Identifies the string that specifies the data item corresponding to the global memory object. This handle must have been created by a previous call to the DdeCreateStringHandle function. If the data handle is to be used in an XTYP_EXECUTE transaction, this parameter must be set to NULL.

uFmt

Specifies the standard clipboard format of the data.

afCmd

Specifies the creation flags. This parameter can be HDATA_APPOWNED, which specifies that the server application that calls the DdeCreate-

DataHandle function will own the data handle that this function creates. This makes it possible for the server to share the data handle with multiple clients instead of creating a separate handle for each request. If this flag is set, the server

	must eventually free the shared memory object associated with this handle by using the DdeFreeDataHandle function. If this flag is not set, after the data handle is returned by the server's DDE callback function or used as a parameter in another DDE Management Library function, the handle becomes invalid in the application that creates the handle.
Return Value	The return value is a data handle if the function is successful. Otherwise, it is NULL.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_MEMORY_ERROR DMLERR_NO_ERROR
Comments	Any locations in the global memory object that are not filled are undefined.
	After a data handle has been used as a parameter in another DDEML function or has been returned by a DDE callback function, the handle may be used only for read access to the global memory object identified by the handle.
	If the application will be adding data to the global memory object (using the DdeAddData function) so that the object exceeds 64K in length, then the application should specify a total length (<i>cbInitData</i> + <i>offSrcData</i>) that is equal to the anticipated maximum length of the object. This avoids unnecessary data copying and memory reallocation by the system.
Example	The following example processes the XTYP_WILDCONNECT transaction by re- turning a data handle to an array of HSZPAIR structures—one for each topic name supported:
	#define CTOPICS 2
	UINT type; UINT fmt; HSZPAIR ahp[(CTOPICS + 1)]; HSZ ahszTopicList[CTOPICS]; HSZ hszServ, hszTopic; WORD i, j;
	if (type == XTYP_WILDCONNECT) {
	/* * Scan the topic list and create array of HSZPAIR data * structures. */

```
i = 0:
   for (i = 0; i < CTOPICS; i++) {
        if (hszTopic == (HSZ) NULL ||
               hszTopic == ahszTopicList[i]) {
            ahp[j].hszSvc = hszServ;
            ahp[j++].hszTopic = ahszTopicList[i]:
        }
   }
    /*
     * End the list with an HSZPAIR structure that contains NULL
    * string handles as its members.
     */
   ahp[j].hszSvc = NULL;
   ahp[j++].hszTopic = NULL;
   /*
     * Return a handle to a global memory object containing the
     * HSZPAIR structures.
     */
    return DdeCreateDataHandle(
        idInst.
                       /* instance identifier
                                                    */
                        /* points to HSZPAIR array */
        &ahp,
        sizeof(HSZ) * j, /* length of the array
                                                    */
        0.
                       /* start at the beginning */
       NULL.
                        /* no item-name string
                                                    */
                       /* return the same format */
        fmt,
       0);
                       /* let the system own it
                                                    */
}
```

DdeCreateStringHandle

#include <ddeml.h>

HSZ DdeCreateStringHandle(<i>idInst</i> , <i>lpszString</i> , <i>codepage</i>)			
DWORD <i>idInst</i> ;	/* instance identifier	*/	
LPCSTR lpszString;	/* address of null-terminated string	*/	
int codepage;	/* code page	*/	

The **DdeCreateStringHandle** function creates a handle that identifies the string pointed to by the *lpszString* parameter. A dynamic data exchange (DDE) client or server application can pass the string handle as a parameter to other DDE Management Library functions.

Parameters	<i>idInst</i> Specifies the application-instance identifier obtained by a previous call to the DdeInitialize function.
	<i>lpszString</i> Points to a buffer that contains the null-terminated string for which a handle is to be created. This string may be any length.
	<i>codepage</i> Specifies the code page used to render the string. This value should be either CP_WINANSI or the value returned by the GetKBCodePage function. A value of zero implies CP_WINANSI.
Return Value	The return value is a string handle if the function is successful. Otherwise, it is NULL.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR DMLERR_SYS_ERROR
Comments	Two identical strings always correspond to the same string handle. String handles are unique across all tasks that use the DDEML. That is, when an application creates a handle for a string and another application creates a handle for an identical string, the string handles returned to both applications are identical—regardless of case.
	The value of a string handle is not related to the case of the string it identifies.
	When an application has either created a string handle or received one in the call- back function and has used the DdeKeepStringHandle function to keep it, the ap- plication must free that string handle when it is no longer needed.
	An instance-specific string handle is not mappable from string handle to string to string handle again. This is shown in the following example, in which the DdeQueryString function creates a string from a string handle and then DdeCreateStringHandle creates a string handle from that string, but the two handles are not the same:
	DWORD idInst; DWORD cb; HSZ hszInst, hszNew; PSZ pszInst;
	DdeQueryString(idInst, hszInst, pszInst, cb, CP_WINANSI); hszNew = DdeCreateStringHandle(idInst, pszInst, CP_WINANSI); /* hszNew != hszInst ! */

Example The following example creates a service-name string handle and a topic-name string handle and then attempts to establish a conversation with a server that supports the service name and topic name. If the attempt fails, the example obtains an error value identifying the reason for the failure. DWORD idInst = 0L; HSZ hszClock: HSZ hszTime: HCONV hconv; UINT uError; hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI); hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI); if ((hconv = DdeConnect(/* instance identifier */ idInst. hszClock. /* server's service name */ hszTime, /* topic name */ NULL)) == NULL) { /* use default CONVCONTEXT */ uError = DdeGetLastError(idInst); }

3.1

DdeDisconnect

BOOL DdeDisconnect(hConv) HCONV hConv; /* handle of conversation */	
	The DdeDisconnect function terminates a conversation started by either the Dde-Connect or DdeConnectList function and invalidates the given conversation handle.
Parameters	<i>hConv</i> Identifies the active conversation to be terminated.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:

3.1

	DMLERR_DLL_NOT_INITIALIZED DMLERR_NO_CONV_ESTABLISHED DMLERR_NO_ERROR
Comments	Any incomplete transactions started before calling DdeDisconnect are immedi- ately abandoned. The XTYP_DISCONNECT transaction type is sent to the dy- namic data exchange (DDE) callback function of the partner in the conversation. Generally, only client applications need to terminate conversations.
See Also	DdeConnect, DdeConnectList, DdeDisconnectList

DdeDisconnectList

BOOL DdeDisconnectList(hConvList)HCONVLIST hConvList;/* handle of conversation list*/		
	The DdeDisconnectList function destroys the given conversation list and termi- nates all conversations associated with the list.	
Parameters	<i>hConvList</i> Identifies the conversation list. This handle must have been created by a pre- vious call to the DdeConnectList function.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:	
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR	
Comments	An application can use the DdeDisconnect function to terminate individual conversations in the list.	
See Also	DdeConnect, DdeConnectList, DdeDisconnect	

DdeEnableCallback

#include <ddeml.h>

BOOL DdeEnable(DWORD idInst; HCONV hConv; UINT uCmd;	Callback(<i>idInst</i> , <i>hConv</i> , <i>i</i> /* instance identifier /* handle of conversation /* the enable/disable fu	*/ 0 n */
		ck function enables or disables transactions for a specific conversations that the calling application currently has es-
	for that conversation in	tions for a conversation, the system places the transactions a transaction queue associated with the application. The ap- le the conversation as soon as possible to avoid losing
Parameters	<i>idInst</i> Specifies the applica DdeInitialize function	tion-instance identifier obtained by a previous call to the on.
	<i>hConv</i> Identifies the conver function affects all c	rsation to enable or disable. If this parameter is NULL, the onversations.
x	<i>uCmd</i> Specifies the function	n code. This parameter can be one of the following values:
、		n code. This parameter can be one of the following values: Meaning
,	Specifies the functio	*
	Specifies the functio Value	Meaning
	Specifies the functio Value EC_ENABLEALL	Meaning Enables all transactions for the specified conversation.
	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	MeaningEnables all transactions for the specified conversation.Enables one transaction for the specified conversation.Disables all blockable transactions for the specified conversation.A server application can disable the following transactions:
	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	MeaningEnables all transactions for the specified conversation.Enables one transaction for the specified conversation.Disables all blockable transactions for the specified conversation.A server application can disable the following transactions:XTYP_ADVSTART
•	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	Meaning Enables all transactions for the specified conversation. Enables one transaction for the specified conversation. Disables all blockable transactions for the specified conversation. A server application can disable the following transactions: XTYP_ADVSTART XTYP_ADVSTOP XTYP_EXECUTE
	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	Meaning Enables all transactions for the specified conversation. Enables one transaction for the specified conversation. Disables all blockable transactions for the specified conversation. A server application can disable the following transactions: XTYP_ADVSTART XTYP_ADVSTOP XTYP_EXECUTE XTYP_POKE
ΥΥΥΥ 	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	Meaning Enables all transactions for the specified conversation. Enables one transaction for the specified conversation. Disables all blockable transactions for the specified conversation. A server application can disable the following transactions: XTYP_ADVSTART XTYP_ADVSTOP XTYP_EXECUTE
	Specifies the functio <u>Value</u> EC_ENABLEALL EC_ENABLEONE	Meaning Enables all transactions for the specified conversation. Enables one transaction for the specified conversation. Disables all blockable transactions for the specified conversation. A server application can disable the following transactions: XTYP_ADVSTART XTYP_ADVSTOP XTYP_EXECUTE XTYP_POKE XTYP_REQUEST

Return Value

The return value is nonzero if the function is successful. Otherwise, it is zero.

3.1

Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_NO_ERROR DMLERR_INVALIDPARAMETER
Comments	An application can disable transactions for a specific conversation by returning CBR_BLOCK from its dynamic data exchange (DDE) callback function. When the conversation is reenabled by using the DdeEnableCallback function, the system generates the same transaction as was in process when the conversation was disabled.
See Also	DdeConnect, DdeConnectList, DdeDisconnect, DdeInitialize

DdeFreeDataHandle

BOOL DdeFreeDat HDDEDATA hData	
	The DdeFreeDataHandle function frees a global memory object and deletes the data handle associated with the object.
Parameters	<i>hData</i> Identifies the global memory object to be freed. This handle must have been created by a previous call to the DdeCreateDataHandle function or returned by the DdeClientTransaction function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR
Comments	An application must call DdeFreeDataHandle under the following circumstances:
	 To free a global memory object that the application allocated by calling the DdeCreateDataHandle function if the object's data handle was never passed

by the application to another Dynamic Data Exchange Management Library (DDEML) function

- To free a global memory object that the application allocated by specifying the HDATA_APPOWNED flag in a call to the **DdeCreateDataHandle** function
- To free a global memory object whose handle the application received from the **DdeClientTransaction** function

The system automatically frees an unowned object when its handle is returned by a dynamic data exchange (DDE) callback function or used as a parameter in a DDEML function.

Example The following example creates a global memory object containing help information, then frees the object after passing the object's handle to the client application:

DWORD idInst; HSZ hszItem; HDDEDATA hDataHelp;

```
char szDdeHelp[] = "DDEML test server help:\r\n"\
   "\tThe 'Server' (service) and 'Test' (topic) names may change.\r\n"\
   "Items supported under the 'Test' topic are:\r\n"\
    "\tCount:\tThis value increments on each data change.\r\n"\
    "\tRand:\tThis value is changed after each data change. \r\n"\
    "\t\tIn Runaway mode, the above items change after a request.\r\n"\
    "\tHuge:\tThis is randomly generated text data >64k that the\r\n"\
    "\t\ttest client can verify. It is recalculated on each\r\n"\
    "\t\trequest. This also verifies huge data poked or executed\r\n"\
    "\t\tfrom the test client.\r\n"\
    "\tHelp:\tThis help information. This data is APPOWNED.\r\n";
    /* Create global memory object containing help information. */
    if (!hDataHelp) {
        hDataHelp = DdeCreateDataHandle(idInst, szDdeHelp,
            strlen(szDdeHelp) + 1, 0, hszItem, CF_TEXT, HDATA_APPOWNED);
    }
    . /* Pass help information to client application. */
    /* Free the global memory object. */
    if (hDataHelp)
        DdeFreeDataHandle(hDataHelp);
```

DdeAccessData, DdeCreateDataHandle

See Also

DdeFreeStringHandle

#include <ddeml.h>

BOOL DdeFreeStr DWORD idInst; HSZ hsz;	ingHandle(idInst, hsz)/* instance identifier*//* handle of string*/
	The DdeFreeStringHandle function frees a string handle in the calling applica- tion.
Parameters	<i>idInst</i> Specifies the application-instance identifier obtained by a previous call to the DdeInitialize function.
	<i>hsz</i> Identifies the string handle to be freed. This handle must have been created by a previous call to the DdeCreateStringHandle function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	An application can free string handles that it creates with the DdeCreateString-Handle function but should not free those that the system passed to the application's dynamic data exchange (DDE) callback function or those returned in the CONVINFO structure by the DdeQueryConvInfo function.
Example	The following example frees string handles during the XTYP_DISCONNECT transaction:
	DWORD idInst = 0L; HSZ hszClock; HSZ hszTime; HSZ hszNow; UINT type;
	if (type == XTYP_DISCONNECT) {
	DdeFreeStringHandle(idInst, hszClock); DdeFreeStringHandle(idInst, hszTime); DdeFreeStringHandle(idInst, hszNow);
	return (HDDEDATA) NULL; }
See Also	DdeCmpStringHandles, DdeCreateStringHandle, DdeInitialize, DdeKeepStringHandle, DdeQueryString

DdeGetData

#include <ddeml.h>

DWORD DdeGetDa HDDEDATA hData void FAR* pDest; DWORD cbMax; DWORD offSrc;	ata(hData, pDest, cbMax, offSrc) '; /* handle of global memory object */ /* address of destination buffer */ /* amount of data to copy */ /* offset to beginning of data */			
	The DdeGetData function copies data from the given global memory object to the specified local buffer.			
Parameters	 <i>hData</i> Identifies the global memory object that contains the data to copy. <i>pDest</i> Points to the buffer that receives the data. If this parameter is NULL, the DdeGetData function returns the amount, in bytes, of data that would be copied to the buffer. 			
	<i>cbMax</i> Specifies the maximum amount, in bytes, of data to copy to the buffer pointed to by the <i>pDest</i> parameter. Typically, this parameter specifies the length of the buffer pointed to by <i>pDest</i> .			
	<i>offSrc</i> Specifies an offset within the global memory object. Data is copied from the object beginning at this offset.			
Return Value	If the <i>pDest</i> parameter points to a buffer, the return value is the size, in bytes, of the memory object associated with the data handle or the size specified in the <i>cbMax</i> parameter, whichever is lower.			
	If the <i>pDest</i> parameter is NULL, the return value is the size, in bytes, of the memory object associated with the data handle.			
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:			
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALID_HDDEDATA DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR			
Example	The following example copies data from a global memory object to a local buffer and then fills the TIME structure with data from the buffer:			

```
HDDEDATA hData;
char szBuf[32];
typedef struct {
    int hour;
    int minute;
    int second;
} TIME;
DdeGetData(hData, (LPBYTE) szBuf, 32L, 0L);
sscanf(szBuf, "%d:%d:%d", &nTime.hour, &nTime.minute,
    &nTime.second);
```

DdeGetLastError

```
3.1
```

#include <ddeml.h>

UINT DdeGetLast DWORD idInst;	Error(<i>idInst</i>) /* instance identifier */		
	The DdeGetLastError function returns failure of a Dynamic Data Exchange Ma resets the error value to DMLERR_NO_	nagement Library (DDEML) function and	
Parameters	<i>idInst</i> Specifies the application-instance iden DdeInitialize function.	ntifier obtained by a previous call to the	
Return Value	The return value is the last error value. Following are the possible DDEML error values:		
	Value	Meaning	
	DMLERR_ADVACKTIMEOUT	A request for a synchronous advise trans- action has timed out.	
	DMLERR_BUSY	The response to the transaction caused the DDE_FBUSY bit to be set.	
	DMLERR_DATAACKTIMEOUT	A request for a synchronous data transac- tion has timed out.	

Value	Meaning
DMLERR_DLL_NOT_INITIALIZED	A DDEML function was called without first calling the DdeInitialize function, or an invalid instance identifier was passed to a DDEML function.
DMLERR_DLL_USAGE	An application initialized as APPCLASS_MONITOR has attempted to perform a DDE transaction, or an application initialized as APPCMD_CLIENTONLY has attempted to perform server transactions.
DMLERR_EXECACKTIMEOUT	A request for a synchronous execute transaction has timed out.
DMLERR_INVALIDPARAMETER	A parameter failed to be validated by the DDEML. Some of the possible causes are as follows:
	• The application used a data handle ini- tialized with a different item-name handle than that required by the trans- action.
	 The application used a data handle that was initialized with a different clip- board data format than that required by the transaction.
	 The application used a client-side conversation handle with a server-side function or vise versa.
	 The application used a freed data handle or string handle.
	 More than one instance of the applica- tion used the same object.
DMLERR_LOW_MEMORY	A DDEML application has created a pro- longed race condition (where the server application outruns the client), causing large amounts of memory to be con- sumed.
DMLERR_MEMORY_ERROR	A memory allocation failed.
DMLERR_NO_CONV_ESTABLISHED	A client's attempt to establish a conversa- tion has failed.
DMLERR_NOTPROCESSED	A transaction failed.
DMLERR_POKEACKTIMEOUT	A request for a synchronous poke transac tion has timed out.
DMLERR_POSTMSG_FAILED	An internal call to the PostMessage func tion has failed.

Value	Meaning
DMLERR_REENTRANCY	An application instance with a syn- chronous transaction already in progress attempted to initiate another synchronous transaction, or the DdeEnableCallback function was called from within a DDEML callback function.
DMLERR_SERVER_DIED	A server-side transaction was attempted on a conversation that was terminated by the client, or the server terminated before completing a transaction.
DMLERR_SYS_ERROR	An internal error has occurred in the DDEML.
DMLERR_UNADVACKTIMEOUT	A request to end an advise transaction has timed out.
DMLERR_UNFOUND_QUEUE_ID	An invalid transaction identifier was passed to a DDEML function. Once the application has returned from an XTYP_XACT_COMPLETE callback, the transaction identifier for that callback is no longer valid.

Example The following example calls the **DdeGetLastError** function if the **DdeCreate-DataHandle** function fails:

```
DWORD idInst:
HDDEDATA hddeMyData;
HSZPAIR ahszp[2];
HSZ hszClock. hszTime:
/* Create string handles. */
hszClock = DdeCreateStringHandle(idInst, (LPSTR) "Clock",
   CP_WINANSI);
hszTime = DdeCreateStringHandle(idInst, (LPSTR) "Time",
   CP_WINANSI);
/* Copy handles to an HSZPAIR structure. */
ahszp[0].hszSvc = hszClock;
ahszp[0].hszTopic = hszTime;
ahszp[1].hszSvc = (HSZ) NULL;
ahszp[1].hszTopic = (HSZ) NULL;
/* Create a global memory object. */
hddeMyData = DdeCreateDataHandle(idInst, ahszp,
        sizeof(ahszp), 0, NULL, CF_TEXT, 0);
   if (hddeMyData == NULL)
```

```
/*
 * Pass error value to application-defined error handling
 * function.
 */
```

HandleError(DdeGetLastError(idInst));

DdeInitialize

#include <ddeml.h>

UINT DdeInitialize DWORD FAR* lpia PFNCALLBACK p DWORD afCmd; DWORD uRes;	dInst;	<i>llback, afCmd, uRes</i>) /* address of instance identifier /* address of callback function /* array of command and filter flags /* reserved	*/ */ */
	change Manag	lize function registers an application wit gement Library (DDEML). An applicatio any other DDEML function.	
should poin stance ident parameter in multiple ins		e application-instance identifier. At initia t to OL. If the function is successful, this tifier for the application. This value shou n all other DDEML functions that requir stances of the DDEML dynamic link libr ifferent callback function for each instan	parameter points to the in- ld be passed as the <i>idInst</i> e it. If an application uses ary, the application should
If <i>lpidInst</i> points to a nonzero value, this implie DDEML. In this case, <i>lpidInst</i> must point to a v fier.			
<i>pfnCallback</i> Points to the application-defined DDE callback function. Thi processes DDE transactions sent by the system. For more inf description of the DdeCallback callback function.			
	vide special	n array of APPCMD_ and CBF_ flags. T I instructions to the DdeInitialize function event specific types of transactions from	on. The CBF_ flags set fil-

function. Using these flags enhances the performance of a DDE application by eliminating unnecessary calls to the callback function.

This parameter can be a combination of the following flags:

Flag	Meaning
APPCLASS_MONITOR	Makes it possible for the application to monitor DDE activity in the system. This flag is for use by DDE monitoring appli- cations. The application specifies the types of DDE activity to monitor by com- bining one or more monitor flags with the APPCLASS_MONITOR flag. For details, see the following Comments sec- tion.
APPCLASS_STANDARD	Registers the application as a standard (nonmonitoring) DDEML application.
APPCMD_CLIENTONLY	Prevents the application from becoming a server in a DDE conversation. The ap- plication can be only a client. This flag reduces resource consumption by the DDEML. It includes the functionality of the CBF_FAIL_ALLSVRXACTIONS flag.
APPCMD_FILTERINITS	Prevents the DDEML from sending XTYP_CONNECT and XTYP_WILDCONNECT transactions to the application until the application has created its string handles and registered its service names or has turned off filtering by a subsequent call to the DdeNameService or DdeInitialize func- tion. This flag is always in effect when an application calls DdeInitialize for the first time, regardless of whether the appli- cation specifies this flag. On subsequent calls to DdeInitialize , not specifying this flag turns off the application's service- name filters; specifying this flag turns on the application's service-name filters.
CBF_FAIL_ALLSVRXACTIONS	Prevents the callback function from re- ceiving server transactions. The system will return DDE_FNOTPROCESSED to each client that sends a transaction to this application. This flag is equivalent to combining all CBF_FAIL_ flags.

Flag	Meaning
CBF_FAIL_ADVISES	Prevents the callback function from receiving XTYP_ADVSTART and XTYP_ADVSTOP transactions. The system will return DDE_FNOTPROCESSED to each client that sends an XTYP_ADVSTART or XTYP_ADVSTOP transaction to the server.
CBF_FAIL_CONNECTIONS	Prevents the callback function from receiving XTYP_CONNECT and XTYP_WILDCONNECT transactions.
CBF_FAIL_EXECUTES	Prevents the callback function from receiving XTYP_EXECUTE transactions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_EXECUTE transac- tion to the server.
CBF_FAIL_POKES	Prevents the callback function from receiving XTYP_POKE trans- actions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_POKE transaction to the server.
CBF_FAIL_REQUESTS	Prevents the callback function from receiving XTYP_REQUEST transactions. The system will return DDE_FNOTPROCESSED to a client that sends an XTYP_REQUEST transac- tion to the server.
CBF_FAIL_SELFCONNECTIONS	Prevents the callback function from re- ceiving XTYP_CONNECT transactions from the application's own instance. This prevents an application from establishing a DDE conversation with its own in- stance. An application should use this flag if it needs to communicate with other instances of itself but not with it- self.
CBF_SKIP_ALLNOTIFICATIONS	Prevents the callback function from re- ceiving any notifications. This flag is equivalent combining all CBF_SKIP_ flags.
CBF_SKIP_CONNECT_CONFIRMS	Prevents the callback function from re- ceiving XTYP_CONNECT_CONFIRM notifications.

	Flag		Meaning	
	CBF_SKIP_DISCC	DNNECTS	Prevents the callback function from re- ceiving XTYP_DISCONNECT notifica- tions.	
	CBF_SKIP_REGIS	STRATIONS	Prevents the callback function from re- ceiving XTYP_REGISTER notifications.	
	CBF_SKIP_UNRE	GISTRATIONS	Prevents the callback function from re- ceiving XTYP_UNREGISTER notifica- tions.	
	<i>uRes</i> Reserved; must be	e set to 0L.		
Return Value	The return value is o	one of the following:		
	DMLERR_DLL_US DMLERR_INVALI DMLERR_NO_ERI DMLERR_SYS_ER	DPARAMETER ROR		
Comments		An application that uses multiple instances of the DDEML must not pass DDEML objects between instances.		
	A DDE monitoring application should not attempt to perform DDE (establish conversations, issue transactions, and so on) within the context of the same application instance.			
		ous transaction will fail with a DMLERR_REENTRANCY error if any the same task has a synchronous transaction already in progress.		
	A DDE monitoring application can combine one or more of the following monitor flags with the APPCLASS_MONITOR flag to specify the types of DDE activity to monitor:			
	Flag	Meaning		
	MF_CALLBACKS		function whenever a transaction is sent to anction in the system.	
	MF_CONV	Notifies the callback lished or terminated.	function whenever a conversation is estab-	
	MF_ERRORS	Notifies the callback	function whenever a DDE error occurs.	
	MF_HSZ_INFO	creates, frees, or incr	function whenever a DDE application ements the use count of a string handle or ndle is freed as a result of a call to the ction.	

	Flag	Meaning	
	MF_LINKS	Notifies the callback function whenever an advise loop is started or ended.	
	MF_POSTMSGS	Notifies the callback function whenever the system or an appli- cation posts a DDE message.	
	MF_SENDMSGS	Notifies the callback function whenever the system or an appli- cation sends a DDE message.	
Example	The following example obtains a procedure-instance address for a DDE callbac function, then initializes the application with the DDEML.		
	DWORD idInst = 0L FARPROC lpDdeProc	,	
	if (DdeInitialize	ProcInstance((FARPROC) DDECallback, hInst); e((LPDWORD) &idInst, (PFNCALLBACK) lpDdeProc, _IENTONLY, ØL))

DdeKeepStringHandle

#include <ddeml.h>

BOOL DdeKeepStr DWORD idInst; HSZ hsz;	ingHandle (<i>idInst</i> , <i>hsz</i>) /* instance identifier /* handle of string	*/ */
	one) associated with the g cation to save a string har change (DDE) callback fu	dle function increments the usage count (increases it by given handle. This function makes it possible for an appli- dle that was passed to the application's dynamic data ex- unction. Otherwise, a string handle passed to the callback the callback function returns.
Parameters	<i>idInst</i> Specifies the application DdeInitialize function <i>hsz</i> Identifies the string ha	

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero. Example The following example is a portion of a DDE callback function that increases the usage count and saves a local copy of two string handles: HSZ hsz1: HSZ hsz2; static HSZ hszServerBase: static HSZ hszServerInst: DWORD idInst; case XTYP_REGISTER: /* Keep the handles for later use. */ DdeKeepStringHandle(idInst, hsz1); DdeKeepStringHandle(idInst, hsz2); hszServerBase = hsz1; hszServerInst = hsz2; . /* Finish processing the transaction. */ See Also DdeCreateStringHandle, DdeFreeStringHandle, DdeInitialize,

DdeCreateStringHandle, DdeFreeStringHandle, DdeInitialize DdeQueryString

DdeNameService

#include <ddeml.h>

HDDEDATA DdeNameService(<i>idInst</i> , <i>hsz1</i> , <i>hszRes</i> , <i>afCmd</i>)			
DWORD idInst;	/* instance identifier	*/	
HSZ hsz1;	/* handle of service-name string	*/	
HSZ hszRes;	/* reserved	*/	
UINT afCmd;	/* service-name flags	*/	

The **DdeNameService** function registers or unregisters the service names that a dynamic data exchange (DDE) server supports. This function causes the system to send XTYP_REGISTER or XTYP_UNREGISTER transactions to other running DDE Management Library (DDEML) client applications.

A server application should call this function to register each service name that it supports and to unregister names that it previously registered but no longer supports. A server should also call this function to unregister its service names just before terminating.

Parameters

idInst

Specifies the application-instance identifier obtained by a previous call to the **D**deInitialize function.

hsz1

Identifies the string that specifies the service name that the server is registering or unregistering. An application that is unregistering all of its service names should set this parameter to NULL.

hszRes

Reserved; should be set to NULL.

afCmd

Specifies the service-name flags. This parameter can be one of the following values:

	Value	Meaning	
	DNS_REGISTER	Registers the given service name.	
	DNS_UNREGISTER	Unregisters the given service name. If the <i>hsz1</i> parameter is NULL, all service names registered by the server will be unregistered.	
	DNS_FILTERON	Turns on service-name initiation filtering. This filter pre- vents a server from receiving XTYP_CONNECT transac- tions for service names that it has not registered. This is the default setting for this filter.	
		If a server application does not register any service names, the application cannot receive XTYP_WILDCONNECT transactions.	
	DNS_FILTEROFF	Turns off service-name initiation filtering. If this flag is set, the server will receive an XTYP_CONNECT transac- tion whenever another DDE application calls the Dde- Connect function, regardless of the service name.	
Return Value	The return value is nonze	ro if the function is successful. Otherwise, it is zero.	
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:		
	DMLERR_DLL_NOT_I DMLERR_DLL_USAGE DMLERR_INVALIDPA DMLERR_NO_ERROR	Ξ	
Comments	the name should contain n an instance-specific name XTYP_REGISTER and X	ed by the <i>hsz1</i> parameter should be a base name (that is, no instance-specific information). The system generates e and sends it along with the base name during the KTYP_UNREGISTER transactions. The receiving appli- to the specific application instance.	

Example The following example initializes an application with the DDEML, creates frequently used string handles, and registers the application's service name:

```
HSZ hszClock:
HSZ hszTime:
HSZ hszNow;
HINSTANCE hinst;
DWORD idInst = 0L:
FARPROC lpDdeProc:
/* Initialize the application for the DDEML. */
lpDdeProc = MakeProcInstance((FARPROC) DdeCallback, hinst);
if (!DdeInitialize((LPDWORD) &idInst, (PFNCALLBACK) lpDdeProc,
        APPCMD_FILTERINITS | CBF_FAIL_EXECUTES, 0L)) {
   /* Create frequently used string handles. */
   hszTime = DdeCreateStringHandle(idInst, "Time", CP_WINANSI);
   hszNow = DdeCreateStringHandle(idInst, "Now", CP_WINANSI);
   hszClock = DdeCreateStringHandle(idInst, "Clock", CP_WINANSI);
    /* Register the service name. */
   DdeNameService(idInst, hszClock, (HSZ) NULL, DNS_REGISTER);
}
```

See Also DdeConnect, DdeConnectList, DdeInitialize

DdePostAdvise

#include <ddeml.h>

BOOL DdePostAd	vise(idInst, hszTopic, hszItem)	
DWORD <i>idInst</i> ;	/* instance identifier	*/
HSZ hszTopic;	/* handle of topic-name string	*/
HSZ hszItem;	/* handle of item-name string	*/

The **DdePostAdvise** function causes the system to send an XTYP_ADVREQ transaction to the calling (server) application's dynamic data exchange (DDE) callback function for each client that has an advise loop active on the specified topic or item name pair. A server application should call this function whenever the data associated with the topic or item name pair changes.

Parameters	<i>idInst</i> Specifies the application-instance identifier obtained by a previous call to the DdeInitialize function.
	<i>hszTopic</i> Identifies a string that specifies the topic name. To send notifications for all top- ics with active advise loops, an application can set this parameter to NULL.
	<i>hszItem</i> Identifies a string that specifies the item name. To send notifications for all items with active advise loops, an application can set this parameter to NULL.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_DLL_USAGE DMLERR_NO_ERROR
Comments	A server that has nonenumerable topics or items should set the <i>hszTopic</i> and <i>hszItem</i> parameters to NULL so that the system will generate transactions for all active advise loops. The server's DDE callback function returns NULL for any advise loops that do not need to be updated.
	If a server calls DdePostAdvise with a topic/item/format name set that includes the set currently being handled in a XTYP_ADVREQ callback, a stack overflow may result.
Example	The following example calls the DdePostAdvise function whenever the time changes:
	<pre>typedef struct { /* tm */ int hour; int minute; int second; } TIME;</pre>
	TIME tmTime; DWORD idInst; HSZ hszTime; HSZ hszNow; TIME tmCurTime;
	. /* Fill tmCurTime with the current time. */

/* Check for any change in second, minute, or hour. */
if ((tmCurTime.second != tmTime.second) ||
 (tmCurTime.minute != tmTime.minute) ||
 (tmCurTime.hour != tmTime.hour)) {
 /* Send the current time to the clients. */
 DdePostAdvise(idInst, hszTime, hszNow);

See Also DdeInitialize

DdeQueryConvInfo

UINT DdeQueryConvInfo (<i>hConv</i> ,	idTransaction, lpConvInfo)	
HCONV hConv;	/* handle of conversation	*/
DWORD idTransaction;	/* transaction identifier	*/
CONVINFO FAR* <i>lpConvInfo</i> ;	/* address of structure with conversation data	*/

The **DdeQueryConvInfo** function retrieves information about a dynamic data exchange (DDE) transaction and about the conversation in which the transaction takes place.

Parameters

hConv

Identifies the conversation.

idTransaction

Specifies the transaction. For asynchronous transactions, this parameter should be a transaction identifier returned by the **DdeClientTransaction** function. For synchronous transactions, this parameter should be QID_SYNC.

lpConvInfo

Points to the **CONVINFO** structure that will receive information about the transaction and conversation. The **cb** member of the **CONVINFO** structure must specify the length of the buffer allocated for the structure.

The CONVINFO structure has the following form:

	#include <ddeml.h></ddeml.h>
	<pre>typedef struct tagCONVINFO { /* ci */ DWORD cb; DWORD hUser; HCONV hConvPartner; HSZ hszSvcPartner; HSZ hszServiceReq; HSZ hszItem; UINT wFmt; UINT wFmt; UINT wStatus; UINT wStatus; UINT wLastError; HCONVLIST hConvList; CONVCONTEXT ConvCtxt; } CONVINFO; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>
Return Value	The return value is the number of bytes copied into the CONVINFO structure, if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_NO_CONV_ESTABLISHED DMLERR_NO_ERROR DMLERR_UNFOUND_QUEUE_ID
Example	The following example fills a CONVINFO structure with information about a syn- chronous conversation and then obtains the names of the partner application and topic:
	DWORD idInst; HCONV hConv; CONVINFO ci; WORD wError; char szSvcPartner[32]; char szTopic[32]; DWORD cchServ, cchTopic;
	<pre>if (!DdeQueryConvInfo(hConv, QID_SYNC, &ci)) wError = DdeGetLastError(idInst);</pre>

```
else {
    cchServ = DdeQueryString(idInst, ci.hszSvcPartner,
        (LPSTR) &szSvcPartner, sizeof(szSvcPartner),
        CP_WINANSI);
    cchTopic =DdeQueryString(idInst, ci.hszTopic,
        (LPSTR) &szTopic, sizeof(szTopic),
        CP_WINANSI);
}
```

DdeConnect, DdeConnectList, DdeQueryNextServer

DdeQueryNextServer

#include <ddeml.h>

	NextServer(hConvList, hConvPrev)vList;/* handle of conversation list*/,/* previous conversation handle*/
	The DdeQueryNextServer function obtains the next conversation handle in the given conversation list.
Parameters	<i>hConvList</i> Identifies the conversation list. This handle must have been created by a pre- vious call to the DdeConnectList function.
	<i>hConvPrev</i> Identifies the conversation handle previously returned by this function. If this parameter is NULL, this function returns the first conversation handle in the list.
Return Value	The return value is the next conversation handle in the list if the list contains any more conversation handles. Otherwise, it is NULL.
Example	The following example uses the DdeQueryNextServer function to count the number of conversation handles in a conversation list and to copy the service-name string handles of the servers to a local buffer:
	HCONVLIST hconvList; /* conversation list */ DWORD idInst; /* instance identifier */ HSZ hszSystem; /* System topic */ HCONV hconv = NULL; /* conversation handle */ CONVINFO ci; /* holds conversation data */ UINT cConv = 0; /* count of conv. handles */ HSZ *pHsz, *aHsz; /* point to string handles */

```
/* Connect to all servers that support the System topic. */
hconvList = DdeConnectList(idInst, (HSZ) NULL, hszSystem,
    (HCONV) NULL, (LPVOID) NULL);
/* Count the number of handles in the conversation list. */
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != (HCONV) NULL)
    cConv++;
/* Allocate a buffer for the string handles. */
hconv = (HCONV) NULL:
aHsz = (HSZ *) LocalAlloc(LMEM_FIXED, cConv * sizeof(HSZ));
/* Copy the string handles to the buffer. */
pHsz = aHsz:
while ((hconv = DdeQueryNextServer(hconvList, hconv)) != (HCONV) NULL) {
    DdeQueryConvInfo(hconv, QID_SYNC, (PCONVINFO) &ci);
    DdeKeepStringHandle(idInst, ci.hszSvcPartner);
    *pHsz++ = ci.hszSvcPartner;
}
. /* Use the handles; converse with servers. */
/* Free the memory and terminate conversations. */
LocalFree((HANDLE) aHsz);
DdeDisconnectList(hconvList):
```

DdeConnectList, DdeDisconnectList

DdeQueryString

#include <ddeml.h>

DWORD DdeQuerys	String(idInst, hsz, lpsz, cchMax, cod	epage)
DWORD <i>idInst</i> ;	/* instance identifier	*/
HSZ hsz;	/* handle of string	*/
LPSTR lpsz;	/* address of destination buffer	*/
DWORD cchMax;	/* length of buffer	*/
int codepage;	/* code page	*/

The DdeQueryString function	copies text a	associated	with a string	g handle into a
buffer.	-			

The string returned in the buffer is always null-terminated. If the string is longer than (cchMax - 1), only the first (cchMax - 1) characters of the string are copied.

If the *lpsz* parameter is NULL, this function obtains the length, in bytes, of the string associated with the string handle. The length does not include the terminating null character.

Parameters

idInst

Specifies the application-instance identifier obtained by a previous call to the **DdeInitialize** function.

hsz

Identifies the string to copy. This handle must have been created by a previous call to the **DdeCreateStringHandle** function.

lpsz

Points to a buffer that receives the string. To obtain the length of the string, this parameter should be set to NULL.

cchMax

Specifies the length, in bytes, of the buffer pointed to by the *lpsz* parameter. If the string is longer than (cchMax - 1), it will be truncated. If the *lpsz* parameter is set to NULL, this parameter is ignored.

codepage

Specifies the code page used to render the string. This value should be either CP_WINANSI or the value returned by the **GetKBCodePage** function.

Return Value The return value is the length, in bytes, of the returned text (not including the terminating null character) if the *lpsz* parameter specified a valid pointer. The return value is the length of the text associated with the *hsz* parameter (not including the terminating null character) if the *lpsz* parameter specified a NULL pointer. The return value is NULL if an error occurs.

Example The following example uses the **DdeQueryString** function to obtain a service name and topic name that a server has registered:

UINT type;

```
HSZ hsz1;
HSZ hsz2;
char szBaseName[16];
char szInstName[16];
```

```
if (type == XTYP_REGISTER) {
```

```
/* Copy the base service name to a buffer. */
DdeQueryString(idInst, hsz1, (LPSTR) &szBaseName,
        sizeof(szBaseName), CP_WINANSI);
    /* Copy the instance-specific service name to a buffer. */
DdeQueryString(idInst, hsz2, (LPSTR) &szInstName,
        sizeof(szInstName), CP_WINANSI);
    return (HDDEDATA) TRUE;
}
```

3.1

DdeReconnect

#include <ddeml.h>

HCONV DdeRecon	
HCONV hConv;	/* handle of conversation to reestablish */
	The DdeReconnect function allows a client Dynamic Data Exchange Manage- ment Library (DDEML) application to attempt to reestablish a conversation with a service that has terminated a conversation with the client. When the conversation is reestablished, the DDEML attempts to reestablish any preexisting advise loops.
Parameters	<i>hConv</i> Identifies the conversation to be reestablished. A client must have obtained the conversation handle by a previous call to the DdeConnect function.
Return Value	The return value is the handle of the reestablished conversation if the function is successful. The return value is NULL if the function fails.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_CONV_ESTABLISHED DMLERR_NO_ERROR

Example

The following example shows the context within which an application should call the **DdeReconnect** function:

```
HDDEDATA EXPENTRY DdeCallback(wType, wFmt, hConv, hsz1,
    hsz2, hData, dwData1, dwData2)
                /* transaction type
WORD wType:
                                                      */
WORD wFmt;
                 /* clipboard format
                                                      */
HCONV hConv:
                 /* handle of the conversation
                                                      */
HSZ hsz1:
                 /* handle of a string
                                                      */
HSZ hsz2:
                /* handle of a string
                                                      */
HDDEDATA hData: /* handle of a global memory object */
DWORD dwData1; /* transaction-specific data
                                                      */
DWORD dwData2; /* transaction-specific data
                                                      */
{
    BOOL fAutoReconnect:
    switch (wType) {
        case XTYP DISCONNECT:
            if (fAutoReconnect) {
                DdeReconnect(hConv); /* attempt to reconnect */
            }
            return 0:
         /* Process other transactions. */
    }
}
```

See Also

DdeConnect, DdeDisconnect

DdeSetUserHandle

#include <ddeml.h>

BOOL DdeSetUser	Handle (hConv, id, hUser)	
HCONV hConv;	/* handle of conversation	*/
DWORD <i>id</i> ;	/* transaction identifier	*/
DWORD hUser;	/* application-defined value	*/

The **DdeSetUserHandle** function associates an application-defined 32-bit value with a conversation handle and transaction identifier. This is useful for simplifying the processing of asynchronous transactions. An application can use the **Dde-QueryConvInfo** function to retrieve this value.

Parameters	<i>hConv</i> Identifies the conversation.
	<i>id</i> Specifies the transaction identifier of an asynchronous transaction. An applica- tion should set this parameter to QID_SYNC if no asynchronous transaction is to be associated with the <i>hUser</i> parameter.
	<i>hUser</i> Identifies the value to associate with the conversation handle.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:
	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR DMLERR_UNFOUND_QUEUE_ID
See Also	DdeQueryConvInfo

DdeUnaccessData

#include <ddeml.h< th=""><th>></th></ddeml.h<>	>		
BOOL DdeUnaccessData(hData)HDDEDATA hData;/* handle of global memory object*/			
	The DdeUnaccessData function frees a global memory object. An application must call this function when it is finished accessing the object.		
Parameters	hData Identifies the global memory object.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Errors	Use the DdeGetLastError function to retrieve the error value, which may be one of the following:		

3.1

Example	DMLERR_DLL_NOT_INITIALIZED DMLERR_INVALIDPARAMETER DMLERR_NO_ERROR The following example obtains a pointer to a global memory object, uses the pointer to copy data from the object to a local buffer, and then uses the Dde- UnaccessData function to free the object:	
	HDDEDATA hData; LPBYTE lpszAdviseData; DWORD cbDataLen; DWORD i; char szData[128];	
	<pre>lpszAdviseData = DdeAccessData(hData, &cbDataLen); for (i = 0; i < cbDataLen; i++) szData[i] = *lpszAdviseData++; DdeUnaccessData(hData);</pre>	
See Also	DdeAccessData, DdeAddData, DdeCreateDataHandle, DdeFreeDataHandle	

DdeUninitialize

#include <ddeml.h></ddeml.h>	•
BOOL DdeUninitia DWORD idInst;	lize(<i>idInst</i>) /* instance identifier */
	The DdeUninitialize function frees all Dynamic Data Exchange Management Library (DDEML) resources associated with the calling application.
Parameters	<i>idInst</i> Specifies the application-instance identifier obtained by a previous call to the DdeInitialize function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The DdeUninitialize function terminates any conversations currently open for the application. If the partner in a conversation fails to terminate its end of the conversation, the system may enter a modal loop while it waits for the conversation to terminate. A timeout period is associated with this loop. If the timeout period expires

before the conversation has terminated, a message box appears that gives the user the choice of waiting for another timeout period (Retry), waiting indefinitely (Ignore), or exiting the modal loop (Abort).

An application should wait until its windows are no longer visible and its message loop has terminated before calling this function.

See Also DdeDisconnect, DdeDisconnectList, DdeInitialize

DebugBreak

3.0

void DebugBreak(void)

	The DebugBreak function causes a breakpoint exception to occur in the caller. This allows the calling process to signal the debugger, forcing it to take some ac- tion. If the process is not being debugged, the system invokes the default break- point exception handler. This may cause the calling process to terminate.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
Comments	This function is the only way to break into a WEP (Windows exit procedure) in a dynamic-link library.
	For more information about using the debugging functions with Microsoft debug- ging tools, see <i>Microsoft Windows Programming Tools</i> .
Example	The following example uses the DebugBreak function to signal the debugger im- mediately before the application handles the WM_DESTROY message:
	case WM_DESTROY:
	DebugBreak(); PostQuitMessage(0); break;
See Also	WEP

3.1

DebugOutput

UINT flags;	ebugOutput(flags, lpsz /* type of message /* address of format	*/	
	The DebugOutput function sends a message to the debugging terminal. Applica- tions can apply the formatting codes to the message string and use filters and op- tions to control the message category.		
Parameters	<i>flags</i> Specifies the type of message to be sent to the debugging terminal. This parameter can be one of the following values:		
	Value	Meaning	
	DBF_TRACE	The message reports that no error has occurred and supplies information that may be useful during debugging. Example: "t Kernel: LoadResource(14AE of GDI)"	
	DBF_WARNING	The message reports a situation that may or may not be an error, depending on the circumstances. Example: "wn Kernel: GlobalWire(17BE of GDI) (try GlobalLock)"	
	DBF_ERROR	The message reports an error resulting from a failed call to a Windows function. The application continues to run. Ex- ample: "err Kernel: LocalShrink(15EA of GDI) (invalid local heap)"	
	DBF_FATAL	The message reports an error that will terminate the applica- tion. Example: "fatl User: SetDeskWallpaper(16CA of USER)"	
	lpszFmt		

Points to a formatting string identical to the formatting strings used by the Windows function **wsprintf**. This string must be less than 160 characters long. Any additional formatting can be done by supplying additional parameters following *lpszFmt*.

Specifies zero or more optional arguments. The number and type of arguments depends on the corresponding format-control character sequences specified in the *lpszFmt* parameter.

Return Value This function does not return a value.

CommentsThe messages sent by the DebugOutput function are affected by the system
debugging options and trace-filter flags that are set and retrieved by using the
GetWinDebugInfo and SetWinDebugInfo functions. These options and flags are
stored in a WINDEBUGINFO structure.Unlike most other Windows functions, DebugOutput uses the C calling conven-
tion (_cdecl), rather than the Pascal calling convention. As a result, the caller must
pop arguments off the stack. Also, arguments must be pushed on the stack from
right to left. In C-language modules, the C compiler performs this task.

See Also GetWinDebugInfo, OutputDebugString, SetWinDebugInfo, wsprintf

DebugProc

LRESULT CALLBACK DebugProc(code, wParam, lParam)			
int code;	/* hook code	*/	
WPARAM wParam;	/* type of hook about to be called	*/	
LPARAM lParam;	/* address of structure with debugging information	*/	

The **DebugProc** function is a library-defined callback function that the system calls before calling any other filter installed by the **SetWindowsHookEx** function. The system passes information about the filter about to be called to the **Debug-Proc** callback function. The callback function can examine the information and determine whether to allow the filter to be called.

3.1

Parameters

code

Specifies the hook code. Currently, HC_ACTION is the only positive valid value. If this parameter is less than zero, the callback function must call the **CallNextHookEx** function without any further processing.

wParam

Specifies the task handle of the task that installed the filter about to be called.

lParam

Contains a long pointer to a **DEBUGHOOKINFO** structure. The **DEBUGHOOKINFO** structure has the following form:

3.0

	typedef struct tagDEBUGHOOKINFO {	
	HMODULE hModuleHook; LPARAM reserved;	
	LPARAM 1Param;	
	WPARAM wParam;	
	int code;	
	} DEBUGHOOKINFO;	
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.	
Return Value	The callback function should return TRUE to prevent the system from calling another filter. Otherwise, the callback function must pass the filter information to the CallNextHookEx function.	
Comments	An application must install this callback function by specifying the WH_DEBUG filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.	
	CallWndProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.	
See Also	CallNextHookEx, SetWindowsHookEx	

DefDlgProc

LRESULT DefDlgP HWND hwndDlg; UINT uMsg; WPARAM wParam; LPARAM lParam;	roc(hwndDlg, uMsg, wParam, lParam)/* handle of dialog box*//* message*//* first message parameter*//* second message parameter*/	
Parameters	The DefDlgProc function provides default processing for any Windows messages that a dialog box with a private window class does not process. <i>hwndDlg</i> Identifies the dialog box.	
	 <i>uMsg</i> Specifies the message to be processed. <i>wParam</i> Specifies 16 bits of additional message-dependent information. 	

	<i>lParam</i> Specifies 32 bits of additional message-dependent information.		
Return Value	The return value specifies the result of the message processing and depends on the message sent.		
Comments	The DefDlgProc function is the window procedure for the DIALOG window class. An application that creates new window classes that inherit dialog box functionality should use this function. DefDlgProc is not intended to be called as the default handler for messages within a dialog box procedure, since doing so will result in recursive execution.		
	An application creates a dialog box by calling one of the following functions: Function Description		
	CreateDialog	Creates a modeless dialog box.	
	CreateDialogIndirect Creates a modeless dialog box.		
	CreateDialogIndirectParam	Creates a modeless dialog box and passes data to it when it is created.	
	CreateDialogParam	Creates a modeless dialog box and passes data to it when it is created.	
	DialogBox	Creates a modal dialog box.	
	DialogBoxIndirect	Creates a modal dialog box.	
	DialogBoxIndirectParam	Creates a modal dialog box and passes data to it when it is created.	
	DialogBoxParamCreates a modal dialog box and passes of when it is created.		
See Also	DefWindowProc		

DefDriverProc

3.1

LRESULT DefDriverProc (<i>dwDriverIdentifier</i> , <i>hdrvr</i> , <i>uMsg</i> , <i>lParam1</i> , <i>lParam2</i>)			
DWORD dwDriverIdentifier;	/* installable-driver identifier	*/	
HDRVR hdrvr;	/* handle of installable driver	*/	
UINT uMsg;	/* message number	*/	
LPARAM lParam1;	/* first message parameter	*/	
LPARAM lParam2;	/* second message parameter	*/	

The **DefDriverProc** function provides default processing for any messages not processed by an installable driver.

3.0

Parameters	<i>dwDriverIdentifier</i> Identifies an installable driver. This parameter must have been obtained by a previous call to the OpenDriver function.	
	<i>hdrvr</i> Identifies the installable driver.	
	<i>uMsg</i> Specifies the message to be processed.	
	<i>lParam1</i> Specifies 32 bits of additional message-dependent information.	
	<i>lParam2</i> Specifies 32 bits of additional message-dependent information.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The DefDriverProc function processes messages that are not handled by the DriverProc function.	
See Also	OpenDriver, SendDriverMessage	

DeferWindowPos

HDWP DeferWindowPos (hdwp, hwnd, hwndInsertAfter, x, y, cx, cy, flags)			
HDWP hdwp;	/* handle of internal structure	*/	
HWND hwnd;	/* handle of window to position	*/	
HWND hwndInsertAfter;	/* placement-order handle	*/	
int x;	/* horizontal position	*/	
int y;	/* vertical position	*/	
int cx;	/* width	*/	
int cy;	/* height	*/	
UINT flags;	/* window-positioning flags	*/	
The DeferWindowPos function updates the given internal structure for the given window. The function then returns the handle of the updated structure. The End-DeferWindowPos function uses the information in this structure to change the position and size of a number of windows simultaneously.			

Parameters

hdwp

Identifies an internal structure that contains size and position information for one or more windows. This structure is returned by the **BeginDeferWindow-Pos** function or by the most recent call to the **DeferWindowPos** function.

hwnd

Identifies the window for which to store update information in the structure.

hwndInsertAfter

Identifies a window that will precede the positioned window in the Z-order. This parameter must be a window handle, or one of the following values:

Value	Meaning
HWND_BOTTOM	Places the window at the bottom of the Z-order. If <i>hwnd</i> identifies a topmost window, the window loses its topmost status.
HWND_TOP	Places the window at the top of the Z-order.
HWND_TOPMOST	Places the window above all non-topmost windows. The window maintains its topmost position even when the window is deactivated.
HWND_NOTOPMOST	Repositions the window to the top of all non-topmost windows (that is, behind all topmost windows).

This parameter is ignored if SWP_NOZORDER is set in the *flags* parameter.

х

Specifies the x-coordinate of the window's upper-left corner.

y

Specifies the y-coordinate of the window's upper-left corner.

сх

Specifies the window's new width.

сy

Specifies the window's new height.

flags

Specifies one of eight possible 16-bit values that affect the size and position of the window. This parameter can be a combination of the following values:

Value	Meaning
SWP_DRAWFRAME	Draws a frame (defined in the window's class descrip- tion) around the window.
SWP_HIDEWINDOW	Hides the window.
SWP_NOACTIVATE	Does not activate the window.
SWP_NOMOVE	Retains current position (ignores x and y parameters).
SWP_NOREDRAW	Does not redraw changes. If this flag is set, no repaint- ing occurs. This applies to the client area, the non- client area (including the title and scroll bars), and any part of the parent window uncovered as a result of the moved window. When this flag is set, the application must explicitly invalidate or redraw any parts of the window and parent window that must be redrawn.

	Value	Meaning	
	SWP_NOSIZE SWP_NOZORDER	Retains current size (ignores the <i>cx</i> and <i>cy</i> parameters). Retains current ordering (ignores the <i>hwndInsertAfter</i> parameter).	
	SWP_SHOWWINDOW	Displays the window.	
Return Value	The return value is a handle of the updated structure if the function is successful. This handle may differ from the one passed to the function as the <i>hdwp</i> parameter and should be passed to the next call to DeferWindowPos or to the EndDefer- WindowPos function.		
		insufficient system resources are available for the sfully and the repositioning process is terminated.	
Comments	If a call to DeferWindowPos fails, the application should abandon the window- positioning operation without calling the EndDeferWindowPos function.		
	If SWP_NOZORDER is not specified, Windows places the window identified by <i>hwnd</i> in the position following the window identified by <i>hwndInsertAfter</i> . If <i>hwndInsertAfter</i> is NULL, Windows places the window identified by <i>hwnd</i> at the top of the list. If <i>hwndInsertAfter</i> is HWND_BOTTOM, Windows places the window dow identified by <i>hwnd</i> at the bottom of the list.		
	All coordinates for child wir window's client area.	ndows are relative to the upper-left corner of the parent	
	HWND_TOPMOST and ena a window's Z-order so that i	pmost window either by setting <i>hwndInsertAfter</i> to suring that SWP_NOZORDER is not set, or by setting t is above any existing topmost windows. When a non- bmost, its owned windows are also made topmost. Its	
	when the application request	ATE nor SWP_NOZORDER is specified (that is, ts that a window be simultaneously activated and ler), the value specified in <i>hwndInsertAfter</i> is used stances:	
	 Neither HWND_TOPMC hwndInsertAfter parameter 	OST nor HWND_NOTOPMOST is specified in the er.	
	• The window specified in	the <i>hwnd</i> parameter is not the active window.	
	top of the Z-order. Applicati	te an inactive window without also bringing it to the ons can change the Z-order of an activated window ate a window and then move it to the top of the top- ws.	

A topmost window is no longer topmost if it is repositioned to the bottom (HWND_BOTTOM) of the Z-order or after any non-topmost window. When a topmost window is made non-topmost, the window and all of its owners, and its owned windows, are also made non-topmost.

A non-topmost window may own a topmost window, but not vice versa. Any window (for example, a dialog box) owned by a topmost window is itself made topmost to ensure that all owned windows stay above their owner.

10

NIDIO

DefFrameProc

LRESULT DefFram	eProc(hwnd, hwndMDIClient, uMsg, wParam, lParam)
HWND hwnd;	/* handle of frame window */
HWND hwndMDICl	<i>ient</i> ; /* handle of client window */
UINT uMsg;	/* message */
WPARAM wParam;	/* first message parameter */
LPARAM lParam;	/* second message parameter */
	The DefFrameProc function provides default processing for any Windows mes- sages that the window procedure of a multiple document interface (MDI) frame window does not process. All window messages that are not explicitly processed by the window procedure must be passed to the DefFrameProc function, not the DefWindowProc function.
Parameters	<i>hwnd</i> Identifies the MDI frame window.
	hwndMDIClient Identifies the MDI client window.
	<i>uMsg</i> Specifies the message to be processed.
	wParam Specifies 16 bits of additional message-dependent information.
	<i>lParam</i> Specifies 32 bits of additional message-dependent information.
Return Value	The return value specifies the result of the message processing and depends on the message sent. If the <i>hwndMDIClient</i> parameter is NULL, the return value is the same as for the DefWindowProc function.

Comments

Typically, when an application's window procedure does not handle a message, it passes the message to the **DefWindowProc** function, which processes the message. MDI applications use the **DefFrameProc** and **DefMDIChildProc** functions instead of **DefWindowProc** to provide default message processing. All messages that an application would usually pass to **DefWindowProc** (such as nonclient messages and WM_SETTEXT) should be passed to **DefFrameProc** instead. In addition to handling these messages, **DefFrameProc** also handles the following messages:

Message	Response
WM_COMMAND	The frame window of an MDI application receives the WM_COMMAND message to activate a particular MDI child window. The window identifier accompanying this message will identify the MDI child window assigned by Windows, starting with the first identifier specified by the application when it created the MDI client window. This value of the first identifier must not conflict with menu-item identifiers.
WM_MENUCHAR	When the user presses the ALT+- key combination, the System menu (often called Control menu) of the active MDI child window will be selected.
WM_SETFOCUS	DefFrameProc passes focus on to the MDI client, which in turn passes the focus on to the active MDI child window.
WM_SIZE	If the frame window procedure passes this message to Def-FrameProc , the MDI client window will be resized to fit in the new client area. If the frame window procedure sizes the MDI client to a different size, it should not pass the message to DefWindowProc .

See Also DefMDIChildProc, DefWindowProc

DefHookProc

DWORD DefHookProc (<i>nCode</i> , <i>uParam</i> , <i>dwParam</i> , <i>lphhook</i>)		
int nCode;	/* process code	*/
UINT uParam;	/* first message parameter	*/
DWORD dwParam;	/* second message parameter	*/
HHOOK FAR* lphhook;	/* points to address of next hook function	*/

This function is obsolete but has been retained for backward compatibility with Windows versions 3.0 and earlier. Applications written for Windows version 3.1 should use the **CallNextHookEx** function.

2.x

	The DefHookProc function calls the next function in a chain of hook functions. A hook function is a function that processes events before they are sent to an application's message-processing loop in the WinMain function. When an application defines more than one hook function by using the SetWindowsHook function, Windows forms a linked list or hook chain. Windows places functions of the same type in a chain.
Parameters	<i>nCode</i> Specifies a code used by the Windows hook function (also called the message-filter function) to determine how to process the message.
	<i>uParam</i> Specifies 16 bits of additional message-dependent information.
	<i>dwParam</i> Specifies 32 bits of additional message-dependent information.
	<i>lphhook</i> Points to the variable that contains the procedure-instance address of the pre- viously installed hook function returned by the SetWindowsHook function.
Return Value	The return value specifies the result of the event processing and depends on the event.
Comments	Windows changes the value at the location pointed to by the <i>lphhook</i> parameter after an application calls the UnhookWindowsHook function. For more information, see the description of the UnhookWindowsHook function.
See Also	SetWindowsHook, UnhookWindowsHook

DefMDIChildProc

LRESULT DefMDIChildProc (<i>hwnd</i> , <i>uMsg</i> , <i>wParam</i> , <i>lParam</i>)		
HWND hwnd;	/* handle of child window	*/
UINT uMsg;	/* message	*/
WPARAM wParam;	/* first message parameter	*/
LPARAM lParam;	/* second message parameter	*/

The **DefMDIChildProc** function provides default processing for any Windows messages that the window procedure of a multiple document interface (MDI) child window does not process. All window messages that are not explicitly processed by the window procedure must be passed to the **DefMDIChildProc** function, not the **DefWindowProc** function.

Parameters	<i>hwnd</i> Identifies the MDI child	window.
	<i>uMsg</i> Specifies the message to	be processed.
	wParam Specifies 16 bits of addit	tional message-dependent information.
	<i>lParam</i> Specifies 32 bits of addit	tional message-dependent information.
Return Value	The return value specifies t message sent.	he result of the message processing and depends on the
Comments	This function assumes that rameter was created with the	the parent of the window identified by the <i>hwnd</i> pa- be MDICLIENT class.
	passes the message to the D sage. MDI applications use instead of DefWindowPro that an application would u sages and WM_SETTEXT	tion's window procedure does not handle a message, it DefWindowProc function, which processes the mes- the DefFrameProc and DefMDIChildProc functions c to provide default message processing. All messages sually pass to DefWindowProc (such as nonclient mes-) should be passed to DefMDIChildProc instead. In ad- ssages, DefMDIChildProc also handles the following
	Message	Response
	WM_CHILDACTIVATE	Performs activation processing when child windows are sized, moved, or shown. This message must be passed.
	WM_GETMINMAXINFO	Calculates the size of a maximized MDI child window based on the current size of the MDI client window.
	WM_MENUCHAR	Sends the keystrokes to the frame window.
	WM_MOVE	Recalculates MDI client scroll bars, if they are present.
	WM_SETFOCUS	Activates the child window if it is not the active MDI child window.
	WM_SIZE	Performs necessary operations when changing the size of a window, especially when maximizing or restoring an MDI child window. Failing to pass this message to
		DefMDIChildProc will produce highly undesirable re- sults. Also handles the next window command.

DefWindowProc

lowProc(hwnd, uMsg, wParam, lParam)
/* handle of window */
/* type of message */ /* first message parameter */
/* second message parameter */
The DefWindowProc function calls the default window procedure. The default window procedure provides default processing for any window messages that an application does not process. This function ensures that every message is processed. It should be called with the same parameters as those received by the window procedure.
hwnd Identifies the window that received the message.
<i>uMsg</i> Specifies the message.
wParam Specifies 16 bits of additional message-dependent information.
<i>lParam</i> Specifies 32 bits of additional message-dependent information.
The return value is the result of the message processing and depends on the message sent.
The source code for the DefWindowProc function is provided on the Microsoft Windows 3.1 Software Development Kit (SDK) disks.
The following example shows a typical window procedure. A switch statement is used to process individual messages. All messages not processed are passed on to the DefWindowProc function.
LONG FAR PASCAL MainWndProc(hwnd, message, wParam, 1Param) HWND hwnd; /* handle of window */ WORD message; /* type of message */ WORD wParam; /* additional information */ LONG 1Param; /* additional information */ { switch (message) {

```
/*
 * Process whatever messages you want here and send the
 * rest to DefWindowProc.
 */
default:
    return (DefWindowProc(hwnd, message, wParam, 1Param));
```

See Also

DefDlgProc

DeleteAtom

ATOM DeleteAtom(*atm*)

ATOM *atm*; /* atom to delete */

The **DeleteAtom** function decrements (decreases by one) the reference count of a local atom by one. If the atom's reference count is reduced to zero, the string associated with the atom is removed from the local atom table.

An atom's reference count specifies the number of times the atom has been added to the atom table. The **AddAtom** function increments (increases by one) the count on each call. **DeleteAtom** decrements the count on each call and removes the string only if the atom's reference count is reduced to zero.

Parameters	<i>atm</i> Identifies the atom and character string to be deleted.
Return Value	The return value is zero if the function is successful. Otherwise, it is equal to the <i>atm</i> parameter.
Comments	The only way to ensure that an atom has been deleted from the atom table is to call this function repeatedly until it fails. When the count is decremented to zero, the next call to the FindAtom or DeleteAtom function will fail.
	DeleteAtom has no effect on integer atoms (atoms created by using the MAKE-INTATOM macro). The function always returns zero for integer atoms.
Example	The following example uses the DeleteAtom function to decrement the reference count for the specified atom:
	ATOM at;
	at = DeleteAtom(atTest);

```
if (at == NULL)
    MessageBox(hwnd, "atom count decremented",
        "DeleteAtom", MB_OK);
else
    MessageBox(hwnd, "atom count could not be decremented",
        "DeleteAtom", MB_ICONEXCLAMATION);
```

See Also

AddAtom, FindAtom, GlobalDeleteAtom

DeleteDC

BOOL DeleteDC(hdc) HDC hdc; /* handle of device context */		
	The DeleteDC function deletes the given device context.	
Parameters	<i>hdc</i> Identifies the device context.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	If the <i>hdc</i> parameter identifies the last device context for a given device, the device is notified and all storage and system resources used by the device are released.	
	An application must not delete a device context whose handle was retrieved by calling the GetDC function. Instead, the application must call the ReleaseDC function to free the device context.	
	An application should not call DeleteDC if the application has selected objects into the device context. Objects must be selected out of the device context before it is deleted.	
Example	The following example uses the CreateDC function to create a device context for a printer and then calls the DeleteDC function when the device context is no longer needed:	
	/* Retrieves a device context for a printer. */	
	hdcPrinter = CreateDC(lpDriverName, lpDeviceName, lpOutput, lpInitData);	
	. /* Use the device context. */	

/* Delete the device context. */

DeleteDC(hdcPrinter);

See Also

CreateDC, GetDC, ReleaseDC

DeleteMenu

BOOL DeleteMenu HMENU hmenu; UINT idltem; UINT fuFlags;	a(<i>hmenu</i> , <i>idItem</i> , <i>fuFlags</i>) /* handle of menu /* menu-item identifier /* menu flags	*/ */ */
		n deletes an item from a menu. If the menu item has an DeleteMenu destroys the handle of the pop-up menu and y the pop-up menu.
Parameters	<i>hmenu</i> Identifies the menu to	be changed.
	<i>idItem</i> Specifies the menu ite	m to be deleted, as determined by the <i>fuFlags</i> parameter.
	<i>fuFlags</i> Specifies how the <i>idIt</i> the following values:	em parameter is interpreted. This parameter can be one of
	Value	Meaning
	MF_BYCOMMAND MF_BYPOSITION	The <i>idltem</i> parameter specifies the menu-item identifier. The <i>idltem</i> parameter specifies the zero-based relative position of the menu item.
Return Value	The return value is nonze	ero if the function is successful. Otherwise, it is zero.
Comments	Whenever a menu changes (whether or not the menu is in a window that is displayed), the application should call the DrawMenuBar function.	
See Also	AppendMenu, CreateM	lenu, DrawMenuBar, InsertMenu, RemoveMenu

DeleteMetaFile

BOOL DeleteMetaFile(<i>hmf</i>) HMETAFILE <i>hmf</i> ; /* handle of metafile */	
	The DeleteMetaFile function invalidates the given metafile handle.
Parameters	<i>hmf</i> Identifies the metafile to be deleted.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The DeleteMetaFile function does not destroy a metafile that is saved on disk. After calling DeleteMetaFile , an application can retrieve a new handle of the metafile by calling the GetMetaFile function.
Example	The following example uses the CreateMetaFile function to create the handle of a memory metafile device context, draws a line in that device context, retrieves a handle of the metafile by calling the CloseMetaFile function, plays the metafile by using the PlayMetaFile function, and finally deletes the metafile by using DeleteMetaFile :
	HDC hdcMeta; HMETAFILE hmf;
	<pre>hdcMeta = CreateMetaFile(NULL); MoveTo(hdcMeta, 10, 10); LineTo(hdcMeta, 100, 100); hmf = CloseMetaFile(hdcMeta); PlayMetaFile(hdc, hmf); DeleteMetaFile(hmf);</pre>
See Also	CreateMetaFile, GetMetaFile

DeleteObject

2.x

BOOL DeleteObject(*hgdiobj*) HGDIOBJ *hgdiobj*; /* handle of object to delete */

The **DeleteObject** function deletes an object from memory by freeing all system storage associated with the object. (Objects include pens, brushes, fonts, bitmaps, regions, and palettes.)

Parameters	<i>hgdiobj</i> Identifies a pen, brush, font, bitmap, region, or palette.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	After the object is deleted, the handle given in the <i>hgdiobj</i> parameter is no longer valid.
	An application should not delete an object that is currently selected into a device context.
	When a pattern brush is deleted, the bitmap associated with the brush is not de- leted. The bitmap must be deleted independently.
Example	The following example creates a pen, selects it into a device context, and uses the pen to draw a rectangle. To delete the pen, the original pen is selected back into the device context and the DeleteObject function is called.
	HPEN hpen, hpenOld;
	hpen = CreatePen(PS_SOLID, 6, RGB(0, 0, 255)); hpenOld = SelectObject(hdc, hpen);
	Rectangle(hdc, 10, 10, 100, 100);
	<pre>SelectObject(hdc, hpenOld); DeleteObject(hpen);</pre>
See Also	SelectObject

DestroyCaret

2.x

void DestroyCaret(void)

	The DestroyCaret function destroys the current caret shape, frees the caret from the window that currently owns it, and removes the caret from the screen if it is visible. The DestroyCaret function checks the ownership of the caret and destroys the caret only if a window in the current task owns it.
	If the caret shape was previously a bitmap, DestroyCaret does not free the bitmap.
Parameters	This function has no parameters.
Return Value	This function does not return a value.

Comments The caret is a shared resource. If a window has created a caret shape, it should destroy that shape before it loses the input focus or becomes inactive.

See Also CreateCaret, HideCaret, ShowCaret

DestroyCursor

3.0

3.0

BOOL DestroyCursor(hcur) HCURSOR hcur; /* handle of cursor to destroy */	
	The DestroyCursor function destroys a cursor that was previously created by the CreateCursor or LoadCursor function and frees any memory that the cursor occupied.
Parameters	<i>hcur</i> Identifies the cursor to be destroyed. The cursor must not be in current use.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also	CreateCursor, CreateIcon, DestroyIcon, LoadCursor

Destroylcon

BOOL DestroyIcon(*hicon*) HICON *hicon*; /* handle of icon to destroy */ The DestroyIcon function destroys an icon that was created by the CreateIcon or LoadIcon function and frees any memory that the icon occupied.
Parameters *hicon* Identifies the icon to be destroyed.
Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also CreateCursor, CreateIcon, DestroyCursor, LoadIcon

DestroyMer	LU 2.x
BOOL DestroyMenu(hmenu) HMENU hmenu; /* handle of menu to destroy */	
	The DestroyMenu function destroys a menu and frees any memory that the menu occupied.
Parameters	<i>hmenu</i> Identifies the menu to be destroyed.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also	CreateMenu

DestroyWindow

BOOL DestroyWindow(*hwnd*)

/ HWND hwnd; / handle of window to destroy

The DestroyWindow function destroys the specified window. The function sends
appropriate messages to the window to deactivate it and remove the input focus. It
also destroys the window's menu, flushes the application queue, destroys outstand-
ing timers, removes clipboard ownership, and breaks the clipboard-viewer chain
(if the window is at the top of the viewer chain). It sends WM_DESTROY and
WM_NCDESTROY messages to the window.

If the given window is the parent of any windows, **DestroyWindow** automatically destroys these child windows when it destroys the parent window. The function destroys child windows first, and then the window itself.

The DestroyWindow function also destroys modeless dialog boxes created by the CreateDialog function.

Parameters	<i>hwnd</i> Identifies the window to be destroyed.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	If the window being destroyed is a child window and does not have the WS_NOPARENTNOTIFY style set, a WM_PARENTNOTIFY message is sent to the parent.

2.x

Example	The following example responds to the application-defined menu command IDM_EXIT, and then calls DestroyWindow to destroy the window:
	<pre>case IDM_EXIT: DestroyWindow(hwnd); return 0;</pre>
See Also	CreateDialog, CreateWindow, CreateWindowEx

DeviceCapabilities

#include <print.h>

DWORD DeviceCa	pabilities(lpszDevice	, lpszPort, fwCa	ipability, lpszOutpi	it, lpdm)

LPSTR lpszDevice;	/* address of device-name string	*/
LPSTR lpszPort;	/* address of port-name string	*/
WORD <i>fwCapability</i> ;	/* device capability to query	*/
LPSTR lpszOutput;	/* address of the output	*/
LPDEVMODE lpdm;	/* address of structure with device data	*/

The **DeviceCapabilities** function retrieves the capabilities of the printer device driver.

Parameters

lpszDevice

Points to a null-terminated string that contains the name of the printer device, such as PCL/HP LaserJet.

lpszPort

Points to a null-terminated string that contains the name of the port to which the device is connected, such as LPT1.

fwCapability

Specifies the capabilities to query. This parameter can be one of the following values:

Value	Meaning
DC_BINNAMES	Copies an array containing a list of the names of the paper bins. This array is in the form char <i>PaperNames</i> [<i>cBinMax</i>][<i>cchBinName</i>] where <i>cchBinName</i> is 24. If the <i>lpszOutput</i> parameter is NULL, the return value is the number of bin en- tries required. Otherwise, the return value is the number of bins copied.

Value	Meaning
DC_BINS	Retrieves a list of available bins. The function co- pies the list to the <i>lpszOutput</i> parameter as a WORD array. If <i>lpszOutput</i> is NULL, the function returns the number of supported bins to allow the application the opportunity to allocate a buffer with the correct size. For more information about these bins, see the description of the dmDefault- Source member of the DEVMODE structure.
DC_COPIES	Returns the number of copies the device can print.
DC_DRIVER	Returns the version number of the printer driver.
DC_DUPLEX	Returns the level of duplex support. The function returns 1 if the printer is capable of duplex print- ing. Otherwise, the return value is zero.
DC_ENUMRESOLUTIONS	Returns a list of available resolutions. If <i>lpszOutput</i> is NULL, the function returns the number of available resolution configurations. Resolutions are represented by pairs of LONG integers representing the horizontal and vertical resolutions (specified in dots per inch).
DC_EXTRA	Returns the number of bytes required for the device-specific portion of the DEVMODE structure for the printer driver.
DC_FIELDS	Returns the dmFields member of the printer driver's DEVMODE structure. The dmFields member indicates which fields in the device- independent portion of the structure are supported by the printer driver.
DC_FILEDEPENDENCIES	Returns a list of files that also need to be loaded when a driver is installed. If the <i>lpszOutput</i> pa- rameter is NULL, the function returns the number of files. Otherwise, <i>lpszOutput</i> points to an array of filenames in the form char [<i>chFileName</i> , 64]. Each filename is a null-terminated string.
DC_MAXEXTENT	Returns a POINT structure containing the maxi- mum paper size that the dmPaperLength and dmPaperWidth members of the printer driver's DEVMODE structure can specify.
DC_MINEXTENT	Returns a POINT structure containing the min- imum paper size that the dmPaperLength and dmPaperWidth members of the printer driver's DEVMODE structure can specify.

Value	Meaning	<u>ا</u>
DC_ORIENTATION	scape orio number o tated cou	he relationship between portrait and land- entations for a device, in terms of the of degrees that portrait orientation is ro- nterclockwise to produce landscape orien- ne return value can be one of the g:
	Value	Meaning
	0	No landscape orientation.
	90	Portrait is rotated 90 degrees to pro- duce landscape. (For example, Hewlett-Packard PCL printers.)
	270	Portrait is rotated 270 degrees to pro- duce landscape. (For example, dot- matrix printers.)
DC_PAPERNAMES	Retrieves a list of supported paper names—for ex- ample, Letter or Legal. If the <i>lpszOutput</i> parameter is NULL, the function returns the number of paper sizes available. Otherwise, <i>lpszOutput</i> points to an array for the paper names in the form char [<i>cPaper</i> - <i>Names</i> , 64]. Each paper name is a null-terminated string.	
DC_PAPERS	tion copie array and array. If <i>l</i> the numb applicatio with the e paper size	a list of supported paper sizes. The func- es the list to <i>lpszOutput</i> as a WORD returns the number of entries in the <i>pszOutput</i> is NULL, the function returns er of supported paper sizes to allow the on the opportunity to allocate a buffer correct size. For more information on es, see the description of the dmPaper - nber of the DEVMODE structure.
DC_PAPERSIZE	sizes, in t POINT s paramete (y-dimen	the dimensions of all supported paper tenths of a millimeter, to an array of structures pointed to by the <i>lpszOutput</i> r. The width (x-dimension) and length sion) of a paper size are returned as if the re in the DMORIENT_PORTRAIT orien-
DC_SIZE		he dmSize member of the printer driver's DDE structure.

DC_TRUETYPE

Retrieves the abilities of the driver to use True-Type fonts. The return value can be one or more of the following:

Value	Meaning
DCTT_BITMAP	Device is capable of printing TrueType fonts as graphics. (For example, dot-matrix and PCL printers.)
DCTT_DOWNLOAD	Device is capable of downloading TrueType fonts. (For example, PCL and PostScript printers.)
DCTT_SUBDEV	Device is capable of substituting device fonts for TrueType fonts. (For example, PostScript printers.)
For DC_TRUETYPE, th should be NULL.	e lpszOutput parameter

DC_VERSION

Returns the specification version to which the printer driver conforms.

lpszOutput

Points to an array of bytes. The format of the array depends on the setting of the *fwCapability* parameter. If *lpszOutput* is zero, **DeviceCapabilities** returns the number of bytes required for the output data.

lpdm

Points to a **DEVMODE** structure. If this parameter is NULL, **Device-Capabilities** retrieves the current default initialization values for the specified printer driver. Otherwise, the function retrieves the values contained in the structure to which *lpdm* points. The **DEVMODE** structure has the following form:

	#include <print.h></print.h>
	<pre>typedef struct tagDEVMODE { /* dm */ char dmDeviceName[CCHDEVICENAME]; UINT dmSpecVersion; UINT dmDriverVersion; UINT dmDriverExtra; DWORD dmFields; int dmOrientation; int dmPaperSize; int dmPaperLength; int dmPaperWidth; int dmScale; int dmCopies; int dmDefaultSource; int dmPrintQuality; int dmColor; int dmColor; int dmTuplex; int dmTUption; } DEVMODE; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.</pre>
Return Value	The return value, if the function is successful, depends on the setting of the <i>fwCapability</i> parameter. The return value is -1 if the function fails.
Comments	This function is supplied by the printer driver. To use the DeviceCapabilities func- tion, an application must retrieve the address of the function by calling the Load- Library and GetProcAddress functions, and it must include the PRINT.H file.
	DeviceCapabilities is not supported by all printer drivers. If the GetProcAddress function returns NULL, DeviceCapabilities is not supported.
See Also	GetProcAddress, LoadLibrary

2.x

DeviceMode

void DeviceMode(hv HWND hwnd; HANDLE hModule; LPSTR lpszDevice; LPSTR lpszOutput;	wnd, hModule, lpszDevice, lpszOutput) /* handle of window owning dialog box */ /* handle of printer-driver module */ /* address of string for device name */ /* address of string for output name */
	The DeviceMode function sets the current printing modes for a specified device by using a dialog box to prompt for those modes. An application calls Device- Mode to allow the user to change the printing modes of the corresponding device. DeviceMode copies the mode information to the environment block that is as- sociated with the device and maintained by the graphics device interface (GDI).
	The ExtDeviceMode function provides a superset of the functionality of the DeviceMode function; new applications should use ExtDeviceMode instead of DeviceMode whenever possible. (Applications can use the DM_IN_PROMPT constant with ExtDeviceMode to duplicate the functionality of DeviceMode .)
Parameters	<i>hwnd</i> Identifies the window that will own the dialog box.
	<i>hModule</i> Identifies the printer-driver module. The application should retrieve this handle by calling either the GetModuleHandle or LoadLibrary function.
	<i>lpszDevice</i> Points to a null-terminated string that specifies the name of the specific device to be supported (for example, Epson FX-80). The device name is the same as the name passed to the CreateDC function.
	<i>lpszOutput</i> Points to a null-terminated string that specifies the MS-DOS filename or device name for the physical output medium (file or output port). The output name is the same as the name passed to the CreateDC function.
Return Value	This function does not return a value.
Comments	The DeviceMode function is part of the printer's device driver, not part of GDI. To call this function, an application must load the printer driver by calling the LoadLibrary function and retrieve the address of the function by using the Get- ProcAddress function. The application can then use the address to set up the printer.
	DeviceMode is not supported by all printer drivers. If the GetProcAddress function returns NULL, DeviceMode is not supported.
See Also	CreateDC, ExtDeviceMode, GetModuleHandle, LoadLibrary

DialogBox

int DialogBox(hinst, HINSTANCE hinst; LPCSTR lpszDlgTen HWND hwndOwner; DLGPROC dlgprc;	
	The DialogBox function creates a modal dialog box from a dialog box template resource.
Parameters	<i>hinst</i> Identifies an instance of the module whose executable file contains the dialog box template.
	<i>lpszDlgTemp</i> Points to a null-terminated string that names the dialog box template.
	<i>hwndOwner</i> Identifies the window that owns the dialog box.
	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation about the dialog box procedure, see the description of the Dialog- Proc callback function.
Return Value	The return value specifies the value of the <i>nResult</i> parameter specified in the End-Dialog function that is used to terminate the dialog box. The system processes values returned by the dialog box procedure and does not return them to the application. The return value is -1 if the function cannot create the dialog box.
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The DialogBox function does not return control until the dialog box procedure ter- minates the modal dialog box by calling the EndDialog function.
	A dialog box can contain up to 255 controls.
Example	The following example uses the DialogBox function to create a modal dialog box: DLGPROC dlgprc; HWND hwndParent;

case IDM_ABOUT:
<pre>dlgprc = (DLGPROC) MakeProcInstance(About, hinst);</pre>
<pre>DialogBox(hinst, "AboutBox", hwndParent, dlgprc);</pre>
<pre>FreeProcInstance((FARPROC) dlgprc);</pre>
break;

DialogBoxIndirect

2.x

int DialogBoxIndire HINSTANCE hinst; HGLOBAL hglbDlg HWND hwndOwner; DLGPROC dlgprc;			
	The DialogBoxIndirect function creates a modal dialog box from a dialog box template in memory.		
Parameters	<i>hinst</i> Identifies the instance of the module that will create the dialog box.		
	<i>hglbDlgTemp</i> Identifies the global memory object that contains a dialog box template used to create the dialog box. This template is in the form of a DialogBoxHeader struc- ture. For more information about this structure, see Chapter 7, "Resource For- mats Within Executable Files," in the <i>Microsoft Windows Programmer's</i> <i>Reference, Volume 4.</i>		
	<i>hwndOwner</i> Identifies the window that owns the dialog box.		
	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation about the dialog box procedure, see the description of the Dialog- Proc callback function.		
Return Value	The return value is the value of the <i>nResult</i> parameter specified in the EndDialog function that is used to terminate the dialog box. The system processes values returned by the dialog box procedure and does not return them to the application. The return value is -1 if the function cannot create the dialog box.		

Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The DialogBoxIndirect function does not return control until the dialog box pro- cedure terminates the modal dialog box by calling the EndDialog function.
	A dialog box can contain up to 255 controls.
Example	The following example uses the DialogBoxIndirect function to create a dialog box from a dialog box template in memory:
	<pre>#define TEMPLATE_SIZE 100 HGLOBAL hglbDlgTemp; DLGPROC dlgprc; int result; HWND hwndParent;</pre>
	/* Allocate a global memory object for the dialog box template. $*/$
	hglbDlgTemp = GlobalAlloc(GHND, TEMPLATE_SIZE);
	. /* Build a DLGTEMPLATE structure in the memory object. */
	dlgprc = (DLGPROC) MakeProcInstance(DialogProc, hinst); result = DialogBoxIndirect(hinst, hglbDlgTemp, hwndParent, dlgprc);
See Also	DialogBox, DialogBoxIndirectParam, DialogBoxParam, DialogProc, End- Dialog, MakeProcInstance

DialogBoxIndirectParam

3.0

int DialogBoxIndirectParam (<i>hinst</i> , <i>hglbDlgTemp</i> , <i>hwndOwner</i> , <i>dlgprc</i> , <i>lParamInit</i>)		
HINSTANCE hinst;	/* handle of application instance	*/
HGLOBAL hglbDlgTemp;	/* handle of memory with dialog box template	*/
HWND hwndOwner;	/* handle of owner window	*/
DLGPROC <i>dlgprc</i> ;	/* instance address of dialog box procedure	*/
LPARAM lParamInit;	/* initialization value	*/

The **DialogBoxIndirectParam** function creates a modal dialog box from a dialog box template in memory. Before displaying the dialog box, the function passes an application-defined value to the dialog box procedure as the *lParam* parameter of

	the WM_INITDIALOG message. An application can use this value to initialize dialog box controls.
Parameters	<i>hinst</i> Identifies the instance of the module that will create the dialog box.
	<i>hglbDlgTemp</i> Identifies the global memory object that contains a dialog box template used to create the dialog box. This template is in the form of a DialogBoxHeader struc- ture. For more information about this structure, see Chapter 7, "Resource For- mats Within Executable Files," in the <i>Microsoft Windows Programmer's</i> <i>Reference, Volume 4.</i>
	<i>hwndOwner</i> Identifies the window that owns the dialog box.
	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more information about the dialog box procedure, see the description of the Dialog-Proc callback function.
	<i>lParamInit</i> Specifies a 32-bit value that DialogBoxIndirectParam passes to the dialog box when the WM_INITDIALOG message is being processed.
Return Value	The return value is the value of the <i>nResult</i> parameter specified in the EndDialog function that is used to terminate the dialog box. The system processes values returned by the dialog box procedure and does not return them to the application. The return value is -1 if the function cannot create the dialog box.
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The DialogBoxIndirectParam function does not return control until the dialog box procedure terminates the modal dialog box by calling the EndDialog function.
	A dialog box can contain up to 255 controls.
Example	The following example uses the DialogBoxIndirectParam function to create a modal dialog box from a dialog box template in memory. The example uses the <i>lParamInit</i> parameter to send two initialization parameters (wInitParm1 and wInitParm2) to the dialog box procedure when the WM_INITDIALOG message is being processed.

<pre>#define TEMPLATE_SIZE 100 HGLOBAL hglbDlgTemp; DLGPROC dlgprc; int result; HWND hwndParent; WORD wInitParm1, wInitParm2;</pre>
/* Allocate a global memory object for the dialog box template. $*/$
hglbDlgTemp = GlobalAlloc(GHND, TEMPLATE_SIZE);
. /* Build a DLGTEMPLATE structure in the memory object. */
dlgprc = (DLGPROC) MakeProcInstance(DialogProc, hinst); result = DialogBoxIndirectParam(hinst, hglbDlgTemp, hwndParent, dlgprc, (LPARAM) MAKELONG(wInitParm1, wInitParm2));

See Also

DialogBox, DialogBoxIndirect, DialogBoxParam, DialogProc, EndDialog, MakeProcInstance

DialogBoxParam

int DialogBoxParam(hinst, lpszDlgTemp, hwndOwner, dlgprc, lParamInit) **HINSTANCE** *hinst*; */ /* handle of application instance LPCSTR lpszDlgTemp; /* address of dialog box template name */ **HWND** hwndOwner; /* handle of owner window */ **DLGPROC** *dlgprc*; /* instance address of dialog box procedure */ LPARAM lParamInit; /* initialization value */

The **DialogBoxParam** function creates a modal dialog box from a dialog box template resource. Before displaying the dialog box, the function passes an application-specified value to the dialog box procedure as the *lParam* parameter of the WM_INITDIALOG message. An application can use this value to initialize dialog box controls.

Parameters

hinst

Identifies an instance of the module whose executable file contains the dialog box template.

lpszDlgTemp

Points to a null-terminated string that names the dialog box template.

hwndOwner

Identifies the window that owns the dialog box.

	<i>dlgprc</i> Specifies the procedure-instance address of the dialog box procedure. The address must be created by using the MakeProcInstance function. For more in- formation about the dialog box procedure, see the description of the Dialog- Proc callback function.
	<i>lParamInit</i> Specifies a 32-bit value that DialogBoxParam passes to the dialog box proce- dure when creating the dialog box.
Return Value	The return value specifies the value of the <i>nResult</i> parameter specified in the End-Dialog function that is used to terminate the dialog box. The system processes values returned by the dialog box procedure and does not return them to the application. The return value is -1 if the function cannot create the dialog box.
Comments	The CreateWindowEx function is called to create the dialog box. The dialog box procedure then receives a WM_SETFONT message (if DS_SETFONT style was specified) and a WM_INITDIALOG message, and then the dialog box is displayed.
	The DialogBoxParam function does not return control until the dialog box proce- dure terminates the modal dialog box by calling the EndDialog function.
	A dialog box can contain up to 255 controls.
Example	The following example uses the DialogBoxParam function to create a modal dialog box. The function passes the dialog box a pointer to a string when the WM_INITDIALOG message is being processed.
	DLGPROC dlgprc; HWND hwndParent; PSTR pszFileName; int result;
	case IDM_OPEN:
	<pre>dlgprc = (DLGPROC) MakeProcInstance(FileOpenProc, hinst); result = DialogBoxParam(hinst, "FileOpenBox", hwndParent,</pre>
See Also	DialogBox, DialogBoxIndirect, DialogBoxIndirectParam, DialogProc, EndDialog, MakeProcInstance

DialogProc

BOOL CALLBACI HWND hwndDlg; UINT msg; WPARAM wParam LPARAM lParam;	K DialogProc(hwndDlg, msg, wParam, lParam) /* handle of dialog box */ /* message */ ; /* first message parameter */ /* second message parameter */
	The DialogProc function is an application-defined callback function that processes messages sent to a modeless dialog box.
Parameters	hwndDlg Identifies the dialog box.
	<i>msg</i> Specifies the message.
	<i>wParam</i> Specifies 16 bits of additional message-dependent information.
	<i>IParam</i> Specifies 32 bits of additional message-dependent information.
Return Value	Except in response to the WM_INITDIALOG message, the dialog box procedure should return nonzero if it processes the message, and zero if it does not. In response to a WM_INITDIALOG message, the dialog box procedure should return zero if it calls the SetFocus function to set the focus to one of the controls in the dialog box. Otherwise, it should return nonzero, in which case the system will set the focus to the first control in the dialog box that can be given the focus.
Comments	The dialog box procedure is used only if the dialog box class is used for the dialog box. This is the default class and is used if no explicit class is given in the dialog box template. Although the dialog box procedure is similar to a window procedure, it must not call the DefWindowProc function to process unwanted messages. Unwanted messages are processed internally by the dialog box window procedure.
	DialogProc is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition file.
See Also	CreateDialog, CreateDialogIndirect, CreateDialogIndirectParam, Create- DialogParam, DefWindowProc, SetFocus

DirectedYield

void DirectedYield(htask)
HTASK htask;

The Directed Yield function puts the current task to sleep and awakens the given task **Parameters** htask Specifies the task to be executed. **Return Value** This function does not return a value. Comments When relinquishing control to other applications (that is, when exiting hard mode), a Windows-based debugger should call **Directed Yield**, identifying the handle of the task being debugged. This ensures that the debugged application runs next and that messages received during debugging are processed by the appropriate windows The Windows scheduler executes a task only when there is an event waiting for it, such as a paint message, or a message posted in the message queue. If an application uses **Directed Yield** for a task with no events scheduled, the task will not be executed. Instead, Windows searches the task queue. In some cases, however, you may want the application to force a specific task to be scheduled. The application can do this by calling the **PostAppMessage** function, specifying a WM_NULL message identifier. Then, when the application calls Directed Yield, the scheduler will run the task regardless of the task's event status. **Directed Yield** starts the task identified by *htask* at the location where it left off. Typically, debuggers should use **TaskSwitch** instead of **DirectedYield**, because TaskSwitch can start a task at any address. **Directed Yield** returns when the current task is reawakened. This occurs when the task identified by *htask* waits for messages or uses the **Yield** or **DirectedYield** function. Execution will continue as before the task switch. **Directed Yield** is located in KRNL286.EXE and KRNL386.EXE and is available in Windows versions 3.0 and 3.1. See Also PostAppMessage, TaskSwitch, TaskGetCSIP, TaskSetCSIP, Yield

DispatchMessage 2.x LONG DispatchMessage(lpmsg) */ const MSG FAR* lpmsg; /* address of structure with message The **DispatchMessage** function dispatches a message to a window. It is typically used to dispatch a message retrieved by the GetMessage function. **Parameters** lpmsg Points to an MSG structure that contains the message. The MSG structure has the following form: typedef struct tagMSG { /* msq */ HWND hwnd: UINT message; WPARAM wParam: LPARAM 1Param: DWORD time: POINT pt: } MSG; The **MSG** structure must contain valid message values. If the *lpmsg* parameter points to a WM TIMER message and the *lParam* parameter of the WM TIMER message is not NULL, then *lParam* points to a function that is called instead of the window procedure. For a full description of this structure, see the *Microsoft Windows Program*mer's Reference, Volume 3. **Return Value** The return value specifies the value returned by the window procedure. Although its meaning depends on the message being dispatched, generally the return value is ignored. Example The following example shows a typical use of the **DispatchMessage** function in an application's main message loop: MSG msg; HWND hwnd: HWND hwndDlgModeless; HANDLE haccl: while (GetMessage(&msg, NULL, 0, 0)) { if ((hwndDlgModeless == NULL || !IsDialogMessage(hwndDlgModeless, &msg)) && !TranslateAccelerator(hwnd, haccl, &msg)) { TranslateMessage(&msg); DispatchMessage(&msg); } }

DlgDirList		2.x	
int DlgDirList(hwn, HWND hwndDlg; LPSTR lpszPath; int idListBox; int idStaticPath; UINT uFileType;	dDlg, lpszPath, idListBox, /* handle of dialog box /* address of path or fil /* identifier of list box /* identifier of static co /* file attributes to disp	with list box */ ename string */ */ ntrol */	
		fills a list box with a file or directory listing. It fills the of all files matching the specified path or filename.	
Parameters	<i>hwndDlg</i> Identifies the dialog b	ox that contains the list box.	
	<i>lpszPath</i> Points to a null-terminated string that contains the path or filename. DlgDirList modifies this string, which should be long enough to contain the modifications. For more information, see the following Comments section.		
	<i>idListBox</i> Specifies the identifier of a list box. If this parameter is zero, DlgDirList assumes that no list box exists and does not attempt to fill one.		
	<i>idStaticPath</i> Specifies the identifier of the static control used for displaying the current drive and directory. If this parameter is zero, DlgDirList assumes that no such con- trol is present.		
	<i>uFileType</i> Specifies the attribute a combination of the f	s of the filenames to be displayed. This parameter can be Following values:	
	Value	Meaning	
	DDL_READWRITE	Read-write data files with no additional attributes.	
	DDL_READONLY	Read-only files.	
	DDL_HIDDEN	Hidden files.	
	DDL_SYSTEM DDL_DIRECTORY	System files. Directories.	
	DDL_DIRECTORT	Archives.	

	Value	Meaning	
	DDL_POSTMSGS	LB_DIR flag. If the LB_DIR flag is set, Windows places the messages generated by DlgDirList in the application's queue; otherwise, they are sent directly to the dialog box procedure.	
	DDL_DRIVES	Drives.	
	DDL_EXCLUSIVE	Exclusive bit. If the exclusive bit is set, only files of the specified type are listed; otherwise, files of the specified type are listed in addition to normal files.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	If you specify a zero-length string for the <i>lpszPath</i> parameter or if you specify only a directory name but do not include any filename, the string will be changed to *.*.		
	The DlgDirList function shows directories enclosed in brackets ([]) and shows drives in the form [- <i>x</i> -], where <i>x</i> is the drive letter.		
	The <i>lpszPath</i> parameter has the following form:		
	[drive:][[\]directory[\directory]\][filename]		
	In this example, <i>drive</i> is a drive letter, <i>directory</i> is a valid MS-DOS directory name, and <i>filename</i> is a valid MS-DOS filename that must contain at least one wildcard. The wildcards are a question mark (?), meaning match any character, and an asterisk (*), meaning match any number of characters.		
	If the <i>lpszPath</i> parameter includes a drive or directory name, or both, the current drive and directory are changed to the specified drive and directory before the list box is filled. The static control identified by the <i>idStaticPath</i> parameter is also updated with the new drive or directory name, or both.		
	After the list box is filled, <i>lpszPath</i> is updated by removing the drive or directory portion, or both, of the path and filename.		
	DlgDirList sends LB_R	ESETCONTENT and LB_DIR messages to the list box.	
See Also	DlgDirListComboBox,	DlgDirSelect, DlgDirSelectComboBox	

DlgDirListComboBox

int DlgDirListCom HWND hwndDlg; LPSTR lpszPath; int idComboBox; int idStaticPath; UINT uFileType;	boBox (<i>hwndDlg</i> , <i>lpszPath</i> /* handle of dialog box /* address of path or fil /* identifier of combo b /* identifier of static co /* file attributes to disp	lename string */ box */ ontrol */
		Box function fills the list box of a combo box with a file or the list box with the names of all files matching the me.
Parameters	<i>hwndDlg</i> Identifies the dialog b	pox that contains the combo box.
		nated string that contains the path and filename. For more ollowing Comments section.
		er of a combo box in a dialog box. If this parameter is zero, ox assumes that no combo box exists and does not attempt
		er of the static control used for displaying the current drive parameter is zero, DlgDirListComboBox assumes that no it.
	<i>uFileType</i> Specifies the attributes of the filenames to be displayed. This parameter car a combination of the following values:	
	Value	Meaning
	DDL_READWRITE	Read-write data files with no additional attributes.
	DDL_READONLY	Read-only files.
	DDL_HIDDEN	Hidden files.
	DDL_SYSTEM	System files.
	DDL_DIRECTORY	Directories.
	DDL_ARCHIVE	Archives.
	DDL_POSTMSGS	CB_DIR flag. If the CB_DIR flag is set, Windows places the messages generated by DlgDirListComboBox in the application's queue; otherwise, they are sent directly to the dialog box procedure.
	DDL_DRIVES	Drives.

	Value	Meaning
	DDL_EXCLUSIVE	Exclusive bit. If the exclusive bit is set, only files of the specified type are listed; otherwise, files of the specified type are listed in addition to normal files.
Return Value	The return value is nonz	zero if the function is successful. Otherwise, it is zero.
Comments		Box function shows directories enclosed in brackets ([]) form [- <i>x</i> -], where <i>x</i> is the drive letter.
	The <i>lpszPath</i> parameter	has the following form:
	[drive:][[\]directory[\dir	rectory]][filename]
	name, and <i>filename</i> is a wildcard. The wildcard	a drive letter, <i>directory</i> is a valid MS-DOS directory valid MS-DOS filename that must contain at least one are a question mark (?), meaning match any character, ning match any number of characters.
	drive and directory are c box is filled. The static	er includes a drive or directory name, or both, the current changed to the specified drive and directory before the list control identified by the <i>idStaticPath</i> parameter is also up- e or directory name, or both.
		combo box is filled, <i>lpszPath</i> is updated by removing the n, or both, of the path and filename.
	DlgDirListComboBox the combo box.	sends CB_RESETCONTENT and CB_DIR messages to

DlgDirSelect

BOOL DlgDirSelect	t(hwndDlg, lpszPath, idListBox)	
HWND hwndDlg;	/* handle of dialog box with list box	*/
LPSTR lpszPath;	/* address of buffer for path or filename string	*/
int idListBox;	/* identifier of list box	*/

The **DlgDirSelect** function retrieves the current selection from a list box. It assumes that the list box has been filled by the **DlgDirList** function and that the selection is a drive letter, a file, or a directory name.

Parameters	hwndDlg Identifies the dialog box that contains the list box.
	<i>lpszPath</i> Points to a 128-byte buffer for the path or filename.
	<i>idListBox</i> Specifies the integer identifier of a list box in the dialog box.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	If the current selection is a directory name or drive letter, DlgDirSelect removes the enclosing brackets (and hyphens, for drive letters) so that the name or letter is ready to be inserted into a new path or filename. If there is no selection, the contents of the buffer pointed to by the <i>lpszPath</i> parameter do not change.
	The DlgDirSelect function does not allow more than one filename to be returned from a list box.
	The list box must not be a multiple-selection list box. If it is, this function will not return a zero value and <i>lpszPath</i> will remain unchanged.
	DlgDirSelect sends LB_GETCURSEL and LB_GETTEXT messages to the list box.
See Also	DlgDirList, DlgDirListComboBox, DlgDirSelectComboBox, DlgDirSelectEx

DlgDirSelectComboBox

BOOL DlgDirSelec HWND hwndDlg; LPSTR lpszPath; int idComboBox;	ctComboBox(hwndDlg, lpszPath, idComboBox) /* handle of dialog box with list box */ /* address of buffer for path or filename string */ /* identifier of combo box */
	The DlgDirSelectComboBox function retrieves the current selection from the list box of a combo box. It assumes that the list box has been filled by the DlgDirList- ComboBox function and that the selection is a drive letter, a file, or a directory name.
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the combo box. <i>lpszPath</i> Points to a 128-byte buffer for the path or filename.

	<i>idComboBox</i> Specifies the integer identifier of the combo box in the dialog box.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The DlgDirSelectComboBox function does not allow more than one selection to be returned from a combo box.
	If the current selection is a directory name or drive letter, DlgDirSelect-ComboBox removes the enclosing brackets (and hyphens, for drive letters) so that the name or letter is ready to be inserted into a new path or filename. If there is no selection, the contents of buffer pointed to by the <i>lpszPath</i> parameter do not change.
	DlgDirSelectComboBox sends CB_GETCURSEL and CB_GETLBTEXT messages to the combo box.
See Also	DlgDirList, DlgDirListComboBox, DlgDirSelect, DlgDirSelectComboBoxEx, DlgDirSelectEx

DlgDirSelectComboBoxEx

BOOL DlgDirSelec	ctComboBoxEx(hwndDlg, lpszPath, cbPat	th, idComboBox)
HWND hwndDlg;	/* handle of dialog box with list box	*/
LPSTR lpszPath;	/* address of buffer for path string	*/
int cbPath;	/* number of bytes in path string	*/
int idComboBox;	/* identifier of combo box	*/
	The DlgDirSelectComboBoxEx function list box of a combo box. The list box sho ComboBox function, and the selection sh directory name.	uld have been filled by the DlgDirList-
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains	the combo box.
	<i>lpszPath</i> Points to a buffer that receives the sele	ected path or filename.
	<i>cbPath</i> Specifies the length, in bytes, of the pa parameter. This value should not be la	ath or filename pointed to by the <i>lpszPath</i> arger than 128.
	<i>idComboBox</i> Specifies the integer identifier of the c	combo box in the dialog box.

2.x

Return Value	The return value is nonzero if the current combo box selection is a directory name. Otherwise, it is zero.
Comments	The DlgDirSelectComboBoxEx function does not allow more than one filename to be returned from a combo box.
	If the current selection is a directory name or drive letter, DlgDirSelect-ComboBoxEx removes the enclosing square brackets (and hyphens, for drive letters) so that the name or letter is ready to be inserted into a new path or filename. If there is no selection, the contents of buffer pointed to by the <i>lpszPath</i> parameter do not change.
	DlgDirSelectComboBoxEx sends CB_GETCURSEL and CB_GETLBTEXT messages to the combo box.
See Also	DlgDirList, DlgDirListComboBox, DlgDirSelect, DlgDirSelectEx, DlgDirSelectComboBox

DIgDirSelectEx

BOOL DlgDirSelec	tEx(hwndDlg, lpszPath, cbPath, idListBox)	
HWND hwndDlg;	/* handle of dialog box with list box	*/
LPSTR lpszPath;	/* address of buffer for path string	*/
int cbPath;	/* number of bytes in path string	*/
int idListBox;	/* identifier of list box	*/
	The DlgDirSelectEx function retrieves the specified list box should have been filled by selection should be a drive letter, a file, or a	y the DlgDirList function, and the
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains th	e list box.
	<i>lpszPath</i> Points to a buffer that receives the select	ed path or filename.
	<i>cbPath</i> Specifies the length, in bytes, of the path parameter. This value should not be larg	· · ·
	<i>idListBox</i> Specifies the integer identifier of a list b	ox in the dialog box.
Return Value	The return value is nonzero if the current li Otherwise, it is zero.	st box selection is a directory name.

Comments	If the current selection is a directory name or drive letter, DlgDirSelectEx re- moves the enclosing square brackets (and hyphens, for drive letters) so that the name or letter is ready to be inserted into a new path or filename. If there is no selection, the contents of buffer pointed to by the <i>lpszPath</i> parameter do not change.
	The DlgDirSelectEx function does not allow more than one filename to be re- turned from a list box.
	The list box must not be a multiple-selection list box. If it is, this function will not return a zero value and <i>lpszPath</i> will remain unchanged.
	DlgDirSelectEx sends LB_GETCURSEL and LB_GETTEXT messages to the list box.
See Also	DlgDirList, DlgDirListComboBox, DlgDirSelect, DlgDirSelectComboBox

	The DOS3Call function allows an application to call an MS-DOS Interrupt 21h function. DOS3Call can be called only from assembly-language routines. It is exported from KRNL286.EXE and KRNL386.EXE and is not defined in any Windows header or include files.
Parameters	Registers must be set up as required by the desired Interrupt 21h function before the application calls the DOS3Call function.
Return Value	The register contents are preserved as they are returned by the Interrupt 21h func- tion.
Comments	Applications should use this function instead of a directly coded MS-DOS Inter- rupt 21h function. The DOS3Call function runs somewhat faster than the equiv- alent MS-DOS Interrupt 21h function running in Windows.
Example	The following example shows how to prototype the DOS3Call function in C:
	extern void FAR PASCAL DOS3Call(void);
	To declare the DOS3Call function in an assembly-language routine, an applica- tion could use the following line:
	extrn DOS3CALL: far

If the application includes CMACROS.INC, the function is declared as follows: extrnFP D0S3Call

The following example is a typical use of the DOS3Call function:

```
extrn DOS3CALL: far
.
.
; set registers
mov ah, DOSFUNC ;DOSFUNC = Int 21h function number
cCall DOS3Call
```

DPtoLP

BOOL DPtoLP(*hdc*, *lppt*, *cPoints*) HDC hdc; /* handle of device context */ **POINT FAR*** *lppt*; /* address of array with points */ /* number of points in array */ int cPoints; The **DPtoLP** function converts device coordinates (points) into logical coordinates. **Parameters** hdc Identifies the device context. lppt Points to an array of **POINT** structures. Each coordinate in each structure is mapped into the logical coordinate system for the current device context. The **POINT** structure has the following form: /* pt */ typedef struct tagPOINT { int x: int y; } POINT; For a full description of this structure, see the *Microsoft Windows Program*mer's Reference, Volume 3. *cPoints* Specifies the number of points in the array. **Return Value** The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments	The conversion depends on the current mapping mode and the settings of the origins and extents for the device's window and viewport.
Example	The following example sets the mapping mode to MM_LOENGLISH, and then calls the DPtoLP function to convert the coordinates of a rectangle into logical coordinates:
	RECT rc;
	SetMapMode(hdc, MM_LOENGLISH); SetRect(&rc, 100, 100, 200, 200); DPtoLP(hdc, (LPPOINT) &rc, 2);
See Also	LPtoDP

DragAcceptFiles

#include <shellapi.h>

<pre>void DragAcceptFi HWND hwnd; BOOL fAccept;</pre>	
	The DragAcceptFiles function registers whether a given window accepts dropped files.
Parameters	<i>hwnd</i> Identifies the window registering whether it accepts dropped files.
	<i>fAccept</i> Specifies whether the window specified by the <i>hwnd</i> parameter accepts dropped files. An application should set this value to TRUE to accept dropped files or FALSE to discontinue accepting dropped files.
Return Value	This function does not return a value.
Comments	When an application calls DragAcceptFiles with <i>fAccept</i> set to TRUE, Windows File Manager (WINFILE.EXE) sends the specified window a WM_DROPFILES message each time the user drops a file in that window.

3.1

DragFinish

#include <shellapi.h>

<pre>void DragFinish(hL HDROP hDrop;</pre>	Drop) /* handle of memory to free */
	The DragFinish function releases memory that Windows allocated for use in transferring filenames to the application.
Parameters	<i>hDrop</i> Identifies the internal data structure that describes dropped files. This handle is passed to the application in the <i>wParam</i> parameter of the WM_DROPFILES message.
Return Value	This function does not return a value.

DragQueryFile

#include <shellapi.h>

HDROP hDrop; UINT iFile;	le (<i>hDrop</i> , <i>iFile</i> , <i>lpszFile</i> , <i>cb</i>) /* handle of structure for dropped files /* index of file to query /* address of buffer for returned filename /* size of buffer for filename	*/ */ */
	The DragQueryFile function retrieves the numbrilenames.	ber of dropped files and their
Parameters	<i>hDrop</i> Identifies the internal data structure containing This handle is passed to the application in the WM_DROPFILES message.	
	<i>iFile</i> Specifies the index of the file to query. The invalue of the <i>iFile</i> parameter is -1, DragQuer dropped. If the value of the <i>iFile</i> parameter is ber of files dropped, DragQueryFile copies to value to the buffer pointed to by the <i>lpszFile</i>	ryFile returns the number of files s between zero and the total num- the filename corresponding to that

	<i>lpszFile</i> Points to a null-terminated string that contains the filename of a dropped file when the function returns. If this parameter is NULL and the <i>iFile</i> parameter specifies the index for the name of a dropped file, DragQueryFile returns the required size, in bytes, of the buffer for that filename.
	<i>cb</i> Specifies the size, in bytes, of the <i>lpszFile</i> buffer.
Return Value	When the function copies a filename to the <i>lpszFile</i> buffer, the return value is the number of bytes copied. If the <i>iFile</i> parameter is 0xFFFF, the return value is the number of dropped files. If <i>iFile</i> is between zero and the total number of dropped files and if <i>lpszFile</i> is NULL, the return value is the required size of the <i>lpszFile</i> buffer.
See Also	DragQueryPoint

DragQueryPoint

#include <shellapi.h>

BOOL DragQueryl	Point(hDrop, lppt)
HDROP hDrop;	/* handle of structure for dropped file */ /* address of structure for cursor coordinates */
	The DragQueryPoint function retrieves the window coordinates of the cursor when a file is dropped.
Parameters	<i>hDrop</i> Identifies the internal data structure that describes the dropped file. This structure is returned in the <i>wParam</i> parameter of the WM_DROPFILES message.
	<i>lppt</i> Points to a POINT structure that the function fills with the coordinates of the position at which the cursor was located when the file was dropped. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.

Return Value	The return value is nonzero if the file is dropped in the client area of the window. Otherwise, it is zero.
Comments	The DragQueryPoint function fills the POINT structure with the coordinates of the position at which the cursor was located when the user released the left mouse button. The window for which coordinates are returned is the window that received the WM_DROPFILES message.
See Also	DragQueryFile

DrawFocusRect

void DrawFocusRec HDC <i>hdc</i> ; const RECT FAR* <i>l</i> į	t(hdc, lprc) /* handle of device context */ prc; /* address of structure with rectangle */
	The DrawFocusRect function draws a rectangle in the style used to indicate that the rectangle has the focus.
Parameters	 hdc Identifies the device context. lprc Points to a RECT structure that contains the logical coordinates of the rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
Comments	Because this is an XOR function, calling it a second time and specifying the same rectangle removes the rectangle from the screen.

The rectangle this function draws cannot be scrolled. To scroll an area containing a rectangle drawn by this function, call **DrawFocusRect** to remove the rectangle from the screen, scroll the area, and then call **DrawFocusRect** to draw the rectangle in the new position.

See Also

FrameRect

Drawlcon

BOOL DrawIcon	(hdc, x, v, hicon)
HDC hdc;	/* handle of device context */
int x;	/* x-coordinate of upper-left corner */
int y;	/* y-coordinate of upper-left corner */
HICON hicon;	/* handle of icon to draw */
	The DrawIcon function draws an icon on the given device. The DrawIcon function places the icon's upper-left corner at the specified location.
Parameters	hdc
	Identifies the device context for a window.
	x Specifies the logical x-coordinate of the upper-left corner of the icon.
	specifies the togical x-coordinate of the upper-tent conter of the fcon.
	<i>y</i> Specifies the logical y-coordinate of the upper-left corner of the icon.
	hicon
	Identifies the icon to be drawn.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The icon resource must have been loaded by using the LoadIcon function. The MM_TEXT mapping mode must be selected before using this function.
See Also	GetMapMode, LoadIcon, SetMapMode

2.x

DrawMen	uBar 2.x
void DrawMenu HWND hwnd;	Bar(<i>hwnd</i>) /* handle of window with menu bar to redraw */
	The DrawMenuBar function redraws the menu bar of the given window. If a menu bar is changed after Windows has created the window, an application should call this function to draw the changed menu bar.
Parameters	<i>hwnd</i> Identifies the window whose menu must be redrawn.
Return Value	This function does not return a value.

DrawText

int DrawText(hdc, lp	psz, cb, lprc, fuFormat)	
HDC hdc;	/* handle of device context	*/
LPCSTR lpsz;	/* address of string to draw	*/
int cb;	/* string length	*/
RECT FAR* <i>lprc</i> ;	/* address of structure with formatting dimensions	*/
UINT <i>fuFormat</i> ;	/* text-drawing flags	*/

The DrawText function draws formatted text into a given rectangle. It formats text by expanding tabs into appropriate spaces, aligning text to the left, right, or center of the rectangle, and breaking text into lines that fit within the rectangle.

The DrawText function uses the device context's selected font, text color, and background color to draw the text. Unless the DT NOCLIP format is specified, DrawText clips the text so that the text does not appear outside the given rectangle. All formatting is assumed to have multiple lines unless the DT SINGLELINE format is specified.

Parameters

Identifies the device context. This cannot be a metafile device context.

lpsz

hdc

Points to the string to be drawn. If the *cb* parameter is -1, the string must be null-terminated.

cb

Specifies the number of bytes in the string. If this parameter is -1, then the *lpsz* parameter is assumed to be a long pointer to a null-terminated string and **DrawText** computes the character count automatically.

lprc

Points to a **RECT** structure that contains the logical coordinates of the upperleft and lower-right corners of the rectangle in which the text is to be formatted. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

fuFormat

Specifies an array of flags that determine how to draw the text. This parameter can be a combination of the following values:

Value	Meaning
DT_BOTTOM	Specifies bottom-aligned text. This value must be combined with DT_SINGLELINE.
DT_CALCRECT	Determines the width and height of the rectangle. If there are multiple lines of text, DrawText will use the width of the rectangle pointed to by the <i>lprc</i> parameter and extend the base of the rectangle to bound the last line of text. If there is only one line of text, DrawText will modify the right side of the rectangle so that it bounds the last character in the line. In either case, DrawText returns the height of the formatted text but does not draw the text.
DT_CENTER	Centers text horizontally.
DT_EXPANDTABS	Expands tab characters. The default number of characters per tab is eight.
DT_EXTERNALLEADING	Includes the font external leading in line height. Normally, external leading is not included in the height of a line of text.
DT_LEFT	Left-aligns text.
DT_NOCLIP	Draws without clipping. DrawText is somewhat faster when DT_NOCLIP is used.

	Value	Meaning
	DT_NOPREFIX	Turns off processing of prefix characters. Nor- mally, DrawText interprets the mnemonic & as a directive to underscore the character that follows, and the mnemonic && as a directive to print a single &. By specifying DT_NOPREFIX, this pro- cessing is turned off.
	DT_RIGHT	Right-aligns text.
	DT_SINGLELINE	Specifies single line only. Carriage returns and linefeeds do not break the line.
	DT_TABSTOP	Sets tab stops. The high-order byte of the <i>fuFormat</i> parameter is the number of characters for each tab. The default number of characters per tab is eight.
	DT_TOP	Specifies top-aligned text (single line only).
	DT_VCENTER	Specifies vertically centered text (single line only).
	DT_WORDBREAK	Specifies word breaking. Lines are automatically broken between words if a word would extend past the edge of the rectangle specified by the <i>lprc</i> pa- rameter. A carriage return–linefeed sequence will also break the line.
		CT, DT_EXTERNALLEADING, LIP, and DT_NOPREFIX values cannot be used ie.
Return Value	The return value specifies the h	eight of the text if the function is successful.
Comments	If the selected font is too large f does not attempt to substitute a	for the specified rectangle, the DrawText function smaller font.
		specified, the RECT structure pointed to by the to reflect the width and height needed to draw the
	function), DrawText will displat than at the left of the given recta	gnment flag has been set (see the SetTextAlign ay text starting at the current position, rather angle. DrawText will not wrap text when the set (the DT_WORDBREAK flag will have no
	The text color must be set by th	e SetTextColor function.

DriverProc

LRESULT CALLBACK DriverProc(*dwDriverIdentifier*, *hDriver*, *wMessage*, *lParam1*, *lParam2*) **DWORD** *dwDriverIdentifier*; /* identifies installable driver */

DWORD dwDriverIdentifier;	/* identifies installable driver	*/
HDRVR hDriver;	/* handle of installable driver	*/
UINT wMessage;	/* message	*/
LPARAM <i>lParam1</i> ;	/* first message parameter	*/
LPARAM lParam2;	/* second message parameter	*/

The DriverProc function processes the specified message.

Parameters

dwDriverIdentifier

Specifies an identifier of the installable driver.

hDriver

Identifies the installable driver. This parameter is a unique handle that Windows assigns to the driver.

wMessage

Identifies a message that the driver must process. Following are the messages that Windows or an application can send to an installable driver:

Message	Description
DRV_CLOSE	Notifies the driver that it should decrement (decrease by one) its usage count and unload the driver if the count is zero.
DRV_CONFIGURE	Notifies the driver that it should display a custom- configuration dialog box. (This message should be sent only if the driver returns a nonzero value when the DRV_QUERYCONFIGURE message is processed.)
DRV_DISABLE	Notifies the driver that its allocated memory is about to be freed.
DRV_ENABLE	Notifies the driver that it has been loaded or re- loaded, or that Windows has been enabled.
DRV_FREE	Notifies the driver that it will be discarded.
DRV_INSTALL	Notifies the driver that it has been successfully in- stalled.
DRV_LOAD	Notifies the driver that it has been successfully loaded.
DRV_OPEN	Notifies the driver that it is about to be opened.
DRV_POWER	Notifies the driver that the device's power source is about to be turned off or turned on.
DRV_QUERYCONFIGURE	Determines whether the driver supports the DRV_CONFIGURE message. The message displays a private configuration dialog box.

2.x

	Message	Description
	DRV_REMOVE	Notifies the driver that it is about to be removed from the system.
	<i>lParam1</i> Specifies the first message pa	rameter.
	<i>lParam2</i> Specifies the second message	parameter.
Return Value	The return value is nonzero if th	e function is successful. Otherwise, it is zero.
Comments	The DriverProc function is the driver; it is supplied by the drive	main function within a Windows installable r developer.
		s DRV_OPEN, <i>lParam1</i> is the string following STEM.INI file and <i>lParam2</i> is the value given as to the OpenDriver function.
		as DRV_CLOSE, <i>lParam1</i> and <i>lParam2</i> are the <i>lParam2</i> parameters in the call to the Close -
See Also	CloseDriver, OpenDriver	

Ellipse

BOOL Ellipse(hdc, r	nLeftRect, nTopRect, nRightRect, nBottomRect)	
HDC hdc;	/* handle of device context	*/
int nLeftRect;	/* x-coordinate upper-left corner bounding rectangle	*/
int nTopRect;	/* y-coordinate upper-left corner bounding rectangle	*/
int nRightRect;	/* x-coordinate lower-right corner bounding rectangle	*/
int nBottomRect;	/* y-coordinate lower-right corner bounding rectangle	*/
	The Ellipse function draws an ellipse. The center of the ellipse specified bounding rectangle. The ellipse is drawn by using the interior is filled by using the current brush.	
	If either the width or the height of the bounding rectangle is ze does not draw the ellipse.	ero, the function
Parameters	hdc	

Identifies the device context.

	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The figure drawn by this function extends up to but does not include the right and bottom coordinates. This means that the height of the figure is determined as follows:
	nBottomRect – nTopRect
	Similarly, the width of the figure is determined as follows:
	nRightRect – nLeftRect
	Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.
See Also	Arc, Chord

EmptyClipboard

2.x

BOOL EmptyClipboard(void)

The **EmptyClipboard** function empties the clipboard and frees handles to data in the clipboard. It then assigns ownership of the clipboard to the window that currently has the clipboard open.

Parameters This function has no parameters.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

3.1

Comments The clipboard must be open when the **EmptyClipboard** function is called.

See Also OpenClipboard

EnableCommNotification

BOOL EnableCom	mNotification(idComDev, hwnd, cbWriteNotify, cbOutQueue)
<pre>int idComDev; HWND hwnd; int cbWriteNotify; int cbOutQueue;</pre>	/* communications-device identifier*//* handle of window receiving messages*//* number of bytes written before notification*//* minimum number of bytes in output queue*/
	The EnableCommNotification function enables or disables WM_COMMNOTIFY message posting to the given window.
Parameters	<i>idComDev</i> Specifies the communications device that is posting notification messages to the window identified by the <i>hwnd</i> parameter. The OpenComm function re- turns the value for the <i>idComDev</i> parameter.
	<i>hwnd</i> Identifies the window whose WM_COMMNOTIFY message posting will be enabled or disabled. If this parameter is NULL, EnableCommNotification dis- ables message posting to the current window.
	<i>cbWriteNotify</i> Indicates the number of bytes the COM driver must write to the application's input queue before sending a notification message. The message signals the ap- plication to read information from the input queue.
	<i>cbOutQueue</i> Indicates the minimum number of bytes in the output queue. When the number of bytes in the output queue falls below this number, the COM driver sends the application a notification message, signaling it to write information to the out- put queue.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero, indi- cating an invalid COM port identifier, a port that is not open, or a function not sup- ported by COMM.DRV.
Comments	If an application specifies –1 for the <i>cbWriteNotify</i> parameter, the WM_COMMNOTIFY message is sent to the specified window for CN_EVENT and CN_TRANSMIT notifications but not for CN_RECEIVE notifications. If –1

EnableHardwareInnut

is specified for the *cbOutQueue* parameter, CN_EVENT and CN_RECEIVE notifications are sent but CN TRANSMIT notifications are not.

If a timeout occurs before as many bytes as specified by the cbWriteNotify parameter are written to the input queue, a WM_COMMNOTIFY message is sent with the CN RECEIVE flag set. When this occurs, another message will not be sent until the number of bytes in the input queue falls below the number specified in the *cbWriteNotify* parameter. Similarly, a WM COMMNOTIFY message in which the CN_RECEIVE flag is set is sent only when the output queue is larger than the number of bytes specified in the *cbOutQueue* parameter.

The Windows 3.0 version of COMM.DRV does not support this function.

EnableHard	vareInput 2.x
BOOL EnableHard BOOL fEnableInpu	<pre>lwareInput(fEnableInput) t; /* for enabling or disabling queuing */</pre>
	The EnableHardwareInput function enables or disables queuing of mouse and keyboard input.
Parameters	<i>fEnableInput</i> Specifies whether to enable or disable queuing of input. If this parameter is TRUE, keyboard and mouse input are queued. If the parameter is FALSE, key- board and mouse input are disabled.
Return Value	The return value is nonzero if queuing of input was previously enabled. Otherwise, it is zero.
Comments	This function does not disable input from installable drivers, nor does it disable device drivers.
See Also	GetInputState

EnableMenultem

HMENU hmenu:

BOOL EnableMenuItem(*hmenu*, *idEnableItem*, *uEnable*)

pop-up menu.

/* handle of menu

UINT *idEnableItem*; /* menu-item identifier */ **UINT** *uEnable*; /* action flag */ The EnableMenuItem function enables, disables, or grays (dims) a menu item. **Parameters** hmenu Identifies the menu. *idEnableItem* Specifies the menu item to be enabled, disabled, or grayed. This parameter can specify pop-up menu items as well as standard menu items. The interpretation of this parameter depends on the value of the *uEnable* parameter. uEnable Specifies the action to take. This parameter can be MF DISABLED, MF ENABLED, or MF GRAYED, combined with MF BYCOMMAND or MF BYPOSITION. These values have the following meanings: Value Meaning MF BYCOMMAND Specifies that the *idEnableItem* parameter gives the menuitem identifier Specifies that the *idEnableItem* parameter gives the posi-MF_BYPOSITION tion of the menu item (the first item is at position zero). MF_DISABLED Specifies that the menu item is disabled. MF_ENABLED Specifies that the menu item is enabled. MF GRAYED Specifies that the menu item is grayed. **Return Value** The return value is 0 if the menu item was previously disabled, 1 if the menu item was previously enabled, and -1 if the menu item does not exist. Comments To disable or enable input to a menu bar, see the WM_SYSCOMMAND message. The CreateMenu, InsertMenu, ModifyMenu, and LoadMenuIndirect functions can also set the state (enabled, disabled, or grayed) of a menu item. Using the MF_BYPOSITION value requires an application to specify the correct menu handle. If the menu handle of the menu bar is specified, a top-level menu item (an item in the menu bar) is affected. To set the state of an item in a pop-up

or nested pop-up menu by position, an application must specify the handle of the

*/

When an application specifies the MF_BYCOMMAND flag, Windows checks all pop-up menu items that are subordinate to the menu identified by the specified menu handle; therefore, unless duplicate menu items are present, specifying the menu handle of the menu bar is sufficient.

CheckMenuItem, HiliteMenuItem

EnableScrollBar

BOOL EnableScrollBan	(hwnd, fnSBFlags, fuArrowFlags)	
HWND hwnd;	/* handle of window or scroll bar	*/
int fnSBFlags;	/* scroll-bar type flag	*/
UINT fuArrowFlags;	/* scroll-bar arrow flag	*/

The **EnableScrollBar** function enables or disables one or both arrows of a scroll bar.

Parameters

hwnd

Identifies a window or a scroll bar, depending on the value of the *fnSBFlags* parameter.

fnSBFlags

Specifies the scroll bar type. This parameter can be one of the following values:

Value	Meaning
SB_BOTH	Enables or disables the arrows of the horizontal and vertical scroll bars associated with the given window. The <i>hwnd</i> parameter identifies the window.
SB_CTL	Identifies the scroll bar as a scroll bar control. The <i>hwnd</i> parameter must identify a scroll bar control.
SB_HORZ	Enables or disables the arrows of the horizontal scroll bar associated with the given window. The <i>hwnd</i> parameter identifies the window.
SB_VERT	Enables or disables the arrows of the vertical scroll bar associated with the given window. The <i>hwnd</i> parameter identifies the window.

fuArrowFlags

Specifies whether the scroll bar arrows are enabled or disabled, and which arrows are enabled or disabled. This parameter can be one of the following values:

Value	Meaning
ESB_ENABLE_BOTH	Enables both arrows of a scroll bar.
ESB_DISABLE_LTUP	Disables the left arrow of a horizontal scroll bar, or the
	up arrow of a vertical scroll bar.

	Value	Meaning
	ESB_DISABLE_RTDN	Disables the right arrow of a horizontal scroll bar, or the down arrow of a vertical scroll bar.
	ESB_DISABLE_BOTH	Disables both arrows of a scroll bar.
Return Value		if the arrows are enabled or disabled as specified. ting that the arrows are already in the requested state or
Example	The following example enables an edit control's vertical scroll bar when the con- trol receives the input focus, and disables the scroll bar when the control loses th focus:	
	case EN_SETFOCUS: EnableScrollBar(hwndl break;	MLEdit, SB_VERT, ESB_ENABLE_BOTH);
	case EN_KILLFOCUS: EnableScrollBar(hwndl break;	MLEdit, SB_VERT, ESB_DISABLE_BOTH);
See Also	ShowScrollBar	

EnableWindow

BOOL EnableWind HWND hwnd; BOOL fEnable;	low(<i>hwnd</i> , <i>fEnable</i>) /* handle of window */ /* flag for enabling or disabling input */
boo Lj <i>Lhable</i> ,	The EnableWindow function enables or disables mouse and keyboard input to the given window or control. When input is disabled, the window ignores input such as mouse clicks and key presses. When input is enabled, the window processes all input.
Parameters	<i>hwnd</i> Identifies the window to be enabled or disabled.
	<i>fEnable</i> Specifies whether to enable or disable the window. If this parameter is TRUE, the window is enabled. If the parameter is FALSE, the window is disabled.
Return Value	The return value is nonzero if the window was previously disabled. Otherwise, the return value is zero.

Comments	If the enabled state of the window is changing, a WM_ENABLE message is sent before this function returns. If a window is already disabled, all its child windows are implicitly disabled, although they are not sent a WM_ENABLE message.
	A window must be enabled before it can be activated. For example, if an applica- tion is displaying a modeless dialog box and has disabled its main window, the ap- plication must enable the main window before destroying the dialog box. Otherwise, another window will receive the input focus and be activated. If a child window is disabled, it is ignored when Windows tries to determine which window should receive mouse messages.
	By default, a window is enabled when it is created. An application can specify the WS_DISABLED style in the CreateWindow or CreateWindowEx function to create a window that is initially disabled. After a window has been created, an application can use the EnableWindow function to enable or disable the window.
	An application can use this function to enable or disable a control in a dialog box. A disabled control cannot receive the input focus, nor can a user access it.
Example	The following example enables a Save push button in a dialog box, depending on whether a user-specified filename exists:
	<pre>static char szFileName[128];</pre>
	case WM_INITDIALOG:
	/* If a filename is specified, enable the Save push button. */
	EnableWindow(GetDlgItem(hdlg, IDOK), (szFileName[0] == '\0' ? FALSE : TRUE)); return TRUE;
See Also	IsWindowEnabled

EndDeferWindowPos

BOOL EndDeferWindowPos(hdwp)

HDWP *hdwp*; /* handle of internal structure */

The **EndDeferWindowPos** function simultaneously updates the position and size of one or more windows in a single screen-refresh cycle.

2.x

Parameters	 hdwp Identifies an internal structure that contains size and position information for one or more windows. This structure is returned by the BeginDeferWindow-Pos function or by the most recent call to the DeferWindowPos function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	This function sends the WM_WINDOWPOSCHANGING and WM_WINDOWPOSCHANGED messages to each window identified in the internal structure.
See Also	BeginDeferWindowPos, DeferWindowPos

EndDialog

void EndDialog(hwn HWND hwndDlg; int nResult;	adDlg, nResult) /* handle of dialog box */ /* value to return */
	The EndDialog function hides a modal dialog box and causes the DialogBox function to return.
Parameters	<i>hwndDlg</i> Identifies the dialog box to be destroyed.
	<i>nResult</i> Specifies the value that is returned to the caller of DialogBox .
Return Value	This function does not return a value.
Comments	The EndDialog function is required to complete processing of a modal dialog box created by the DialogBox function. An application calls EndDialog from within the dialog box procedure.
	A dialog box procedure can call EndDialog at any time, even during the processing of the WM_INITDIALOG message. If the function is called while WM_INITDIALOG is being processed, the dialog box is hidden before it is shown and before the input focus is set.

EndDialog does not destroy the dialog box immediately. Instead, it sets a flag that directs Windows to destroy the dialog box when the **DialogBox** function returns.

See Also DialogBox

EndDoc

3.1

int EndDoc(hdc) HDC hdc; /* ha	andle of device context */
	The EndDoc function ends a print job. This function replaces the ENDDOC printer escape for Windows version 3.1.
Parameters	<i>hdc</i> Identifies the device context for the print job.
Return Value	The return value is greater than or equal to zero if the function is successful. Otherwise, it is less than zero.
Comments	An application should call the EndDoc function immediately after finishing a successful print job. To terminate a print job because of an error or if the user chooses to cancel the job, an application should call the AbortDoc function.
	Do not use the EndDoc function inside metafiles.
See Also	AbortDoc, Escape, StartDoc

EndPage

int EndPage(hdc)
HDC hdc; /* handle of device context */

The **EndPage** function signals the device that the application has finished writing to a page. This function is typically used to direct the driver to advance to a new page.

This function replaces the **NEWFRAME** printer escape for Windows 3.1. Unlike **NEWFRAME**, this function is always called after printing a page.

2.x

Parameters	<i>hdc</i> Identifies the device context for the print job.	
Return Value	The return value is greater than or equal to zero if the function is successful. Otherwise, it is an error value.	
Errors	If the function fails, it returns one of the following error values:	
	Value	Meaning
	SP_ERROR	General error.
	SP_APPABORT	Job was terminated because the application's print- canceling function returned zero.
	SP_USERABORT	User terminated the job by using Windows Print Manager (PRINTMAN.EXE).
	SP_OUTOFDISK	Not enough disk space is currently available for spooling, and no more space will become available.
	SP_OUTOFMEMORY	Not enough memory is available for spooling.
Comments	The ResetDC function can be used to change the device mode, if necessary, after calling the EndPage function.	
See Also	Escape, ResetDC, Star	tPage

EndPaint

<pre>void EndPaint(hwnd, lpps)</pre>		
HWND hwnd;	/* handle of window	*/
const PAINTSTRUCT FAR* lpps;	/* address of structure for paint data	*/

The **EndPaint** function marks the end of painting in the given window. This function is required for each call to the **BeginPaint** function, but only after painting is complete.

Parameters

hwnd

Identifies the window that has been repainted.

lpps

Points to a **PAINTSTRUCT** structure that contains the painting information retrieved by the **BeginPaint** function. The **PAINTSTRUCT** structure has the following form:

	<pre>typedef struct tagPAINTSTRUCT { /* ps */ HDC hdc; BOOL fErase; RECT rcPaint; BOOL fRestore; BOOL fIncUpdate; BYTE rgbReserved[16]; } PAINTSTRUCT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>	
Return Value	This function does not return a value.	
Comments	If the caret was hidden by the BeginPaint function, the EndPaint function restores the caret to the screen.	
See Also	BeginPaint	

EnumChildProc

BOOL CALLBACH HWND hwnd; LPARAM lParam;	K EnumChildProc(hwnd, lParam) /* handle of child window */ /* application-defined value */		
	The EnumChildProc function is an application-defined callback function that receives child window handles as a result of a call to the EnumChildWindows function.		
Parameters	<i>hwnd</i> Identifies a child window of the parent window specified in the Enum- ChildWindows function.		
	<i>lParam</i> Specifies the application-defined value specified in the EnumChildWindows function.		
Return Value	The callback function must return nonzero to continue enumeration; to stop enumeration, it must return zero.		
Comments	The callback function can carry out any desired task.		
	An application must register this callback function by passing its address to the EnumChildWindows function. The EnumChildProc function is a placeholder		

for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also EnumChildWindows

EnumChildWindows

BOOL EnumChildWindows(*hwndParent*, *wndenmprc*, *lParam*) **HWND** hwndParent: /* handle of parent window */ **WNDENUMPROC** wndenmprc; /* address of callback function */ LPARAM lParam: /* application-defined value */ The **EnumChildWindows** function enumerates the child windows that belong to the given parent window by passing the handle of each child window, in turn, to an application-defined callback function. EnumChildWindows continues until the last child window is enumerated or the callback function returns zero. **Parameters** *hwndParent* Identifies the parent window whose child windows are to be enumerated. wndenmprc Specifies the procedure-instance address of the application-supplied callback function. The address must have been created by using the MakeProcInstance function. For more information about the callback function, see the description of the EnumChildProc callback function. lParam Specifies a 32-bit application-defined value to pass to the callback function. **Return Value** The return value is nonzero if the function is successful. Otherwise, it is zero. Comments This function does not enumerate top-level windows that belong to the parent window. If a child window has created child windows of its own, the function enumerates those windows as well. A child window that is moved or repositioned in the Z-order during the enumeration process will be properly enumerated. The function will not enumerate a child window that is destroyed before it is enumerated or that is created during the enumeration process. These measures ensure that the EnumChildWindows function is reliable even when the application causes odd side effects, whereas an appli-

cation that uses a **GetWindow** loop risks being caught in an infinite loop or referencing a handle to a window that has been destroyed.

2.x

See Also EnumChildProc, MakeProcInstance

EnumClipboardFormats

	ardFormats(uFormat) /* known clipboard format */
	The EnumClipboardFormats function enumerates the formats found in a list of available formats that belong to the clipboard. Each call to this function specifies a known available format; the function returns the format that appears next in the list.
Parameters	<i>uFormat</i> Specifies a known format. If this parameter is zero, the function returns the first format in the list.
Return Value	The return value specifies the next known clipboard data format if the function is successful. It is zero if the <i>uFormat</i> parameter specifies the last format in the list of available formats, or if the clipboard is not open.
Comments	Before it enumerates the formats by using the EnumClipboardFormats function, an application must open the clipboard by using the OpenClipboard function.
	An application puts (or "donates") alternative formats for the same data into the clipboard in the same order that the enumerator uses when returning them to the pasting application. The pasting application should use the first format enumerated in the list that it can handle. This gives the donor application an opportunity to recommend formats that involve the least loss of data.
See Also	CountClipboardFormats, GetClipboardFormatName, GetPriorityClipboard- Format, IsClipboardFormatAvailable, OpenClipboard, RegisterClipboard- Format

EnumFontFamilies

int EnumFontFamil HDC hdc; LPCSTR lpszFamily FONTENUMPROC LPARAM lParam;	lies(hdc, lpszFamily, fntenmprc, lParam) /* handle of device context */ /* address of font-family name */ /; /* address of callback function */ /* application-defined data */
	The EnumFontFamilies function enumerates the fonts in a specified font family that are available on a given device. EnumFontFamilies continues until there are no more fonts or the callback function returns zero.
Parameters	<i>hdc</i> Identifies the device context.
	<i>lpszFamily</i> Points to a null-terminated string that specifies the family name of the desired fonts. If this parameter is NULL, the EnumFontFamilies function selects and enumerates one font from each available font family.
	<i>fntenmprc</i> Specifies the procedure-instance address of the application-defined callback function. The address must be created by the MakeProcInstance function. For more information about the callback function, see the description of the Enum- FontFamProc callback function.
	<i>lParam</i> Specifies a 32-bit application-defined value that is passed to the callback function along with the font information.
Return Value	The return value specifies the last value returned by the callback function, if the function is successful. This value depends on which font families are available for the given device.
Comments	The EnumFontFamilies function differs from the EnumFonts function in that it retrieves the style names associated with a TrueType font. Using EnumFont-Families , an application can retrieve information about unusual font styles (for example, Outline) that cannot be enumerated by using the EnumFonts function. Applications should use EnumFontFamilies instead of EnumFonts .
	For each font having the font name specified by the <i>lpszFamily</i> parameter, the EnumFontFamilies function retrieves information about that font and passes it to the function pointed to by the <i>fntenmprc</i> parameter. The application-supplied callback function can process the font information, as necessary.
Example	The following example uses the MakeProcInstance function to create a pointer to the callback function for the EnumFontFamilies function. The FreeProcInstance

function is called when enumeration is complete. Because the second parameter is NULL, **EnumFontFamilies** enumerates one font from each family that is available in the given device context. The aFontCount variable points to an array that is used inside the callback function.

```
FONTENUMPROC lpEnumFamCallBack;
int aFontCount[] = { 0, 0, 0 };
lpEnumFamCallBack = (FONTENUMPROC) MakeProcInstance(
    (FARPROC) EnumFamCallBack, hAppInstance);
EnumFontFamilies(hdc, NULL, lpEnumFamCallBack, (LPARAM) aFontCount);
FreeProcInstance((FARPROC) lpEnumFamCallBack);
```

See Also EnumFonts, EnumFontFamProc

EnumFontFamProc

int CALLBACK En LOGFONT FAR* <i>l</i> TEXTMETRIC FA int FontType; LPARAM <i>lParam</i> ;	pnlf ;		with logical-font data with physical-font data	*/ */ */ */
		ontFamProc function i rmation about available	s an application-defined cal e fonts.	lback function that
Parameters	<i>lpnlf</i> Points to a NEWLOGFONT structure that contains information about the logi- cal attributes of the font. This structure is locally-defined and is identical to the Windows LOGFONT structure except for two new members. The NEWLOGFONT structure has the following form:			
	struct ta int int int int BYTE BYTE BYTE	<pre>gNEWLOGFONT { IfHeight; IfWidth; IfEscapement; IfOrientation; IfWeight; IfItalic; IfUnderline; IfStrikeOut;</pre>	/* nlf */	

```
BYTE lfCharSet;
BYTE lfOutPrecision;
BYTE lfClipPrecision;
BYTE lfQuality;
BYTE lfPitchAndFamily;
BYTE lfFaceName[LF_FACESIZE];
BYTE lfFullName[2 * LF_FACESIZE]; /* TrueType only */
BYTE lfStyle[LF_FACESIZE]; /* TrueType only */
} NEWLOGFONT;
```

The **lfFullName** and **lfStyle** members are appended to a **LOGFONT** structure when a TrueType font is enumerated in the **EnumFontFamProc** function.

The **lfFullName** member is a character array specifying the full name for the font. This name contains the font name and style name.

The lfStyle member is a character array specifying the style name for the font.

For example, when bold italic Arial® is enumerated, the last three members of the NEWLOGFONT structure contain the following strings:

```
lfFaceName = "Arial";
lfFullName = "Arial Bold Italic";
lfStyle = "Bold Italic";
```

For a full description of the **LOGFONT** structure, see the *Microsoft Windows Programmer's Reference, Volume 3.*

lpntm

Points to a **NEWTEXTMETRIC** structure that contains information about the physical attributes of the font, if the font is a TrueType font. If the font is not a TrueType font, this parameter points to a **TEXTMETRIC** structure.

The NEWTEXTMETRIC structure has the following form:

```
typedef struct tagNEWTEXTMETRIC {
                                   /* ntm */
   int
         tmHeight:
   int
         tmAscent;
   int
         tmDescent:
   int
         tmInternalLeading;
   int
         tmExternalLeading;
   int
         tmAveCharWidth;
   int
         tmMaxCharWidth:
   int
         tmWeight:
   BYTE tmItalic;
   BYTE tmUnderlined;
   BYTE tmStruckOut:
   BYTE tmFirstChar;
   BYTE tmLastChar;
   BYTE tmDefaultChar;
   BYTE tmBreakChar;
   BYTE tmPitchAndFamily;
```

	BYTE tmCharSet; int tmOverhang; int tmDigitizedAspectX; int tmDigitizedAspectY; DWORD ntmFlags; UINT ntmSizeEM; UINT ntmCellHeight; UINT ntmAvgWidth; > NEWTEXTMETRIC; The TEXTMETRIC structure is identical to NEWTEXTMETRIC except
	that it does not include the last four members. For a full description of these structures, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>FontType</i> Specifies the type of the font. This parameter can be a combination of the fol- lowing masks:
	DEVICE_FONTTYPE RASTER_FONTTYPE TRUETYPE_FONTTYPE
	<i>lParam</i> Points to the application-defined data passed by EnumFontFamilies .
Return Value	This function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.
Comments	An application must register this callback function by passing its address to the EnumFontFamilies function. The EnumFontFamProc function is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file.
	The AND (&) operator can be used with the RASTER_FONTTYPE, DEVICE_FONTTYPE, and TRUETYPE_FONTTYPE constants to determine the font type. If the RASTER_FONTTYPE bit is set, the font is a raster font. If the TRUETYPE_FONTTYPE bit is set, the font is a TrueType font. If neither bit is set, the font is a vector font. A third mask, DEVICE_FONTTYPE, is set when a device (for example, a laser printer) supports downloading TrueType fonts; it is zero if the font is not a device font. (Any device can support device fonts, includ- ing display adapters and dot-matrix printers.) An application can also use the DEVICE_FONTTYPE mask to distinguish GDI-supplied raster fonts from device- supplied fonts. GDI can simulate bold, italic, underline, and strikeout attributes for GDI-supplied raster fonts, but not for device-supplied fonts.
See Also	EnumFontFamilies, EnumFonts

EnumFonts

int EnumFonts(hdc HDC hdc; LPCSTR lpszFace; FONTENUMPRO LPARAM lParam;	c, lpszFace, fntenmprc, lParam) /* handle of device context */ /* address of font name */ C fntenmprc; /* address of callback function */ /* application-defined data */		
	The EnumFonts function enumerates the fonts available for a given device. This function is provided for backwards compatibility with earlier versions of Windows; current applications should use the EnumFontFamilies function.		
	EnumFonts continues until there are no more fonts or the callback function re- turns zero.		
Parameters	<i>hdc</i> Identifies the device context.		
	<i>lpszFace</i> Points to a null-terminated string that specifies the names of the requested fonts. If this parameter is NULL, the EnumFonts function randomly selects and enumerates one font from each available typeface.		
	<i>fntenmprc</i> Specifies the procedure-instance address of the application-defined callback function. The address must be created by the MakeProcInstance function. For more information about the callback function, see the description of the Enum- FontsProc callback function.		
	<i>lParam</i> Specifies a 32-bit application-defined value that is passed to the callback func- tion along with the font information.		
Return Value	The return value specifies the last value returned by the callback function and is defined by the user.		
Comments	The EnumFonts function retrieves information about the specified font and passes it to the function pointed to by the <i>fntenmprc</i> parameter. The application-supplied callback function can process the font information, as necessary.		
	If the device is capable of text transformations (scaling, italicizing, and so on), only the base font will be enumerated. The user must know the device's text-trans- formation abilities to determine which additional fonts are available directly from the device. The graphics device interface (GDI) can simulate the bold, italic, under- lined, and strikeout attributes for any GDI-based font.		
	The EnumFonts function enumerates fonts from the GDI internal table only. This does not include fonts that are generated by a device, such as fonts that are		

Example	 transformations of fonts from the internal table. The GetDeviceCaps function can be used to determine which transformations a device can perform. This information is available by using the TEXTCAPS index. GDI can scale GDI-based raster fonts by one to five units horizontally and one to eight units vertically, unless PROOF_QUALITY is being used. The following example uses the MakeProcInstance function to create a pointer to the callback function for the EnumFonts function. The FreeProcInstance function is called when enumeration is complete. Because the second parameter is "Arial", EnumFonts enumerates the Arial fonts available in the given device context. The cArial variable is passed to the callback function.
	FONTENUMPROC lpEnumFontsCallBack; int cArial = 0;
	<pre>lpEnumFontsCallBack = (FONTENUMPROC) MakeProcInstance(</pre>
See Also	EnumFontFamilies, EnumFontsProc

EnumFontsProc

lplf

int CALLBACK EnumFontsProc(lplf, lpntm, FontType, lpData)			
LOGFONT FAR* lplf;	/* address of logical-font data structure	*/	
NEWTEXTMETRIC FAR* lpntm;	/* address of physical-font data structure */		
int FontType;	/* type of font	*/	
LPARAM lpData;	/* address of application-defined data	*/	
The EnumFontsProc function is an application-defined callback function that processes font data from the EnumFonts function.			

Parameters

Points to a **LOGFONT** structure that contains information about the logical attributes of the font. The **LOGFONT** structure has the following form:

typedef struct tagLOGFONT { /* lf */
 int lfHeight;
 int lfWidth;
 int lfEscapement;
 int lfOrientation;
 int lfWeight;
 BYTE lfItalic;

```
BYTE lfUnderline;
BYTE lfStrikeOut;
BYTE lfCharSet;
BYTE lfOutPrecision;
BYTE lfClipPrecision;
BYTE lfQuality;
BYTE lfPitchAndFamily;
BYTE lfFaceName[LF_FACESIZE];
} LOGFONT:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

lpntm

Points to a **NEWTEXTMETRIC** structure that contains information about the physical attributes of the font, if the font is a TrueType font. If the font is not a TrueType font, this parameter points to a **TEXTMETRIC** structure.

The **NEWTEXTMETRIC** structure has the following form:

```
typedef struct tagNEWTEXTMETRIC {
                                   /* ntm */
    int
         tmHeight:
    int
         tmAscent;
    int
         tmDescent:
    int
         tmInternalLeading;
    int
         tmExternalLeading;
    int
         tmAveCharWidth:
    int
         tmMaxCharWidth:
    int
         tmWeight;
    BYTE tmItalic;
    BYTE tmUnderlined;
    BYTE tmStruckOut:
    BYTE tmFirstChar:
    BYTE tmLastChar;
    BYTE tmDefaultChar;
    BYTE tmBreakChar:
    BYTE tmPitchAndFamily;
    BYTE tmCharSet;
    int
         tmOverhang;
    int
         tmDigitizedAspectX;
         tmDigitizedAspectY;
    int
    DWORD ntmFlags:
    UINT ntmSizeEM:
    UINT ntmCellHeight;
    UINT ntmAvgWidth;
} NEWTEXTMETRIC;
```

The **TEXTMETRIC** structure is identical to **NEWTEXTMETRIC** except that it does not include the last four members. For a full description of these structures, see the *Microsoft Windows Programmer's Reference, Volume 3*.

	 FontType Specifies the type of the font. This parameter can be a combination of the following masks: DEVICE_FONTTYPE RASTER_FONTTYPE TRUETYPE_FONTTYPE <i>lpData</i> Points to the application-defined data passed by the EnumFonts function.
Return Value	This function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero.
Comments	An application must register this callback function by passing its address to the EnumFonts function. The EnumFontsProc function is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file.
	The AND (&) operator can be used with the RASTER_FONTTYPE, DEVICE_FONTTYPE, and TRUETYPE_FONTTYPE constants to determine the font type. If the RASTER_FONTTYPE bit is set, the font is a raster font. If the TRUETYPE_FONTTYPE bit is set, the font is a TrueType font. If neither bit is set, the font is a vector font. A third mask, DEVICE_FONTTYPE, is set when a device (for example, a laser printer) supports downloading TrueType fonts; it is zero if the device is a display adapter, dot-matrix printer, or other raster device. An application can also use the DEVICE_FONTTYPE mask to distinguish GDI- supplied raster fonts from device-supplied fonts. GDI can simulate bold, italic, underline, and strikeout attributes for GDI-supplied raster fonts, but not for device- supplied fonts.

EnumMetaFile

BOOL EnumMetaFile(hdc, hmf, mfenmprc, lParam)			
HDC hdc;	/* handle of device context	*/	
HLOCAL hmf;	/* handle of metafile	*/	
MFENUMPROC <i>mfenmprc</i> ;	/* address of callback function	*/	
LPARAM lParam;	/* application-defined data	*/	

The **EnumMetaFile** function enumerates the metafile records in a given metafile. **EnumMetaFile** continues until there are no more graphics device interface (GDI) calls or the callback function returns zero.

Parameters	<i>hdc</i> Identifies the device context associated with the metafile.		
	<i>hmf</i> Identifies the metafile.		
	Note The HLOCAL type for this parameter is incorrect in the WINDOWS.H file. The type of this parameter is actually HMETAFILE . Developers should cast this parameter to an HLOCAL type to avoid compiler warnings.		
	<i>mfenmprc</i> Specifies the procedure-instance address of the application-supplied callback function. The address must be created by using the MakeProcInstance func- tion. For more information about the callback function, see the description of the EnumMetaFileProc callback function.		
	<i>lParam</i> Specifies a 32-bit application-defined value that is passed to the callback func- tion along with the metafile information.		
Return Value	The return value is nonzero if the callback function enumerates all the GDI calls in a metafile. Otherwise, it is zero.		
Comments	The EnumMetaFile function retrieves metafile records and passes them to a call- back function. An application can modify the metafile record inside the callback function. The application can also use the PlayMetaFileRecord function inside the callback function; this is useful for very large metafiles, when using the Play- MetaFile function might be time-consuming.		
Example	The following example creates a dashed green pen and passes it to the callback function for the EnumMetaFile function. If the first element in the array of object handles is a handle, that handle is replaced by the handle of the green pen before the PlayMetaFileRecord function is called. (For this example, it is assumed that the table of object handles contains only one handle and that it is the handle of a pen.)		
	MFENUMPROC lpEnumMetaProc; HPEN hpenGreen;		
	<pre>lpEnumMetaProc = (MFENUMPROC) MakeProcInstance(</pre>		

```
int FAR PASCAL EnumMetaFileProc(HDC hdc, HANDLETABLE FAR* lpHTable,
    METARECORD FAR* lpMFR, int cObj, BYTE FAR* lpClientData)
{
    if (lpHTable->objectHandle[0] != 0)
        lpHTable->objectHandle[0] = *(HPEN FAR *) lpClientData;
    PlayMetaFileRecord(hdc, lpHTable, lpMFR, cObj);
    return 1;
}
```

EnumMetaFileProc

int CALLBACK EnumMetaFileProc(hdc, lpht, lpmr, cObj, lParam) HDC hdc; /* handle of device context */ **HANDLETABLE FAR*** *lpht*; /* address of table of object handles */ **METARECORD FAR*** *lomr*: /* address of metafile record */ /* number of objects in handle table */ int *cObj*; LPARAM lParam: /* address of application-defined data */ The **EnumMetaFileProc** function is an application-defined callback function that processes metafile data from the EnumMetaFile function. **Parameters** hdc Identifies the special device context that contains the metafile. lpht Points to a table of handles associated with the objects (pens, brushes, and so on) in the metafile. lomr Points to a metafile record contained in the metafile. cObi Specifies the number of objects with associated handles in the handle table. lParam Points to the application-defined data. **Return Value** The callback function must return a nonzero value to continue enumeration; to stop enumeration, it must return zero. Comments An application must register this callback function by passing its address to the EnumMetaFile function.

The **EnumMetaFileProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

given device called with th	ojects function enumerates the pens context. For each object of a given ty e information for that object. Enum cts or the callback function returns z	ype, the callback function is Objects continues until there are		

Parameters

Identifies the device context.

fnObjectType

hdc

Specifies the object type. This parameter can be one of the following values:

Value	Meaning
OBJ_BRUSH	Specifies a brush.
OBJ_PEN	Specifies a pen.

goenmprc

Specifies the procedure-instance address of the application-supplied callback function. The address must be created by the **MakeProcInstance** function. For more information about the callback function, see the description of the **EnumObjectsProc** callback function.

lParam

Specifies a 32-bit application-defined value that is passed to the callback function.

Return Value The return value specifies the last value returned by the callback function and is defined by the user.

Example The following example retrieves the number of horizontally hatched brushes and fills **LOGBRUSH** structures with information about each of them:

```
#define MAXBRUSHES 50
GOBJENUMPROC lpProcCallback;
HGLOBAL hglbl;
LPBYTE lpbCountBrush:
lpProcCallback = (GOBJENUMPROC) MakeProcInstance(
    (FARPROC) Callback, hinst);
hglbl = GlobalAlloc(GMEM_FIXED, sizeof(LOGBRUSH)
    * MAXBRUSHES);
lpbCountBrush = (LPBYTE) GlobalLock(hglbl);
*lpbCountBrush = 0:
EnumObjects(hdc, OBJ_BRUSH, lpProcCallback,
    (LPARAM) lpbCountBrush);
FreeProcInstance((FARPROC) lpProcCallback);
int FAR PASCAL Callback(LPLOGBRUSH lpLogBrush, LPBYTE pbData)
ſ
    /*
     * The pbData parameter contains the number of horizontally
     * hatched brushes; the lpDest parameter is set to follow the
     * byte reserved for pbData and the LOGBRUSH structures that
     * have been filled with brush information.
     */
    LPLOGBRUSH 1pDest =
        (LPLOGBRUSH) (pbData + 1 + (*pbData * sizeof(LOGBRUSH)));
   if (lpLogBrush->lbStyle ==
            BS_HATCHED && /* if horiz hatch */
            lpLogBrush->1bHatch == HS HORIZONTAL) {
        *lpDest++ = *lpLogBrush: /* fills structure with brush info */
        (*pbData) ++:
                                 /* increments brush count
                                                                     */
        if (*pbData >= MAXBRUSHES)
            return 0:
    }
   return 1;
}
```

EnumPropFixedProc

BOOL CALLBACH HWND hwnd; LPCSTR lpsz; HANDLE hData;	X EnumPropFixedProc(hwnd, lpsz, hData) /* handle of window with property */ /* address of property string or atom */ /* handle data of property data */			
	The EnumPropFixedProc function is an application-defined callback function that receives a window's property data as a result of a call to the EnumProps function.			
Parameters	 <i>hwnd</i> Identifies the handle of the window that contains the property list. <i>lpsz</i> Points to the null-terminated string associated with the property data identified by the <i>hData</i> parameter. The application specified the string and data in a previous call to the SetProp function. If the application passed an atom instead of a string to SetProp, the <i>lpsz</i> parameter contains the atom in the low-order word and zero in the high-order word. <i>hData</i> Identifies the property data.			
Return Value	The callback function must return TRUE to continue enumeration; it must return FALSE to stop enumeration.			
Comments	This form of the property-enumeration callback function should be used in applica- tions and dynamic-link libraries with fixed data segments and in dynamic libraries with movable data segments that do not contain a stack.			
	The following restrictions apply to the callback function:			
	 The callback function must not yield control or do anything that might yield control to other tasks. 			
	• The callback function can call the RemoveProp function. However, Remove- Prop can remove only the property passed to the callback function through the callback function's parameters.			
	 The callback function should not attempt to add properties. 			
	The EnumPropFixedProc function is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file.			
See Also	EnumPropMovableProc, EnumProps, RemoveProp, SetProp			

EnumPropMovableProc

BOOL CALLBACH HWND hwnd; LPCSTR lpsz; HANDLE hData;	K EnumPropMovableProc(hwnd, lpsz, hData) /* handle of window with property */ /* address of property string or atom */ /* handle of property data */				
	The EnumPropMovableProc function is an application-defined callback function that receives a window's property data as a result of a call to the EnumProps function.				
Parameters	 <i>hwnd</i> Identifies the handle of the window that contains the property list. <i>lpsz</i> Points to the null-terminated string associated with the data identified by the <i>hData</i> parameter. The application specified the string and data in a previous call to the SetProp function. If the application passed an atom instead of a string to SetProp, the <i>lpsz</i> parameter contains the atom. 				
	hData Identifies the property data.				
Return Value	The callback function must return TRUE to continue enumeration; to stop enumeration, it must return FALSE.				
Comments	This form of the property-enumeration callback function should be used in applica- tions with movable data segments and in dynamic libraries whose movable data segments also contain a stack. This form is required since movement of the data will invalidate any long pointer to a variable on the stack, such as the <i>lpsz</i> parame- ter. The data segment typically moves if the callback function allocates more space in the local heap than is currently available.				
	The following restrictions apply to the callback function:				
	• The callback function must not yield control or do anything that might yield control to other tasks.				
	• The callback function can call the RemoveProp function. However, Remove- Prop can remove only the property passed to the callback function through the callback function's parameters.				
	 The callback function should not attempt to add properties. 				
	The EnumPropMovableProc function is a placeholder for the application- defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file.

EnumProps			2. x		
int EnumProps(hwna HWND hwnd; PROPENUMPROC		/* handle of window /* address of callback function	*/ */		
	window. It enur	os function enumerates all entries in nerates the entries by passing them on. EnumProps continues until the on returns zero.	, one by one, to the specified		
Parameters	<i>hwnd</i> Identifies the	window whose property list is enu	merated.		
	<i>prpenmprc</i> Specifies the procedure-instance address of the callback function. For more in- formation, see the descriptions of the EnumPropFixedProc and EnumProp- MovableProc callback functions.				
Return Value	The return value specifies the last value returned by the callback function. It is -1 if the function did not find a property to enumerate.				
Comments	The form of the callback function depends on whether the application or dynar link library (DLL) uses fixed or movable data segments. If the application or library uses fixed data segments (or if the library uses movable data segments to do not contain a stack), see the description of the EnumPropFixedProc callbact function. If the application uses movable data segments (or if the library uses r able data segments that also contain a stack), see the description of the Enum- PropMovableProc callback function.				
	An application's EnumPropFixedProc or EnumPropMovableProc callback function should not add new properties to a window. If the callback function de- letes a window's properties, it should delete only the property currently being enumerated. The callback function should not delete other properties belonging to the window; if it does, the enumeration process terminates early.				
	The address passed in the <i>prpenmprc</i> parameter must be created by using the MakeProcInstance function.

EnumTaskWindows

BOOL EnumTaskV HTASK htask; WNDENUMPROC LPARAM lParam;	Windows(htask, wndenmprc, lParam) /* handle of task */ /* handle of task */ C wndenmprc; /* address of callback function */ /* application-defined value */
	The EnumTaskWindows function enumerates all windows associated with a given task. (A task is any program that executes as an independent unit. All applications are executed as tasks, and each instance of an application is a task.) The function enumerates the windows by passing their handles, one by one, to the specified callback function. EnumTaskWindows continues until the last entry is enumerated or the callback function returns zero.
Parameters	<i>htask</i> Identifies the task. The task handle must be retrieved by a previous call to the GetCurrentTask function.
	<i>wndenmprc</i> Specifies the procedure-instance address of the callback function. For more in- formation, see the description of the EnumTaskWndProc callback function.
	<i>lParam</i> Specifies a 32-bit application-defined value that is passed to the callback func- tion along with each window handle.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	This function enumerates all top-level windows but does not enumerate child windows.
	The EnumTaskWindows function is reliable even when the application causes odd side effects, whereas an application that uses a GetWindow loop risks being caught in an infinite loop or referencing a handle to a window that has been destroyed.
	The address passed in the <i>wndenmprc</i> parameter must be created by using the MakeProcInstance function.
See Also	EnumTaskWndProc, GetCurrentTask

EnumTaskWndProc

BOOL CALLBACI HWND hwnd; LPARAM lParam;	K EnumTaskWndProc(<i>hwnd</i> , <i>lParam</i>) /* handle of a window */ /* application-defined value */
	The EnumTaskWndProc function is an application-defined callback function that receives the window handles associated with a task as a result of a call to the EnumTaskWindows function.
Parameters	<i>hwnd</i> Identifies a window associated with the task specified in the EnumTask- Windows function.
	<i>lParam</i> Specifies the application-defined value specified in the EnumTaskWindows function.
Return Value	The callback function must return TRUE to continue enumeration; to stop enumeration, it must return FALSE.
Comments	The callback function can carry out any desired task.
	The EnumTaskWndProc function is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file.
See Also	EnumTaskWindows

EnumWindows

2.x

BOOL EnumWindows(wndenmpro	r, lParam)	
WNDENUMPROC wndenmprc;	/* address of callback function	*/
LPARAM lParam;	/* application-defined value	*/

The **EnumWindows** function enumerates all parent windows on the screen by passing the handle of each window, in turn, to an application-defined callback function. **EnumWindows** continues until the last parent window is enumerated or the callback function returns zero.

Parameters	 wndenmprc Specifies the procedure-instance address of the callback function. For more information, see the description of the EnumWindowsProc callback function. <i>lParam</i> Specifies a 32-bit application-defined value that is passed to the callback function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The EnumWindows function does not enumerate child windows.
	EnumWindows is reliable even when the application causes odd side effects, whereas an application that uses a GetWindow loop risks being caught in an infinite loop or referencing a handle to a window that has been destroyed.
	The address passed as the <i>wndenmprc</i> parameter must be created by using the MakeProcInstance function.
See Also	EnumWindowsProc, MakeProcInstance

EnumWindowsProc

BOOL CALLBACH HWND hwnd; LPARAM lParam;	X EnumWindowsProc(hwnd, lParam) /* handle of parent window */ /* application-defined value */
	The EnumWindowsProc function is an application-defined callback function that receives parent window handles as a result of a call to the EnumWindows function.
Parameters	hwnd Identifies a parent window.
	<i>lParam</i> Specifies the application-defined value specified in the EnumWindows func- tion.
Return Value	The callback function must return nonzero to continue enumeration; to stop enumeration, it must return zero.
Comments	The callback function can carry out any desired task.

2.x

The **EnumWindowsProc** function is a placeholder for the application-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the application's module-definition (.DEF) file.

See Also EnumWindows

EqualRect

BOOL EqualRect(<i>l</i> const RECT FAR* const RECT FAR*	<i>lprc1</i> ; /* address of structure with first rectangle */
	The EqualRect function determines whether the two given rectangles are equal by comparing the coordinates of their upper-left and lower-right corners.
Parameters	<i>lprc1</i> Points to a RECT structure that contains the logical coordinates of the first rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lprc2</i> Points to a RECT structure that contains the logical coordinates of the second rectangle.
Return Value	The return value is nonzero if the two rectangles are identical. Otherwise, it is zero.

EqualRgn

BOOL EqualRgn(h HRGN hrgnSrc1; HRGN hrgnSrc2;	<i>rgnSrc1</i> , <i>hrgnSrc2</i>) /* handle of first region to test for equality /* handle of second region to test for equality	*/ */
	The EqualRgn function determines whether two gives	ven regions are identical.
Parameters	hrgnSrc1 Identifies the first region. hrgnSrc2	
	Identifies the second region.	
Return Value	The return value is nonzero if the two regions are eq	ual. Otherwise, it is zero.
Example	The following example uses the EqualRgn function against two other regions. In this case, hrgn2 is iden identical to hrgn1.	
	BOOL fEqual; HRGN hrgn1, hrgn2, hrgn3; LPSTR lpszEqual = "Regions are equal."; LPSTR lpszNotEqual = "Regions are not equal."	;
	hrgn1 = CreateRectRgn(10, 10, 110, 110); /* 1 hrgn2 = CreateRectRgn(10, 10, 110, 110); hrgn3 = CreateRectRgn(100, 100, 210, 210); /*	
	fEqual = EqualRgn(hrgn1, hrgn2); if (fEqual)	
	TextOut(hdc, 10, 10, lpszEqual, lstrlen(l else	pszEqual));
	TextOut(hdc, 10, 10, lpszNotEqual, lstrle	n(lpszNotEqual));
	fEqual = EqualRgn(hrgn1, hrgn3); if (fEqual)	
	TextOut(hdc, 10, 30, lpszEqual, lstrlen(l else	pszEqual));
	TextOut(hdc, 10, 30, lpszNotEqual, lstrle	n(lpszNotEqual));
	<pre>DeleteObject(hrgn1); DeleteObject(hrgn2); DeleteObject(hrgn3);</pre>	

Escape

int Escape(hdc, nEsc HDC hdc; int nEscape; int cbInput; LPCSTR lpszInData void FAR* lpvOutDc		ice context pe function ire for input ucture for input	*/ */ */ */
	device that are not direc	tly available throug	access capabilities of a particular the graphics device interface (GDI). nslated and sent to the driver.
Parameters	<i>hdc</i> Identifies the device	context.	
			ormed. For a complete list of printer grammer's Reference, Volume 3.
	<i>cbInput</i> Specifies the number	of bytes of data po	inted to by the <i>lpszInData</i> parameter.
	<i>lpszInData</i> Points to the input str	ructure required for	the specified escape.
	<i>lpvOutData</i> Points to the structure should be NULL if n		ut from this escape. This parameter
Return Value	The return value specifies the outcome of the function. It is greater than zero if the function is successful, except for the QUERYESCSUPPORT printer escape, which checks for implementation only. The return value is zero if the escape is not implemented. A return value less than zero indicates an error.		
Errors	If the function fails, the return value is one of the following:		
	Value	Meaning	
	SP_ERROR	General error.	
	SP_OUTOFDISK		ace is currently available for spooling, will become available.
	SP_OUTOFMEMORY	Not enough memor	ry is available for spooling.

User terminated the job through Print Manager.

SP_USERABORT

EscapeCommFunction

LONG EscapeCommFunction(*idComDev*, *nFunction*)

<pre>int idComDev;</pre>	/* identifies communications device	*/
int nFunction;	/* code of extended function	*/

The **EscapeCommFunction** function directs the specified communications device to carry out an extended function.

Parameters

idComDev

Specifies the communications device that will carry out the extended function. The **OpenComm** function returns this value.

nFunction

Specifies the function code of the extended function. It can be one of the following values:

Value	Meaning
CLRDTR	Clears the DTR (data-terminal-ready) signal.
CLRRTS	Clears the RTS (request-to-send) signal.
GETMAXCOM	Returns the maximum COM port identifier supported by the system. This value ranges from 0x00 to 0x7F, such that 0x00 corresponds to COM1, 0x01 to COM2, 0x02 to COM3, and so on.
GETMAXLPT	Returns the maximum LPT port identifier supported by the system. This value ranges from 0x80 to 0xFF, such that 0x80 corresponds to LPT1, 0x81 to LPT2, 0x82 to LPT3, and so on.
RESETDEV	Resets the printer device if the <i>idComDev</i> parameter specifies an LPT port. No function is performed if <i>idComDev</i> specifies a COM port.
SETDTR	Sends the DTR (data-terminal-ready) signal.
SETRTS	Sends the RTS (request-to-send) signal.
SETXOFF	Causes transmission to act as if an XOFF character has been received.
SETXON	Causes transmission to act as if an XON character has been received.

Return Value

The return value is zero if the function is successful. Otherwise, it is less than zero.

ExcludeClipRect

<pre>int ExcludeClipRect HDC hdc; int nLeftRect; int nTopRect; int nRightRect; int nBottomRect;</pre>	t(hdc, nLeftRect, nTopRect, nRightRect, nBottomRect) /* handle of device context */ /* x-coordinate top-left corner of rectangle */ /* y-coordinate bottom-right corner of rectangle */ /* y-coordinate bottom-right corner of rectangle */
	The ExcludeClipRect function creates a new clipping region that consists of the existing clipping region minus the specified rectangle.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the rectangle.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the rectangle.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the rectangle.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the rectangle.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR (no region is created).
Comments	The width of the rectangle, specified by the absolute value of $nRightRect - nLeftRect$, must not exceed 32,767 units. This limit applies to the height of the rectangle as well.
Example	The following example uses the ExcludeClipRect function to create a clipping re- gion in the shape of a frame that is 20 units wide. The frame is painted red when the FillRect function is used to paint the client area.
	RECT rc; HRGN hrgn; HBRUSH hbrRed;
	GetClientRect(hwnd, &rc); hrgn = CreateRectRgn(10, 10, 110, 110); SelectClipRgn(hdc, hrgn);
	ExcludeClipRect(hdc, 30, 30, 90, 90);

```
hbrRed = CreateSolidBrush(RGB(255, 0, 0));
FillRect(hdc, &rc, hbrRed);
DeleteObject(hbrRed);
DeleteObject(hrgn);
```

See Also

CombineRgn

ExcludeUpdateRgn

2.x

int ExcludeUpda	iteRgn(hdc, hwnd)
	/* handle of device context */
HWND hwnd;	/* handle of window */
	The ExcludeUpdateRgn function prevents drawing within invalid areas of a win- dow by excluding an updated region in the window from a clipping region.
Parameters	hdc
	Identifies the device context associated with the clipping region.
	<i>hwnd</i> Identifies the window to be updated.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR (no region is created).
See Also	BeginPaint, GetUpdateRect, GetUpdateRgn, UpdateWindow

ExitWindows

BOOL ExitWindows(dwReturnCode, reserved)DWORD dwReturnCode;/* return or restart code*/UINT reserved;/* reserved; must be zero*/

The **ExitWindows** function can restart Windows, terminate Windows and return control to MS-DOS, or terminate Windows and restart the system. Windows sends the WM_QUERYENDSESSION message to notify all applications that a request

3.0

3.0

	has been made to restart or terminate Windows. If all applications "agree" to termi- nate, Windows sends the WM_ENDSESSION message to all applications before terminating.	
Parameters	<i>dwReturnCode</i> Specifies whether Windows should restart, terminate and return control to MS-DOS, or terminate and restart the system. The high-order word of this pa- rameter should be zero. The low-order word specifies the return value to be passed to MS-DOS when Windows terminates. The low-order word can be one of the following values:	
	Value	Meaning
	EW_REBOOTSYSTEM Causes Windows to terminate and the sys start.	
EW_RESTARTWINDOWS Causes Wir		Causes Windows to restart.
	<i>reserved</i> Reserved; must be zero.	
Return Value	The return value is zero if one or more applications refuse to terminate. The func- tion does not return a value if all applications agree to be terminated.	
See Also	ExitWindowsExec	

ExitWindowsExec

BOOL ExitWindowsExec(*lpszExe*, *lpszParams*) LPCSTR lpszExe; LPCSTR lpszParams;

The ExitWindowsExec function terminates Windows, runs a specified MS-DOS application, and then restarts Windows. **Parameters** *lpszExe* Points to a null-terminated string specifying the path and filename of the executable file for the system to run after Windows has been terminated. This string

must not be longer than 128 bytes (including the null terminating character).

lpszParams

Points to a null-terminated string specifying any parameters for the executable file specified by the *lpszExe* parameter. This string must not be longer than 127 bytes (including the null terminating character). This value can be NULL.

Return Value	The return value is FALSE if the function fails. (The function could fail because of a memory-allocation error or if one of the applications in the system does not terminate.)
Comments	The ExitWindowsExec function is typically used by installation programs to replace components of Windows which are active when Windows is running.
See Also	ExitWindows

ExtDeviceMode

#include <print.h>

int ExtDeviceMode (<i>hwnd</i> , <i>hDriver</i> , <i>lpdmOutput</i> , <i>lpszDevice</i> , <i>lpszPort</i> , <i>lpdmInput</i> , <i>lpszProfile</i> , <i>fwMode</i>)			
HWND hwnd;	/* handle of window	*/	
HANDLE hDriver;	/* handle of driver	*/	
LPDEVMODE lpdmOutput;	/* address of structure for driver output	*/	
LPSTR lpszDevice;	/* string for name of device	*/	
LPSTR lpszPort;	/* string for name of port	*/	
LPDEVMODE lpdmInput;	/* address of structure for driver input	*/	
LPSTR lpszProfile;	/* string for profile filename	*/	
WORD fwMode;	/* operations mask	*/	
The ExtDeviceMode function retrieves or modifies device initialization informa- tion for a given printer driver or displays a driver-supplied dialog box for configur- ing the printer driver. Printer drivers that support device initialization by applications export ExtDeviceMode so that applications can call it.			
Be see a la se			

Parameters

hwnd

Identifies a window. If the application calls the **ExtDeviceMode** function to display a dialog box, the specified window is the parent window of the dialog box.

3.0

hDriver

Identifies the device-driver module. The **GetModuleHandle** function or **Load-Library** function returns a module handle.

lpdmOutput

Points to a **DEVMODE** structure. The driver writes the initialization information supplied in the *lpdmInput* parameter to this structure. The **DEVMODE** structure has the following form:

```
#include <print.h>
typedef struct tagDEVMODE {
                              /* dm */
   char dmDeviceName[CCHDEVICENAME];
   UINT dmSpecVersion:
   UINT dmDriverVersion:
   UINT dmSize:
   UINT dmDriverExtra:
   DWORD dmFields:
          dmOrientation;
   int
   int
          dmPaperSize:
          dmPaperLength:
   int
          dmPaperWidth;
    int
    int
          dmScale:
   int
          dmCopies;
    int
          dmDefaultSource;
    int
          dmPrintQuality:
   int
          dmColor;
   int
          dmDuplex:
   int
          dmYResolution:
    int
          dmTTOption;
```

} DEVMODE;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

lpszDevice

Points to a null-terminated string that contains the name of the printer device—for example, PCL/HP LaserJet.

lpszPort

Points to a null-terminated string that contains the name of the port to which the device is connected—for example, LPT1.

lpdmInput

Points to a **DEVMODE** structure that supplies initialization information to the printer driver.

lpszProfile

Points to a null-terminated string that contains the name of the initialization file, where initialization information is recorded and read from. If this parameter is NULL, WIN.INI is the default initialization file.

fwMode

Specifies a mask of values that determines the operations the function performs. If this parameter is zero, the **ExtDeviceMode** function returns the number of bytes required by the printer driver's **DEVMODE** structure. Otherwise, the *fwMode* parameter can be one or more of the following values (to change the print settings, the application must specify at least one input value and one output value):

	Value	Meaning
	DM_IN_BUFFER	Input value. Before prompting, copying, or updating, this value merges the printer driver's current print set- tings with the settings in the DEVMODE structure iden- tified by the <i>lpdmInput</i> parameter. The structure is updated only for those members indicated by the applica- tion in the dmFields member. This value is also defined as DM_MODIFY.
	DM_IN_PROMPT	Input value. This value presents the printer driver's Print Setup dialog box and then changes the settings in the printer's DEVMODE structure to values specified by the user. This value is also defined as DM_PROMPT.
	DM_OUT_BUFFER	Output value. This value writes the printer driver's cur- rent print settings (including private data) to the DEV- MODE structure identified by the <i>lpdmOutput</i> parameter. The calling application must allocate a buffer sufficiently large to contain the information. If this bit is clear, <i>lpdmOutput</i> can be NULL. This value is also de- fined as DM_COPY.
	DM_OUT_DEFAULT	Output value. This value updates graphics device inter- face (GDI)'s current printer environment and the WIN.INI file, using the contents of the printer driver's DEVMODE structure. Avoid using this value, because it permanently changes the print settings for all applica- tions. This value is also defined as DM_UPDATE.
Return Value	to contain the printer drive than a DEVMODE struct ture.) If the function displa IDOK or IDCANCEL, dep	s zero, the return value is the size of the buffer required er initialization data. (Note that this buffer can be larger ure, if the printer driver appends private data to the struc- ays the initialization dialog box, the return value is either pending on which button the user selects. If the function g box and is successful, the return value is IDOK. The re- o if the function fails.
Comments	The ExtDeviceMode function is part of the printer's device driver and not part of GDI. To use this function, an application must retrieve the address of the function by calling the LoadLibrary and GetProcAddress functions, and it must include the header file PRINT.H. The application can then use the address to set up the printer.	
	ExtDeviceMode is not supported by all printer drivers. If the GetProcAddress function returns NULL, ExtDeviceMode is not supported.	
	To make changes to print settings that are local to the application, an application should call the ExtDeviceMode function, specifying the DM_OUT_BUFFER value; modify the returned DEVMODE structure; and then pass the modified DEVMODE structure back to ExtDeviceMode , specifying DM_IN_BUFFER	

and DM_OUT_BUFFER (combined by using the OR operator). The **DEVMODE** structure returned by this second call to **ExtDeviceMode** can be used as an argument in a call to the **CreateDC** function.

Any call to **ExtDeviceMode** must set either DM_OUT_BUFFER or DM_OUT_DEFAULT.

An application can set the *fwMode* parameter to DM_OUT_BUFFER to obtain a **DEVMODE** structure filled with the printer driver's initialization data. The application can then pass this structure to the **CreateDC** function to set a private environment for the printer device context.

See Also CreateDC, DeviceMode, GetModuleHandle, GetProcAddress, LoadLibrary

ExtFloodFill

BOOL ExtFloodFill (<i>hdc</i> , <i>nXStart</i> , <i>nYStart</i> , <i>clrref</i> , <i>fuFillType</i>)			
HDC hdc;	/* handle of device context		
int nXStart;	/* x-coordinate where filling begins		
int nYStart;	/* y-coordinate where filling begins		
COLORREF clrref;	/* color of fill		
UINT fuFillType;	/* fill type		

The **ExtFloodFill** function fills an area of the screen surface by using the current brush. The type of flood fill specified determines which part of the screen is filled.

*/ */ */ */

Parameters

Identifies the device context.

nXStart

hdc

Specifies the logical x-coordinate at which to begin filling.

nYStart

Specifies the logical y-coordinate at which to begin filling.

clrref

Specifies the color of the boundary or area to be filled. The interpretation of this parameter depends on the value of the *fuFillType* parameter.

fuFillType

Specifies the type of flood fill to be performed. It must be one of the following values:

3.0

	Value	Meaning	
	FLOODFILLBORDER	Fill area is bounded by the color specified by the <i>clrref</i> parameter. This style is identical to the filling performed by the FloodFill function.	
	FLOODFILLSURFACE	Fill area is defined by the color specified by the <i>clrref</i> parameter. Filling continues outward in all directions as long as the color is encountered. This style is useful for filling areas that have multicolored boundaries.	
Return Value	not be completed, if the given parameter (if FLOODFILLB have the color specified by <i>c</i>	rn value is nonzero if the function is successful. It is zero if the filling can- ompleted, if the given point has the boundary color specified by the <i>clrref</i> er (if FLOODFILLBORDER was requested), if the given point does not color specified by <i>clrref</i> (if FLOODFILLSURFACE was requested), or if is outside the clipping region.	
Comments	Only memory device contexts and devices that support raster-display technology support the ExtFloodFill function. For more information about raster capabilities, see the description of the GetDeviceCaps function.		
	If the <i>fuFillType</i> parameter is the FLOODFILLBORDER value, the area is assumed to be completely bounded by the color specified by the <i>clrref</i> parameter. The ExtFloodFill function begins at the coordinates specified by the <i>nXStart</i> and <i>nYStart</i> parameters and fills in all directions to the color boundary.		
	specified by <i>nXStart</i> and <i>nYS</i>	<i>fuFillType</i> is FLOODFILLSURFACE, ExtFloodFill begins at the coordinates ecified by <i>nXStart</i> and <i>nYStart</i> and continues in all directions, filling all adjacent eas containing the color specified by <i>clrref</i> .	
See Also	FloodFill, GetDeviceCaps		

Extracticon

#include <shellapi.h>

HICON ExtractIcon (<i>hinst</i> , <i>lpszExeName</i> , <i>iIcon</i>)			
HINSTANCE hinst;	/* instance handle	*/	
LPCSTR lpszExeName;	/* address of string for file	*/	
UINT ilcon;	/* index of icon to retrieve	*/	

The **ExtractIcon** function retrieves the handle of an icon from a specified executable file, dynamic-link library (DLL), or icon file.

3.1

Parameters	<i>hinst</i> Identifies the instance of the application calling the function.
	<i>lpszExeName</i> Points to a null-terminated string specifying the name of an executable file, dynamic-link library, or icon file.
	<i>iIcon</i> Specifies the index of the icon to be retrieved. If this parameter is zero, the function returns the handle of the first icon in the specified file. If the parameter is -1 , the function returns the total number of icons in the specified file.
Return Value	The return value is the handle of an icon if the function is successful. It is 1 if the file specified in the <i>lpszExeName</i> parameter is not an executable file, dynamic-link library, or icon file. Otherwise, it is NULL, indicating that the file contains no icons.

ExtTextOut

2.x

BOOL ExtTextOut(*hdc*, *nXStart*, *nYStart*, *fuOptions*, *lprc*, *lpszString*, *cbString*, *lpDx*) **HDC** *hdc*: /* handle of device context */

. ,		c,
HDC hdc;	/* handle of device context	*/
int nXStart;	/* x-coordinate of starting position	*/
int nYStart;	/* y-coordinate of starting position	*/
UINT fuOptions;	/* rectangle type	*/
const RECT FAR* lprc;	/* address of structure with rectangle	*/
LPCSTR lpszString;	/* address of string	*/
UINT <i>cbString</i> ;	/* number of bytes in string	*/
int FAR* <i>lpDx</i> ;	/* spacing between character cells	*/

The **ExtTextOut** function writes a character string within a rectangular region, using the currently selected font. The rectangular region can be opaque (filled by using the current background color as set by the **SetBkColor** function), and it can be a clipping region.

Parameters

hdc

Identifies the device context.

nXStart

Specifies the logical x-coordinate at which the string begins.

nYStart

Specifies the logical y-coordinate at which the string begins.

fuOptions

Specifies the rectangle type. This parameter can be one, both, or neither of the following values:

Value	Meaning	
ETO_CLIPPED	Text is clipped to the rectangle.	
ETO_OPAQUE	Current background color fills the rectangle. (An application can set and query the current background color by using the SetBkColor and GetBkColor functions.)	

lprc

Points to a **RECT** structure that determines the dimensions of the rectangle. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

lpszString

Points to the specified character string.

cbString

Specifies the number of bytes in the string.

lpDx

Points to an array of values that indicate the distance, in logical units, between origins of adjacent character cells. The *n*th element in the array specifies the number of logical units that separate the origin of the *n*th item in the string from the origin of item n + 1. If this parameter is NULL, **ExtTextOut** uses the default spacing between characters. Otherwise, the array contains the number of elements specified in the *cbString* parameter.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments If the *fuOptions* parameter is zero and the *lprc* parameter is NULL, the **Ext**-**TextOut** function writes text to the device context without using a rectangular region.

By default, the current position is not used or updated by **ExtTextOut**. If an application needs to update the current position when it calls **ExtTextOut**, the application can call the **SetTextAlign** function with the *wFlags* parameter set to TA_UPDATECP. When this flag is set, Windows ignores the *nXStart* and *nYStart* parameters on subsequent calls to **ExtTextOut**, using the current position instead. When an application uses TA_UPDATECP to update the current position, **Ext-TextOut** sets the current position either to the end of the previous line of text or to

the position specified by the last element of the array pointed to by the lpDX parameter, whichever is greater.

Example The following example uses the **ExtTextOut** function to clip text to a rectangular region defined by a **RECT** structure:

RECT rc;	
SetRect(&rc, 90, 190, 250, 220);	
<pre>&rc,</pre>	*/ */ */ */
(LPINT) NULL); /* default character spacing	*/

FatalAppExit		3.0
UINT fuAction;	uAction, lpszMessageText) /* must be zero geText; /* string to display in message box	*/ */
	The FatalAppExit function displays a message when the message box is closed. If the user is re the Windows operating system, the message bo terminate the application or to cancel the message	unning the debugging version of x gives the user the opportunity to
Parameters	<i>fuAction</i> Reserved; must be zero.	
	<i>lpszMessageText</i> Points to a null-terminated string that is disp sage is displayed on a single line. To accomm string should contain no more than 35 character	nodate low-resolution screens, the
Return Value	This function does not return a value.	

Comments	An application should call the FatalAppExit function only when it is incapable of terminating any other way. FatalAppExit may not always free an application's memory or close its files, and it may cause a general failure of Windows. An application that encounters an unexpected error should terminate by freeing all its memory and returning from its main message loop.
See Also	FatalExit, TerminateApp

FatalExit

void FatalExit(nErr int nErrCode; /*	<i>Code</i>) * error value to	display	*/
			nds the current state of Windows to the debugger and a how to proceed.
	call the functi	on in a retail	this function for debugging purposes only; it should not version of the application. Calling this function in the e the application.
Parameters	<i>nErrCode</i> Specifies tl	he error valu	e to be displayed.
Return Value	This function	does not retu	ırn a value.
Comments	The displayed information includes an error value followed by a symbolic stack trace, showing the flow of execution up to the point of the call.		
	The FatalExit function prompts the user to respond to an Abort, Break, or Ignore message. Windows processes the response as follows:		
	Response	Description	
	A (Abort)	Terminate in	nmediately.
	B (Break)	Enter the de	bugger.
	I (Ignore)	Return to th	e caller.
	since the mea value –1 mus	ning of the v t always be r	bination of error values for the <i>nErrCode</i> parameter, alues is unique to your application. However, the error eserved for the stack-overflow message. When this vs automatically displays a stack-overflow message.
a			

2.x

FillRect

int FillRect(hdc, lprc, HDC hdc; const RECT FAR* lp HBRUSH hbr;	/* handle of device context */
	The FillRect function fills a given rectangle by using the specified brush. The FillRect function fills the complete rectangle, including the left and top borders, but does not fill the right and bottom borders.
Parameters	<i>hdc</i> Identifies the device context.
	<i>lprc</i> Points to a RECT structure that contains the logical coordinates of the rectangle to be filled. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>hbr</i> Identifies the brush used to fill the rectangle.
Return Value	The return value is not used and has no meaning.
	The brush must be created by using either the CreateHatchBrush , Create- PatternBrush , or CreateSolidBrush function, or retrieved by using the Get- StockObject function.
	When filling the specified rectangle, the FillRect function does not include the rec- tangle's right and bottom sides. Graphics device interface (GDI) fills a rectangle up to, but not including, the right column and bottom row, regardless of the cur- rent mapping mode.
	FillRect compares the values of the top , bottom , left , and right members of the specified RECT structure. If bottom is less than or equal to top , or if right is less than or equal to left , the function does not draw the rectangle.
	CreateHatchBrush, CreatePatternBrush, CreateSolidBrush, GetStockObject, InvertRect

FillRgn

BOOL FillRgn(/ HDC hdc; HRGN hrgn; HBRUSH hbr;	adc, hrgn, hbr) /* handle of device context */ /* handle of region */ /* handle of brush */
	The FillRgn function fills the given region by using the specified brush.
Parameters	 hdc Identifies the device context. hrgn Identifies the region to be filled. The coordinates for the given region are specified in device units.
	<i>hbr</i> Identifies the brush to be used to fill the region.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Example	The following example uses a blue brush to fill a rectangular region. Note that it is not necessary to select the brush into the device context before using it to fill the region.
	HRGN hrgn; HBRUSH hBrush;
	hrgn = CreateRectRgn(10, 10, 110, 110); SelectObject(hdc, hrgn);
	hBrush = CreateSolidBrush(RGB(0, 0, 255));
	FillRgn(hdc, hrgn, hBrush);
	<pre>DeleteObject(hrgn);</pre>
See Also	CreateBrushIndirect, CreateDIBPatternBrush, CreateHatchBrush, CreatePatternBrush, CreateSolidBrush, PaintRgn

FindAtom	2.x
ATOM FindAtom(lp LPCSTR lpszString;	
	The FindAtom function searches the local atom table for the specified character string and retrieves the atom associated with that string.
Parameters	<i>lpszString</i> Points to the null-terminated character string to search for.
Return Value	The return value identifies the atom associated with the given string if the function is successful. Otherwise (if the string is not in the table), the return value is zero.
Example	The following example uses the FindAtom function to retrieve the atom for the string "This is an atom":
	ATOM at; char szMsg[80];
	<pre>if ((at = FindAtom("This is an atom")) == 0) MessageBox(hwnd, "could not find atom", "FindAtom", MB_ICONEXCLAMATION);</pre>
	<pre>else { wsprintf(szMsg, "atom = %u", at); MessageBox(hwnd, szMsg, "FindAtom", MB_OK); }</pre>
See Also	AddAtom, DeleteAtom

FindExecutable

3.1

#include <shellapi.h>

HINSTANCE FindEx	xecutable (<i>lpszFile</i> , <i>lpszDir</i> , <i>lpszResult</i>)	
LPCSTR lpszFile;	/* address of string for filename	*/
LPCSTR <i>lpszDir</i> ;	/* address of string for default directory	*/
LPSTR lpszResult;	/* address of string for executable file on return	*/

The **FindExecutable** function finds and retrieves the executable filename that is associated with a specified filename.

Parameters		s to a null-terminated string specifying a filename. This can be a document ecutable file.		
	<i>lpszDir</i> Points to a null-terminated string specifying the drive letter and path for the default directory.			
	returr	<i>dt</i> s to a buffer that receives the name of an executable file when the function ns. This null-terminated string specifies the application that is started when pen command is chosen from the File menu in File Manager.		
Return Value	The return value is greater than 32 if the function is successful. If the return value is less than or equal to 32, it specifies an error code.			
Errors		dExecutable function returns 31 if there is no association for the specified . The other possible error values are as follows:		
	Value	Meaning		
	0	System was out of memory, executable file was corrupt, or relocations were invalid.		
	2	File was not found.		
	3	Path was not found.		
	5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.		
	6	Library required separate data segments for each task.		
	8	There was insufficient memory to start the application.		
	10	Windows version was incorrect.		
	11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.		
	12	Application was designed for a different operating system.		
	13	Application was designed for MS-DOS 4.0.		
	14	Type of executable file was unknown.		
	15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).		
	16	Attempt was made to load a second instance of an executable file contain- ing multiple data segments that were not marked read-only.		
	19	Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.		
	20	Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application was corrupt.		
	21	Application requires Microsoft Windows 32-bit extensions.		

Comments	The filename specified in the <i>lpszFile</i> parameter is associated with an executable
	file when an association has been registered between that file's filename extension
	and an executable file in the registration database. An application that produces
	files with a given filename extension typically associates the extension with an ex-
	ecutable file when the application is installed.

See Also RegQueryValue, ShellExecute

FindResource

2.x

HRSRC FindResource((hinst, lpszName, lpszType)	
HINSTANCE hinst;	/* handle of module containing resource	*/
LPCSTR lpszName;	/* address of resource name	*/
LPCSTR lpszType;	/* address of resource type	*/

The **FindResource** function determines the location of a resource in the specified resource file.

Parameters

hinst

Identifies the instance of the module whose executable file contains the resource.

lpszName

Specifies the name of the resource. For details, see the following Comments section.

lpszType

Specifies the resource type. For details, see the following Comments section. For predefined resource types, this parameter should be one of the following values:

Value	Meaning
RT_ACCELERATOR	Accelerator table
RT_BITMAP	Bitmap resource
RT_CURSOR	Cursor resource
RT_DIALOG	Dialog box
RT_FONT	Font resource
RT_FONTDIR	Font directory resource
RT_ICON	Icon resource
RT_MENU	Menu resource
RT_RCDATA	User-defined resource (raw data)
RT_STRING	String resource

Return Value	The return value is the handle of the named resource if the function is successful. Otherwise, it is NULL.
Comments	If the high-order word of the <i>lpszName</i> or <i>lpszType</i> parameter is zero, the low- order word specifies the integer identifier of the name or type of the given re- source. Otherwise, the parameters are long pointers to null-terminated strings. If the first character of the string is a pound sign (#), the remaining characters repre- sent a decimal number that specifies the integer identifier of the resource's name or type. For example, the string #258 represents the integer ID 258.
	To reduce the amount of memory required for the resources used by an applica- tion, the application should refer to the resources by integer identifier instead of by name.
	An application must not call the FindResource and LoadResource functions to load cursor, icon, and string resources. Instead, it must load these resources by calling the LoadCursor , LoadIcon , and LoadString functions, respectively.
	Although the application can call the FindResource and LoadResource functions to load other predefined resource types, it should load the corresponding resources by calling the LoadAccelerators , LoadBitmap , and LoadMenu functions.
See Also	LoadAccelerators, LoadBitmap, LoadCursor, LoadIcon, LoadMenu, LoadResource, LoadString

FindText

#include <commdlg.h>

HWND FindText(*lpfr*) **FINDREPLACE FAR*** *lpfr*;

/* address of structure with initialization data

*/

3.1

The **FindText** function creates a system-defined modeless dialog box that makes it possible for the user to find text within a document. The application must perform the search operation.

Parameters

lpfr

Points to a FINDREPLACE structure that contains information used to initialize the dialog box. When the user makes a selection in the dialog box, the system fills this structure with information about the user's selection and then sends a message to the application. This message contains a pointer to the FINDREPLACE structure.

The **FINDREPLACE** structure has the following form:

	#include <commdlg.h></commdlg.h>	
	<pre>typedef struct tagFINDREPLACE { /* fr */ DWORD lStructSize; HWND hwndOwner; HINSTANCE hInstance; DWORD Flags; LPSTR lpstrFindWhat; LPSTR lpstrReplaceWith; UINT wFindWhatLen; UINT wFindWhatLen; LPARAM lCustData; UINT (CALLBACK* lpfnHook)(HWND, UINT, WPARAM, LPARAM); LPCSTR lpTemplateName; } FINDREPLACE;</pre>	
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.	
Return Value	The return value is the window handle of the dialog box if the function is successful. Otherwise, it is NULL. An application can use this window handle to communicate with or to close the dialog box.	
Errors	Use the CommDlgExtendedError function to retrieve the error value, which may be one of the following values: CDERR_FINDRESFAILURE CDERR_INITIALIZATION CDERR_LOCKRESFAILURE CDERR_LOADRESFAILURE CDERR_LOADSTRFAILURE CDERR_MEMALLOCFAILURE CDERR_MEMLOCKFAILURE CDERR_NOHINSTANCE CDERR_NOHOOK CDERR_NOTEMPLATE CDERR_STRUCTSIZE FRERR_BUFFERLENGTHZERO	
Comments	The dialog box procedure for the Find dialog box passes user requests to the application through special messages. The <i>lParam</i> parameter of each of these messages contains a pointer to a FINDREPLACE structure. The procedure sends the messages to the window identified by the hwndOwner member of the FIND-REPLACE structure. An application can register the identifier for these messages by specifying the "commdlg_FindReplace" string in a call to the Register-WindowMessage function.	

For the TAB key to function correctly, any application that calls the **FindText** function must also call the **IsDialogMessage** function in its main message loop. (The **IsDialogMessage** function returns a value that indicates whether messages are intended for the Find dialog box.)

If the hook function (to which the **lpfnHook** member of the **FINDREPLACE** structure points) processes the WM_CTLCOLOR message, this function must return a handle of the brush that should be used to paint the control background.

Example

The following example initializes a **FINDREPLACE** structure and calls the **FindText** function to display the Find dialog box:

FINDREPLACE fr;

/* Set all structure members to zero. */

memset(&fr, 0, sizeof(FINDREPLACE));

```
fr.lStructSize = sizeof(FINDREPLACE);
fr.hwndOwner = hwnd;
fr.lpstrFindWhat = szFindWhat;
fr.wFindWhatLen = sizeof(szFindWhat);
```

```
hDlg = FindText(&fr);
```

break;

In addition to initializing the members of the **FINDREPLACE** structure and calling the **FindText** function, an application must register the special FINDMSGSTRING message and process messages from the dialog box.

The following example registers the message by using the **RegisterWindow-Message** function:

```
UINT uFindReplaceMsg;
/* Register the FindReplace message. */
uFindReplaceMsg = RegisterWindowMessage(FINDMSGSTRING);
```

After the application registers the FINDMSGSTRING message, it can process messages by using the **RegisterWindowMessage** return value. An application must check the FR_DIALOGTERM bit in the **Flags** member of the **FIND**-**REPLACE** structure when it processes this message, as in the following example:

LRESULT CALLBACK MainWndProc(HWND hwnd, UINT msg, WPARAM wParam, LPARAM 1Param)

2.x

```
{
  static FINDREPLACE FAR* lpfr;
  if (msg == uFindReplaceMsg) {
    lpfr = (FINDREPLACE FAR*) lParam;
    SearchFile((B00L) (lpfr->Flags & FR_DOWN),
        (B00L) (lpfr->Flags & FR_MATCHCASE));
    return 0;
  }
  SearchFile((B00L) (lpfr->Flags & FR_DOWN),
        (B00L) (lpfr->Flags & FR_DOWN),
        (B00L) (lpfr->Flags & FR_MATCHCASE));
  return 0;
}
```

See Also IsDialogMessage, RegisterWindowMessage, ReplaceText

FindWindow

LPCSTR lpszClassN	w(lpszClassName, lpszWindow)lame;/* address of class-name string*/w;/* address of window-name string*/
	The FindWindow function retrieves the handle of the window whose class name and window name match the specified strings. This function does not search child windows.
Parameters	<i>lpszClassName</i> Points to a null-terminated string that contains the window's class name. If this parameter is NULL, all class names match.
	<i>lpszWindow</i> Points to a null-terminated string that specifies the window name (the window's title). If this parameter is NULL, all window names match.
Return Value	The return value is the handle of the window that has the specified class name and window name if the function is successful. Otherwise, it is NULL.
Example	The following example searches for the main window of Windows Control Panel (CONTROL.EXE) and, if it does not find it, starts Control Panel:
	<pre>if (FindWindow("CtlPanelClass", "Control Panel") == NULL) WinExec("control.exe", SW_SHOWNA);</pre>
See Also	EnumWindows, GetWindow, WindowFromPoint

FlashWindow

BOOL FlashWind	low(hwnd, fInvert)	
HWND hwnd; BOOL fInvert;	/* handle of window to flash /* invert flag	*/ */
	means changing the appearance from inactive to active status of	ashes the given window once. Flashing a window e of its title bar as if the window were changing r vice versa. (An inactive title bar changes to an ac- ar changes to an inactive title bar.)
	Typically, a window is flashed tion but that it does not current	to inform the user that the window requires atten- ly have the input focus.
Parameters	<i>hwnd</i> Identifies the window to be imized.	flashed. The window can be either open or min-
	parameter is TRUE, the win	he window or return it to its original state. If this dow is flashed from one state to the other. If the pa- ow is returned to its original state (either active or
Return Value	The return value is nonzero if t Window function. Otherwise,	he window was active before the call to the Flash - it is zero.
Comments	The FlashWindow function flating, the application should created	ashes the window only once; for successive flash- tte a system timer.
		e FALSE only when the window is receiving the be flashing; it should be TRUE on successive calls ocus.
		onzero for minimized windows. If the window is aply flashes the window's icon; <i>fInvert</i> is ignored

2.x

FloodFill	
-----------	--

BOOL FloodFill(hdo HDC hdc; int nXStart; int nYStart; COLORREF clrref;	, nXStart, nYStart, clrref)/* handle of device context/* x-coordinate of starting position/* y-coordinate of starting position/* color of fill boundary
	The FloodFill function fills an area of the screen surface by using the current brush. The area is assumed to be bounded as specified by the <i>clrref</i> parameter. The FloodFill function begins at the point specified by the <i>nXStart</i> and <i>nYStart</i> parameters and continues in all directions to the color boundary.
Parameters	hdc Identifies the device context. nXStart Specifies the logical x-coordinate at which to begin filling. nYStart Specifies the logical y-coordinate at which to begin filling. clrref Specifies the color of the boundary.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero, indi- cating that the filling cannot be completed, that the given point has the boundary color specified by <i>clrref</i> , or that the point is outside the clipping region.
Comments	Only memory device contexts and devices that support raster-display technology support the FloodFill function. For more information about raster capabilities, see the description of the GetDeviceCaps function.
See Also	ExtFloodFill, GetDeviceCaps

FlushComm

2.x

int FlushComm(idComDev, fnQueue)
int idComDev; /* communications-device identifier
int fnQueue; /* queue to flush

The **FlushComm** function flushes all characters from the transmission or receiving queue of the specified communications device.

*/ */

Parameters	<i>idComDev</i> Specifies the communication device to be flushed. The OpenComm function returns this value.
	<i>fnQueue</i> Specifies the queue to be flushed. If this parameter is zero, the transmission queue is flushed. If the parameter is 1, the receiving queue is flushed.
Return Value	The return value is zero if the function is successful. It is less than zero if $idCom-Dev$ is not a valid device or if $fnQueue$ is not a valid queue. The return value is positive if there is an error for the specified device. For a list of the possible error values, see the GetCommError function.
See Also	GetCommError, OpenComm

FMExtensionProc

#include <wfext.h>

HMENU FAR PAS HWND hwnd; WORD wMsg; LONG lParam;	SCAL FMExtensionProc(<i>hwnd</i> , <i>wh</i> /* handle of the extension window /* menu-item identifier or message /* additional message information	*/	
		an application-defined callback function, essages sent to a File Manager extension	
Parameters	<i>hwnd</i> Identifies the File Manager window. An extension DLL should use this handle to specify the parent for any dialog boxes or message boxes that the DLL may display and to send request messages to File Manager.		
	<i>wMsg</i> Specifies the message. This parameter may be one of the following values:		
	Value	Meaning	
	1–99	Identifier for the menu item that the user selected.	
	FMEVENT_INITMENU	User selected the extension's menu.	
	FMEVENT_LOAD	File Manager is loading the extension DLL.	
	FMEVENT_SELCHANGE	Selection in File Manager's directory window, or Search Results window, changed.	

3.1

	Value	Meaning
	FMEVENT_UNLOAD FMEVENT_USER_REFRESH	File Manager is unloading the extension DLL. User chose the Refresh command from the Win- dow menu.
	<i>lParam</i> Specifies 32 bits of additional n	nessage-dependent information.
Return Value	The callback function should retur tual return value depends on the m	n the result of the message processing. The ac- essage that is processed.
Comments	its directory windows (for changes turns. This allows the extension to without excessive repainting by th	FMExtensionProc function, it waits to refresh in the file system) until after the function re- perform large numbers of file operations e File Manager. The extension does not need to WS message to notify File Manager to repaint

FrameRect

lprc, hbr)		
/* handle of device context	*/	
<i>prc</i> ; /* address of structure with rectangle	*/	
/* handle of brush	*/	
The FrameRect function draws a border around brush. The width and height of the border are al		
hdc		
Identifies the device context in which to draw the border.		
<i>lprc</i> Points to a RECT structure that contains the left and lower-right corners of the rectangle. lowing form:		
<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>		
	<pre>/* handle of device context prc; /* address of structure with rectangle /* handle of brush The FrameRect function draws a border around brush. The width and height of the border are al hdc Identifies the device context in which to draw lprc Points to a RECT structure that contains the left and lower-right corners of the rectangle. lowing form: typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom;</pre>	

	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>hbr</i> Identifies the brush that will be used to draw the border.
Return Value	The return value is not used and has no meaning.
Comments	The border drawn by the FrameRect function is in the same position as a border drawn by the Rectangle function using the same coordinates (if Rectangle uses a pen that is one logical unit wide). The interior of the rectangle is not filled when an application calls FrameRect .
	FrameRect compares the values of the top , bottom , left , and right members of the specified RECT structure. If bottom is less than or equal to top , or if right is less than or equal to left , FrameRect does not draw the rectangle.

FrameRgn

BOOL FrameRg	n(hdc, hrgn, hbr, nWidth, nHeig	ht)	
HDC hdc;	/* handle of device context	*/	
HRGN hrgn;	/* handle of region	*/	
HBRUSH hbr;	/* handle of brush	*/	
int nWidth;	/* width of region frame	*/	
int nHeight;	/* height of region frame	*/	
	The FrameRgn function dra specified brush.	aws a border around the given region, using the	
Parameters	<i>hdc</i> Identifies the device contended	ext.	
	<i>hrgn</i> Identifies the region to be	enclosed in a border.	
	<i>hbr</i> Identifies the brush to be used to draw the border.		
	<i>nWidth</i> Specifies the width, in de	vice units, of vertical brush strokes.	
	<i>nHeight</i> Specifies the height, in de	evice units, of horizontal brush strokes.	

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Example The following example uses a blue brush to frame a rectangular region. Note that it is not necessary to select the brush or the region into the device context.

HRGN hrgn; HBRUSH hBrush; int Width = 5, Height = 2; hrgn = CreateRectRgn(10, 10, 110, 110); hBrush = CreateSolidBrush(RGB(0, 0, 255)); FrameRgn(hdc, hrgn, hBrush, Width, Height); DeleteObject(hrgn); DeleteObject(hBrush);

See Also FillRgn, PaintRgn

FreeAllGDIMem

#include <stress.h>

void FreeAllGDIMem(void)

	The FreeAllGDIMem function frees all memory allocated by the AllocGDIMem function.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
See Also	AllocGDIMem

3.1

FreeAllMem

#include <stress.h>

void FreeAllMem(void)

The FreeAllMem function frees all memory allocated by the AllocMem function.ParametersThis function has no parameters.Return ValueThis function does not return a value.See AlsoAllocMem

FreeAllUserMem

#include <stress.h>

void FreeAllUserMem(void)

The **FreeAllUserMem** function frees all memory allocated by the **AllocUserMem** function.

Parameters This function has no parameters.

Return Value This function does not return a value.

See Also AllocUserMem

FreeLibrary

2.x

void FreeLibrary(hinst)
HINSTANCE hinst; /* handle of loaded library module */

The **FreeLibrary** function decrements (decreases by one) the reference count of the loaded library module. When the reference count reaches zero, the memory occupied by the module is freed.

3.1

3.1

3.0

Parameters	<i>hinst</i> Identifies the loaded library module.
Return Value	This function does not return a value.
Comments	A dynamic-link library (DLL) must not call the FreeLibrary function within its WEP function (Windows exit procedure).
	The reference count for a library module is incremented (increased by one) each time an application calls the LoadLibrary function for the library module.
Example	The following example uses the LoadLibrary function to load TOOLHELP.DLL and the FreeLibrary function to free it:
	HINSTANCE hinstToolHelp = LoadLibrary("TOOLHELP.DLL");
	if ((UINT) hinstToolHelp > 32) {
	. /* use GetProcAddress to use TOOLHELP functions */
	} else { ErrorHandler(); }
	if ((UINT) hinstToolHelp > 32) FreeLibrary(hinstToolHelp); /* free TOOLHELP.DLL */
See Also	GetProcAddress, LoadLibrary, WEP

FreeModule

BOOL FreeModule HINSTANCE hinst	
	The FreeModule function decrements (decreases by one) the reference count of the loaded module. When the reference count reaches zero, the memory occupied by the module is freed.
Parameters	hinst Identifies the loaded module.
Return Value	The return value is zero if the reference count is decremented to zero and the mod- ule's memory is freed. Otherwise, the return value is nonzero.

Comments The reference count for a module is incremented (increased by one) each time an application calls the **LoadModule** function for the module.

See Also LoadModule

FreeProcInstance

void FreeProcInstance(*lpProc*) */ FARPROC lpProc; /* instance address of function to free The **FreeProcInstance** function frees the specified function from the data segment bound to it by the MakeProcInstance function. **Parameters** *lpProc* Points to the procedure-instance address of the function to be freed. It must be created by using the MakeProcInstance function. **Return Value** This function does not return a value. Comments After a procedure instance has been freed, attempts to call the function using the freed procedure-instance address will result in an unrecoverable error. See Also MakeProcInstance

FreeResource

2.x

2.x

BOOL FreeResource(*hglbResource*) **HGLOBAL** *hglbResource*; /* handle of loaded resource */

The **FreeResource** function decrements (decreases by one) the reference count of a loaded resource. When the reference count reaches zero, the memory occupied by the resource is freed.

Parameters

hglbResource

Identifies the data associated with the resource. The handle is assumed to have been created by using the **LoadResource** function.

Return Value	The return value is zero if the function is successful. Otherwise, it is nonzero, indi- cating that the function has failed and the resource has not been freed.
Comments	The reference count for a resource is incremented (increased by one) each time an application calls the LoadResource function for the resource.
See Also	LoadResource

FreeSelector

3.0

UINT FreeSelector(uselecior)
UINT uSelector;	/* selector to be freed */
	The FreeSelector function frees a selector originally allocated by the Alloc-Selector or AllocDStoCSAlias function. After the application calls this function, the selector is invalid and must not be used.
	An application should not use this function unless it is absolutely necessary, since its use violates preferred Windows programming practices.
Parameters	<i>uSelector</i> Specifies the selector to be freed.
Return Value	The return value is zero if the function is successful. Otherwise, it is the selector specified by the <i>uSelector</i> parameter.
See Also	AllocDStoCSAlias, AllocSelector

GetActiveWindow

2.x

HWND GetActiveWindow(void)

The **GetActiveWindow** function retrieves the window handle of the active window. The active window is either the top-level window associated with the input focus or the window explicitly made active by the **SetActiveWindow** function.

Parameters This function has no parameters.

Return Value The return value is the handle of the active window or NULL if no window was active at the time of the call.

See Also GetCapture, GetFocus, GetLastActivePopup, SetActiveWindow

GetAspectRatioFilter

DWORD GetAspectRatioFilter(*hdc*)

HDC *hdc*; /* handle of device context */

The **GetAspectRatioFilter** function retrieves the setting for the current aspectratio filter. The aspect ratio is the ratio formed by a device's pixel width and height. Information about a device's aspect ratio is used in the creation, selection, and display of fonts. Windows provides a special filter, the aspect-ratio filter, to select fonts designed for a particular aspect ratio from all of the available fonts. The filter uses the aspect ratio specified by the **SetMapperFlags** function.

Parameters	<i>hdc</i> Identifies the device context that contains the specified aspect ratio.
Return Value	The low-order word of the return value contains the x-coordinate of the aspect ratio if the function is successful; the high-order word contains the y-coordinate.
See Also	SetMapperFlags

GetAspectRatioFilterEx

BOOL GetAspectRatioFilterEx(*hdc*, *lpAspectRatio*) **HDC** *hdc*; **SIZE FAR*** *lpAspectRatio*;

> The **GetAspectRatioFilterEx** function retrieves the setting for the current aspectratio filter. The aspect ratio is the ratio formed by a device's pixel width and height. Information about a device's aspect ratio is used in the creation, selection, and displaying of fonts. Windows provides a special filter, the aspect-ratio filter, to select fonts designed for a particular aspect ratio from all of the available fonts. The filter uses the aspect ratio specified by the **SetMapperFlags** function.

3.1

Parameters	<i>hDC</i> Identifies the device context that contains the specified aspect ratio.
	<i>lpAspectRatio</i> Pointer to a SIZE structure where the current aspect ratio filter will be returned.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also	SetMapperFlags

GetAsyncKeyState

int GetAsyncKeyState(vkey) int vkey; /* virtual-key code */		
	The GetAsyncKeyState function determines whether a key is up or down at the time the function is called and whether the key was pressed after a previous call to the GetAsyncKeyState function.	
Parameters	vkey Specifies one of 256 possible virtual-key codes.	
Return Value	The return value specifies whether the key was pressed since the last call to the GetAsyncKeyState function and whether the key is currently up or down. If the most significant bit is set, the key is down, and if the least significant bit is set, the key was pressed after a preceding GetAsyncKeyState call.	
Comments	If VK_LBUTTON or VK_RBUTTON is specified in the <i>vkey</i> parameter, this func- tion returns the state of the physical left or right mouse button regardless of whether the SwapMouseButton function has been used to reverse the meaning of the buttons.	
See Also	$Get Key board State, \ Get Key State, \ Set Key board State, \ Swap Mouse Button$	

GetAtomHandle

HLOCAL GetA ATOM atm;	tomHandle(<i>atm</i>) /* atom to retrieve handle of */
	The GetAtomHandle function retrieves a handle of the specified atom.
	This function is only provided for compatibility with Windows, versions $1.x$ and $2.x$. It should not be used with Windows 3.0 and later.
Parameters	atm Specifies an atom whose handle is to be retrieved.
Return Value	The return value is a handle of the specified atom if the function is successful.
See Also	GetAtomName, GlobalGetAtomName

GetAtomName

UINT GetAtomNan	ne(atm, lpszBuffer, cbBuffer)	
ATOM atm;	/* atom identifying character string	*/
LPSTR lpszBuffer;	/* address of buffer for atom string	*/
int cbBuffer;	/* size of buffer	*/
	The GetAtomName function retrieves a co with the specified local atom.	py of the character string associated
Parameters atm Specifies the local atom that identifies the character string to be retried		e character string to be retrieved.
	<i>lpszBuffer</i> Points to the buffer for the character string	ng.
	<i>cbBuffer</i> Specifies the maximum size, in bytes, of	the buffer.
Return Value	The return value specifies the number of by is successful.	tes copied to the buffer, if the function
Comments	The string returned for an integer atom (an ATOM macro) will be a null-terminated st pound sign (#) and the remaining character INTATOM .	ring, where the first character is a

2.x

Example	The following example uses the GetAtomName function to retrieve the character string associated with a local atom:
	char szBuf[80];
	<pre>GetAtomName(atTest, szBuf, sizeof(szBuf));</pre>
	MessageBox(hwnd, szBuf, "GetAtomName", MB_OK);
See Also	AddAtom, DeleteAtom, FindAtom

GetBitmapBits

LONG GetBitmapH HBITMAP hbm; LONG cbBuffer; void FAR* lpvBits;	pBits(hbm, cbBuffer, lpvBits) /* handle of bitmap */ /* number of bytes to copy to buffer */ ;; /* address of buffer for bitmap bits */		
	The GetBitmapBits function copies the bits	of the specified bitmap into a buffer.	
Parameters	<i>hbm</i> Identifies the bitmap.		
	<i>cbBuffer</i> Specifies the number of bytes to be copie	d.	
	<i>lpvBits</i> Points to the buffer that is to receive the b bytes. This array conforms to a structure multiples of 16 bits.		
Return Value	The return value specifies the number of byt successful. It is zero if there is an error.	es in the bitmap if the function is	
Comments	An application can use the GetObject function to determine the number of bytes to copy into the buffer pointed to by the <i>lpvBits</i> parameter.		
See Also	GetObject, SetBitmapBits		

GetBitmapDimension

DWORD GetBitma	pDimension(<i>hbm</i>)	
HBITMAP hbm;	/* handle of bitmap */	
	The GetBitmapDimension function returns the width and height of the specified bitmap. The height and width is assumed to have been set by the SetBitmap-Dimension function.	
Parameters	hbm Identifies the bitmap.	
Return Value	The low-order word of the return value contains the bitmap width, in tenths of a millimeter, if the function is successful; the high-order word contains the height. If the bitmap width and height have not been set by using the SetBitmapDimension function, the return value is zero.	
See Also	SetBitmapDimension	

GetBitmapDimensionEx

BOOL GetBitmap	Dimensio	nEx (hBitmap, lpDimension)		
HBITMAP hBitmap;		/* handle of bitmap	*/	
SIZE FAR* lpDim	ension;	/* address of dimension structu	ire */	
	viously	tBitmapDimensionEx function r set by the SetBitmapDimension efault of 0,0 will be returned.		
Parameters	<i>hBitmaj</i> Iden	p tifies the bitmap.		
		<i>nsion</i> ts to a SIZE structure to which th cture has the following form:	e dimensions are returned	l. The SIZE
		def struct tagSIZE { int cx; int cy; ZE;		
		a full description of this structure, <i>'s Reference</i> , <i>Volume 3</i> .	, see the Microsoft Windo	ws Program-

2.x

2.x

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

See Also SetBitmapDimensionEx

GetBkColor

COLORREF GetBkColor(*hdc*) HDC hdc: /* handle of device context */ The GetBkColor function returns the current background color. **Parameters** hdc Identifies the device context. **Return Value** The return value is an RGB (red, green, blue) color value if the function is successful. Comments If the background mode is OPAQUE, the system uses the background color to fill the gaps in styled lines, the gaps between hatched lines in brushes, and the background in character cells. The system also uses the background color when converting bitmaps between color and monochrome device contexts. Example The following example uses the **GetBkColor** function to determine whether the current background color is white. If it is, the **SetBkColor** function sets it to red. DWORD dwBackColor: dwBackColor = GetBkColor(hdc); if (dwBackColor == RGB(255, 255, 255)) { /* if color is white */ SetBkColor(hdc, RGB(255, 0, 0)); /* sets color to red */ TextOut(hdc, 100, 200, "SetBkColor test.", 16); } See Also GetBkMode, SetBkColor, SetBkMode

GetBkMode

int GetBkMo HDC hdc;	ode(hdc)/* handle of device context*/
	The GetBkMode function returns the background mode. The background mode defines whether the system removes existing background colors on the drawing surface before drawing text, hatched brushes, or any pen style that is not a solid line.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the current background mode if the function is successful. It can be OPAQUE, TRANSPARENT, or TRANSPARENT1.
Example	The following example determines the current background mode by calling the GetBkMode function. If the mode is OPAQUE, the SetBkMode function sets it to TRANSPARENT.
	int nBackMode;
	<pre>nBackMode = GetBkMode(hdc); if (nBackMode == OPAQUE) { TextOut(hdc, 90, 100, "This background mode is OPAQUE.", 31); SetBkMode(hdc, TRANSPARENT); }</pre>
See Also	GetBkColor, SetBkColor, SetBkMode

GetBoundsRect

UINT GetBoundsRect (<i>hdc</i> , <i>lprcBounds</i> , <i>flags</i>)			
HDC hdc;	/* handle of device context	*/	
RECT FAR* <i>lprcBounds</i> ;	/* address of structure for bounding rectangle	*/	
UINT flags;	/* specifies information to return	*/	

The **GetBoundsRect** function returns the current accumulated bounding rectangle for the specified device context.

3.1

2.x

Parameters	<i>hdc</i> Identifies the device context to return the bounding rectangle for.	
	<i>lprcBounds</i> Points to a buffer that will receive the current bounding rectangle. The rectangle is returned in logical coordinates.	
	<i>flags</i> Specifies whether the bounding rectangle is to be cleared after it is returned. This parameter can be DCB_RESET, to clear the rectangle. Otherwise, it should be zero.	
Return Value	The return value is DCB_SET if the bounding rectangle is not empty. Otherwise, it is DCB_RESET.	
Comments	To ensure that the bounding rectangle is empty, check both the DCB_RESET bit and the DCB_ACCUMULATE bit in the return value. If DCB_RESET is set and DCB_ACCUMULATE is not, the bounding rectangle is empty.	
See Also	SetBoundsRect	

GetBrushOrg

DWORD GetH HDC hdc;	BrushOrg(hdc) /* handle of device context */
	The GetBrushOrg function retrieves the origin, in device coordinates, of the brush currently selected for the given device context.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The low-order word of the return value contains the current x-coordinate of the brush, in device coordinates, if the function is successful; the high-order word contains the y-coordinate.

Comments	The initial brush origin is at the coordinates $(0,0)$ in the client area. The return value specifies these coordinates in device units relative to the origin of the desk-top window.	
Example	The following example uses the LOWORD and HIWORD macros to extract the x- and y-coordinate of the current brush from the return value of the GetBrush-Org function:	
	DWORD dwBrOrg; WORD wXBrOrg, wYBrOrg;	
	dwBrOrg = GetBrushOrg(hdc); wXBrOrg = LOWORD(dwBrOrg); wYBrOrg = HIWORD(dwBrOrg);	
See Also	SelectObject, SetBrushOrg	

GetBrushOrgEx

 BOOL GetBrushOrgEx(hDC, lpPoint)

 HDC hDC;
 /* handle of device context
 */

 POINT FAR* lpPoint;
 /* address of structure for brush origin
 */

 The GetBrushOrgEx function retrieves the current brush origin for the given device context.
 Parameters
 hDC

 Identifies the device context.
 Identifies the device context.
 Identifies the device context.

lpPoint

Points to a **POINT** structure to which the device coordinates of the brush origin are to be returned. The **POINT** structure has the following form:

```
typedef struct tagPOINT { /* pt */
    int x;
    int y;
} POINT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

3.1

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments The initial brush origin is at the coordinate (0,0).

See Also SetBrushOrg

GetCapture

2.x

2.x

HWND GetCapture(void)

	The GetCapture function retrieves a handle of the window that has the mouse capture. Only one window has the mouse capture at any given time; this window receives mouse input whether or not the cursor is within its borders.	
Parameters	This function has no parameters.	
Return Value	The return value is a handle identifying the window that has the mouse capture if the function is successful. It is NULL if no window has the mouse capture.	
Comments	A window receives the mouse capture when its handle is passed as the <i>hwnd</i> parameter of the SetCapture function.	
See Also	SetCapture	

GetCaretBlinkTime

UINT GetCaretBlinkTime(void)

The **GetCaretBlinkTime** function retrieves the caret blink rate. The blink rate is the elapsed time, in milliseconds, between flashes of the caret.

Parameters This function has no parameters.

Return Value The return value specifies the blink rate, in milliseconds, if the function is successful.

See Also SetCaretBlinkTime

GetCaretPos

<pre>void GetCaretPos(l POINT FAR* lppt;</pre>	<pre>ppt) /* address of structure to receive coordinates */</pre>
	The GetCaretPos function retrieves the current position of the caret.
Parameters	<i>lppt</i> Points to a POINT structure that receives the client coordinates of the caret's current position. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
Comments	The caret position is always given in the client coordinates of the window that con- tains the caret.
See Also	SetCaretPos

GetCharABCWidths

BOOL GetCharABCWidths (<i>hdc</i> , <i>uFirstChar</i> , <i>uLastChar</i> , <i>lpabc</i>)			
HDC hdc;	/* handle of device context	*/	
UINT uFirstChar;	/* first character in range to query	*/	
UINT uLastChar;	/* last character in range to query	*/	
LPABC lpabc;	/* address of ABC width structures	*/	

3.1

	The GetCharABCWidths function retrieves the widths of consecutive characters in a specified range from the current TrueType font. The widths are returned in logical units. This function succeeds only with TrueType fonts.	
Parameters	<i>hdc</i> Identifies the device context.	
	<i>uFirstChar</i> Specifies the first character in the range of characters from the current font for which character widths are returned.	
	<i>uLastChar</i> Specifies the last character in the range of characters from the current font for which character widths are returned.	
	<i>lpabc</i> Points to an array of ABC structures that receive the character widths when the function returns. This array must contain at least as many ABC structures as there are characters in the range specified by the <i>uFirstChar</i> and <i>uLastChar</i> parameters.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The TrueType rasterizer provides ABC character spacing after a specific point size has been selected. "A" spacing is the distance that is added to the current position before placing the glyph. "B" spacing is the width of the black part of the glyph. "C" spacing is added to the current position to account for the white space to the right of the glyph. The total advanced width is given by $A + B + C$.	
	When the GetCharABCWidths function retrieves negative "A" or "C" widths for a character, that character includes underhangs or overhangs.	
	To convert the ABC widths to font design units, an application should create a font whose height (as specified in the lfHeight member of the LOGFONT structure) is equal to the value stored in the ntmSizeEM member of the NEWTEXT-METRIC structure. (The value of the ntmSizeEM member can be retrieved by calling the EnumFontFamilies function.)	
	The ABC widths of the default character are used for characters that are outside the range of the currently selected font.	
	To retrieve the widths of characters in non-TrueType fonts, applications should use the GetCharWidth function.	
See Also	EnumFontFamilies, GetCharWidth	

GetCharWidth

BOOL GetCharWid HDC hdc; UINT uFirstChar; UINT uLastChar; int FAR* lpnWidths;	Ith(hdc, uFirstChar, uLastChar, lpnWidths) /* handle of device context */ /* first character in range to query */ /* last character in range to query */ /* address of buffer for widths */	
	The GetCharWidth function retrieves the widths of individual characters in a range of consecutive characters in the current font.	
Parameters	<i>hdc</i> Identifies the device context.	
	<i>uFirstChar</i> Specifies the first character in a group of consecutive characters in the current font.	
	<i>uLastChar</i> Specifies the last character in a group of consecutive characters in the current font.	
	<i>lpnWidths</i> Points to a buffer that receives the width values for a group of consecutive characters in the current font.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	If a character in the group of consecutive characters does not exist in a particular font, it will be assigned the width value of the default character.	
Example	The following example uses the GetCharWidth function to retrieve the widths of the characters from "I" through "S" and displays the total number of widths re- trieved in a message box:	
	HDC hdc; WORD wTotalValues; WORD wFirstChar, wLastChar; int InfoBuffer[256]; char szMessage[30];	
	wFirstChar = (WORD) 'I'; wLastChar = (WORD) 'S';	
	<pre>hdc = GetDC(hwnd);</pre>	

```
if (GetCharWidth(hdc, wFirstChar, wLastChar, (int FAR*) InfoBuffer)) {
    wTotalValues = wLastChar - wFirstChar + 1;
    wsprintf(szMessage, "Total values received: %d", wTotalValues);
    MessageBox(hwnd, szMessage, "GetCharWidth", MB_OK);
}
else
    MessageBox(hwnd, "GetCharWidth was unsuccessful", "ERROR!",
    MB_OK);
ReleaseDC(hwnd, hdc);
GetCharABCWidths
```

GetClassInfo

See Also

3.0

BOOL GetClassInfo(hinst, lpszClassName, lpwc)HINSTANCE hinst;/* handle of application instance*/LPCSTR lpszClassName;/* address of class-name string*/WNDCLASS FAR* lpwc;/* address of structure for class data*/

The **GetClassInfo** function retrieves information about a window class. This function is used for creating subclasses of a given class.

Parameters

hinst

Identifies the instance of the application that created the class. To retrieve information about classes defined by Windows (such as buttons or list boxes), set this parameter to NULL.

lpszClassName

Points to a null-terminated string containing the class name. The class name is either an application-specified name as defined by the **RegisterClass** function or the name of a preregistered window class. If the high-order word of this parameter is NULL, the low-order word is assumed to be a value returned by the **MAKEINTRESOURCE** macro used when the class was created.

lpwc

Points to a **WNDCLASS** structure that receives the information about the class. The **WNDCLASS** structure has the following form:

```
typedef struct tagWNDCLASS {  /* wc */
 UINT style;
 WNDPROC lpfnWndProc;
 int cbClsExtra;
 int cbWndExtra;
 HINSTANCE hInstance;
 HICON hIcon;
```

	HCURSOR hCursor; HBRUSH hbrBackground; LPCSTR 1pszMenuName; LPCSTR 1pszClassName; } WNDCLASS;		
	For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero, indi- cating the function did not find a matching class.		
Comments	The GetClassInfo function does not set the lpszClassName and lpszMenuName members of the WNDCLASS structure. The menu name is not stored internally and cannot be returned. The class name is already known, since it is passed to this function. GetClassInfo returns all other members with the values used when the class was registered.		
See Also	GetClassLong, GetClassName, GetClassWord, RegisterClass		

GetClassLong

	sLong(hwnd, offset) /* handle of window */ /* offset of value to retrieve */
	The GetClassLong function retrieves a 32-bit (long) value at the specified offset into the extra class memory for the window class to which the given window belongs. Extra class memory is reserved by specifying a nonzero value in the cbClsExtra member of the WNDCLASS structure used with the RegisterClass function.
Parameters	<i>hwnd</i> Identifies the window.
	offset Specifies the zero-based byte offset of the value to be retrieved. Valid values are in the range zero through the number of bytes of class memory minus four (for example, if 12 or more bytes of extra class memory was specified, a value of 8 would be an index to the third 32-bit integer) or one of the following values:

	Value	Meaning
	GCL_MENUNAME	Retrieves a 32-bit pointer to the menu-name string.
	GCL_WNDPROC	Retrieves a 32-bit pointer to the window procedure.
Return Value	The return value is the specified 32-bit value in the extra class memory if the func- tion is successful. Otherwise, it is zero, indicating the <i>hwnd</i> or <i>offset</i> parameter is invalid.	
Comments	To access any extra four-byte values allocated when the window-class structure was created, use a positive byte offset as the index specified by the <i>offset</i> parameter, starting at 0 for the first four-byte value in the extra space, 4 for the next four-byte value, and so on.	
See Also	GetClassInfo, GetClassName, GetClassWord, RegisterClass, SetClassLong	

GetClassName

HWND hwnd;	(hwnd, lpszClassName, cchClassName) /* handle of window ame; /* address of buffer for class name /* size of buffer	*/ */ */
	The GetClassName function retrieves the class	name of a window.
Parameters	<i>hwnd</i> Identifies the window.	
	<i>lpszClassName</i> Points to a buffer that receives the null-termin	nated class name string.
	<i>cchClassName</i> Specifies the length of the buffer pointed to b The class name string is truncated if it is long	
Return Value	The return value is the length, in bytes, of the re the terminating null character. The return value handle is invalid.	

GetClassWord

WORD GetClass HWND hwnd; int offset;		*/ */
	into the extra class memory for the belongs. Extra class memory is the belongs.	trieves a 16-bit (word) value at the specified offset the window class to which the given window reserved by specifying a nonzero value in the DCLASS structure used with the RegisterClass
Parameters	<i>hwnd</i> Identifies the window.	
	are in the range zero through (for example, if 10 or more b	offset of the value to be retrieved. Valid values the number of bytes of class memory minus two ytes of extra class memory was specified, a value fifth 16-bit integer) or one of the following values:
	Value	Meaning
	GCW_CBCLSEXTRA GCW_CBWNDEXTRA	Retrieves the number of bytes of additional class information. For information about how to access this memory, see the following Comments section. Retrieves the number of bytes of additional win-
		dow information. For information about how to access this memory, see the following Comments section.
	GCW_HBRBACKGROUND	Retrieves the handle of the background brush.
	GCW_HCURSOR	Retrieves the handle of the cursor.
	GCW_HICON	Retrieves the handle of the icon.
	GCW_HMODULE	Retrieves the handle of the module.
	GCW_STYLE	Retrieves the window-class style bits.
Return Value		lue in the window's reserved memory, if the func- is zero, indicating the <i>hwnd</i> or <i>offset</i> parameter is
Comments	was created, use a positive byte	lues allocated when the window-class structure offset as the index specified by the <i>offset</i> parame-byte value in the extra space, 2 for the next two-
See Also	GetClassInfo, GetClassLong,	GetClassName, RegisterClass, SetClassWord

GetClientRect

	(hwnd, lprc) /* handle of window */ /* address of structure for rectangle */
	The GetClientRect function retrieves the client coordinates of a window's client area. The client coordinates specify the upper-left and lower-right corners of the client area. Because client coordinates are relative to the upper-left corner of a window's client area, the coordinates of the upper-left corner are (0,0).
Parameters	<i>hwnd</i> Identifies the window whose client coordinates are to be retrieved. <i>lprc</i>
	Points to a RECT structure that receives the client coordinates. The left and top members will be zero. The right and bottom members will contain the width and height of the window. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
See Also	GetWindowRect

GetClipboardData

HANDLE GetClipboardData(uFormat) ·*/ **UINT** *uFormat*;

/* data format

The GetClipboardData function retrieves a handle of the current clipboard data having a specified format. The clipboard must have been opened previously.

2.x

Parameters	<i>uFormat</i> Specifies the format of the data accessed by this function. For a description of the possible data formats, see the description of the SetClipboardData function.
Return Value	The return value is a handle of the clipboard data in the specified format, if the function is successful. Otherwise, it is NULL.
Comments	The available formats can be enumerated in advance by using the Enum- ClipboardFormats function.
	The data handle returned by the GetClipboardData function is controlled by the clipboard, not by the application. The application should copy the data immediately, instead of relying on the data handle for long-term use. The application should not free the data handle or leave it locked.
	Windows supports two formats for text: CF_TEXT (the default Windows text clipboard format) and CF_OEMTEXT (the format Windows uses for text in non-Windows applications). If you call GetClipboardData to retrieve data in one text format and the other text format is the only available text format, Windows automatically converts the text to the requested format before supplying it to your application.
	If the clipboard contains data in the CF_PALETTE (logical color palette) format, the application should assume that any other data in the clipboard is realized against that logical palette.
See Also	CloseClipboard, EnumClipboardFormats, IsClipboardFormatAvailable, OpenClipboard, SetClipboardData

GetClipboardFormatName

int GetClipboardFormatNa	me(uFormat, lpszFormatName, cl	oMax)
UINT <i>uFormat</i> ;	/* format to retrieve	*/
LPSTR lpszFormatName;	/* address of buffer for name	*/
int cbMax;	/* length of name string	*/

The **GetClipboardFormatName** function retrieves the name of a registered clipboard format.

2.x

Parameters

uFormat

Specifies the registered format to retrieve. This parameter must not specify any of the predefined clipboard formats.

	<i>lpszFormatName</i> Points to a buffer that receives the format name.
	<i>cbMax</i> Specifies the maximum length, in bytes, of the format-name string. The format-name string is truncated if it is longer.
Return Value	The return value is the length, in bytes, of the returned format name if the function is successful. Otherwise, it is zero, indicating the requested format does not exist or is predefined.
See Also	CountClipboardFormats, EnumClipboardFormats, GetPriorityClipboard- Format, IsClipboardFormatAvailable, RegisterClipboardFormat

GetClipboardOwner

HWND GetClipboardOwner(void)

	The GetClipboardOwner function retrieves the handle of the window that cur- rently owns the clipboard, if any.
Parameters	This function has no parameters.
Return Value	The return value identifies the window that owns the clipboard if the function is successful. Otherwise, it is NULL.
Comments	The clipboard can still contain data even if the clipboard is not currently owned.
See Also	Close Clipboard, Get Clipboard Data, Get Clipboard Viewer, Open Clipboard

GetClipboardViewer

2.x

2.x

HWND GetClipboardViewer(void)

The **GetClipboardViewer** function retrieves the handle of the first window in the clipboard-viewer chain.

Parameters This function has no parameters.

See Also	CloseClipboard, GetClipboardData, GetClipboardOwner, OpenClipboard
Return Value	The return value identifies the window currently responsible for displaying the clipboard, if the function is successful. Otherwise, it is NULL (if there is no viewer, for example).

GetClipBox

<pre>int GetClipBox(hdc HDC hdc; RECT FAR* lprc;</pre>	<pre>r, lprc) /* handle of device context</pre>
	completely contains the current clipping region.
Parameters	<i>hdc</i> Identifies the device context.
	<i>lprc</i> Points to the RECT structure that receives the logical coordinates of the rec- tangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.
See Also	GetBoundsRect, GetRgnBox, GetTextExtent, SelectClipRgn

2.x

GetClipCurs	Or 3.1
<pre>void GetClipCurso RECT FAR* lprc;</pre>	r(lprc) /* address of structure for rectangle */
	The GetClipCursor function retrieves the screen coordinates of the rectangle to which the cursor has been confined by a previous call to the ClipCursor function.
Parameters	<i>lprc</i> Points to a RECT structure that receives the screen coordinates of the confining rectangle. The structure receives the dimensions of the screen if the cursor is not confined to a rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
See Also	ClipCursor, GetCursorPos

GetCodeHandle

HGLOBAL GetCodeHandle(*lpProc*) FARPROC *lpProc*; /* instance address of function

*/

The GetCodeHandle function determines which code segment contains the specified function.

Parameters	<i>lpProc</i> Points to the procedure-instance address of the function for which to return the code segment. Typically, this address is returned by the MakeProcInstance function.
Return Value	The return value identifies the code segment that contains the function if the Get-CodeHandle function is successful. Otherwise, it is NULL.

Comments	If the code segment that contains the function is already loaded, the GetCode-Handle function marks the segment as recently used. If the code segment is not loaded, GetCodeHandle attempts to load it. Thus, an application can use this function to attempt to preload one or more segments necessary to perform a particular task.
See Also	MakeProcInstance

GetCodeInfo

3.0

void GetCodeInfo(FARPROC lpProc; SEGINFO FAR* lp	lpProc, lpSegInfo)/* function address or module handle/* address of structure for segment information*/
	The GetCodeInfo function retrieves a pointer to a structure containing informa- tion about a code segment.
Parameters	<i>lpProc</i> Specifies the procedure-instance address of the function (typically, returned by the MakeProcInstance function) in the segment for which information is to be retrieved, or it specifies a module handle (typically, returned by the Get-ModuleHandle function) and segment number.
	<i>lpSegInfo</i> Points to a SEGINFO structure that will be filled with information about the code segment. The SEGINFO structure has the following form:
	<pre>typedef struct tagSEGINFO { UINT offSegment; UINT cbSegment; UINT flags; UINT cbAlloc; HGLOBAL h; UINT alignShift; UINT reserved[2]; } SEGINFO;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	This function does not return a value.
See Also	GetModuleHandle, MakeProcInstance

GetCommEr	ror				2.x
int GetCommError int idComDev; COMSTAT FAR* lp	/* comm	unications device i ss of device-status		*/ */	
	The GetCommEr status for the speci		ves the most re	ecent error value and curre	nt
	When a communic until GetCommE			eks the communications p	ort
Parameters	<i>idComDev</i> Specifies the co tion returns this		ice to be exam	ined. The OpenComm fu	nc-
	rameter is NUL			eive the device status. If the rror values. The COMST	
	typedef struct BYTE statu UINT cbInC UINT cbOut } COMSTAT;	ıs; lue;	/* count of	transmission characters in Rx Queue characters in Tx Queue	
	For a full descri mer's Reference		ure, see the <i>Mi</i>	crosoft Windows Program	<i>1</i> -
Return Value	The return value sp function call to the			ost recent communications rror is successful.	} -
Errors	The return value ca	an be a combinatio	n of the follow	ving values:	
	Value	Meaning			
	CE_BREAK	Hardware detected	a break condition	on.	
	CE_CTSTO		w for the duration	e a character was being trans- on specified by the fCtsHold re.	
	CE_DNS	Parallel device was	not selected.		
	CE_DSRTO		w for the durati	le a character was being tran on specified by the fDsrHol	
	CE_FRAME	Hardware detected	a framing error.		

Meaning
I/O error occurred during an attempt to communicate with a paral- lel device.
Requested mode is not supported, or the <i>idComDev</i> parameter is invalid. If set, CE_MODE is the only valid error.
Parallel device signaled that it is out of paper.
Character was not read from the hardware before the next charac- ter arrived. The character was lost.
Timeout occurred during an attempt to communicate with a paral- lel device.
RLSD (receive-line-signal-detect) timeout. While a character was being transmitted, RLSD was low for the duration specified by the fRlsdHold member of COMSTAT .
Receiving queue overflowed. There was either no room in the input queue or a character was received after the end-of-file character was received.
Hardware detected a parity error.
Transmission queue was full when a function attempted to queue a character.

2.x

See Also OpenComm

GetCommEventMask

UINT GetComml	EventMask(idComDev, fnEvtClear)
<pre>int idComDev;</pre>	/* communications device identifier */
int fnEvtClear;	/* events to clear in the event word */
	The GetCommEventMask function retrieves and then clears the event word for a communications device.
Parameters	<i>idComDev</i> Specifies the communication device to be examined. The OpenComm function returns this value.
	<i>fnEvtClear</i> Specifies which events are to be cleared in the event word. For a list of the event values, see the description of the SetCommEventMask function.
Return Value	The return value specifies the current event-word value for the specified com- munications device if the function is successful. Each bit in the event word speci- fies whether a given event has occurred; a bit is set (to 1) if the event has occurred.

Comments	Before the GetCommEventMask function can record the occurrence of an event, an application must enable the event by using the SetCommEventMask function.
	If the communication device event is a line-status or printer error, the application should call the GetCommError function after calling GetCommEventMask .
See Also	GetCommError, OpenComm, SetCommEventMask

GetCommState

	(<i>idComDev</i> , <i>lpdcb</i>) /* communications device i /* address of structure for d		
	The GetCommState function device.	n retrieves the device control block for the spe	cified
Parameters	value.	examined. The OpenComm function returns	this
		re that is to receive the current device control l s the control settings for the device. It has the	
	typedef struct tagDCB	/* dcb	*/

	fInX			enable input XON/XOFF	*/
UINT	fPeChar	:1;	/*	enable parity err replacement	*/
UINT	fNull	:1;	/*	enable null stripping	*/
UINT	fChEvt	:1;	/*	enable Rx character event	*/
UINT	fDtrflow	:1;	/*	DTR handshake on input	*/
UINT	fRtsflow			RTS handshake on input	*/
UINT	fDummy2	:1;			
char	XonChar:		/*	Tx and Rx XON character	*/
char	XoffChar;		/*	Tx and Rx XOFF character	*/
UINT	XonLim;		/*	transmit XON threshold	*/
UINT	XoffLim:		/*	transmit XOFF threshold	*/
char	PeChar;		/*	parity error replacement char	*/
	EofChar:			end of Input character	*/
	EvtChar;			received event character	*/
	TxDelay:		/*	amount of time between chars	*/
} DCB;					

Return Value The return value is zero if the function is successful. Otherwise, it is less than zero.

See Also OpenComm, SetCommState

GetCurrentPDB

3.0

UINT GetCurrentPDB(void)

	The GetCurrentPDB function returns the selector address of the current MS-DOS program database (PDB), also known as the program segment prefix (PSP).
Parameters	This function has no parameters.
Return Value	The return value is the selector address of the current PDB if the function is successful.
Example	The following example uses the GetCurrentPDB function to list the current com- mand tail:

```
typedef struct {
    WORD pspInt20;
                             /* Int 20h instruction
                                                                */
    WORD pspNextParagraph; /* segment addr. of next paragraph */
    BYTE res1:
                             /* reserved
                                                                */
   BYTE pspDispatcher[5]; /* long call to MS-DOS
                                                                 */
    DWORD pspTerminateVector: /* termination address (Int 22h)
                                                                */
    DWORD pspControlCVector; /* addr of CTRL+C (Int 23h)
                                                                */
    DWORD pspCritErrorVector; /* addr of Crit-Error (Int 24h)
                                                                */
    WORD res2[11];
                             /* reserved
                                                                 */
    WORD pspEnvironment; /* segment address of environment
                                                                */
   WORD res3[23];
                            /* reserved
                                                                 */
    BYTE pspFCB 1[16];
                             /* default FCB #1
                                                                */
    BYTE pspFCB_2[16];
                             /* default FCB #2
                                                                */
    DWORD res4:
                             /* reserved
                                                                */
    BYTE pspCommandTail[128]; /* command tail (also default DTA) */
} PSP. FAR* LPSP:
    LPSP lpsp = (LPSP) MAKELP(GetCurrentPDB(), 0);
    MessageBox(NULL, lpsp->pspCommandTail, "PDB Command Tail", MB_OK);
```

GetCurrentPosition

DWORD GetCurrentPosition(*hdc*)

HDC *hdc*; /* handle of device context */

The **GetCurrentPosition** function retrieves the logical coordinates of the current position. The current position is set by using the **MoveTo** function.

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The low-order word of the return value contains the logical x-coordinate of the cur- rent position if the function is successful; the high-order word contains the logical y-coordinate.
See Also	LineTo, MoveTo

GetCurrentPositionEx

BOOL GetCurrentPositionEx(*hdc*, *lpPoint*) **HDC** *hdc*; **POINT FAR*** *lpPoint*;

The **GetCurrentPositionEx** function retrieves the current position in logical coordinates.

Parameters	<i>hdc</i> Identifies the device context to get the current position from.
	<i>lpPoint</i> Points to a POINT structure that gets filled with the current position.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

GetCurrentTask

HTASK GetCurrentTask(void)

The GetCurrentTask function retrieves the handle of the current (running) task.

Parameters This function has no parameters.

Return Value The return value is a handle of the current task if the function is successful. Otherwise, it is NULL.

GetCurrentTime

DWORD GetCurrentTime(void)

The **GetCurrentTime** function retrieves the number of milliseconds that have elapsed since Windows was started.

Parameters This function has no parameters.

2.x

Return Value	The return value is the number of milliseconds that have elapsed since Windows was started, if the function was successful.
Comments	The GetCurrentTime function is identical to the GetTickCount function. Applications should use the GetTickCount function, since its name matches more closely with what the function does.
See Also	GetTickCount

GetCursor

HCURSOR GetCursor(void)

The GetCursor function retrieves the handle of the current cursor.

,

Parameters	This function has no parameters.
------------	----------------------------------

Return Value The return value is the handle of the current cursor if a cursor exists. Otherwise, it is NULL.

See Also SetCursor

GetCursorPos

<pre>void GetCursorPos POINT FAR* lppt;</pre>	
	The GetCursorPos function retrieves the screen coordinates of the cursor's current position.
Parameters	<i>lppt</i> Points to the POINT structure that receives the cursor position, in screen coordinates. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>

2.x

3.1

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.Return ValueThis function does not return a value.CommentsThe cursor position is always given in screen coordinates and is not affected by the mapping mode of the window that contains the cursor.See AlsoClipCursor, SetCursorPos

2.x

GetDC

HDC GetDC(hwnd, HWND hwnd;) /* handle of window */
	The GetDC function retrieves the handle of a device context for the client area of the given window. The device context can be used in subsequent graphics device interface (GDI) functions to draw in the client area.
	The GetDC function retrieves a common, class, or private device context, depend- ing on the class style specified for the given window. For common device con- texts, GetDC assigns default attributes to the context each time it is retrieved. For class and private contexts, GetDC leaves the previously assigned attributes un- changed.
Parameters	<i>hwnd</i> Identifies the window where drawing will occur. If this parameter is NULL, the function returns a device context for the screen.
Return Value	The return value is a handle of the device context for the given window's client area, if the function is successful. Otherwise, it is NULL.
Comments	Unless the device context belongs to a window class, the ReleaseDC function must be called to release the context after drawing. Since only five common device contexts are available at any given time, failure to release a device context can prevent other applications from accessing a device context. If the <i>hwnd</i> pa- rameter of the GetDC function is NULL, the first parameter of ReleaseDC should also be NULL.
	A device context belonging to the window's class is returned by the GetDC func- tion if CS_CLASSDC, CS_OWNDC, or CS_PARENTDC style was specified in the WNDCLASS structure when the class was registered.

BeginPaint, GetWindowDC, ReleaseDC

GetDCEx		3.1
HDC GetDCEx(hw register HWND hw HRGN hrgnClip; DWORD fdwOption	/* clipping region that ma	ay be combined */
		es the handle of a device context for the given win- used in subsequent graphics device interface client area.
		sion to the GetDC function, gives an application ther a device context for a window is clipped.
Parameters	<i>hwnd</i> Identifies the window where <i>hrgnClip</i> Identifies a clipping region th client window.	drawing will occur. hat may be combined with the visible region of the
	fdwOptions	text is created. This parameter can be a combina-
	Value	Meaning
	DCX_CACHE	Returns a device context from the cache, rather than the OWNDC or CLASSDC win- dow. Essentially overrides CS_OWNDC and CS_CLASSDC.
	DCX_CLIPCHILDREN	Excludes the visible regions of all child win- dows below the window identified by the <i>hwnd</i> parameter.
	DCX_CLIPSIBLINGS	Excludes the visible regions of all sibling win- dows above the window identified by the <i>hwnd</i> parameter.
	DCX_EXCLUDERGN	Excludes the clipping region identified by the <i>hrgnClip</i> parameter from the visible region of the returned device context.
	DCX_INTERSECTRGN	Intersects the clipping region identified by the <i>hrgnClip</i> parameter with the visible region of the returned device context.

	Value	Meaning	
	DCX_LOCKWINDOWUPDATE	Allows drawing even if there is a Lock- WindowUpdate call in effect that would otherwise exclude this window. This value is used for drawing during tracking.	
	DCX_PARENTCLIP	Uses the visible region of the parent window, ignoring the parent window's WS_CLIPCHILDREN and WS_PARENTDC style bits. This value sets the device context's origin to the upper-left corner of the window identified by the <i>hwnd</i> parameter.	
	DCX_WINDOW	Returns a device context corresponding to the window rectangle rather than the client rectangle.	
Return Value	The return value is a handle of the de function is successful. Otherwise, it i	evice context for the specified window, if the s NULL.	
Comments	Unless the device context belongs to a window class, the ReleaseDC function must be called to release the context after drawing. Since only five common device contexts are available at any given time, failure to release a device context can prevent other applications from accessing a device context.		
	 A device context belonging to the window's class is returned by the GetDCEx function if the CS_CLASSDC, CS_OWNDC, or CS_PARENTDC class style was specified in the WNDCLASS structure when the class was registered. In order to obtain a cached device context, an application must specify DCX_CACHE. If DCX_CACHE is not specified and the window is neither CS_OWNDC nor CS_CLASSDC, this function returns NULL. 		
See Also	BeginPaint, GetDC, GetWindowD	C, ReleaseDC	

GetDCOrg

2.x

DWORD GetDCOrg(*hdc*) **HDC** *hdc*; /* handle of device context */

> The **GetDCOrg** function retrieves the coordinates of the final translation origin for the device context. This origin specifies the offset used by Windows to translate device coordinates into client coordinates for points in an application's window. The final translation origin is relative to the physical origin of the screen.

3.0

Parameters	<i>hdc</i> Identifies the device context whose origin is to be retrieved.
Return Value	The low-order word of the return value contains the x-coordinate of the final trans- lation origin, in device coordinates, if the function is successful; the high-order word contains the y-coordinate.
Example	The following example uses the CreateIC function to create an information context for the screen and then retrieves the context's origin by using the GetDCOrg function:
	HDC hdcIC; DWORD dwOrigin;
	hdcIC = CreateIC("DISPLAY", NULL, NULL, NULL); dwOrigin = GetDCOrg(hdcIC);
	<pre>DeleteDC(hdcIC);</pre>
See Also	CreateIC

GetDesktopWindow

HWND GetDesktopWindow(void)

	The GetDesktopWindow function retrieves the handle of the desktop window. The desktop window covers the entire screen and is the area on top of which all icons and other windows are painted.
Parameters	This function has no parameters.
Return Value	The return value is a handle of the desktop window.
See Also	GetTopWindow, GetWindow

GetDeviceCaps

int GetDeviceCaps(hdc, iCapability)

HDC hdc;	/* handle of device context	*/
int iCapability;	/* index of capability to query	*/

The **GetDeviceCaps** function retrieves device-specific information about a given display device.

Parameters

Identifies the device context.

iCapability

hdc

Specifies the type of information to be returned. It can be one of the following indices:

Index	Description	
DRIVERVERSION	Version number of the device driver.	
TECHNOLOGY	Device technology. It can be one of the following values:	
	Value	Meaning
	DT_PLOTTER	Vector plotter
	DT_RASDISPLAY	Raster display
	DT_RASPRINTER	Raster printer
	DT_RASCAMERA	Raster camera
	DT_CHARSTREAM	Character stream
	DT_METAFILE	Metafile
	DT_DISPFILE	Display file
HORZSIZE	Width of the physical di	splay, in millimeters.
VERTSIZE	Height of the physical d	isplay, in millimeters.
HORZRES	Width of the display, in	pixels.
VERTRES	Height of the display, in	raster lines.
LOGPIXELSX	Number of pixels per lo	gical inch along the display width.
LOGPIXELSY	Number of pixels per lo	gical inch along the display height.
BITSPIXEL	Number of adjacent col	or bits for each pixel.
PLANES	Number of color planes	- -
NUMBRUSHES	Number of device-speci	fic brushes.
NUMPENS	Number of device-speci	
NUMMARKERS	Number of device-speci	
NUMFONTS	Number of device-speci	
NUMCOLORS	Number of entries in the	

Index	Description	
ASPECTX	Relative width of a device pixel used for line drawing.	
ASPECTY	Relative height of a device pixel used for line drawing.	
ASPECTXY	Diagonal width of a device pixel used for line drawing.	
PDEVICESIZE	Size of the PDEVICE	L internal structure, in bytes.
CLIPCAPS	Clipping capabilities the device supports. It can be one of the following values:	
	Value	Meaning
	CP_NONE	Output is not clipped.
	CP_RECTANGLE	Output is clipped to rectangles.
	CP_REGION	Output is clipped to regions.
SIZEPALETTE	valid only if the devic	he system palette. This index is e driver sets the RC_PALETTE bit index; it is available only if the 'indows 3.0 or later.
NUMRESERVED	This index is valid onl RC_PALETTE bit in t	ntries in the system palette. y if the device driver sets the he RASTERCAPS index; it is avail- is written for Windows 3.0 or later.
COLORRES	Color resolution of the device, in bits per pixel. This index is valid only if the device driver sets the RC_PALETTE bit in the RASTERCAPS index; it is available only if the driver is written for Windows 3.0 or later.	
RASTERCAPS	Raster capabilities the device supports. It can be a combi- nation of the following values:	
	Value	Meaning
	RC_BANDING	Supports banding.
	RC_BIGFONT	Supports fonts larger than 64K.
	RC_BITBLT	Transfers bitmaps.
	RC_BITMAP64	Supports bitmaps larger than 64K.
	RC_DEVBITS	Supports device bitmaps.
	RC_DI_BITMAP	Supports the SetDIBits and GetDIBits functions.
	RC_DIBTODEV	Supports the SetDIBitsTo- Device function.
	RC_FLOODFILL	Performs flood fills.
	RC_GDI20_OUTPUT	Supports Windows version 2.0 features.

Index	Description	
	Value	Meaning
	RC_GDI20_STATE	Includes a state block in the device context.
	RC_NONE	Supports no raster operations.
	RC_OP_DX_OUTPUT	Supports dev opaque and DX array.
	RC_PALETTE	Specifies a palette-based device.
	RC_SAVEBITMAP	Saves bitmaps locally.
	RC_SCALING	Supports scaling.
	RC_STRETCHBLT	Supports the StretchBlt func- tion.
	RC_STRETCHDIB	Supports the StretchDIBits function.

CURVECAPS Curve capabilities the device supports. It can be a combination of the following values:

Value	Meaning
CC_NONE	Supports curves.
CC_CIRCLES	Supports circles.
CC_PIE	Supports pie wedges.
CC_CHORD	Supports chords.
CC_ELLIPSES	Supports ellipses.
CC_WIDE	Supports wide borders.
CC_STYLED	Supports styled borders.
CC_WIDESTYLED	Supports wide, styled borders.
CC_INTERIORS	Supports interiors.
CC_ROUNDRECT	Supports rectangles with rounded corners.

LINECAPS

Line capabilities the device supports. It can be a combination of the following values:

Value	Meaning
LC_NONE	Supports no lines.
LC_POLYLINE	Supports polylines.
LC_MARKER	Supports markers.
LC_POLYMARKER	Supports polymarkers.

Index	Description	
	Value	Meaning
	LC_WIDE	Supports wide lines.
	LC_STYLED	Supports styled lines.
	LC_WIDESTYLED	Supports wide, styled lines.
	LC_INTERIORS	Supports interiors.
POLYGONALCAPS	Polygonal capabilities the device supports. It can be a combination of the following values:	
	Value	Meaning
	PC_NONE	Supports no polygons.
	PC_POLYGON	Supports alternate fill poly- gons.
	PC_RECTANGLE	Supports rectangles.
	PC_WINDPOLYGON	Supports winding number fill polygons.
	PC_SCANLINE	Supports scan lines.
	PC_WIDE	Supports wide borders.
	PC_STYLED	Supports styled borders.
	PC_WIDESTYLED	Supports wide, styled borders.
	PC_INTERIORS	Supports interiors.
TEXTCAPS	Text capabilities the devic tion of the following value	e supports. It can be a combina- es:
	Value	Meaning
	TC_OP_CHARACTER	Supports character output pre- cision, which indicates the device can place device fonts at any pixel location. This is required for any device with device fonts.
	TC_OP_STROKE	Supports stroke output preci- sion, which indicates the device can omit any stroke of a device font.
	TC_CP_STROKE	Supports stroke clip preci- sion, which indicates the device can clip device fonts to a pixel boundary.

Index	Description	
	Value	Meaning
	TC_CR_90	Supports 90-degree character rotation, which indicates the device can rotate characters only 90 degrees at a time.
	TC_CR_ANY	Supports character rotation at any degree, which indicates the device can rotate device fonts through any angle.
	TC_SF_X_YINDEP	Supports scaling independent of x and y directions, which indicates the device can scale device fonts separately in x and y directions.
	TC_SA_DOUBLE	Supports doubled characters for scaling, which indicates the device can double the size of device fonts.
	TC_SA_INTEGER	Supports integer multiples for scaling, which indicates the device can scale the size of device fonts in any integer multiple.
	TC_SA_CONTIN	Supports any multiples for exact scaling, which indicates the device can scale device fonts by any amount but still preserve the x and y ratios.
	TC_EA_DOUBLE	Supports double-weight char- acters, which indicates the device can make device fonts bold. If this bit is not set for printer drivers, graphics device interface (GDI) at- tempts to create bold device fonts by printing them twice.
	TC_IA_ABLE	Supports italics, which indi- cates the device can make device fonts italic. If this bit is not set, GDI assumes italics are not available.

Index	Description	
	Value	Meaning
	TC_UA_ABLE	Supports underlining, which indicates the device can un- derline device fonts. If this bit is not set, GDI creates un- derlines for device fonts.
	TC_SO_ABLE	Supports strikeouts, which in- dicates the device can strikeout device fonts. If this bit is not set, GDI creates strikeouts for device fonts.
	TC_RA_ABLE	Supports raster fonts, which indicates that GDI should enumerate any raster or True- Type fonts available for this device in response to a call to the EnumFonts or Enum- FontFamilies function. If this bit is not set, GDI- supplied raster or TrueType fonts are not enumerated when these functions are called.
	TC_VA_ABLE	Supports vector fonts, which indicates that GDI should enumerate any vector fonts available for this device in response to a call to the EnumFonts or EnumFont- Families function. This is sig- nificant for vector devices only (that is, for plotters). Display drivers (which must be able to use raster fonts) and raster printer drivers al- ways enumerate vector fonts, because GDI rasterizes vector fonts before sending them to the driver.
	TC_RESERVED	Reserved; must be zero.

Return Value	The return value is the value of the requested capability if the function is successful.
Example	The following example uses the GetDeviceCaps function to determine whether a device supports raster capabilities and is palette-based. If so, the example calls the GetSystemPaletteUse function.
	WORD nUse;
	<pre>hdc = GetDC(hwnd); if ((GetDeviceCaps(hdc, RASTERCAPS) & RC_PALETTE) == 0) { ReleaseDC(hwnd, hdc); break; } nUse = GetSystemPaletteUse(hdc); ReleaseDC(hwnd, hdc);</pre>

GetDialogBaseUnits

DWORD GetDialogBaseUnits(void)

	The GetDialogBaseUnits function returns the dialog box base units used by Windows when creating dialog boxes. An application should use these values to calculate the average width of characters in the system font.	
Parameters	This function has no parameters.	
Return Value	The low-order word of the return value contains the width, in pixels, of the current dialog box base-width unit, if the function is successful (this base unit is derived from the system font); the high-order word of the return value contains the height, in pixels.	
Comments	The values returned represent dialog box base units before being scaled to dialog box units. The dialog box unit in the x-direction is one-fourth of the width returned by the GetDialogBaseUnits function. The dialog box unit in the y-direction is one-eighth of the height returned by the function.	
	To use GetDialogBaseUnits to determine the height and width, in pixels, of a con- trol, given the width (x) and height (y) in dialog box units and the return value (lDlgBaseUnits), use the following formulas:	
	(x * LOWORD(1D1gBaseUnits)) / 4 (v * HIWORD(1D1gBaseUnits)) / 8	

3.0

(y * HIWORD(1D1gBaseUnits)) / 8

To avoid rounding problems, perform the multiplication before the division, in case the dialog box base units are not evenly divisible by four.

Example The following example calculates tab stops based on the dialog box base units:

```
HMENU hmenu;
WORD DlgWidthUnits;
WORD TabStopList[4];
case WM_CREATE:
    hmenu = LoadMenu(hinst, "TabStopsMenu");
    SetMenu(hwnd, hmenu);
    DlgWidthUnits = LOWORD(GetDialogBaseUnits()) / 4;
    TabStopList[0] = (DlgWidthUnits * 16 * 2);
    TabStopList[1] = (DlgWidthUnits * 32 * 2);
    TabStopList[2] = (DlgWidthUnits * 58 * 2);
    TabStopList[3] = (DlgWidthUnits * 84 * 2);
    break;
```

GetDIBits

int GetDIBits(hdc, hbmp, nStartScan, cScanLines, lpvBits, lpbmi, fuColorUse) */ HDC hdc; /* handle of device context HBITMAP hbmp; /* handle of bitmap */ /* first scan line to set in destination bitmap */ **UINT** *nStartScan*; **UINT** cScanLines: /* number of scan lines to copy */ */ **void FAR*** *lpvBits*; /* address of array for bitmap bits **BITMAPINFO FAR*** *lpbmi*: /* address of structure with bitmap data */ **UINT** fuColorUse: /* type of color table */ The **GetDIBits** function retrieves the bits of the specified bitmap and copies them, in device-independent format, into the buffer pointed to by the *lpvBits* parameter. The *lpbmi* parameter retrieves the color format for the device-independent bits. **Parameters** hdc Identifies the device context. hbmp Identifies the bitmap. nStartScan Specifies the first scan line to be set in the bitmap received in the *lpvBits* parameter. *cScanLines* Specifies the number of lines to be copied.

lpvBits

Points to a buffer that will receive the bitmap bits in device-independent format.

lpbmi

Points to a **BITMAPINFO** structure that specifies the color format and dimension for the device-independent bitmap. The **BITMAPINFO** structure has the following form:

```
typedef struct tagBITMAPINFO { /* bmi */
BITMAPINFOHEADER bmiHeader;
RGBQUAD bmiColors[1];
} BITMAPINFO;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

fuColorUse

Specifies whether the **bmiColors** members of the **BITMAPINFO** structure are to contain explicit RGB values or indices into the currently realized logical palette. The *fuColorUse* parameter must be one of the following values:

Value	Meaning
DIB_PAL_COLORS	Color table is to consist of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	Color table is to contain literal RGB values.

- **Return Value** The return value specifies the number of scan lines copied from the bitmap if the function is successful. Otherwise, it is zero.
- **Comments** If the *lpvBits* parameter is NULL, the **GetDIBits** function fills in the **BIT-MAPINFO** structure to which the *lpbmi* parameter points but does not retrieve bits from the bitmap.

The bitmap identified by the *hbmp* parameter must not be selected into a device context when the application calls this function.

The origin for device-independent bitmaps (DIBs) is the lower-left corner of the bitmap, not the upper-left corner, which is the origin when the mapping mode is MM_TEXT.

See Also SetDIBits

GetDIgCtrIID

int GetDlgCtrlID(hv HWND hwnd; / ³	<i>wnd</i>) * handle of child window */ The GetDlgCtrIID function returns a handle of a child window.
Parameters	<i>hwnd</i> Identifies the child window.
Return Value	The return value is a handle of the child window if the function is successful. Otherwise, it is NULL.
Comments	This function returns a handle of any child window, not just that of a control in a dialog box.
	Since top-level windows do not have an identifier, the GetDlgCtrIID function's return value is invalid if the <i>hwnd</i> parameter identifies a top-level window.
See Also	GetDlgItem, GetDlgItemInt, GetDlgItemText

GetDIgItem

HWND GetDlgItem	(hwndDlg, idControl)
HWND hwndDlg;	/* handle of dialog box */
int idControl;	/* identifier of control */
	The GetDlgItem function retrieves the handle of a control that is in the given dialog box.
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the control.
	<i>idControl</i> Specifies the identifier of the control to be retrieved.
Return Value	The return value is the handle of the given control if the function is successful. Otherwise, it is NULL, indicating either an invalid dialog box handle or a nonex- istent control.
Comments	The GetDlgItem function can be used with any parent-child window pair, not just dialog boxes. As long as the <i>hwndDlg</i> parameter identifies a parent window and

2.x

the child window has a unique identifier (as specified by the *hmenu* parameter in the **CreateWindow** function that created the child window), **GetDlgItem** returns the handle of the child window.

GetDigitemInt

UINT GetDlgIteml HWND hwndDlg; int idControl; BOOL FAR* lpfTra BOOL fSigned;		g, <i>idControl</i> , <i>lpfTranslated</i> , <i>fSigned</i>) /* handle of dialog box /* identifier of control /* address of variable for error flag /* signed or unsigned indicator	*/ */ */ */
		lgItemInt function translates the text of n integer value.	a control in the given dialog
Parameters	idControl	ies the dialog box. es the identifier of the dialog box control	to be translated.
	<i>lpfTranslated</i> Points to the Boolean variable that is to receive the translated flag.		
	<i>fSigned</i> Specifi	es whether the value to be retrieved is sig	gned.
Return Value	function i ter must b	n value specifies the translated value of the successful. Since zero is a valid return value at to detect errors. If an application is st the return value as an int type.	value, the <i>lpfTranslated</i> parame-
Comments	WM_GE ⁷ extra spac tion stops numeric c checks for	ion retrieves the text of the given control TTEXT message. The function then transfers at the beginning of the text and convert ranslating when it reaches the end of the haracter. If the <i>fSigned</i> parameter is TRU r a minus sign $(-)$ at the beginning of the number. Otherwise, it creates an unsigned	lates the text by stripping any rting decimal digits. The func- e text or encounters a non- JE, the GetDlgItemInt function text and translates the text into
	GetDlgIt	emInt returns zero if the translated numb	per is greater than 32.767 (for

GetDigitemInt returns zero if the translated number is greater than 32,767 (for signed numbers) or 65,535 (for unsigned numbers). When a error occurs, such as

encountering nonnumeric characters and exceeding the given maximum, **Get-DigItemInt** copies zero to the location pointed to by the *lpfTranslated* parameter. If there are no errors, *lpfTranslated* receives a nonzero value. If *lpfTranslated* is NULL, **GetDigItemInt** does not warn about errors.

See Also GetDlgCtrlID, GetDlgItem, GetDlgItemText

GetDIgItemText

int GetDlgItemText(hwndDlg, idControl, lpsz, cbMax) HWND hwndDlg; */ /* handle of dialog box int idControl: /* identifier of control */ /* address of buffer for text */ LPSTR lpsz; int cbMax; */ /* maximum size of string The GetDlgItemText function retrieves the title or text associated with a control in a dialog box. **Parameters** hwndDlg Identifies the dialog box that contains the control. idControl Specifies the identifier of the control whose title is to be retrieved. lpsz. Points to a buffer that is to receive the control's title or text. cbMax Specifies the maximum length, in bytes, of the string to be copied to the buffer pointed to by the *lpsz* parameter. The string is truncated if it is longer. **Return Value** The return value specifies the number of bytes copied to the buffer, not including the terminating null character, if the function is successful. Otherwise, it is zero. Comments The **GetDlgItemText** function sends a WM GETTEXT message to the control. See Also GetDlgCtrlID, GetDlgItem, GetDlgItemInt

2.x

GetDOSEnvironment

LPSTR GetDOSEnvironment(void)

	The GetDOSEnvironment function returns a far pointer to the environment string of the current (running) task.
Parameters	This function has no parameters.
Return Value	The return value is a far pointer to the current environment string.
Comments	Unlike an application, a dynamic-link library (DLL) does not have a copy of the environment string. As a result, the library must call this function to retrieve the environment string.
Example	The following example uses the GetDOSEnvironment function to return a pointer to the environment, and then lists the environment settings:
	LPSTR 1pszEnv;
	lpszEnv = GetDOSEnvironment(); while (*lpszEnv != '\0') {
	. /* process the environment string */
	/* Move to the next environment string */
	<pre>lpszEnv += lstrlen(lpszEnv) + 1; }</pre>

GetDoubleClickTime

2.x

UINT GetDoubleClickTime(void)

The **GetDoubleClickTime** function retrieves the current double-click time for the mouse. A double-click is a series of two clicks of the mouse button, the second occurring within a specified time after the first. The double-click time is the maximum number of milliseconds that may occur between the first and second click of a double-click.

Parameters This function has no parameters.

Return Value The return value specifies the current double-click time, in milliseconds.

See Also GetCapture

GetDriverInfo

3.1

HDRVR hdrvr;	erInfo(hdrvr, lpdis) TRUCT FAR* lpdis;	/* handle of installable dr /* address of structure for	
	The GetDriverInfo	function retrieves informati	on about an installable driver.
Parameters	<i>hdrvr</i> Identifies the ins Driver function.	tallable driver. This handle n	nust be retrieved by the Open-
		ERINFOSTRUCT structure	re that receives the driver informa has the following form:
	UINT 1 HDRVR F HINSTANCE F char s } DRIVERINFOSTF	Module; szAliasName[128]; RUCT;	/* drvinfst */ <i>Microsoft Windows Program-</i>
	mer's Reference,		

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

GetDriverModuleHandle

HINSTANCE GetDriverModuleHandle(hdrvr)

HDRVR *hdrvr*; /* handle of installable driver

The **GetDriverModuleHandle** function retrieves the instance handle of a module that contains an installable driver.

*/

Parameters	<i>hdrvr</i> Identifies the installable driver. This parameter must be retrieved by the Open-Driver function.
Return Value	The return value is an instance handle of the driver module if the function is successful. Otherwise, it is NULL.
See Also	OpenDriver

GetDriveType

3.0

UINT GetDriveType	(DriveNumber)	
int DriveNumber;	/* 0 = A, 1 = B, and so on	*/

The **GetDriveType** function determines whether a disk drive is removable, fixed, or remote.

ParametersDriveNumberSpecifies the drive for which the type is to be determined (0 = drive A,
1 = drive B, 2 = drive C, and so on).

Return Value The return value is DRIVE_REMOVABLE (disk can be removed from the drive), DRIVE_FIXED (disk cannot be removed from the drive), or DRIVE_REMOTE (drive is a remote, or network, drive), if the function is successful. Otherwise, the return value is zero.

Example The following example uses the **GetDriveType** function to determine the drive type for all possible disk drives (letters A through Z):

int iDrive; WORD wReturn; char szMsg[80]; for (iDrive = 0, wReturn = 0; (iDrive < 26) && (wReturn != 1); iDrive++) { wReturn = GetDriveType(iDrive); sprintf(szMsg, "drive %c: ", iDrive + 'A');

```
switch (wReturn) {
        case 0:
            strcat(szMsg, "undetermined");
            break;
        case DRIVE_REMOVABLE:
            strcat(szMsg, "removable");
            break;
        case DRIVE_FIXED:
            strcat(szMsg, "fixed");
            break;
        case DRIVE REMOTE:
            strcat(szMsg, "remote (network)");
            break;
    }
    TextOut(hdc, 10, 15 * iDrive, szMsg, strlen(szMsg));
}
```

GetExpandedName

#include <lzexpand.h>

int GetExpandedNa LPCSTR lpszSource LPSTR lpszBuffer;	ame(lpszSource, lpszBuffer)e;/* specifies name of compressed file/* points to buffer receiving original filename*/
	The GetExpandedName function retrieves the original name of a compressed file if the file was compressed with the COMPRESS.EXE utility and the /r option was specified.
Parameters	<i>lpszSource</i> Points to a string that specifies the name of a compressed file.
	<i>lpszBuffer</i> Points to a buffer that receives the name of the compressed file.
Return Value	The return value is TRUE if the function is successful. Otherwise, it is an error value that is less than zero, and it may be LZERROR_BADINHANDLE, which means that the handle identifying the source file was not valid.

Example The following example uses the **GetExpandedName** function to retrieve the original filename of a compressed file:

```
char szSrc[] = {"readme.cmp"};
char szFileName[128];
OFSTRUCT ofStrSrc:
OFSTRUCT ofStrDest:
HFILE hfSrcFile, hfDstFile, hfCompFile;
int cbRead:
BYTE abBuf[512]:
/* Open the compressed source file. */
hfSrcFile = OpenFile(szSrc, &ofStrSrc, OF_READ);
/*
 * Initialize internal data structures for the decompression
* operation.
*/
hfCompFile = LZInit(hfSrcFile);
/* Retrieve the original name for the compressed file. */
GetExpandedName(szSrc, szFileName);
/* Create the destination file using the original name. */
hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);
/* Copy the compressed source file to the destination file. */
do {
    if ((cbRead = LZRead(hfCompFile, abBuf, sizeof(abBuf))) > 0)
        _lwrite(hfDstFile, abBuf, cbRead);
    else {
        . /* handle error condition */
    }
} while (cbRead == sizeof(abBuf));
/* Close the files. */
LZClose(hfSrcFile):
LZClose(hfDstFile);
```

Comments This function retrieves the original filename from the header of the compressed file. If the source file is not compressed, the filename to which *lpszSource* points is copied to the buffer to which *lpszBuffer* points.

If the /r option was not set when the file was compressed, the string in the buffer to which *lpszBuffer* points is invalid.

GetFileResource

#include <ver.h>

BOOL GetFileReson LPCSTR lpszFileNa LPCSTR lpszResTyp LPCSTR lpszResID; DWORD dwFileOffs DWORD dwResLen; void FAR* lpvData;	/* address of buffer for resource type */ /* address of buffer for resource ID */ set; /* resource offset in file */
	The GetFileResource function copies the specified resource from the specified file into the specified buffer. To obtain the appropriate buffer size, the application can call the GetFileResourceSize function before calling GetFileResource .
Parameters	<i>lpszFileName</i> Points to the buffer that contains the name of the file containing the resource.
	<i>lpszResType</i> Points to a value that is created by using the MAKEINTRESOURCE macro with the numbered resource type. This value is typically VS_FILE_INFO.
	<i>lpszResID</i> Points to a value that is created by using the MAKEINTRESOURCE macro with the numbered resource identifier. This value is typically VS_VERSION_INFO.
	<i>dwFileOffset</i> Specifies the offset of the resource within the file. The GetFileResourceSize function returns this value. If this parameter is NULL, the GetFileResource function searches the file for the resource.
	<i>dwResLen</i> Specifies the buffer size, in bytes, identified by the <i>lpvData</i> parameter. The Get-FileResourceSize function returns the buffer size required to hold the resource. If the buffer is not large enough, the resource data is truncated to the size of the buffer.

3.1

	<i>lpvData</i> Points to the buffer that will receive a copy of the resource. If the buffer is not large enough, the resource data is truncated.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero, indi- cating the function could not find the file, could not find the resource, or produced an MS-DOS error. The GetFileResource function returns no information about the type of error that occurred.
Comments	If the <i>dwFileOffset</i> parameter is zero, the GetFileResource function determines the location of the resource by using the <i>lpszResType</i> and <i>lpszResID</i> parameters.
	If <i>dwFileOffset</i> is not zero, GetFileResource assumes that <i>dwFileOffset</i> is the re- turn value of GetFileResourceSize and, therefore, ignores <i>lpszResType</i> and <i>lpszResID</i> .
See Also	GetFileResourceSize

GetFileResourceSize

#include <ver.h>

DWORD GetFileResourceSize(lpsz	zFileName, lpszResType, lpszResID, lpdwFi	leOffset)
LPCSTR lpszFileName;	/* address of buffer for filename	*/
LPCSTR lpszResType;	/* address of buffer for resource type	*/
LPCSTR lpszResID;	/* address of buffer for resource ID	*/
DWORD FAR *lpdwFileOffset;	/* address of resource offset in file	*/

The **GetFileResourceSize** function searches the specified file for the resource of the specified type and identifier.

Parameters

lpszFileName

Points to the buffer that contains the name of the file in which to search for the resource.

lpszResType

Points to a value that is created by using the **MAKEINTRESOURCE** macro with the numbered resource type. This value is typically VS_FILE_INFO.

lpszResID

Points to a value that is created by using the **MAKEINTRESOURCE** macro with the numbered resource identifier. This value is typically VS_VERSION_INFO.

3.1

	<i>lpdwFileOffset</i> Points to a 16-bit value that the GetFileResourceSize function fills with the off- set to the resource within the file.
Return Value	The return value is the size of the resource, in bytes. The return value is NULL if the function could not find the file, the file does not have any resources attached, or the function produced an MS-DOS error. The GetFileResourceSize function returns no information about the type of error that occurred.
See Also	GetFileResource

GetFileTitle

#include <commdlg.h>

int GetFileTitle(lps. LPCSTR lpszFile; LPSTR lpszTitle; UINT cbBuf;		*/ */ */
	The GetFileTitle function returns the title of the file identition rameter.	fied by the <i>lpszFile</i> pa-
Parameters	<i>lpszFile</i> Points to the name and location of an MS-DOS file.	
	<i>lpszTitle</i> Points to a buffer into which the function is to copy the	name of the file.
	<i>cbBuf</i> Specifies the length, in bytes, of the buffer to which the points.	<i>lpszTitle</i> parameter
Return Value	The return value is zero if the function is successful. The renumber if the filename is invalid. The return value is a posifies the required buffer size, in bytes, if the buffer to which points is too small.	tive integer that speci-
Comments	The function returns an error value if the buffer pointed to ter contains any of the following:	by the <i>lpszFile</i> parame-
	 An empty string 	
	• A string containing a wildcard (*), opening bracket ([), o	or closing bracket (])

- A string that ends with a colon (:), slash mark (/), or backslash (\)
- A string whose length exceeded the length of the buffer
- An invalid character (for example, a space or unprintable character).

The required buffer size includes the terminating null character.

GetFileVersionInfo

#include <ver.h>

BOOL GetFileVersi	onInfo(lpszFileName, handle, cbBuf, lpvData)
LPCSTR lpszFileNa	
DWORD handle;	/* file-version information */
DWORD cbBuf;	/* size of buffer */
<pre>void FAR* lpvData;</pre>	/* address of buffer for file-version info */
	The GetFileVersionInfo function returns version information about the specified
	file. The application must call the GetFileVersionInfoSize function before calling GetFileVersionInfo to obtain the appropriate handle if the handle is not NULL.
Parameters	<i>lpszFileName</i> Points to the buffer that contains the name of the file.
	<i>handle</i> Identifies the file-version information. The GetFileVersionInfoSize function returns this handle, or it may be NULL. If the <i>handle</i> parameter is NULL, the GetFileVersionInfo function searches the file for the version information.
	<i>cbBuf</i> Specifies the buffer size, in bytes, identified by the <i>lpvData</i> parameter. The Get-FileVersionInfoSize function returns the buffer size required to hold the file-version information. If the buffer is not large enough, the file-version information is truncated to the size of the buffer.
	<i>lpvData</i> Points to the buffer that will receive the file-version information. This parameter is used by a subsequent call to the VerQueryValue function.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero, indicating the file does not exist or the <i>handle</i> parameter is invalid. The GetFile - VersionInfo function returns no information about the type of error that occurred.
Comments	The file version information is organized in a VERSIONINFO statement.

Currently, the **GetFileVersionInfo** function recognizes only version-information created by Microsoft Resource Compiler (RC).

See Also GetFileVersionInfoSize, VerQueryValue

GetFileVersionInfoSize

#include <ver.h>

DWORD GetFileVersionInfoSize(lpszFileName, lpdwHandle)LPCSTR lpszFileName;/* address of buffer for filenameDWORD FAR *lpdwHandle;/* address of handle for info		
	The GetFileVersionInfoSize function determines whether it can obtain version in- formation from the specified file. If version information is available, GetFile-VersionInfoSize returns the size of the buffer required to hold the version information. It also returns a handle that can be used in a subsequent call to the GetFileVersionInfo function.	
Parameters	<i>lpszFileName</i> Points to the buffer that contains the name of the file.	
	<i>lpdwHandle</i> Points to a 32-bit value that the GetFileVersionInfoSize function fills with the handle to the file-version information. The GetFileVersionInfo function can use this handle.	
Return Value	The return value is the buffer size, in bytes, required to hold the version informa- tion if the function is successful. The return value is NULL if the function could not find the file, could not find the version information, or produced an MS-DOS error. The GetFileVersionInfoSize function returns no information about the type of error that occurred.	
Comments	The file version information is organized in a VERSIONINFO statement.	
See Also	GetFileVersionInfo	

GetFocus

HWND GetFocus(void)

	The GetFocus function retrieves the handle of the window that currently has the input focus.
Parameters	This function has no parameters.
Return Value	The return value is the handle of the focus window. If no window has the focus, it is NULL.
See Also	GetActiveWindow, GetCapture, SetFocus

GetFontData

DWORD GetFontDat	a (hdc, dwTable, dwOffset, lpvBuffer, c	bData)
HDC hdc;	/* handle of device context	*/
DWORD dwTable:	/* metric table to query	*/

DWORD dwTable;	/* metric table to query	*/
DWORD dwOffset;	/* offset into table being queried	*/
<pre>void FAR* lpvBuffer;</pre>	/* address of buffer for font data	*/
DWORD <i>cbData</i> ;	/* length of data to query	*/

The **GetFontData** function retrieves font-metric information from a scalable font file. The information to retrieve is identified by specifying an offset into the font file and the length of the information to return.

Parameters

hdc

Identifies the device context.

dwTable

Specifies the name of the metric table to be returned. This parameter can be one of the metric tables documented in the TrueType Font Files specification, published by Microsoft Corporation. If this parameter is zero, the information is retrieved starting at the beginning of the font file.

dwOffset

Specifies the offset from the beginning of the table at which to begin retrieving information. If this parameter is zero, the information is retrieved starting at the beginning of the table specified by the dwTable parameter. If this value is greater than or equal to the size of the table, **GetFontData** returns zero.

	<i>lpvBuffer</i> Points to a buffer that will receive the font information. If this value is NULL, the function returns the size of the buffer required for the font data specified in the <i>dwTable</i> parameter.
	<i>cbData</i> Specifies the length, in bytes, of the information to be retrieved. If this parameter is zero, GetFontData returns the size of the data specified in the <i>dwTable</i> parameter.
Return Value	The return value specifies the number of bytes returned in the buffer pointed to by the <i>lpvBuffer</i> parameter, if the function is successful. Otherwise, it is -1 .
Comments	An application can sometimes use the GetFontData function to save a TrueType font with a document. To do this, the application determines whether the font can be embedded and then retrieves the entire font file, specifying zero for the <i>dwTable</i> , <i>dwOffset</i> , and <i>cbData</i> parameters.
	Applications can determine whether a font can be embedded by checking the otmfsType member of the OUTLINETEXTMETRIC structure. If bit 1 of otmfsType is set, embedding is not permitted for the font. If bit 1 is clear, the font can be embedded. If bit 2 is set, the embedding is read-only.
	If an application attempts to use this function to retrieve information for a non-TrueType font, the GetFontData function returns -1 .
Example	The following example retrieves an entire TrueType font file:
	HGLOBAL hglb; DWORD dwSize; void FAR* lpvBuffer;
	dwSize = GetFontData(hdc, NULL, 0L, NULL, 0L);
	hglb = GlobalAlloc(GPTR, dwSize); /* allocate memory */ lpvBuffer = GlobalLock(hglb); GetFontData(hdc, NULL, 0L, lpvBuffer, dwSize); /* retrieve data */
	The following retrieves an entire TrueType font file 4K at a time:
	#define SIZE 4096 BYTE Buffer[SIZE]; DWORD dwOffset; DWORD dwSize;

```
dwOffset = 0L;
while(dwSize = GetFontData(hdc, NULL, dwOffset, Buffer, SIZE)) {
    .
    . /* process data in buffer */
    .
    dwOffset += dwSize;
}
```

The following example retrieves a TrueType font table:

```
HGLOBAL hglb;
DWORD dwSize;
void FAR* lpvBuffer;
LPSTR lpszTable;
DWORD dwTable;
lpszTable = "cmap";
dwTable = *(LPDWORD) lpszTable; /* construct DWORD type */
dwSize = GetFontData(hdc, dwTable, 0L, NULL, 0L); /* get table size */
hglb = GlobalAlloc(GPTR, dwSize); /* allocate memory */
lpvBuffer = GlobalLock(hglb);
GetFontData(hdc, dwTable, 0L, lpvBuffer, dwSize); /* retrieve data */
```

See Also GetOutlineTextMetrics

GetFreeFileHandles

#include <stress.h>

int GetFreeFileHandles(void)

The **GetFreeFileHandles** function returns the number of file handles available to the current instance.

3.1

Parameters This function has no parameters.

Return Value The return value is the number of file handles available to the current instance.

GetFreeSpace

DWORD GetFree	
UINT fuFlags;	/* ignored in Windows 3.1 */
	The GetFreeSpace function scans the global heap and returns the number of bytes of memory currently available.
Parameters	<i>fuFlags</i> This parameter is ignored in Windows 3.1.
Return Value	The return value is the amount of available memory, in bytes, if the function is successful.
Comments	The amount of memory specified by the return value is not necessarily contiguous; the GlobalCompact function returns the number of bytes in the largest block of free global memory.
	In standard mode, the value returned represents the number of bytes in the global heap that are not used and that are not reserved for code.
	In 386-enhanced mode, the return value is an estimate of the amount of memory available to an application. It does not account for memory held in reserve for non-Windows applications.
See Also	GlobalCompact

,

GetFreeSystemResources

	mResources (<i>fuSysResource</i>) ; /* type of resource to check */
	The GetFreeSystemResources function returns the percentage of free space for system resources.
Parameters	<i>fuSysResource</i> Specifies the type of resource to be checked. This parameter can be one of the following values:

3.0

	Value	Meaning
	GFSR_SYSTEMRESOURCES	Returns the percentage of free space for system resources.
	GFSR_GDIRESOURCES	Returns the percentage of free space for GDI re- sources. GDI resources include device-context handles, brushes, pens, regions, fonts, and bit- maps.
	GFSR_USERRESOURCES	Returns the percentage of free space for USER resources. These resources include window and menu handles.
Return Value	The return value specifies the perc tion is successful.	entage of free space for resources, if the func-
Comments	Since the return value from this function does not guarantee that an application will be able to create a new object, applications should not use this function to determine whether it will be possible to create an object.	
See Also	GetFreeSpace	

GetGlyphOutline

3.1

DWORD GetGlyphOutline(<i>hdc</i> ,	uChar, fuFormat, lpgm, cbBuffer, lpBuffer, lpmat2)	
HDC hdc;	/* handle of device context	*/
UINT uChar;	/* character to query	*/
UINT fuFormat;	/* format of data to return	*/
LPGLYPHMETRICS lpgm;	/* address of structure with glyph metrics	*/
DWORD <i>cbBuffer</i> ;	/* size of buffer for data	*/
void FAR* lpBuffer;	/* address of buffer for outline data	*/
LPMAT2 lpmat2;	/* address of structure with transform matrix	*/

The **GetGlyphOutline** function retrieves the outline curve or bitmap for an outline character in the current font.

Parameters

hdc

Identifies the device context.

uChar

Specifies the character for which information is to be returned.

fuFormat

Specifies the format in which the function is to return information. It can be one of the following values:

Value	Meaning
GGO_BITMAP	Returns the glyph bitmap. When the function returns, the buffer pointed to by the <i>lpBuffer</i> parameter contains a 1-bit-per-pixel bitmap whose rows start on doubleword boundaries.
GGO_NATIVE	Returns the curve data points in the rasterizer's native format, using device units. When this value is specified, any transformation specified in the <i>lpmat2</i> parameter is ignored.

When the value of this parameter is zero, the function fills in a **GLYPHMETRICS** structure but does not return glyph-outline data.

lpgm

Points to a **GLYPHMETRICS** structure that describes the placement of the glyph in the character cell. The **GLYPHMETRICS** structure has the following form:

```
typedef struct tagGLYPHMETRICS { /* gm */
UINT gmBlackBoxX;
UINT gmBlackBoxY;
POINT gmptGlyphOrigin;
int gmCellIncX;
int gmCellIncY;
} GLYPHMETRICS;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

cbBuffer

Specifies the size of the buffer into which the function copies information about the outline character. If this value is zero and the *fuFormat* parameter is either the GGO_BITMAP or GGO_NATIVE values, the function returns the required size of the buffer.

lpBuffer

Points to a buffer into which the function copies information about the outline character. If the *fuFormat* parameter specifies the GGO_NATIVE value, the information is copied in the form of **TTPOLYGONHEADER** and **TTPOLY-CURVE** structures. If this value is NULL and the *fuFormat* parameter is either the GGO_BITMAP or GGO_NATIVE value, the function returns the required size of the buffer.

lpmat2

Points to a **MAT2** structure that contains a transformation matrix for the character. This parameter cannot be NULL, even when the GGO_NATIVE value is specified for the *fuFormat* parameter. The **MAT2** structure has the following form:

```
typedef struct tagMAT2 { /* mat2 */
    FIXED eM11;
    FIXED eM12;
    FIXED eM21;
    FIXED eM22;
} MAT2;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Return Value The return value is the size, in bytes, of the buffer required for the retrieved information if the *cbBuffer* parameter is zero or the *lpBuffer* parameter is NULL. Otherwise, it is a positive value if the function is successful, or -1 if there is an error.

Comments An application can rotate characters retrieved in bitmap format by specifying a 2-by-2 transformation matrix in the structure pointed to by the *lpmat2* parameter.

A glyph outline is returned as a series of contours. Each contour is defined by a **TTPOLYGONHEADER** structure followed by as many **TTPOLYCURVE** structures as are required to describe it. All points are returned as **POINTFX** structures and represent absolute positions, not relative moves. The starting point given by the **pfxStart** member of the **TTPOLYGONHEADER** structure is the point at which the outline for a contour begins. The **TTPOLYCURVE** structures that follow can be either polyline records or spline records. Polyline records are a series of points; lines drawn between the points describe the outline of the character. Spline records represent the quadratic curves used by TrueType (that is, quadratic b-splines).

For example, the **GetGlyphOutline** function retrieves the following information about the lowercase "i" in the Arial TrueType font:

dwrc = 88	/* total size of native buffer	*/
TTPOLYGONHEADER #1 cb = 44 dwType = 24 pfxStart = 1.000, 11.000	/* contour for dot on i /* size for contour /* TT_POLYGON_TYPE	*/ */ */
TTPOLYCURVE #1 wType = TT_PRIM_LINE cpfx = 3 pfx[0] = 1.000, 12.000 pfx[1] = 2.000, 12.000 pfx[2] = 2.000, 11.000	/* automatically close to pfxStart	*/
TTPOLYGONHEADER #2 cb = 44	/* contour for body of i	*/
dwType = 24 pfxStart = 1.000, 0.000	/* TT_POLYGON_TYPE	*/

TTPOLYCURVE #1 wType = TT_PRIM_LINE cpfx = 3 pfx[0] = 1.000, 9.000 pfx[1] = 2.000, 9.000 pfx[2] = 2.000, 0.000 /* automatically close to pfxStart */

GetOutlineTextMetrics

GetInputState

2.x

2.x

BOOL GetInputState(void)

	The GetInputState function determines whether there are mouse clicks or key- board events in the system queue that require processing. Keyboard events occur when a user presses one or more keys. The system queue is the location in which Windows stores mouse clicks and keyboard events.
Parameters	This function has no parameters.
Return Value	The return value is nonzero if the function detects a mouse click or keyboard event in the system queue. Otherwise, it is zero.
See Also	EnableHardwareInput

GetInstanceData

int GetInstanceData(hinst, npbData, cbData)HINSTANCE hinst;/* handle of previous instance*/BYTE* npbData;/* address of current instance data buffer*/int cbData;/* number of bytes to transfer*/

The **GetInstanceData** function copies data from a previous instance of an application into the data area of the current instance.

Parameters

hinst

Identifies a previous instance of the application.

	<i>npbData</i> Points to a buffer in the current instance.
	<i>cbData</i> Specifies the number of bytes to be copied.
Return Value	The return value specifies the number of bytes copied if the function is successful. Otherwise, it is zero.

GetKBCodePage

int GetKBCodePage(void)

The GetKBCodePage function returns the current Windows code page.

3.0

- **Parameters** This function has no parameters.
- **Return Value** The return value specifies the code page currently loaded by Windows, if the function is successful. It can be one of the following values:

Value	Meaning
437	Default (United States, used by most countries: indicates that there is no OEMANSI.BIN in the Windows directory)
850	International (OEMANSI.BIN = XLAT850.BIN)
860	Portugal (OEMANSI.BIN = XLAT860.BIN)
861	Iceland (OEMANSI.BIN = XLAT861.BIN)
863	French Canadian (OEMANSI.BIN = XLAT863.BIN)
865	Norway/Denmark (OEMANSI.BIN = XLAT865.BIN)

Comments The keyboard driver provides the **GetKBCodePage** function. An application using this function must include the following information in its module-definition (.DEF) file:

IMPORTS

KEYBOARD.GETKBCODEPAGE

If the OEMANSI.BIN file is in the Windows directory, Windows reads it and overwrites the OEM/ANSI translation tables in the keyboard driver.

When the user selects a language from the Setup program and the language does not use the default code page (437), Setup copies the appropriate file (such as XLAT850.BIN) to OEMANSI.BIN in the Windows system directory. If the lan-

3.1

guage uses the default code page, Setup deletes OEMANSI.BIN, if it exists, from the Windows system directory.

The following example uses the **GetKBCodePage** function to display the current code page:

```
char szBuf[80];
int i, cp, subtype, f_keys, len;
char *apszKeyboards[] = {
    "IBM PX/XT",
    "Olivetti ICO",
    "IBM AT",
    "IBM Enhanced",
    "Nokia 1050",
    "Nokia 9140".
    "Standard Japanese",
    };
cp = GetKBCodePage();
if ((i = GetKeyboardType(0)) == 0 || i > 7) 
    MessageBox(NULL, "invalid keyboard type",
        "GetKeyboardType", MB_ICONSTOP);
    break:
}
subtype = GetKeyboardType(1);
f_keys = GetKeyboardType(2);
len = wsprintf(szBuf, "%s keyboard, subtype %d\n",
    apszKeyboards[i - 1], subtype);
len = wsprintf(szBuf + len, " %d function keys, code page %d",
    f_keys, cp);
MessageBox(NULL, szBuf, "Keyboard Information", MB_OK);
```

See Also GetKeyboardType

р ,

1 1

GetKerningPairs

10 117

Example

pair)	
/* handle of device context	*/
/* number of kerning pairs	*/
/* pointer to structures for kerning pairs	*/
	/* handle of device context /* number of kerning pairs

• `

The **GetKerningPairs** function retrieves the character kerning pairs for the font that is currently selected in the specified device context.

Parameters	<i>hdc</i> Identifies a device context. The GetKerningPairs function retrieves kerning pairs for the current font for this device context.
	<i>cPairs</i> Specifies the number of KERNINGPAIR structures pointed to by the <i>lpkrnpair</i> parameter. The function will not copy more kerning pairs than specified by <i>cPairs</i> .
	The KERNINGPAIR structure has the following form:
	<pre>typedef struct tagKERNINGPAIR { WORD wFirst; WORD wSecond; int iKernAmount; } KERNINGPAIR;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lpkrnpair</i> Points to an array of KERNINGPAIR structures that receive the kerning pairs when the function returns. This array must contain at least as many structures as specified by the <i>cPairs</i> parameter. If this parameter is NULL, the function re- turns the total number of kerning pairs for the font.
Return Value	The return value specifies the number of kerning pairs retrieved or the total num- ber of kerning pairs in the font, if the function is successful. It is zero if the func- tion fails or there are no kerning pairs for the font.

GetKeyboardState

2.x

void GetKeyboardState(lpbKeyState)BYTE FAR* lpbKeyState;/* address of array to receive virtual-key codes*/		
	The GetKeyboardState function copies the status of the 256 virtual-keyboard keys to the specified buffer.	
Parameters	<i>lpbKeyState</i> Points to the 256-byte buffer that will receive the virtual-key codes.	
Return Value	This function does not return a value.	

3.0

Comments	An application calls the GetKeyboardState function in response to a keyboard- input message. This function retrieves the state of the keyboard at the time the input message was generated.		
	If the high-order bit is 1, the key is down; otherwise, it is up. If the low-order bit is 1, the key is toggled. A toggle key, such as the CAPSLOCK key, is toggled if it has been pressed an odd number of times since the system was started. The key is untoggled if the low-order bit is 0.		
	For a list of virtual-key codes and their corresponding mouse or keyboard equivalents, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.		
Example	The following example simulates a pressed CTRL key:		
	BYTE pbKeyState[256];		
	GetKeyboardState((LPBYTE) &pbKeyState); pbKeyState[VK_CONTROL] = 0x80; SetKeyboardState((LPBYTE) &pbKeyState);		
See Also	GetKeyState, SetKeyboardState		

GetKeyboardType

<pre>int GetKeyboardTy int fnKeybInfo;</pre>		<i>b</i>) <i>p</i> e of information to retrieve */
	The GetKey	boardType function retrieves information about the current keyboard.
Parameters	<i>fnKeybInfo</i> Determines the type of keyboard information to be retrieved. This parameter can be one of the following values:	
	Value	Meaning
	0	Retrieves the keyboard type.
	1	Retrieves the keyboard subtype.
	2	Retrieves the number of function keys on the keyboard.
Return Value	The return value specifies the requested information if the function is successful. Otherwise, it is zero.	
Comments	The subtype ing values:	is an OEM-dependent value. The subtype may be one of the follow-

Value	Meaning	
1	IBM PC/XT, or compatible (83-key) keyboard	
2	Olivetti "ICO" (102-key) keyboard	
3	IBM AT (84-key) or similar keyboard	
4	IBM Enhanced (101- or 102-key) keyboard	
5	Nokia 1050 and similar keyboards	
6	Nokia 9140 and similar keyboards	
7	Japanese keyboard	

The keyboard driver provides the **GetKeyboardType** function. An application using this function must include the following information in its module-definition (.DEF) file:

IMPORTS KEYBOARD.GETKEYBOARDTYPE

The application can also determine the number of function keys on a keyboard from the keyboard type. The number of function keys for each keyboard type follows:

Туре	Number of function keys
1	10
2	12 (sometimes 18)
3	10
4	12
5	10
6	24
7	This value is hardware-dependent and must be specified by the OEM.

Example

The following example uses the **GetKeyboardType** function to display information about the current keyboard:

```
char szBuf[80];
int i, cp, subtype, f_keys, len;
char *apszKeyboards[] = {
    "IBM PX/XT",
    "Olivetti ICO",
    "IBM AT",
    "IBM Enhanced",
    "Nokia 1050",
    "Nokia 9140",
    "Standard Japanese",
    };
```

```
cp = GetKBCodePage();
if ((i = GetKeyboardType(0)) == 0 || i > 7) {
    MessageBox(NULL, "invalid keyboard type",
        "GetKeyboardType", MB_ICONSTOP);
    break;
}
subtype = GetKeyboardType(1);
f_keys = GetKeyboardType(2);
len = wsprintf(szBuf, "%s keyboard, subtype %d\n",
    apszKeyboards[i - 1], subtype);
len = wsprintf(szBuf + len, " %d function keys, code page %d",
    f_keys, cp);
MessageBox(NULL, szBuf, "Keyboard Information", MB_OK);
```

GetKeyNameText

int GetKeyNameText(lParam, lpszBuffer, cbMaxKey) */ LONG *lParam*: /* 32-bit parameter of keyboard message */ **LPSTR** *lpszBuffer*; /* address of a buffer for key name /* specifies maximum key string length */ int cbMaxKey; The **GetKeyNameText** function retrieves a string that represents the name of a key. Parameters lParam Specifies the 32-bit parameter of the keyboard message (such as WM_KEYDOWN) to be processed. The GetKeyNameText function interprets the following portions of *lParam*: Bits Meaning 16 - 23Character scan code. 24 Extended bit. Distinguishes some keys on an enhanced keyboard.

25 "Don't care" bit. The application calling this function sets this bit to indicate that the function should not distinguish between left and right CTRL and SHIFT keys, for example.

lpszBuffer

Points to a buffer that will receive the key name.

	<i>cbMaxKey</i> Specifies the maximum length, in bytes, of the key name, not including the ter- minating null character (this parameter should one less than the size of the buff- er pointed to by the <i>lpszBuffer</i> parameter).
Return Value	The return value is the length, in bytes, of the string copied to the specified buffer, if the function is successful. Otherwise, it is zero.
Comments	The format of the key-name string depends on the current keyboard driver. This driver maintains a list of names in the form of character strings for keys with names longer than a single character. The key name is translated, according to the layout of the currently installed keyboard, into the principal language supported by the keyboard driver.

GetKeyState

,	
int GetKeyState int vkey; /* v	(<i>vkey</i>) irtual key */
	The GetKeyState function retrieves the state of the specified virtual key. The state specifies whether the key is up, down, or toggled (on, off—alternating each time the key is pressed).
Parameters	<i>vkey</i> Specifies a virtual key. If the requested virtual key is a letter or digit (A through Z, a through z, or 0 through 9), <i>vkey</i> must be set to the ASCII value of that character. For other keys, it must be a virtual-key code. For a list of virtual-key codes, see the <i>Microsoft Windows Programmer's Reference, Volume 3</i> .
Return Value	The return value specifies the state of the given virtual key. If the high-order bit is 1, the key is down; otherwise, it is up. If the low-order bit is 1, the key is toggled. A toggle key, such as the CAPSLOCK key, is toggled if it has been pressed an odd number of times since the system was started. The key is untoggled if the low-order bit is 0.
Comments	An application calls the GetKeyState function in response to a keyboard-input message. This function retrieves the state of the key at the time the input message was generated.
See Also	GetAsyncKeyState, GetKeyboardState

3.0

GetLastActivePopup

HWND GetLastActivePopup(hwndOwner)HWND hwndOwner;/* handle of owner window*/		
	The GetLastActivePopup function determines which pop-up window owned by the given window was most recently active.	
Parameters	<i>hwndOwner</i> Identifies the owner window.	
Return Value	The return value is the handle of most-recently active pop-up window if the func- tion is successful.	
Comments	The return value handle will be the same as the handle in the <i>hwndOwner</i> parameter if any of the following conditions are met:	
	• The window identified by <i>hwndOwner</i> was most recently active.	
	• The window identified by <i>hwndOwner</i> does not own any pop-up windows.	
	 The window identified by <i>hwndOwner</i> is not a top-level window or is owned by another window. 	
See Also	AnyPopup, GetActiveWindow, ShowOwnedPopups	

GetMapMode

2.x

int GetMapMode(hdc)HDC hdc;/* handle of device context*/

The GetMapMode function retrieves the current mapping mode.

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the mapping mode if the function is successful.
Comments	For a complete list of mapping modes, see the description of the SetMapMode function.
Example	The following example uses the GetMapMode function to determine whether the current mapping mode is MM_TEXT:

```
if (GetMapMode(hdc) != MM_TEXT) {
    TextOut(hdc, 100, -200, "Mapping mode must be MM_TEXT", 28);
    return FALSE;
}
```

2.x

3.0

See Also SetMapMode

GetMenu

HMENU GetMent HWND hwnd;	u(<i>hwnd</i>) /* handle of window */	
	The GetMenu function retrieves the handle of the menu associated with the given window.	
Parameters	hwnd Identifies the window whose menu handle is retrieved.	
Return Value	The return value is the handle of the menu if the function is successful. It is NULL if the given window has no menu. It is undefined if the window is a child window.	
See Also	GetSubMenu, SetMenu	

GetMenuCheckMarkDimensions

DWORD GetMenuCheckMarkDimensions(void)

The **GetMenuCheckMarkDimensions** function returns the dimensions of the default check mark bitmap. Windows displays this bitmap next to checked menu items. Before calling the **SetMenuItemBitmaps** function to replace the default check mark, an application should determine the correct size for the bitmaps by calling the **GetMenuCheckMarkDimensions** function.

Parameters

This function has no parameters.

2.x

Return Value The low-order word of the return value contains the width, in pixels, of the default check mark bitmap, if the function is successful; the high-order word contains the height.

See Also SetMenuItemBitmaps

GetMenultemCount

int GetMenuItemC HMENU hmenu;	Count(hmenu) /* handle of menu */
	The GetMenuItemCount function determines the number of items in a pop-up or top-level menu.
Parameters	<i>hmenu</i> Identifies the handle of the menu to be examined.
Return Value	The return value specifies the number of items in the menu if the function is successful. Otherwise, it is -1 .
Example	The following example initializes the items in a pop-up menu:
	WORD wCount; WORD wItem; WORD wID;
	<pre>case WM_INITMENUPOPUP: wCount = GetMenuItemCount((HMENU) wParam); for (wItem = 0; wItem < wCount; wItem++) { wID = GetMenuItemID((HMENU) wParam, wItem); . /* Initialize menu items. */</pre>
	} break;
See Also	GetMenu, GetMenuItemID, GetSubMenu

GetMenultemID

UINT GetMenuIter HMENU hmenu; int pos;	mID(<i>hmenu</i> , <i>pos</i>) /* handle of menu */ /* position of menu item */	
	The GetMenuItemID function retrieves the identifier for a menu item located at the given position.	
Parameters	<i>hmenu</i> Identifies the pop-up menu that contains the item whose identifier is to be re- trieved.	
	<i>pos</i> Specifies the zero-based position of the menu item whose identifier is to be re- trieved.	
Return Value	The return value specifies the identifier of the pop-up menu item if the function is successful. If the <i>hmenu</i> parameter is NULL or if the specified item is a pop-up menu (as opposed to an item within the pop-up menu), the return value is -1 . If the <i>pos</i> parameter corresponds to a SEPARATOR menu item, the return value is zero.	
Example	The following example initializes the items in a pop-up menu:	
	WORD wCount; WORD wItem; WORD wID;	
	case WM_INITMENUPOPUP: wCount = GetMenuItemCount((HMENU) wParam); for (wItem = 0; wItem < wCount; wItem++) { wID = GetMenuItemID((HMENU) wParam, wItem);	
	. /* Initialize menu items. */	
	} break;	
See Also	GetMenu, GetMenuItemCount, GetSubMenu	

GetMenuState

UINT GetMenuSta HMENU hmenu; UINT idItem; UINT fuFlags;	ate(hmenu, idItem, fuFlags) /* handle of menu /* menu-item identifier /* menu flags) */ */ */
		tion retrieves the status flags associated with the ne menu item is a pop-up menu, this function also returns e pop-up menu.
Parameters	<i>hmenu</i> Identifies the menu.	
	<i>idItem</i> Specifies the menu ite <i>fuFlags</i> parameter.	m for which the state is retrieved, as determined by the
	<i>fuFlags</i> Specifies the nature of values:	f the <i>idItem</i> parameter. It can be one of the following
	Value	Meaning
	MF_BYCOMMAND	Specifies the menu-item identifier.
	MF_BYPOSITION	Specifies the zero-based position of the menu item.
Return Value	identifies a pop-up menu ber of items in the pop-up associated with the pop-u	the specified item does not exist. If the <i>idItem</i> parameter , the high-order byte of the return value contains the num- p menu, and the low order byte contains the menu flags ip menu. Otherwise, the return value is a mask (Boolean ne following list (this mask describes the status of the entifies):

Value	Meaning
MF_BITMAP	Item is a bitmap.
MF_CHECKED	Check mark is placed next to item (pop-up menus only).
MF_DISABLED	Item is disabled.
MF_ENABLED	Item is enabled. Note that the value of this constant is zero; an application should not test against zero for failure when using this value.
MF_GRAYED	Item is disabled and grayed.
MF_MENUBARBREAK	Same as MF_MENUBREAK, except for pop-up menus where the new column is separated from the old column by a vertical dividing line.

	Value	Meaning	
	MF_MENUBREAK	Item is placed on a new line (static menus) or in a new column (pop-up menus) without separating columns.	
	MF_SEPARATOR	Horizontal dividing line is drawn (pop-up menus only). This line cannot be enabled, checked, grayed, or highlighted. The <i>idItem</i> and <i>fuFlags</i> parameters are ig- nored.	
	MF_UNCHECKED	Check mark is not placed next to item (default). Note that the value of this constant is zero; an application should not test against zero for failure when using this value.	
Example	The following example retrieves the handle of a pop-up menu, retrieves the checked state of a menu item in the menu, and then toggles the checked stat the item:		
	HMENU hmenu; BOOL fOwnerDraw;		
	/* Retrieve a handle to	the Colors menu. */	
	hmenu = GetSubMenu(GetMenu(hwnd), ID_COLORS_POS);		
	/* Retrieve the current state of the item. */		
	fOwnerDraw = GetMenuState(hmenu, IDM_COLOROWNERDR, MF_BYCOMMAND) & MF_CHECKED;		
	/* Toggle the state of	the item. */	
	CheckMenuItem(hmenu, ID MF_BYCOMMAND (fOw	M_COLOROWNERDR, nerDraw ? MF_UNCHECKED : MF_CHECKED));	
See Also	GetMenu, GetMenuItem	Count, GetSubMenu	

GetMenuString

int GetMenuString HMENU hmenu; UINT idItem; LPSTR lpsz;	(hmenu, idItem, lpsz, cbMa /* handle of menu /* menu-item identifier /* address of buffer for la	*/
int cbMax;	/* maximum length of la	
UINT fwFlags;	/* menu flags	*/
	e	ction copies the label of a menu item into a buffer.
Parameters	<i>hmenu</i> Identifies the menu.	
	<i>idItem</i> Specifies the menu iter <i>fwFlags</i> parameter.	n whose label is to be copied, as determined by the
	<i>lpsz</i> Points to a buffer that	will receive the null-terminated label string.
	<i>cbMax</i> Specifies the maximum length, in bytes, of the label string. The label string is truncated if it is longer.	
	<i>fwFlags</i> Specifies the nature of the <i>idItem</i> parameter. It can be one of the following values:	
	Value	Meaning
	MF_BYCOMMAND	Specifies the menu-item identifier.
	MF_BYPOSITION	Specifies the zero-based position of the menu item.
Return Value	The return value is the length, in bytes, of the returned label, if the function is successful. The length does not include the terminating null character.	
Comments	The <i>cbMax</i> parameter should be one larger than the number of characters in the label to accommodate the null character that terminates the string.	
See Also	GetMenu, GetMenuIter	nID

GetMessage

BOOL GetMessage(lpmsg, hwnd, uMsgFilterMin, uMsgFilterMax)MSG FAR* lpmsg;/* address of structure with messageHWND hwnd;/* handle of the windowUINT uMsgFilterMin;/* first messageVINT uMsgFilterMax;/* last message

The **GetMessage** function retrieves a message from the application's message queue and places the message in a **MSG** structure. If no message is available, **Get-Message** yields control to other applications until a message becomes available.

GetMessage retrieves messages associated only with the given window and within the given range of message values. The function does not retrieve messages for windows that belong to other applications.

Parameters

lpmsg

Points to an **MSG** structure that contains message information from the application's message queue. The **MSG** structure has the following form:

```
typedef struct tagMSG { /* msg */
HWND hwnd;
UINT message;
WPARAM wParam;
LPARAM 1Param;
DWORD time;
POINT pt;
} MSG:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

hwnd

Identifies the window whose messages are to be retrieved. If this parameter is NULL, **GetMessage** retrieves messages for any window that belongs to the application making the call.

uMsgFilterMin

Specifies the integer value of the lowest message value to be retrieved.

uMsgFilterMax

Specifies the integer value of the highest message value to be retrieved.

Return Value The return value is nonzero if a message other than WM_QUIT is retrieved. It is zero if the WM_QUIT message is retrieved.

Comments	The return value is usually used to decide whether to terminate the application's main loop and exit the program.		
	The WM_KEYFIRST and WM_KEYLAST constants can be used as filter values to retrieve all messages related to keyboard input; the WM_MOUSEFIRST and WM_MOUSELAST constants can be used to retrieve all mouse-related messages. If the <i>uMsgFilterMin</i> and <i>uMsgFilterMax</i> parameters are both zero, the Get-Message function returns all available messages (without performing any filtering).		
	In addition to yielding control to other applications when no messages are available, the GetMessage and PeekMessage functions also yield control when WM_PAINT or WM_TIMER messages for other tasks are available.		
	The GetMessage , PeekMessage , and WaitMessage functions are the only ways to let other applications run. If your application does not call any of these functions for long periods of time, other applications cannot run.		
Example	The following example uses the GetMessage function to retrieve messages from a message queue, translates virtual-key messages into character messages, and dispatches messages to the appropriate window procedures:		
	MSG msg;		
	<pre>while (GetMessage(&msg, (HWND) NULL, 0, 0)) { TranslateMessage(&msg); DispatchMessage(&msg); }</pre>		
See Also	GetMessageExtraInfo, PeekMessage, PostQuitMessage, SetMessageQueue, WaitMessage		

GetMessageExtraInfo

3.1

LONG GetMessageExtraInfo(void)

The **GetMessageExtraInfo** function retrieves the extra information associated with the last message retrieved by the **GetMessage** or **PeekMessage** function. This extra information may be added to a message by the driver for a pointing device or keyboard.

Parameters This function has no parameters.

Return Value The return value specifies the extra information if the function is successful. The meaning of the extra information is device-specific.

See Also GetMessage, hardware_event, PeekMessage

GetMessagePos

2.x

DWORD GetMessagePos(void)

	The GetMessagePos function returns a long value that represents a cursor posi- tion, in screen coordinates. This position is the point occupied by the cursor when the last message retrieved by the GetMessage function occurred.
Parameters	This function has no parameters.
Return Value	The return value specifies the x- and y-coordinates of the cursor position if the function is successful.
Comments	To retrieve the current position of the cursor instead of the position at the time the last message occurred, use the GetCursorPos function.
	The x-coordinate is in the low-order word of the return value; the y-coordinate is in the high-order word. If the return value is assigned to a variable, you can use the MAKEPOINT macro to obtain a POINT structure from the return value. You can also use the LOWORD or HIWORD macro to extract the x- or the y-coordinate.
See Also	GetCursorPos, GetMessage, GetMessageTime

GetMessageTime

2.x

LONG GetMessageTime(void)

The **GetMessageTime** function returns the message time for the last message retrieved by the **GetMessage** function. The time is a long integer that specifies the elapsed time, in milliseconds, from the time the system was started to the time the message was created (placed in the application queue).

Parameters

This function has no parameters.

Return Value The return value specifies the message time if the function is successful.

Comments The return value of the GetMessageTime function does not necessarily increase between subsequent messages, because the value wraps to zero if the timer count exceeds the maximum value for long integers.

> To calculate time delays between messages, verify that the time of the second message is greater than the time of the first message and then subtract the time of the first message from the time of the second message.

See Also GetMessage, GetMessagePos

GetMetaFile

HMETAFILE GetN LPCSTR lpszFile;	
	The GetMetaFile function creates a handle of a specified metafile.
Parameters	<i>lpszFile</i> Points to the null-terminated string that specifies the MS-DOS filename of the metafile. The metafile is assumed to exist.
Return Value	The return value is the handle of a metafile if the function is successful. Otherwise, it is NULL.
Example	The following example uses the CopyMetaFile function to copy a metafile to a specified file, plays the copied metafile, uses the GetMetaFile function to retrieve a handle to the copied metafile, uses the SetWindowOrg function to change the position at which the metafile is played 200 logical units to the right, and then plays the metafile at the new location:
	HANDLE hmf, hmfSource, hmfOld; LPSTR lpszFile1 = "MFTest";
	<pre>hmf = CopyMetaFile(hmfSource, lpszFile1); PlayMetaFile(hdc, hmf); DeleteMetaFile(hmf);</pre>
	hmfOld = GetMetaFile(lpszFile1); SetWindowOrg(hdc, -200, 0); PlayMetaFile(hdc, hmfOld);

DeleteMetaFile(hmfSource): DeleteMetaFile(hmf0ld);

See Also CopyMetaFile, PlayMetaFile, SetWindowOrg

GetMetaFileBits

HGLOBAL GetMetaFileBits(hmf) **HMETAFILE** *hmf*; /* handle of metafile

> The GetMetaFileBits function returns a handle of the global memory object that contains the specified metafile as a collection of bits. The memory object can be used to determine the size of the metafile or to save the metafile as a file. The memory object should not be modified.

Parameters	<i>hmf</i> Identifies the memory metafile.
Return Value	The return value is the handle of the global memory object that contains the meta- file, if the function is successful. Otherwise, it is NULL.
Comments	The handle contained in the <i>hmf</i> parameter becomes invalid when the GetMeta-FileBits function returns, so the returned global memory handle must be used to refer to the metafile.
	When it no longer requires a global memory object that is associated with a meta- file, an application should remove the object by using the GlobalFree function.
See Also	GlobalFree

*/

GetModuleFileName

int GetModuleFileName(hinst, lpszFilename, cbFileName)		
HINSTANCE hinst;	/* handle of module	
LPSTR lpszFilename;	/* address of buffer for filename	
int cbFileName;	/* maximum number of bytes to copy	

The GetModuleFileName function retrieves the full path and filename of the executable file from which the specified module was loaded.

*/ */ */ 2.x

2.x

Parameters	<i>hinst</i> Identifies the module or the instance of the module.
	<i>lpszFilename</i> Points to the buffer that is to receive the null-terminated filename.
	<i>cbFileName</i> Specifies the maximum number of bytes to copy, including the terminating null character. The filename is truncated if it is longer than <i>cbFileName</i> . This parameter should be set to the length of the filename buffer.
Return Value	The return value specifies the length, in bytes, of the string copied to the specified buffer, if the function is successful. Otherwise, it is zero.
Example	The following example retrieves an application's filename by using the instance handle passed to the application in the WinMain function:
	<pre>int PASCAL WinMain(HINSTANCE hinst, HINSTANCE hPrevInst, LPSTR lpCmdLine, int nCmdShow) {</pre>
	char szModuleName[260];
	<pre>GetModuleFileName(hinst, szModuleName, sizeof(szModuleName)); }</pre>
See Also	GetModuleHandle

GetModuleHandle

HMODULE GetN LPCSTR lpszMod	ModuleHandle(lpszModuleName) luleName; /* address of name of module */
	The GetModuleHandle function retrieves the handle of the specified module.
Parameters	<i>lpszModuleName</i> Points to a null-terminated string that specifies the name of the module.
Return Value	The return value is the handle of the module if the function is successful. Otherwise, it is NULL.
See Also	GetModuleFileName

GetModuleUsage

int GetModuleUsag HINSTANCE hinst;	e(hinst) /* handle of module */
	The GetModuleUsage function retrieves the reference count of a specified module.
Parameters	<i>hinst</i> Identifies the module or an instance of the module.
Return Value	The return value specifies the reference count of the module if the function is successful.
Comments	Windows increments (increases by one) a module's reference count each time an application calls the LoadModule function. The count is decremented (decreased by one) when an application calls the FreeModule function.
See Also	FreeModule, LoadModule

GetMsgProc

LRESULT CALLBA	ACK GetMsgProc(code, wParam, l.	Param)
int code;	/* process-message flag	*/
WPARAM wParam;	/* undefined	*/
LPARAM lParam;	/* pointer to MSG structure	*/
	calls whenever the GetMessage fun	ry-defined callback function that the system action has retrieved a message from an applica- etrieved message to the callback function estination window procedure.
Parameters	CallNextHookEx function. If this	nction should process the message or call the is parameter is less than zero, the callback func- CallNextHookEx without further processing.
	<i>wParam</i> Specifies a NULL value.	
	<i>lParam</i> Points to an MSG structure that o MSG structure has the following	contains information about the message. The form:

2.x

3.1

	<pre>typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM lParam; DWORD time; POINT pt; } MSG;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The callback function should return zero.
Comments	The GetMsgProc callback function can examine or modify the message as desired. Once the callback function returns control to the system, the GetMessage function returns the message, with any modifications, to the application that originally called it. The callback function does not require a return value.
	This callback function must be in a dynamic-link library (DLL).
	An application must install the callback function by specifying the WH_GETMESSAGE filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.
	GetMsgProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition (.DEF) file.
See Also	CallNextHookEx, GetMessage, SetWindowsHookEx
GetNearest	Color 2.x
COLORREF Get HDC hdc; COLORREF clrre	NearestColor(hdc, clrref) /* handle of device context */ /f; /* color to match */

The **GetNearestColor** function retrieves the solid color that best matches a specified logical color; the given device must be able to represent this solid color.

Parameters

hdc

Identifies the device context.

clrref

Specifies the color to be matched.

Return Value The return value specifies an RGB (red, green, blue) color value that defines the solid color closest to the *clrref* value that the device can represent.

3.0

See Also GetNearestPaletteIndex

GetNearestPaletteIndex

UINT GetNearestPa HPALETTE hpal; COLORREF clrref;	aletteIndex(hpal, clrref) /* handle of palette */ /* color to match */
	The GetNearestPaletteIndex function retrieves the index of the logical-palette entry that best matches the specified color value.
Parameters	hpal Identifies the logical palette. clrref Specifies the color to be matched.
Return Value	The return value is the index of the logical-palette entry whose corresponding color best matches the specified color.
Example The following example uses the GetNearestPaletteIndex function to recolor index from a palette. It then creates a brush with that retrieved color the PALETTEINDEX macro in a call to the CreateSolidBrush function	
	WORD nColor; HPALETTE hpal; DWORD dwBrushColors[8][8]; HBRUSH hbr; int x, y;
	. /* Initialize the array of brush colors. */
	nColor = GetNearestPaletteIndex(hpal, dwBrushColors[x][y]); hbr = CreateSolidBrush(PALETTEINDEX(nColor));
	. /* Use the brush handle. */
	DeleteObject(hbr);
See Also	CreateSolidBrush, GetNearestColor, GetPaletteEntries, GetSystemPaletteEntries

GetNextDlgGroupItem

HWND GetNextDl HWND hwndDlg; HWND hwndCtrl; BOOL fPrevious;	gGroupItem(hwndDlg, hwndCtrl, fPrevious) /* handle of dialog box */ /* handle of control */ /* direction flag */
	The GetNextDlgGroupItem function searches for the previous (or next) control within a group of controls in a dialog box. A group of controls begins with a control with the WS_GROUP style and ends with the last control that does not contain a WS_GROUP style.
Parameters	<i>hwndDlg</i> Identifies the dialog box to be searched.
	<i>hwndCtrl</i> Identifies the control to be used as the starting point for the search.
	<i>fPrevious</i> Specifies how the function is to search the group of controls in the dialog box. If this parameter is TRUE, the function searches for the previous control in the group. If this parameter is FALSE, the function searches for the next control in the group.
Return Value	The return value is the window handle of the previous (or next) control in the group, if the function is successful.
Comments	If the <i>hwndCtrl</i> parameter identifies the last control in the group and the <i>fPrevious</i> parameter is FALSE, the GetNextDlgGroupItem function returns the window handle of the first control in the group. If <i>hwndCtrl</i> identifies the first control in the group and <i>fPrevious</i> is TRUE, GetNextDlgGroupItem returns the window handle of the last control in the group.
Example	The following example sets the check state of a group of radio buttons. It is as- sumed that the group contains only radio buttons and no other type of control:
	HWND hwndStart, hwndCurrent;
	<pre>case WM_COMMAND: switch (HIWORD(1Param)) { case BN_CLICKED:</pre>
	/* * If a radio button was clicked, clear the current * selection and select the one that was clicked. */
	hwndStart = GetDlgItem(hdlg, wParam);

2.x

See Also

GetDlgItem, GetNextDlgTabItem

GetNextDlgTabltem

}

HWND GetNextDl HWND hwndDlg; HWND hwndCtrl; BOOL fPrevious;	gTabItem(hwndDlg, hwndCtrl, fPrevious) /* handle of dialog box */ /* handle of known control */ /* direction flag */
	The GetNextDlgTabItem function retrieves the handle of the first control that has the WS_TABSTOP style that precedes (or follows) the specified control.
Parameters	hwndDlg Identifies the dialog box to be searched.
	<i>hwndCtrl</i> Identifies the control to be used as the starting point for the search.
	<i>fPrevious</i> Specifies how the function is to search the dialog box. If this parameter is TRUE, the function searches for the previous control in the dialog box. If this parameter is FALSE, the function searches for the next control in the dialog box.
Return Value	The return value is the window handle of the previous (or next) control that has the WS_TABSTOP style, if the function is successful.
Example	The following example retrieves the handle of the previous control that has the WS_TABSTOP style, relative to the control that has the input focus:

HWND hdlg; HWND hwndControl; hwndControl = GetNextDlgTabItem(hdlg, GetFocus(), TRUE);

GetDlgItem, GetNextDlgGroupItem

GetNextDriver

3.1

HDRVR GetNextD HDRVR hdrvr; DWORD fdwFlag;	river(hdrvr, fdwFlag) /* handle of installable driver /* search flag	*/ */	
	The GetNextDriver function enum	nerates instances of an installable driver.	
Parameters	<i>hdrvr</i> Identifies the installable driver for which instances should be enumerated. This parameter must be retrieved by the OpenDriver function. If this parameter is NULL, the enumeration begins at either the beginning or end of the list of installable drivers (depending on the setting of the flags in the <i>fdwFlag</i> parameter).		
	<i>fdwFlag</i> Specifies whether the function should return a handle identifying only the first instance of a driver and whether the function should return handles identifying the instances of the driver in the order in which they were loaded. This parameter can be one or more of the following flags:		
Value Meaning			
	GND_FIRSTINSTANCEONLY	Returns a handle identifying the first instance of an installable driver. When this flag is set, the function will enumerate only the first in- stance of an installable driver, no matter how many times the driver has been installed.	
	GND_FORWARD	Enumerates subsequent instances of the driver. (Using this flag has the same effect as not using the GND_REVERSE flag.)	
	GND_REVERSE	Enumerates instances of the driver as it was loaded—each subsequent call to the function returns the handle of the next instance.	

Return Value The return value is the instance handle of the installable driver if the function is successful.

GetNextWindow

	Window(<i>hwnd</i> , <i>uFlag</i>) /* handle of current windo /* direction flag	DW */ */	
	The GetNextWindow function searches for the handle of the next (or previous) window in the window manager's list. The window manager's list contains entries for all top-level windows, their associated child windows, and the child windows of any child windows. If the given window is a top-level window, the function searches for the next (or previous) handle of a top-level window. If the given window is a child window, the function searches for the handle of the next (or previous) child window.		
Parameters	<i>hwnd</i> Identifies the current window. <i>uFlag</i> Specifies whether the function should return a handle to the next window or to		
	the previous window. It can be either of the following values:		
	Value	Meaning	
	GW_HWNDNEXT	Returns a handle of the next window.	
	GW_HWNDPREV	Returns a handle of the previous window.	
Return Value	The return value is the l manager's list if the fur	nandle of the next (or previous) window in the window action is successful.	
See Also	GetTopWindow, GetV	Vindow	

GetNumTasks

2.x

UINT GetNumTasks(void)

The GetNumTasks function retrieves the number of currently running tasks.

- **Parameters** This function has no parameters.
- **Return Value** The return value specifies the number of current tasks if the function is successful. Otherwise, it is zero.

int GetObject(hgdio HGDIOBJ hgdiobj; int cbBuffer; void FAR* lpvObjec	bj, cbBuffer, lpvObject)/* handle of object/* size of buffer for object information/*, /* address of buffer for object information	
	The GetObject function fills a buffer with information that defines a given object. The function retrieves a LOGPEN , LOGBRUSH , LOGFONT , or BITMAP structure, or an integer, depending on the specified object.	
Parameters	<i>hgdiobj</i> Identifies a logical pen, brush, font, bitmap, or palette.	
	<i>cbBuffer</i> Specifies the number of bytes to be copied to the buffer.	
	<i>lpvObject</i> Points to the buffer that is to receive the information.	
Return Value	The return value specifies the number of bytes retrieved if the function is success ful. Otherwise, it is zero.	
Comments	The buffer pointed to by the <i>lpvObject</i> parameter must be sufficiently large to ceive the information.	
	If the <i>hgdiobj</i> parameter identifies a bitmap, the GetObject function returns only the width, height, and color format information of the bitmap. The bits can be retrieved by using the GetBitmapBits function.	
	If <i>hgdiobj</i> identifies a logical palette, GetObject retrieves an integer that specifies the number of entries in the palette; the function does not retrieve the LOG-PALETTE structure that defines the palette. To retrieve information about palette entries, an application can call the GetPaletteEntries function.	
Example	The following example uses the GetObject function to fill a LOGBRUSH structure with the attributes of the current brush and then tests whether the brush style is BS_SOLID:	
	LOGBRUSH 1b;	
	HBRUSH hbr;	
	<pre>GetObject(hbr, sizeof(LOGBRUSH), (LPSTR) &lb);</pre>	

```
if (lb.lbStyle == BS_SOLID) {
    .
    .
    .
}
```

See Also

GetBitmapBits, GetPaletteEntries, GetStockObject

GetOpenClipboardWindow

HWND GetOpenClipboardWindow(void)

	The GetOpenClipboardWindow function retrieves the handle of the window that currently has the clipboard open.
Parameters	This function has no parameters.
Return Value	The return value is the handle of the window that has the clipboard open, if the function is successful. Otherwise, it is NULL.
See Also	GetClipboardOwner, GetClipboardViewer, OpenClipboard

GetOpenFileName

lpofn

#include <commdlg.h>

BOOL GetOpenFileName(*lpofn*) **OPENFILENAME FAR*** *lpofn*; /* address of structure with initialization data */

7⁺ address of structure with initialization data

The **GetOpenFileName** function creates a system-defined dialog box that makes it possible for the user to select a file to open.

Parameters

Points to an **OPENFILENAME** structure that contains information used to initialize the dialog box. When the **GetOpenFileName** function returns, this structure contains information about the user's file selection.

The **OPENFILENAME** structure has the following form:

3.1

3.1

	#include <commdlg.h></commdlg.h>
	<pre>typedef struct tagOPENFILENAME { /* ofn */ DWORD lStructSize;</pre>
	HWND hwndOwner;
	HINSTANCE hInstance;
	LPCSTR lpstrFilter;
	LPSTR lpstrCustomFilter;
	DWORD nMaxCustFilter;
	DWORD nFilterIndex:
	LPSTR lpstrFile;
	DWORD nMaxFile;
	LPSTR lpstrFileTitle;
	DWORD nMaxFileTitle;
	LPCSTR lpstrInitialDir;
	LPCSTR lpstrTitle;
	DWORD Flags;
	UINT nFileOffset;
	UINT nFileExtension;
	LPCSTR lpstrDefExt;
	LPARAM 1CustData;
	UINT (CALLBACK* 1pfnHook) (HWND, UINT, WPARAM, LPARAM);
	LPCSTR lpTemplateName;
	OPENFILENAME;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the user selects a file to open. It is zero if an error oc- curs, if the user chooses the Cancel button, if the user chooses the Close command on the System menu to close the dialog box, or if the buffer identified by the lpstrFile member of the OPENFILENAME structure is too small to contain the string that specifies the selected file.
Errors	The CommDlgExtendedError function retrieves the error value, which may be one of the following values:
	CDERR_FINDRESFAILURE CDERR_INITIALIZATION CDERR_LOCKRESFAILURE CDERR_LOADRESFAILURE CDERR_LOADSTRFAILURE CDERR_MEMALLOCFAILURE CDERR_MEMLOCKFAILURE CDERR_NOHINSTANCE CDERR_NOHOOK

Comments If the hook function (to which the **lpfnHook** member of the **OPENFILENAME** structure points) processes the WM_CTLCOLOR message, this function must return a handle of the brush that should be used to paint the control background.

Example The following example copies file-filter strings into a buffer, initializes an **OPEN-FILENAME** structure, and then creates an Open dialog box.

The file-filter strings are stored in the resource file in the following form:

```
STRINGTABLE
BEGIN
IDS_FILTERSTRING "Write Files(*.WRI)|*.wri|Word Files(*.DOC)|*.doc|"
END
```

The replaceable character at the end of the string is used to break the entire string into separate strings, while still guaranteeing that all the strings are continguous in memory.

```
OPENFILENAME ofn:
char szDirName[256]:
char szFile[256], szFileTitle[256];
UINT i, cbString;
char chReplace;
                    /* string separator for szFilter */
char szFilter[256];
HFILE hf;
/* Get the system directory name and store in szDirName */
GetSystemDirectory(szDirName, sizeof(szDirName));
szFile[0] = '\0';
if ((cbString = LoadString(hinst, IDS FILTERSTRING,
        szFilter, sizeof(szFilter))) == 0) {
    ErrorHandler():
    return 0L:
}
chReplace = szFilter[cbString - 1]; /* retrieve wild character */
for (i = 0; szFilter[i] != '\0'; i++) {
    if (szFilter[i] == chReplace)
       szFilter[i] = '\0';
}
```

```
/* Set all structure members to zero. */
memset(&ofn, 0, sizeof(OPENFILENAME));
ofn.lStructSize = sizeof(OPENFILENAME);
ofn.hwnd0wner = hwnd:
ofn.lpstrFilter = szFilter:
ofn.nFilterIndex = 1;
ofn.lpstrFile= szFile:
ofn.nMaxFile = sizeof(szFile);
ofn.lpstrFileTitle = szFileTitle;
ofn.nMaxFileTitle = sizeof(szFileTitle);
ofn.lpstrInitialDir = szDirName:
ofn.Flags = OFN SHOWHELP | OFN PATHMUSTEXIST | OFN FILEMUSTEXIST;
if (GetOpenFileName(&ofn)) {
    hf = _lopen(ofn.lpstrFile, OF READ);
         /* Perform file operations */
}
else
    ErrorHandler();
```

GetSaveFileName

GetOutlineTextMetrics

WORD GetOutlineTextMetrics(hdc, cbData, lpotm)HDC hdc;/* handle of device contextUINT cbData;/* size of buffer for informationOUTLINETEXTMETRIC FAR* lpotm;/* address of structure for metrics

The **GetOutlineTextMetrics** function retrieves metric information for TrueType fonts.

Parameters

hdc

Identifies the device context.

cbData

Specifies the size, in bytes, of the buffer to which information is returned.

lpotm

Points to an **OUTLINETEXTMETRIC** structure. If this parameter is NULL, the function returns the size of the buffer required for the retrieved metric information. The **OUTLINETEXTMETRIC** structure has the following form:

3.1

*/

*/

*/

	typedef struct UINT TEXTMETRIC	<pre>tagOUTLINETEXTMETRIC { otmSize; otmTextMetrics;</pre>
	BYTE	otmFiller;
	PANOSE	otmPanoseNumber;
	UINT	otmfsSelection;
	UINT	otmfsType;
	UINT UINT	otmsCharSlopeRise; otmsCharSlopeRun;
	UINT	otmItalicAngle;
	UINT	otmEMSquare;
	INT	otmAscent;
	INT	otmDescent;
	UINT	otmLineGap;
	UINT	otmsXHeight;
	UINT	otmsCapEmHeight;
	RECT	otmrcFontBox;
	INT	otmMacAscent;
	INT	otmMacDescent;
	UINT	otmMacLineGap;
	UINT POINT	otmusMinimumPPEM; otmptSubscriptSize;
	POINT	otmptSubscriptOffset;
	POINT	otmptSuperscriptSize;
	POINT	otmptSuperscriptOffset;
	UINT	otmsStrikeoutSize;
	INT	otmsStrikeoutPosition;
	INT	otmsUnderscorePosition;
	UINT	otmsUnderscoreSize;
	PSTR	otmpFamilyName;
	PSTR	otmpFaceName;
	PSTR	otmpStyleName;
	PSTR	otmpFullName;
	<pre>} OUTLINETEXTME</pre>	IKIC;
	For a full descrip <i>mer's Reference</i> ,	tion of this structure, see the <i>Microsoft Windows Program-Volume 3</i> .
Return Value	The return value is a	nonzero if the function is successful. Otherwise, it is zero.
Comments	The OUTLINETEXTMETRIC structure contains most of the font metric infor- mation provided with the TrueType format, including a TEXTMETRIC struc- ture. The last four members of the OUTLINETEXTMETRIC structure are pointers to strings. Applications should allocate space for these strings in addition to the space required for the other members. Because there is no system-imposed limit to the size of the strings, the simplest method for allocating memory is to re- trieve the required size by specifying NULL for the <i>lpotm</i> parameter in the first call to the GetOutlineTextMetrics function.

3.0

GetParent

HWND GetParent HWND hwnd;	(<i>hwnd</i>) /* handle of window */	
	The GetParent function retrieves the handle of the given window's parent window (if any).	
Parameters	<i>hwnd</i> Identifies the window whose parent window handle is to be retrieved.	
Return Value	The return value is the handle of the parent window if the function is successful. Otherwise, it is NULL, indicating an error or no parent window.	
See Also	SetParent	

COLORREF HDC hdc; int nXPos; int nYPos;	GetPixel(hdc, nXPos, nYPos)/* handle of device context*//* x-coordinate of pixel to retrieve*//* y-coordinate of pixel to retrieve*/
	The GetPixel function retrieves the RGB (red, green, blue) color value of the pixel at the specified coordinates. The point must be in the clipping region; if it is not, the function is ignored.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXPos</i> Specifies the logical x-coordinate of the point to be examined.
	<i>nYPos</i> Specifies the logical y-coordinate of the point to be examined.
Return Value	The return value specifies an RGB color value for the color of the given point, if the function is successful. It is -1 if the coordinates do not specify a point in the clipping region.
Comments	Not all devices support the GetPixel function. For more information, see the de- scription of the GetDeviceCaps function.

2.x

See Also GetDeviceCaps, SetPixel

GetPolyFillMode 2.x	
int GetPolyFillMoo HDC hdc; /* ha	de(<i>hdc</i>) andle of device context */
	The GetPolyFillMode function retrieves the current polygon-filling mode.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the polygon-filling mode, ALTERNATE or WINDING, if the function is successful.
Comments	When the polygon-filling mode is ALTERNATE, the system fills the area be- tween odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.
	When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. When- ever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, a count is incremented. When the line passes through a counterclockwise line segment, the count is decremented. The area is filled if the count is nonzero when the line reaches the outside of the figure.
Example	The following example uses the GetPolyFillMode function to determine whether the current polygon-filling mode is ALTERNATE:
	int nPolyFillMode;
	nPolyFillMode = GetPolyFillMode(hdc); if (nPolyFillMode == ALTERNATE) {
	· · ·
See Also	SetPolyFillMode

GetPriorityClipboardFormat

int GetPriorityClipboardFormat(lpuPriorityList, cEntries)		
UINT FAR* <i>lpuPric</i>		
int cEntries;	/* count of entries in list */	
	The GetPriorityClipboardFormat function retrieves the first clipboard format in a list for which data exists in the clipboard.	
Parameters	<i>lpuPriorityList</i> Points to an integer array that contains a list of clipboard formats in priority order. For a description of the data formats, see the description of the Set- ClipboardData function.	
	<i>cEntries</i> Specifies the number of entries in the priority list. This value must not be greater than the number of entries in the list.	
Return Value	The return value is the highest priority clipboard format in the list for which data exists. If no data exists in the clipboard, the return value is NULL. If data exists in the clipboard that does not match any format in the list, the return value is -1 .	
See Also	CountClipboardFormats, EnumClipboardFormats, GetClipboardFormat- Name, IsClipboardFormatAvailable, RegisterClipboardFormat, SetClipboardData	

GetPrivateProfileInt

LPCSTR lpszFilename;

UINT GetPrivateProfileInt(lpszSection, lpszEntry, default, lpszFilename)LPCSTR lpszSection;/* address of section*/LPCSTR lpszEntry;/* address of entry*/int default;/* return value if entry not found*/

/* return value if entry not found	*/
/* address of initialization filename	*/

The **GetPrivateProfileInt** function retrieves the value of an integer from an entry within a specified section of a specified initialization file.

Parameters

lpszSection

Points to a null-terminated string containing the section heading in the initialization file.

3.0

3.0

	<i>lpszEntry</i> Points to the null-terminated string containing the entry whose value is to be re- trieved.
	<i>default</i> Specifies the default value to return if the entry cannot be found in the initializa- tion file. This value must be a positive integer in the range 0 through 32,767 (0x0000 through 0x7FFF).
	<i>lpszFilename</i> Points to a null-terminated string that names the initialization file. If this parameter does not contain a full path, Windows searches for the file in the Windows directory.
Return Value	The return value is the integer value of the specified entry if the function is successful. It is the value of the <i>default</i> parameter if the function does not find the entry. The return value is zero if the value that corresponds to the specified entry is not an integer.
Comments	The function searches the file for an entry that matches the name specified by the <i>lpszEntry</i> parameter under the section heading specified by the <i>lpszSection</i> parameter. An integer entry in the initialization file must have the following form:
	[section] entry=value
	If the value that corresponds to the entry consists of digits followed by non- numeric characters, the function returns the value of the digits. For example, the function would return 102 for the line "Entry=102abc".

The **GetPrivateProfileInt** function is not case-dependent, so the strings in the *lpszSection* and *lpszEntry* parameters may contain a combination of uppercase and lowercase letters.

GetPrivateProfileInt supports hexadecimal notation. When GetPrivate-ProfileInt is used to retrieve a negative integer, the value should be cast to an int.

An application can use the **GetProfileInt** function to retrieve an integer value from the WIN.INI file.

Example The following example uses the GetPrivateProfileInt function to retrieve the last line number by reading the LastLine entry from the [MyApp] section of TESTCODE.INI: WORD wInt; char szMsg[144]; wInt = GetPrivateProfileInt("MyApp", "LastLine",

```
0, "testcode.ini");
sprintf(szMsg, "last line was %d", wInt);
MessageBox(hwnd. szMsg. "GetPrivateProfileInt", MB_OK);
```

See Also GetPrivateProfileString, GetProfileInt

GetPrivateProfileString

 $int \ Get Private Profile String (lpsz Section, lpsz Entry, lpsz Default, lpsz Return Buffer, cb Return Buffer, lpsz Return$

lpszFilename)	
LPCSTR lpszSection;	/* address of section
LPCSTR lpszEntry;	/* address of entry
LPCSTR lpszDefault;	/* address of default string
LPSTR lpszReturnBuffer;	/* address of destination buffer
int cbReturnBuffer;	/* size of destination buffer
LPCSTR lpszFilename;	/* address of initialization filename

The **GetPrivateProfileString** function retrieves a character string from the specified section in the specified initialization file.

Parameters

lpszSection

Points to a null-terminated string that specifies the section containing the entry.

*/

*/

*/

*/

*/

*/

lpszEntry

Points to the null-terminated string containing the entry whose associated string is to be retrieved. If this value is NULL, all entries in the section specified by the *lpszSection* parameter are copied to the buffer specified by the *lpszReturn-Buffer* parameter. For more information, see the following Comments section.

lpszDefault

Points to a null-terminated string that specifies the default value for the given entry if the entry cannot be found in the initialization file. This parameter must never be NULL.

3.0

	<i>lpszReturnBuffer</i> Points to the buffer that receives the character string.
	<i>cbReturnBuffer</i> Specifies the size, in bytes, of the buffer pointed to by the <i>lpszReturnBuffer</i> parameter.
	<i>lpszFilename</i> Points to a null-terminated string that names the initialization file. If this parameter does not contain a full path, Windows searches for the file in the Windows directory.
Return Value	The return value specifies the number of bytes copied to the specified buffer, not including the terminating null character.
Comments	The function searches the file for an entry that matches the name specified by the <i>lpszEntry</i> parameter under the section heading specified by the <i>lpszSection</i> parameter. If the entry is found, its corresponding string is copied to the buffer. If the entry does not exist, the default character string specified by the <i>lpszDefault</i> parameter is copied. A string entry in the initialization file must have the following form:
	[section] entry=string

.

If *lpszEntry* is NULL, the **GetPrivateProfileString** function copies all entries in the specified section to the supplied buffer. Each string will be null-terminated, with the final string ending with two zero-termination characters. If the supplied destination buffer is too small to hold all the strings, the last string will be truncated and followed with two zero-termination characters.

If the string associated with *lpszEntry* is enclosed in single or double quotation marks, the marks are discarded when **GetPrivateProfileString** returns the string.

GetPrivateProfileString is not case-dependent, so the strings in *lpszSection* and *lpszEntry* may contain a combination of uppercase and lowercase letters.

An application can use the **GetProfileString** function to retrieve a string from the WIN.INI file.

The *lpszDefault* parameter must point to a valid string, even if the string is empty (its first character is zero).

Example The following example uses the **GetPrivateProfileString** function to determine the last file saved by the [MyApp] application by reading the LastFile entry in TESTCODE.INI:

char szMsg[144], szBuf[80];

sprintf(szMsg, "last file was %s", szBuf); MessageBox(hwnd, szMsg, "GetPrivateProfileString", MB_OK);

See Also GetProfileString, WritePrivateProfileString

GetProcAddress

FARPROC GetProcAddress(*hinst*, *lpszProcName*) **HINSTANCE** *hinst*; /* handle of module */ LPCSTR lpszProcName; /* address of function */ The GetProcAddress function retrieves the address of the given module function. **Parameters** hinst Identifies the module that contains the function. lpszProcName Points to a null-terminated string containing the function name, or specifies the ordinal value of the function. If it is an ordinal value, the value must be in the low-order word and the high-order word must be zero. **Return Value** The return value is the address of the module function's entry point if the GetProcAddress function is successful. Otherwise, it is NULL. If the *lpszProcName* parameter is an ordinal value and a function with the specified ordinal does not exist in the module, GetProcAddress can still return a non-NULL value. In cases where the function may not exist, specify the function by name rather than ordinal value. Comments Use the **GetProcAddress** function to retrieve addresses of exported functions in dynamic-link libraries (DLLs). The MakeProcInstance function can be used to access functions within different instances of the current module.

```
The spelling of the function name (pointed to by the lpszProcName parameter)
                   must be identical to the spelling as it appears in the EXPORTS section of the
                   source DLL's module-definition (.DEF) file.
Example
                   The following example uses the GetProcAddress function to retrieve the address
                   of the TimerCount function in TOOLHELP.DLL:
                   char szBuf[80]:
                   TIMERINFO timerinfo:
                   HINSTANCE hinstToolHelp:
                   BOOL (FAR *lpfnTimerCount) (TIMERINFO FAR*);
                   /* Turn off the "File not found" error box. */
                   SetErrorMode(SEM NOOPENFILEERRORBOX):
                   /* Load the TOOLHELP.DLL library module. */
                   hinstToolHelp = LoadLibrary("TOOLHELP.DLL");
                   if (hinstToolHelp > HINSTANCE_ERROR) { /* loaded successfully */
                       /* Retrieve the address of the TimerCount function. */
                       (FARPROC) lpfnTimerCount =
                           GetProcAddress(hinstToolHelp, "TimerCount");
                       if (lpfnTimerCount != NULL) {
                           /* Call the TimerCount function. */
                           timerinfo.dwSize = sizeof(TIMERINFO);
                           if ((*lpfnTimerCount) ((TIMERINFO FAR *) &timerinfo)) {
                                sprintf(szBuf, "task: %lu seconds\nVM: %lu seconds",
                                    timerinfo.dwmsSinceStart / 1000.
                                    timerinfo.dwmsThisVM / 1000);
                           }
                           else {
                               strcpy(szBuf, "TimerCount failed");
                           }
                       }
                       else {
                           strcpy(szBuf, "GetProcAddress failed");
                       }
                       /* Free the TOOLHELP.DLL library module. */
                       FreeLibrary(hinstToolHelp);
                   }
```

```
else {
   strcpy(szBuf, "LoadLibrary failed");
}
MessageBox(NULL, szBuf, "Library Functions", MB_ICONHAND);
```

GetProfileInt

UINT GetProfileInt LPCSTR lpszSection LPCSTR lpszEntry; int default;	
	The GetProfileInt function retrieves the value of an integer from an entry within a specified section of the WIN.INI initialization file.
Parameters	<i>lpszSection</i> Points to a null-terminated string that specifies the section containing the entry.
	<i>lpszEntry</i> Points to the null-terminated string containing the entry whose value is to be re- trieved.
	<i>default</i> Specifies the default value to return if the entry cannot be found. This value can be an unsigned value in the range 0 through $65,536$ or a signed value in the range $-32,768$ through $32,768$. Hexadecimal notation is accepted for both posi- tive and negative values.
Return Value	The return value is the integer value of the string following the specified entry, if the function is successful. The return value is the value of the <i>default</i> parameter if the function does not find the entry. The return value is zero if the value that corresponds to the specified entry is not an integer.
Comments	The GetProfileInt function is not case-dependent, so the strings in the <i>lpszSection</i> and <i>lpszEntry</i> parameters may contain a combination of uppercase and lowercase letters.
	GetProfileInt supports hexadecimal notation. When the function is used to re- trieve a negative integer, the value should be cast to an int .
	An interest entry in the WINI INIT file except here the following a former

An integer entry in the WIN.INI file must have the following form:

2.x

See Also	GetPrivateProfileInt, GetProfileString
	sprintf(szMsg, "timeout time is %d", wTimeOut); MessageBox(hwnd, szMsg, "GetProfileInt", MB_OK);
	<pre>wTimeOut = GetProfileInt("windows", "ScreenSaveTimeOut", 0);</pre>
	WORD wTimeOut; char szMsg[80];
Example	The following example uses the GetProfileInt function to retrieve the screen-save timeout time from the WIN.INI file:
	An application can use the GetPrivateProfileInt function to retrieve an integer from a specified file.
	If the value that corresponds to the entry consists of digits followed by non- numeric characters, the function returns the value of the digits. For example, the function would return 102 for the line "Entry=102abc".
	· ·
	entry=value
	[section]

GetProfileString

	szSection, lpszEntry, lpszDefault, lpszReturnBuffer, cbReturnBuffer)
LPCSTR lpszSection;	/* address of section */
LPCSTR lpszEntry;	/* address of entry */
LPCSTR lpszDefault;	/* address of default string */
LPSTR lpszReturnBuffe	er; /* address of destination buffer */
int cbReturnBuffer;	/* size of destination buffer */
_	szSection
the	e specified section in the WIN.INI initialization file.
1	Points to a null-terminated string that specifies the section containing the entry.
lp.	<i>szEntry</i> Points to the null-terminated string containing the entry whose associated string is to be retrieved. If this value is NULL, all entries in the section specified by

	the <i>lpszSection</i> parameter are copied to the buffer specified by the <i>lpszReturn-Buffer</i> parameter. For more information, see the following Comments section.
	<i>lpszDefault</i> Points to the default value for the given entry if the entry cannot be found in the initialization file. This parameter must never be NULL.
	<i>lpszReturnBuffer</i> Points to the buffer that will receive the character string.
	<i>cbReturnBuffer</i> Specifies the size, in bytes, of the buffer pointed to by the <i>lpszReturnBuffer</i> parameter.
Return Value	The return value is the number of bytes copied to the buffer, not including the ter- minating zero, if the function is successful.
Comments	If the <i>lpszEntry</i> parameter is NULL, the GetProfileString function copies all en- tries in the specified section to the supplied buffer. Each string will be null-termi- nated, with the final string terminating with two null characters. If the supplied destination buffer is too small to hold all the strings, the last string will be trun- cated and followed by two terminating null characters.
	If the string associated with <i>lpszEntry</i> is enclosed in single or double quotation marks, the marks are discarded when GetProfileString returns the string.
	GetProfileString is not case-dependent, so the strings in the <i>lpszSection</i> and <i>lpszEntry</i> parameters may contain a combination of uppercase and lowercase letters.
	A string entry in the WIN.INI file must have the following form:
	[section] entry=string
1	• • • • • • • • • • • • • • • • • • •
	An application can use the GetPrivateProfileString function to retrieve a string from a specified file.
	The <i>lpszDefault</i> parameter must point to a valid string, even if the string is empty (its first character is zero).
Example	The following example uses the GetProfileString function to list all the entries and strings in the [windows] section of the WIN.INI file:

```
int c, cc;
PSTR pszBuf, pszKey;
char szMsg[80], szVal[80];
/* Allocate a buffer for the entries. */
pszBuf = (PSTR) LocalAlloc(LMEM_FIXED, 1024);
/* Retrieve all the entries in the [windows] section. */
GetProfileString("windows", NULL, "", pszBuf, 1024);
 /*
    Retrieve the string for each entry, until
 *
 *
    reaching the double null character.
 */
for (pszKey = pszBuf, c = 0;
        *pszKey != '\0'; pszKey += strlen(pszKey) + 1) {
    /* Retrieve the value for each entry in the buffer. */
    GetProfileString("windows", pszKey, "not found",
        szVal, sizeof(szVal));
   cc = sprintf(szMsg, "%s = %s", pszKey, szVal);
   TextOut(hdc, 10, 15 * c++, szMsg, cc);
ł
LocalFree((HANDLE) pszBuf);
GetPrivateProfileString, WriteProfileString
```

GetProp

See Also

HANDLE GetPr HWND hwnd; LPCSTR lpsz;	cop(hwnd, lpsz)/* handle of window*//* atom or address of string*/
	The GetProp function retrieves a data handle from the property list of a window. The character string pointed to by the <i>lpsz</i> parameter identifies the handle to be re- trieved. The string and handle must be added to the property list by a previous call to the SetProp function.
Parameters	<i>hwnd</i> Identifies the window whose property list is to be searched.

	<i>lpsz</i> Points to a null-terminated string or an atom that identifies a string. If an atom is given, it must be a global atom created by a previous call to the GlobalAdd - Atom function. The atom, a 16-bit value, must be placed in the low-order word of the <i>lpsz</i> parameter; the high-order word must be zero.
Return Value	The return value is the associated data handle if the property list contains the given string. Otherwise, it is NULL.
Comments	The value retrieved by the GetProp function can be any 16-bit value useful to the application.
See Also	GlobalAddAtom, RemoveProp, SetProp

*/

GetQueueStatus

DWORD GetQueueStatus(*fuFlags*)

UINT *fuFlags*; /* queue-status flags

The **GetQueueStatus** function returns a value that indicates the type of messages in the queue.

3.1

This function is very fast and is typically used inside speed-critical loops to determine whether the **GetMessage** or **PeekMessage** function should be called to process input.

GetQueueStatus returns two sets of information: whether any new messages have been added to the queue since GetQueueStatus, GetMessage, or PeekMessage was last called, and what kinds of events are currently in the queue.

Parameters

fuFlags

Specifies the queue-status flags to be retrieved. This parameter can be a combination of the following values:

Value	Meaning
QS_KEY	WM_CHAR message is in the queue.
QS_MOUSE	WM_MOUSEMOVE or WM_*BUTTON* message is in the queue.
QS_MOUSEMOVE	WM_MOUSEMOVE message is in the queue.
QS_MOUSEBUTTON	WM_*BUTTON* message is in the queue.
QS_PAINT	WM_PAINT message is in the queue.

3.1

	Value	Meaning
	QS_POSTMESSAGE	Posted message other than those listed above is in the queue.
	QS_SENDMESSAGE	Message sent by another application is in the queue.
	QS_TIMER	WM_TIMER message is in the queue.
Return Value	in the queue. The low-orde	e return value indicates the types of messages currently er word shows the types of messages added to the queue ince the last call to the GetQueueStatus , GetMessage ,
Comments	The existence of a QS_ flag in the return value does not guarantee that a sub- sequent call to the PeekMessage or GetMessage function will return a message. GetMessage and PeekMessage perform some internal filtering computation that may cause the message to be processed internally. For this reason, the return value from GetQueueStatus should be considered only a hint as to whether GetMessage or PeekMessage should be called.	
See Also	GetInputState, GetMessa	age, PeekMessage

GetRasterizerCaps

BOOL GetRasterizerCaps(*lpraststat*, *cb*) **RASTERIZER_STATUS** FAR* lpraststat; */ /* address of structure for status */ int cb; /* number of bytes in structure The GetRasterizerCaps function returns flags indicating whether TrueType fonts are installed in the system.

Parameters

lpraststat

Points to a **RASTERIZER_STATUS** structure that receives information about the rasterizer. The RASTERIZER_STATUS structure has the following form:

```
typedef struct tagRASTERIZER_STATUS {
                                          /* rs */
    int
         nSize;
    int
         wFlags;
    int
          nLanguageID;
} RASTERIZER_STATUS;
```

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

	<i>cb</i> Specifies the number of bytes that will be copied into the structure pointed to by the <i>lpraststat</i> parameter.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The GetRasterizerCaps function enables applications and printer drivers to deter- mine whether TrueType is installed.
	If the TT_AVAILABLE flag is set in the wFlags member of the RASTERIZER_STATUS structure, at least one TrueType font is installed. If the TT_ENABLED flag is set, TrueType is enabled for the system.
See Also	GetOutlineTextMetrics

3.0

GetRgnBox

<pre>int GetRgnBox(hrgn HRGN hrgn; RECT FAR* lprc;</pre>	n, lprc) /* handle of region */ /* address of structure with rectangle */
	The GetRgnBox function retrieves the coordinates of the bounding rectangle of the given region.
Parameters	hrgn Identifies the region.
	<i>lprc</i> Points to a RECT structure that receives the coordinates of the bounding rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Program-</i> mer's Reference, Volume 3.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.

Example The following example uses the **GetRgnBox** function to determine the type of a region:

```
RECT rc;
HRGN hrgn;
int RgnType;
RgnType = GetRgnBox(hrgn, &rc);
if (RgnType == COMPLEXREGION)
    TextOut(hdc, 10, 10, "COMPLEXREGION", 13);
else if (RgnType == SIMPLEREGION)
    TextOut(hdc, 10, 10, "SIMPLEREGION", 12);
else
    TextOut(hdc, 10, 10, "NULLREGION", 10);
```

GetROP2

int GetROP2(HDC hdc;	(<i>hdc</i>) /* handle of device context	*/
		n retrieves the current drawing mode. The drawing mode rs of the pen and the interior of filled objects are combined on the screen surface.
Parameters	<i>hdc</i> Identifies the device	e context.
Return Value	The return value specif	fies the drawing mode if the function is successful.
Comments	The drawing mode is for It can be any of the following the	or raster devices only and does not apply to vector devices. lowing values:
	Value	Meaning
	R2_BLACK	Pixel is always black.
	R2_WHITE	Pixel is always white.
	R2_NOP	Pixel remains unchanged.
	R2_NOT	Pixel is the inverse of the screen color.
	R2_COPYPEN	Pixel is the pen color.
	R2_NOTCOPYPEN	Pixel is the inverse of the pen color.
	R2_MERGEPENNOT	Pixel is a combination of the pen color and the inverse of the screen color (final pixel = (~screen pixel) pen).

Value	Meaning
R2_MASKPENNOT	Pixel is a combination of the colors common to both the per and the inverse of the screen (final pixel = (~screen pixel) & pen).
R2_MERGENOTPEN	Pixel is a combination of the screen color and the inverse of the pen color (final pixel = (~pen) screen pixel).
R2_MASKNOTPEN	Pixel is a combination of the colors common to both the screen and the inverse of the pen (final pixel = (~pen) & screen pixel).
R2_MERGEPEN	Pixel is a combination of the pen color and the screen color (final pixel = pen screen pixel).
R2_NOTMERGEPEN	Pixel is the inverse of the R2_MERGEPEN color (final pixel = ~(pen screen pixel)).
R2_MASKPEN	Pixel is a combination of the colors common to both the per and the screen (final pixel = pen & screen pixel).
R2_NOTMASKPEN	Pixel is the inverse of the R2_MASKPEN color (final pixel = ~(pen & screen pixel)).
R2_XORPEN	Pixel is a combination of the colors that are in the pen and in the screen, but not in both (final pixel = pen ^ screen pixel).
R2_NOTXORPEN	Pixel is the inverse of the R2_XORPEN color (final pixel = ~(pen ^ screen pixel)).

Example The following example uses the **GetROP2** function to test whether the current drawing mode is R2_COPYPEN:

int nROP;

nROP = GetROP2(hdc); if (nROP == R2_COPYPEN) TextOut(hdc, 100, 100, "ROP is R2_COPYPEN.", 18);

See Also GetDeviceCaps, SetROP2

GetSaveFileName

#include <commdlg.h>

BOOL GetSaveFileName(*lpofn*) */ **OPENFILENAME FAR*** *lpofn*: /* address of structure with initialization data

The GetSaveFileName function creates a system-defined dialog box that makes it possible for the user to select a file to save.

Parameters

lpofn Points to an **OPENFILENAME** structure that contains information used to initialize the dialog box. When the GetSaveFileName function returns, this structure contains information about the user's file selection.

The **OPENFILENAME** structure has the following form:

#include <commdlg.h>

typedef struc	t tagOPENFILENAME { /* ofn */
DWORD	lStructSize;
HWND	hwndOwner;
HINSTANCE	hInstance;
LPCSTR	lpstrFilter;
LPSTR	lpstrCustomFilter;
DWORD	nMaxCustFilter;
DWORD	nFilterIndex;
LPSTR	lpstrFile;
DWORD	nMaxFile;
LPSTR	lpstrFileTitle;
DWORD	nMaxFileTitle;
LPCSTR	lpstrInitialDir;
LPCSTR	lpstrTitle;
DWORD	Flags;
UINT	nFileOffset;
UINT	nFileExtension;
LPCSTR	lpstrDefExt;
LPARAM	lCustData;
UINT	(CALLBACK* lpfnHook) (HWND, UINT, WPARAM, LPARAM);
LPCSTR	lpTemplateName;
} OPENFILENAM	Ε;

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

Return Value The return value is nonzero if the user selects a file to save. It is zero if an error occurs, if the user clicks the Cancel button, if the user chooses the Close command on the System menu to close the dialog box, or if the buffer identified by the lpstrFile member of the OPENFILENAME structure is too small to contain the string that specifies the selected file.

3.1

Errors

The **CommDlgExtendedError** retrieves the error value, which may be one of the following values:

CDERR_FINDRESFAILURE CDERR_INITIALIZATION CDERR_LOCKRESFAILURE CDERR_LOADRESFAILURE CDERR_LOADSTRFAILURE CDERR_MEMALLOCFAILURE CDERR_MEMLOCKFAILURE CDERR_NOHINSTANCE CDERR_NOHOOK CDERR_NOTEMPLATE CDERR_STRUCTSIZE FNERR_BUFFERTOOSMALL FNERR_INVALIDFILENAME FNERR_SUBCLASSFAILURE

Comments If the hook function (to which the **lpfnHook** member of the **OPENFILENAME** structure points) processes the WM_CTLCOLOR message, this function must return a handle for the brush that should be used to paint the control background.

Example The following example copies file-filter strings (filename extensions) into a buffer, initializes an **OPENFILENAME** structure, and then creates a Save As dialog box.

The file-filter strings are stored in the resource file in the following form:

```
STRINGTABLE
BEGIN
IDS_FILTERSTRING "Write Files(*.WRI)|*.wri|Word Files(*.DOC)|*.doc|"
END
```

GetScrollPos

<pre>int GetScrollPos(HWND hwnd; int fnBar;</pre>	hwnd, fnBar) /* handle of windo /* scroll bar flags	ow with scroll bar	*/ */
	of a scroll bar. T scrolling range.	The current position is a	a relative value that depends on the current olling range is 0 through 100 and the scroll ent position is 50.
Parameters		vindow that has standar lue of the <i>fnBar</i> parame	d scroll bars or a scroll bar control, depend- eter.
	<i>fnBar</i> Specifies the	scroll bar to examine.	It can be one of the following values:
	Value	Meaning	
1	SB_CTL	-	of a scroll bar control. In this case, the <i>hwnd</i> window handle of a scroll bar control.
	SB_HORZ	Retrieves the position of	of a window's horizontal scroll bar.
	SB_VERT	Retrieves the position of	of a window's vertical scroll bar.
Return Value	the function is s		position of the scroll box in the scroll bar, if t is zero, indicating that the <i>hwnd</i> parameter have a scroll bar.

GetScrollRange

void GetScrollRange(hwnd, fnBar, lpnMinPos, lpnMaxPos)HWND hwnd;/* handle of window with scroll bar*/int fnBar;/* scroll bar flags*/int FAR* lpnMinPos;/* receives minimum position*/int FAR* lpnMaxPos;/* receives maximum position*/

The **GetScrollRange** function retrieves the current minimum and maximum scroll bar positions for the given scroll bar.

Parameters	<i>hwnd</i> Identifies a window that has standard scroll bars or a scroll bar control, depend- ing on the value of the <i>fnBar</i> parameter.		
	<i>fnBar</i> Specifies wh ing values:	nich scroll bar to retrieve. This parameter can be one of the follow-	
	Value	Meaning	
	SB_CTL	Retrieves the position of a scroll bar control; in this case, the <i>hwnd</i> parameter must be the handle of a scroll bar control.	
	SB_HORZ	Retrieves the position of a window's horizontal scroll bar.	
	SB_VERT	Retrieves the position of a window's vertical scroll bar.	
	<i>lpnMinPos</i> Points to the integer variable that receives the minimum position.		
	<i>lpnMaxPos</i> Points to the	integer variable that receives the maximum position.	
Return Value	This function d	oes not return a value.	
Comments	0	ndow does not have standard scroll bars or is not a scroll bar con- rollRange function copies zero to the <i>lpnMinPos</i> and <i>lpnMaxPos</i>	
		ge for a standard scroll bar is 0 through 100. The default range for trol is empty (both values are zero).	
See Also	GetScrollPos,	SetScrollPos, SetScrollRange	

GetSelectorBase

3.1

DWORD GetSelectorBase(*uSelector*) UINT *uSelector*;

uSelector

The GetSelectorBase function retrieves the base address of a selector.

Parameters

Specifies the selector whose base address is retrieved.

Return Value This function returns the base address of the specified selector.

See Also GetSelectorLimit, SetSelectorBase, SetSelectorLimit

GetSelectorLimit

3.1

DWORD GetSelector;	orLimit(uSelector)
	The GetSelectorLimit function retrieves the limit of a selector.
Parameters	<i>uSelector</i> Specifies the selector whose limit is being retrieved.
Return Value	This function returns the limit of the specified selector.
See Also	GetSelectorBase, SetSelectorBase, SetSelectorLimit

GetStockObj	ject
-------------	------

GetStock	Object	2.x
HGDIOBJ Ge int fnObject;	tStockObject(fnObject) /* type of stock object	*/
	The GetStockObject f pens, brushes, or fonts.	function retrieves a handle of one of the predefined stock
Parameters	<i>fnObject</i> Specifies the type of can be one of the fol	f stock object for which to retrieve a handle. This parameter llowing values:
	Value	Meaning
	BLACK_BRUSH	Black brush.
	DKGRAY_BRUSH	Dark-gray brush.
	GRAY_BRUSH	Gray brush.
	HOLLOW_BRUSH	Hollow brush.
	LTGRAY_BRUSH	Light-gray brush.
	NULL_BRUSH	Null brush.

	Value	Meaning
	WHITE_BRUSH	White brush.
	BLACK_PEN	Black pen.
	NULL_PEN	Null pen.
	WHITE_PEN	White pen.
	ANSI_FIXED_FONT	Windows fixed-pitch system font.
	ANSI_VAR_FONT	Windows variable-pitch system font.
	DEVICE_DEFAULT_FONT	Device-dependent font.
	OEM_FIXED_FONT	OEM-dependent fixed font.
	SYSTEM_FONT	System font. By default, Windows uses the sys- tem font to draw menus, dialog box controls, and other text. In Windows versions 3.0 and later, the system font is a variable-pitch font width; earlier versions of Windows use a fixed-pitch system font.
	SYSTEM_FIXED_FONT	Fixed-pitch system font used in Windows ver- sions earlier than 3.0. This object is available for compatibility with earlier versions of Windows.
	DEFAULT_PALETTE	Default color palette. This palette consists of the static colors in the system palette.
Return Value	The return value is the handle of Otherwise, it is NULL.	the specified object if the function is successful.
Comments	should be used only in windows class styles. Using a gray stock b	² BRUSH, and LTGRAY_BRUSH objects with the CS_HREDRAW and CS_VREDRAW orush in any other style of window can lead to mis- a window is moved or sized. The origins of stock
Example		the handle of a black brush by calling the Get - e brush into the device context, and fills a sh:
	HBRUSH hbr, hbr0ld;	
	hbr = GetStockObject(BLACK_B hbrOld = SelectObject(hdc, h Rectangle(hdc, 10, 10, 100,	br);
See Also	GetObject, SetBrushOrg	

GetStretchBltMode

	hBltMode(<i>hdc</i>) /* handle of device context */
	The GetStretchBltMode function retrieves the current bitmap-stretching mode. The bitmap-stretching mode defines how information is removed from bitmaps that were compressed by using the StretchBlt function.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the current bitmap-stretching mode— STRETCH_ANDSCANS, STRETCH_DELETESCANS, or STRETCH_ORSCANS—if the function is successful.
Comments	The STRETCH_ANDSCANS and STRETCH_ORSCANS modes are typically used to preserve foreground pixels in monochrome bitmaps. The STRETCH_DELETESCANS mode is typically used to preserve color in color bitmaps. For more information, see the SetStretchBltMode function.
Example	The following example uses the GetStretchBltMode function to determine whether the current bitmap-stretching mode is STRETCH_DELETESCANS; if so, it uses the StretchBlt function to display a compressed bitmap.
	HDC hdcMem;
	<pre>int nStretchMode;</pre>
	<pre>nStretchMode = GetStretchBltMode(hdc); if (nStretchMode == STRETCH_DELETESCANS) { StretchBlt(hdc, 50, 175, 32, 32, hdcMem, 0, 0, 64, 64,</pre>
See Also	SetStretchBltMode, StretchBlt

GetSubMenu

HMENU GetSubM HMENU hmenu; int nPos;	lenu(hmenu, nPos) /* handle of menu with pop-up menu /* position of pop-up menu	*/ */
	The GetSubMenu function retrieves the ha	undle of a pop-up menu.
Parameters	<i>hmenu</i> Identifies the menu with the pop-up men	u whose handle is to be retrieved.
	<i>nPos</i> Specifies the position in the given menu start at zero (zero-based) for the first men cannot be used in this function.	
Return Value	The return value is the handle of the given p ful. Otherwise, it is NULL, indicating that r tion.	
See Also	CreatePopupMenu, GetMenu	

GetSysColor

COLORREF GetS int nDspElement;	SysColor(nDspElement) /* display element */		
		s the current color of the specified display ele- ous parts of a window and the Windows dis- en.	
Parameters	<i>nDspElement</i> Specifies the display element whose color is to be retrieved. This parameter can be one of the following values:		
	Value	Meaning	
	COLOR_ACTIVEBORDER	Active window border.	
	COLOR_ACTIVECAPTION	Active window title.	
	COLOR_APPWORKSPACE	Background color of multiple document interface (MDI) applications.	
	COLOR_BACKGROUND	Desktop.	

2.x

Value	Meaning
COLOR_BTNFACE	Face shading on push buttons.
COLOR_BTNHIGHLIGHT	Selected button in a control.
COLOR_BTNSHADOW	Edge shading on push buttons.
COLOR_BTNTEXT	Text on push buttons.
COLOR_CAPTIONTEXT	Text in title bar, size button, scroll-bar arrow button.
COLOR_GRAYTEXT	Grayed (dimmed) text. This color is zero if the current display driver does not sup- port a solid gray color.
COLOR_HIGHLIGHT	Background of selected item in a control.
COLOR_HIGHLIGHTTEXT	Text of selected item in a control.
COLOR_INACTIVEBORDER	Inactive window border.
COLOR_INACTIVECAPTION	Inactive window title.
COLOR_INACTIVECAPTIONTEXT	Color of text in an inactive title.
COLOR_MENU	Menu background.
COLOR_MENUTEXT	Text in menus.
COLOR_SCROLLBAR	Scroll-bar gray area.
COLOR_WINDOW	Window background.
COLOR_WINDOWFRAME	Window frame.
COLOR_WINDOWTEXT	Text in windows.

Comments An application can use the **GetRValue**, **GetGValue**, and **GetBValue** macros to extract the various colors from the return value.

See Also GetSystemMetrics, SetSysColors

GetSysModalWindow

HWND GetSysModalWindow(void)

	The GetSysModalWindow function retrieves the handle of the system-modal window, if one is present.
Parameters	This function has no parameters.
Return Value	The return value is the handle of the system-modal window, if one is present. Otherwise, it is NULL.
See Also	SetSysModalWindow

GetSystemDebugState

LONG GetSystemDebugState(void)

The **GetSystemDebugState** function retrieves information about the state of the system. A Windows-based debugger can use this information to determine whether to enter hard mode or soft mode upon encountering a breakpoint.

Parameters This function has no parameters.

Return Value The return value can be one or more of the following values:

Value	Meaning
SDS_MENU	Menu is displayed.
SDS_SYSMODAL	System-modal dialog box is displayed.
SDS_NOTASKQUEUE	Application queue does not exist yet and, therefore, the ap plication cannot accept posted messages.
SDS_DIALOG	Dialog box is displayed.
SDS_TASKLOCKED	Current task is locked and, therefore, no other task is per- mitted to run.

2.x

3.1

GetSystemDir

#include <ver.h>

	ir(lpszWinDir, lpszBuf, cbBuf) ir; /* address of Windows directory */ /* address of buffer for path */ /* size of buffer */	
	The GetSystemDir function retrieves the path of the Windows system directory. This directory contains such files as Windows libraries, drivers, and fonts.	
	GetSystemDir is used by MS-DOS applications that set up Windows applica- tions; it exists only in the static-link version of the File Installation library. Win- dows applications should use the GetSystemDirectory function to determine the Windows directory.	
Parameters	<i>lpszWinDir</i> Points to the Windows directory retrieved by a previous call to the Get-WindowsDir function.	
	<i>lpszBuf</i> Points to the buffer that is to receive the null-terminated string containing the path.	
	<i>cbBuf</i> Specifies the size, in bytes, of the buffer pointed to by the <i>lpszBuf</i> parameter.	
Return Value	The return value is the length of the string copied to the buffer, in bytes, including the terminating null character, if the function is successful. If the return value is greater than the <i>cbBuf</i> parameter, the return value is the size of the buffer required to hold the path. The return value is zero if the function fails.	
Comments	An application must call the GetWindowsDir function before calling the Get- SystemDir function to obtain the correct <i>lpszWinDir</i> value.	
	The path that this function retrieves does not end with a backslash unless the Win- dows system directory is the root directory. For example, if the system directory is named WINDOWS\SYSTEM on drive C, the path of the system directory re- trieved by this function is C:\WINDOWS\SYSTEM.	
See Also	GetSystemDirectory, GetWindowsDir	

3.1

3.0

GetSystemDirectory

UINT GetSystemDi LPSTR lpszSysPath; UINT cbSysPath;	rectory(lpszSysPath, cbSysPath) /* address of buffer for system directory */ /* size of directory buffer */	
	The GetSystemDirectory function retrieves the path of the Windows system directory. The system directory contains such files as Windows libraries, drivers, and font files.	
Parameters	<i>lpszSysPath</i> Points to the buffer that is to receive the null-terminated string containing the path of the system directory.	
	<i>cbSysPath</i> Specifies the maximum size, in bytes, of the buffer. This value should be set to at least 144 to allow sufficient room in the buffer for the path.	
Return Value	The return value is the length, in bytes, of the string copied to the <i>lpszSysPath</i> parameter, not including the terminating null character. If the return value is greater than the size specified in the <i>cbSysPath</i> parameter, the return value is the size of the buffer required to hold the path. The return value is zero if the function fails.	
Comments	Applications should <i>not</i> create files in the system directory. If the user is running a shared version of Windows, the application will not have write access to the system directory. Applications should create files only in the directory returned by the GetWindowsDirectory function.	
	The path that this function retrieves does not end with a backslash unless the sys- tem directory is the root directory. For example, if the system directory is named WINDOWS\SYSTEM on drive C, the path of the system directory retrieved by this function is C:\WINDOWS\SYSTEM.	
	A similar function, GetSystemDir , is intended for use by MS-DOS applications that set up Windows applications. Windows applications should use GetSystem-Directory , not GetSystemDir .	
Example	The following example uses the GetSystemDirectory function to determine the path of the Windows system directory:	
	WORD wReturn; char szBuf[144];	
	<pre>wReturn = GetSystemDirectory((LPSTR) szBuf, sizeof(szBuf));</pre>	

:¶-

```
if (wReturn == 0)
    MessageBox(hwnd, "function failed",
        "GetSystemDirectory", MB_ICONEXCLAMATION);
else if (wReturn > sizeof(szBuf))
    MessageBox(hwnd, "buffer is too small",
        "GetSystemDirectory", MB_ICONEXCLAMATION);
else
    MessageBox(hwnd, szBuf, "GetSystemDirectory", MB_OK);
```

See Also GetWindowsDirectory

GetSystemMenu

HMENU GetSystemMenu(*hwnd*, *fRevert*) */ HWND hwnd: /* handle of window to own the System menu **BOOL** *fRevert*; */ /* reset flag The **GetSystemMenu** function allows the application to access the System menu for copying and modification. **Parameters** hwnd Identifies the window that will own a copy of the System menu. fRevert Specifies the action to be taken. If this parameter is FALSE, the GetSystem-**Menu** function returns a handle of a copy of the System menu currently in use. This copy is initially identical to the System menu, but can be modified. If the parameter is TRUE, GetSystemMenu resets the System menu back to the Windows default state. The previous System menu, if any, is destroyed. The return value is undefined in this case. **Return Value** The return value is the handle of a copy of the System menu, if the *fRevert* parameter is FALSE. If *fRevert* is TRUE, the return value is undefined. Comments Any window that does not use the **GetSystemMenu** function to make its own copy of the System menu receives the standard System menu. The handle that **GetSystemMenu** returns can be used with the **AppendMenu**, **InsertMenu**, or **ModifyMenu** function to change the System menu. The System menu initially contains items identified by various identifier values such as SC_CLOSE, SC_MOVE, and SC_SIZE. Menu items on the System menu send

WM_SYSCOMMAND messages. All predefined System-menu items have

	identifier numbers greater than 0xF000. If an application adds commands to the System menu, it should use identifier numbers less than 0xF000.	
	Windows automatically grays (dims) items on the standard System menu, depend- ing on the situation. The application can carry out its own checking or graying by responding to the WM_INITMENU message, which is sent before any menu is displayed.	
Example	The following example appends the About item to the System menu:	
	HMENU hmenu;	
	hmenu = GetSystemMenu(hwnd, FALSE); AppendMenu(hmenu, MF_SEPARATOR, 0, (LPSTR) NULL); AppendMenu(hmenu, MF_STRING, IDM_ABOUT, "About");	
See Also	AppendMenu, InsertMenu, ModifyMenu	

GetSystemMetrics

int GetSystemMetrics(<i>nIndex</i>)			
int nIndex;	/* system measurement to retrieve	*/	

The **GetSystemMetrics** function retrieves the system metrics. The system metrics are the widths and heights of the various elements displayed by Windows. **Get-SystemMetrics** can also return flags that indicate whether the current version of the Windows operating system is a debugging version, whether a mouse is present, or whether the meanings of the left and right mouse buttons have been exchanged.

Parameters

nIndex

Specifies the system measurement to be retrieved. All measurements are given in pixels. The system measurement must be one of the following values:

Value	Meaning
SM_CXBORDER	Width of window frame that cannot be sized.
SM_CYBORDER	Height of window frame that cannot be sized.
SM_CYCAPTION	Height of window title. This is the title height plus the height of the window frame that cannot be sized (SM_CYBORDER).
SM_CXCURSOR	Width of cursor.
SM_CYCURSOR	Height of cursor.

Value	Meaning
SM_CXDOUBLECLK	Width of the rectangle around the location of the first click in a double-click sequence. The second click must occur within this rectangle for the system to consider the two clicks a double-click.
SM_CYDOUBLECLK	Height of the rectangle around the location of the first click in a double-click sequence. The second click must occur within this rectangle for the system to consider the two clicks a double-click.
SM_CXDLGFRAME	Width of frame when window has the WS_DLGFRAME style.
SM_CYDLGFRAME	Height of frame when window has the WS_DLGFRAME style.
SM_CXFRAME	Width of window frame that can be sized.
SM_CYFRAME	Height of window frame that can be sized.
SM_CXFULLSCREEN	Width of window client area for a full-screen window.
SM_CYFULLSCREEN	Height of window client area for a full-screen window (equivalent to the height of the screen minus the height of the window title).
SM_CXICON	Width of icon.
SM_CYICON	Height of icon.
SM_CXICONSPACING	Width of rectangles the system uses to posi- tion tiled icons.
SM_CYICONSPACING	Height of rectangles the system uses to posi- tion tiled icons.
SM_CYKANJIWINDOW	Height of Kanji window.
SM_CYMENU	Height of single-line menu bar. This is the menu height minus the height of the window frame that cannot be sized (SM_CYBORDER).
SM_CXMIN	Minimum width of window.
SM_CYMIN	Minimum height of window.
SM_CXMINTRACK	Minimum tracking width of window.
SM_CYMINTRACK	Minimum tracking height of window.
SM_CXSCREEN	Width of screen.
SM_CYSCREEN	Height of screen.
SM_CXHSCROLL	Width of arrow bitmap on a horizontal scroll bar.
SM_CYHSCROLL	Height of arrow bitmap on a horizontal scroll bar.

3.0

	Value	Meaning
	SM_CXVSCROLL	Width of arrow bitmap on a vertical scroll bar.
	SM_CYVSCROLL	Height of arrow bitmap on a vertical scroll bar.
	SM_CXSIZE	Width of bitmaps contained in the title bar.
	SM_CYSIZE	Height of bitmaps contained in the title bar.
	SM_CXHTHUMB	Width of scroll box (thumb) on horizontal scroll bar.
	SM_CYVTHUMB	Height of scroll box on vertical scroll bar.
	SM_DBCSENABLED	Nonzero if current version of Windows uses double-byte characters; otherwise, this value returns zero.
	SM_DEBUG	Nonzero if the Windows version is a debug- ging version.
	SM_MENUDROPALIGNMENT	Alignment of pop-up menus. If this value is zero, the left side of a pop-up menu is aligned with the left side of the corresponding menu- bar item. If this value is nonzero, the left side of a pop-up menu is aligned with the right side of the corresponding menu-bar item.
	SM_MOUSEPRESENT	Nonzero if the mouse hardware is installed.
	SM_PENWINDOWS	Handle of the Pen Windows dynamic-link library (DLL) if Pen Windows is installed.
	SM_SWAPBUTTON	Nonzero if the left and right mouse buttons are swapped.
Return Value	The return value specifies the reque	ested system metric if the function is successful.
Comments	System metrics depend on the type of screen and may vary from screen to screen.	

Comments System metrics depend on the type of screen and may vary from screen to screen.

See Also GetSysColor, SystemParametersInfo

GetSystemPaletteEntries

UINT GetSystemPaletteEntries (<i>hdc</i> , <i>iStart</i> , <i>cEntries</i> , <i>lppe</i>)			
HDC hdc;	/* handle of device context	*/	
UINT iStart;	/* first palette entry to retrieve	*/	
UINT cEntries;	/* number of entries to retrieve	*/	
PALETTEENTRY FAR* lppe;	/* address of structure for palette entries	*/	

The **GetSystemPaletteEntries** function retrieves a range of palette entries from the system palette.

Parameters	<i>hdc</i> Identifies the device context. <i>iStart</i>	
	Specifies the first system-palette entry to be retrieved.	
	<i>cEntries</i> Specifies the number of system-palette entries to be retrieved.	
	<i>lppe</i> Points to an array of PALETTEENTRY structures that receives the palette entries. The array must contain at least as many structures as specified by the <i>cEntries</i> parameter. The PALETTEENTRY structure has the following form:	
	<pre>typedef struct tagPALETTEENTRY { /* pe */ BYTE peRed; BYTE peGreen; BYTE peBlue; BYTE peFlags; } PALETTEENTRY;</pre>	
	For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.	
Return Value	The return value is the number of entries retrieved from the system palette, if the function is successful. Otherwise, it is zero.	
Example	The following example uses the GetDeviceCaps function to determine whether the specified device is palette-based. If the device supports palettes, the Get- SystemPaletteEntries function is called, using GetDeviceCaps again, this time to determine the number of entries in the system palette.	
	PALETTEENTRY pe[MAXNUMBER];	
	<pre>hdc = GetDC(hwnd); if (!(GetDeviceCaps(hdc, RASTERCAPS) & RC_PALETTE)) { ReleaseDC(hwnd, hdc); break; }</pre>	
	<pre>GetSystemPaletteEntries(hdc, 0, GetDeviceCaps(hdc, SIZEPALETTE),</pre>	
See Also	GetDeviceCaps, GetPaletteEntries	

GetSystemPaletteUse

UINT GetSystemPaletteUse(*hdc*) */ HDC hdc: /* handle of device context The GetSystemPaletteUse function determines whether an application has access to the entire system palette. **Parameters** hdc Identifies the device context. This device context must support color palettes. **Return Value** The return value specifies the current use of the system palette, if the function is successful. This parameter can be one of the following values: Value Meaning SYSPAL NOSTATIC System palette contains no static colors except black and white. SYSPAL STATIC System palette contains static colors that do not change when an application realizes its logical palette. Comments The system palette contains 20 default static colors that are not changed when an application realizes its logical palette. An application can gain access to most of these colors by calling the SetSystemPaletteUse function. Example The following example uses the **GetDeviceCaps** function to determine whether the specified device is palette-based. If the device supports palettes, the Get-SystemPaletteUse function is called. WORD nUse; hdc = GetDC(hwnd):if ((GetDeviceCaps(hdc, RASTERCAPS) & RC PALETTE) == 0) { ReleaseDC(hwnd, hdc); break: } nUse = GetSystemPaletteUse(hdc); ReleaseDC(hwnd, hdc); See Also GetDeviceCaps, SetSystemPaletteUse

GetTabbedTextExtent

DWORD GetTabbe HDC hdc; LPCSTR lpszString int cChars; int cTabs; int FAR* lpnTabs;	edTextExtent(hdc, lpszString, cChars, cTabs, lpnTabs) /* handle of device context */ ; /* address of string */ /* number of characters in string */ /* number of tab positions */ /* address of array of tab positions */	
	The GetTabbedTextExtent function computes the width and height of a character string. If the string contains one or more tab characters, the width of the string is based upon the specified tab stops. GetTabbedTextExtent uses the currently selected font to compute the dimensions of the string.	
Parameters	<i>hdc</i> Identifies the device context.	
	<i>lpszString</i> Points to a character string.	
	<i>cChars</i> Specifies the number of characters in the text string.	
	<i>cTabs</i> Specifies the number of tab-stop positions in the array pointed to by the <i>lpnTabs</i> parameter.	
	<i>lpnTabs</i> Points to an array containing the tab-stop positions, in device units. The tab stops must be sorted in increasing order; the smallest x-value should be the first item in the array.	
Return Value	The low-order word of the return value contains the string width, in logical units, if the function is successful; the high-order word contains the string height.	
Comments	The current clipping region does not affect the width and height returned by the GetTabbedTextExtent function.	
	Since some devices do not place characters in regular cell arrays (that is, they kern the characters), the sum of the extents of the characters in a string may not be equal to the extent of the string.	

3.0

	If the <i>cTabs</i> parameter is zero and the <i>lpn</i> panded to eight times the average charact separated by the distance specified by the points.	er width. If <i>cTabs</i> is 1, the tab stops are
Example	The following example uses the LOWOI width and height of the string from the va tent function:	
	LPSTR lpszTabbedText = "Column 1\tCo int aTabs[2] = { 150, 300 }; DWORD dwTabExtent; WORD wStringWidth, wStringHeight;	lumn 2\tTest of TabbedTextOut";
	<pre>dwTabExtent = GetTabbedTextExtent(hd lpszTabbedText, lstrlen(lpszTabbedText), sizeof(aTabs) / sizeof(int), aTabs);</pre>	<pre>/* address of text */ /* number of characters */</pre>
	wStringWidth = LOWORD(dwTabExtent); wStringHeight = HIWORD(dwTabExtent);

GetTextExtent, TabbedTextOut

GetTempDrive

BYTE GetTempDrive(chDriveLetter) char chDriveLetter; /* ignored */		
	The GetTempDrive function returns a letter that specifies a disk drive the applica- tion can use for temporary files.	
Parameters	chDriveLetter This parameter is ignored.	
Return Value	The return value specifies a disk drive for temporary files if the function is successful. If at least one hard disk drive is available, the function returns the letter of the first hard disk drive (usually C). If no hard disk drives are available, the function returns the letter of the current drive.	

Example The following example uses the **GetTempDrive** function to determine a suitable disk drive for temporary files:

char szMsg[80]; BYTE bTempDrive; bTempDrive = GetTempDrive(0); sprintf(szMsg, "temporary drive: %c", bTempDrive); MessageBox(hwnd, szMsg, "GetTempDrive", MB_OK);

See Also GetTempFileName

GetTempFileName

int GetTempFileName(bDriveLetter, lpszPrefixString, uUnique, lpszTempFileName)BYTE bDriveLetter;/* suggested driveLPCSTR lpszPrefixString;/* address of filename prefixUINT uUnique;/* number to use as prefixLPSTR lpszTempFileName;/* address of buffer for created filename

The **GetTempFileName** function creates a temporary filename of the following form:

drive:\path\prefixuuuu.TMP

The following list describes the filename syntax:

Element	Description
drive	Drive letter specified by the bDriveLetter parameter
path	Path of the temporary file (either the Windows directory or the directory specified in the TEMP environment variable)
prefix	All the letters (up to the first three) of the string pointed to by the <i>lpszPrefixString</i> parameter
ииии	Hexadecimal value of the number specified by the <i>uUnique</i> parameter

Parameters

bDriveLetter

Specifies the suggested drive for the temporary filename. If this parameter is zero, Windows uses the current default drive.

lpszPrefixString

Points to a null-terminated string to be used as the temporary filename prefix. This string must consist of characters in the OEM-defined character set.

	 <i>uUnique</i> Specifies an unsigned short integer. If this parameter is nonzero, it will be appended to the temporary filename. If the parameter is zero, Windows uses the current system time to create a number to append to the filename. <i>lpszTempFileName</i> Points to the buffer that will receive the temporary filename. This string consists of characters in the OEM-defined character set. This buffer should be at least 144 bytes in length to allow sufficient room for the path.
Return Value	The return value specifies a unique numeric value used in the temporary filename. If the <i>uUnique</i> parameter is nonzero, the return value specifies this same number.
Comments	Temporary files created with this function are <i>not</i> automatically deleted when Windows shuts down.
	To avoid problems resulting from converting an OEM character string to a Win- dows string, an application should call the _lopen function to create the temporary file.
	The GetTempFileName function uses the suggested drive letter for creating the temporary filename, except in the following cases:
	• If a hard disk is present, GetTempFileName always uses the drive letter of the first hard disk.
	• If, however, a TEMP environment variable is defined and its value begins with a drive letter, that drive letter is used.
	If the TF_FORCEDRIVE bit of the <i>bDriveLetter</i> parameter is set, the preceding exceptions do not apply. The temporary filename will always be created in the current directory of the drive specified by <i>bDriveLetter</i> , regardless of the presence of a hard disk or the TEMP environment variable.
	If the <i>uUnique</i> parameter is zero, GetTempFileName attempts to form a unique number based on the current system time. If a file with the resulting filename exists, the number is increased by one and the test for existence is repeated. This continues until a unique filename is found; GetTempFileName then creates a file by that name and closes it. No attempt is made to create and open the file when <i>uUnique</i> is nonzero.
Example	The following example uses the GetTempFileName function to create a unique temporary filename on the first available hard disk:
	HFILE hfTempFile; char szBuf[144];

```
/* Create a temporary file. */
GetTempFileName(0, "tst", 0, szBuf);
hfTempFile = _lcreat(szBuf, 0);
if (hfTempFile == HFILE_ERROR) {
    ErrorHandler();
}
```

GetTempDrive, _lopen

GetTextAlign

UINT GetTextAlign(*hdc*) HDC *hdc*; /* handle of device context */

The **GetTextAlign** function retrieves the status of the text-alignment flags for the given device context.

ParametershdcIdentifies the device context.

Return Value The return value specifies the status of the text-alignment flags. This parameter can be one or more of the following values:

Value	Meaning
TA_BASELINE	Specifies alignment of the x-axis and the base line of the chosen font within the bounding rectangle.
TA_BOTTOM	Specifies alignment of the x-axis and the bottom of the bound- ing rectangle.
TA_CENTER	Specifies alignment of the y-axis and the center of the bound- ing rectangle.
TA_LEFT	Specifies alignment of the y-axis and the left side of the bounding rectangle.
TA_NOUPDATECP	Specifies that the current position is not updated.
TA_RIGHT	Specifies alignment of the y-axis and the right side of the bounding rectangle.
TA_TOP	Specifies alignment of the x-axis and the top of the bounding rectangle.
TA_UPDATECP	Specifies that the current position is updated.

Comments	The text-alignment flags retrieved by the GetTextAlign function are used by the TextOut and ExtTextOut functions. These flags determine how TextOut and ExtTextOut align a string of text in relation to the string's starting point.
	The text-alignment flags are not necessarily single-bit flags and may be equal to zero. To test whether a flag is set, an application should follow three steps:
	1. Apply the bitwise OR operator to the flag and its related flags.
	Following are the groups of related flags:
	 TA_LEFT, TA_CENTER, and TA_RIGHT
	 TA_BASELINE, TA_BOTTOM, and TA_TOP
	 TA_NOUPDATECP and TA_UPDATECP
	2. Apply the bitwise AND operator to the result and the return value of the GetTextAlign function.
	3. Test for the equality of this result and the flag.
Example	The following example uses the method described in the preceding Comments section to determine whether text is aligned at the right, left, or center of the bounding rectangle. If the TA_RIGHT flag is set, the SetTextAlign function is used to set the text alignment to the left side of the rectangle.
	<pre>switch ((TA_LEFT TA_CENTER TA_RIGHT) & GetTextAlign(hdc)) { case TA_RIGHT: TextOut(hdc, 200, 100, "This is TA_RIGHT.", 17); SetTextAlign(hdc, TA_LEFT); TextOut(hdc, 200, 120, "This is TA_LEFT.", 16); break; case TA_LEFT: . case TA_CENTER: . . .</pre>

See Also

ExtTextOut, SetTextAlign, TextOut

GetTextCharacterExtra

int GetTextCharacterExtra(*hdc*)

HDC hdc; /* handle of device context */

The **GetTextCharacterExtra** function retrieves the current setting for the amount of intercharacter spacing. Graphics device interface (GDI) adds this spacing to each character, including break characters, when it writes a line of text to the device context.

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the amount of intercharacter spacing if the function is successful.
Comments	The default value for the amount of intercharacter spacing is zero.
See Also	SetTextCharacterExtra

GetTextColor

COLORREF HDC hdc;	GetTextColor(<i>hdc</i>) /* handle of device context */
	The GetTextColor function retrieves the current text color. The text color is the foreground color of characters drawn by using the graphics device interface (GDI) text-output functions.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the current text color as a red, green, blue (RGB) color value, if the function is successful.
Example	The following example sets the text color to red if the GetTextColor function determines that the current text color is black:

2.x

DWORD dwColor; dwColor = GetTextColor(hdc); if (dwColor == RGB(0, 0, 0)) /* if current color is black */ SetTextColor(hdc, RGB(255, 0, 0)); /* sets color to red */

See Also

GetBkColor, GetBkMode, SetBkMode, SetTextColor

GetTextExtent

DWORD GetTextExtent(*hdc*, *lpszString*, *cbString*) HDC hdc: */ /* handle of device context LPCSTR lpszString: /* address of string */ int cbString: /* number of bytes in string */ The GetTextExtent function computes the width and height of a line of text, using the current font to compute the dimensions. **Parameters** hdc Identifies the device context. *lpszString* Points to a character string. cbString Specifies the number of bytes in the string. **Return Value** The low-order word of the return value contains the string width, in logical units, if the function is successful; the high-order word contains the string height. Comments The current clipping region does not affect the width and height returned by the GetTextExtent function. Since some devices do not place characters in regular cell arrays (that is, they kern characters), the sum of the extents of the characters in a string may not be equal to the extent of the string. Example The following example retrieves the number of characters in a string by using the Istrlen function, calls the GetTextExtent function to retrieve the dimensions of the string, and then uses the LOWORD macro to determine the string width, in logical units:

```
DWORD dwExtent;
WORD wTextWidth;
LPSTR lpszJustified = "Text to be justified in this test.";
dwExtent = GetTextExtent(hdc, lpszJustified, lstrlen(lpszJustified));
wTextWidth = LOWORD(dwExtent);
```

```
See Also
```

GetTabbedTextExtent, SetTextJustification

GetTextExtentPoint

BOOL GetTextExtentPoint(hdc, lpszString, cbString, lpSize)HDC hdc;/* handle of device context*/LPCSTR lpszString;/* address of text string*/int cbString;/* number of bytes in string*/SIZE FAR* lpSize;/* address if structure for string size*/

The **GetTextExtentPoint** function computes the width and height of the specified text string. The **GetTextExtentPoint** function uses the currently selected font to compute the dimensions of the string. The width and height, in logical units, are computed without considering any clipping.

3.1

The **GetTextExtentPoint** function may be used as either a wide-character function (where text arguments must use Unicode) or an ANSI function (where text arguments must use characters from the Windows 3.x character set).

Parameters

hdc

Identifies the device context.

lpszString

Points to a text string.

cbString

Specifies the number of bytes in the text string.

lpSize

Points to a **SIZE** structure that will receive the dimensions of the string The **SIZE** structure has the following form:

```
typedef struct tagSIZE {
    int cx;
    int cy;
} SIZE;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

2.x

Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Because some devices do not place characters in regular cell arrays—that is, be- cause they carry out kerning—the sum of the extents of the characters in a string may not be equal to the extent of the string.
	The calculated width takes into account the intercharacter spacing set by the SetTextCharacterExtra function.
See Also	SetTextCharacterExtra

GetTextFace

	c, cbBuffer, lpszFace)
HDC hdc;	/* handle of device context */
int cbBuffer;	/* size of buffer for face name */
LPSTR lpszFace;	/* pointer to buffer for face name */
	The GetTextFace function copies the typeface name of the current font into a buffer. The typeface name is copied as a null-terminated string.
Parameters	<i>hdc</i> Identifies the device context.
	<i>cbBuffer</i> Specifies the buffer size, in bytes. If the typeface name is longer than the number of bytes specified by this parameter, the name is truncated.
	<i>lpszFace</i> Points to the buffer for the typeface name.
Return Value	The return value specifies the number of bytes copied to the buffer, not including the terminating null character, if the function is successful. Otherwise, it is zero.
Example	The following example uses the GetTextFace function to retrieve the name of the current typeface, calls the SetTextAlign function so that the current position is updated when the TextOut function is called, and then writes some introductory text and the name of the typeface by calling TextOut :
	<pre>int nFaceNameLen; char aFaceName[80];</pre>

sizeof(aFaceName),	<pre>ice(hdc, /* returns length of string /* size of face-name buffer /* address of face-name buffer</pre>
SatTaxtAlian(bda	
SetTextAlign(hdc,	
TA_UPDATECP);	<pre>/* updates current position</pre>
MoveTo(hdc, 100, 100);	<pre>/* sets current position</pre>
TextOut(hdc, 0, 0,	<pre>/* uses current position for text</pre>
"This is the current	face name: ", 31);
	Name, nFaceNameLen);

See Also GetTextMetrics, SetTextAlign, TextOut

GetTextMetrics

2.x

BOOL GetTextMetrics(hdc, lptn	n)	
HDC hdc;	/* handle of device context	*/
TEXTMETRIC FAR* <i>lptm</i> ;	/* pointer to structure for font metrics	*/

The GetTextMetrics function retrieves the metrics for the current font.

Parameters

....

Identifies the device context.

lptm

hdc

Points to the **TEXTMETRIC** structure that receives the metrics. The **TEXT-METRIC** structure has the following form:

```
typedef struct tagTEXTMETRIC { /* tm */
   int tmHeight;
   int
        tmAscent;
   int
        tmDescent;
        tmInternalLeading;
   int
   int tmExternalLeading;
   int tmAveCharWidth;
   int
        tmMaxCharWidth;
        tmWeight;
   int
   BYTE tmItalic;
   BYTE tmUnderlined;
   BYTE tmStruckOut;
   BYTE tmFirstChar;
   BYTE tmLastChar;
   BYTE tmDefaultChar;
   BYTE tmBreakChar;
   BYTE tmPitchAndFamily:
   BYTE tmCharSet;
```

	<pre>int tmOverhang; int tmDigitizedAspectX; int tmDigitizedAspectY; } TEXTMETRIC; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.</pre>
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Example	The following example calls the GetTextMetrics function and then uses informa- tion in a TEXTMETRIC structure to determine how many break characters are in a string of text:
	TEXTMETRIC tm; int j, cBreakChars, cchString; LPSTR lpszJustified = "Text to be justified in this test.";
	<pre>GetTextMetrics(hdc, &tm);</pre>
	<pre>cchString = lstrlen(lpszJustified);</pre>
	<pre>for (cBreakChars = 0, j = 0; j < cchString; j++) if(*(lpszJustified + j) == (char) tm.tmBreakChar) cBreakChars++;</pre>

GetTextAlign, GetTextExtent, GetTextFace, SetTextJustification

GetThresholdEvent

2.x

int FAR* GetThresholdEvent(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

GetThresholdStatus

int GetThresholdStatus(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

GetTickCount

DWORD GetTickCount(void)

The **GetTickCount** function retrieves the number of milliseconds that have elapsed since Windows was started.

- **Parameters** This function has no parameters.
- **Return Value** The return value specifies the number of milliseconds that have elapsed since Windows was started.
- **Comments** The internal timer will wrap around to zero if Windows is run continuously for approximately 49 days.

The **GetTickCount** function is identical to the **GetCurrentTime** function. Applications should use **GetTickCount**, because its name matches more closely with what the function does.

Example The following example calls **GetTickCount** to determine the number of milliseconds that Windows has been running, converts the value into seconds, and displays the value in a message box:

char szBuf[255];

sprintf(szBuf, "Windows has been running for %lu seconds\n", GetTickCount() / 1000L); MessageBox(hwnd, szBuf, "", MB_OK);

GetTimerResolution

DWORD GetTimerResolution(void)

The **GetTimerResolution** function retrieves the number of microseconds per timer tick.

Parameters This function has no parameters.

Return Value The return value is the number of microseconds per timer tick.

See Also GetTickCount, SetTimer

GetTopWindow

HWND GetTopy HWND hwnd;	Window(hwnd)/* handle of parent window*/
	The GetTopWindow function retrieves the handle of the top-level child window that belongs to the given parent window. If the parent window has no child windows, this function returns NULL.
Parameters	<i>hwnd</i> Identifies the parent window. If this parameter is NULL, the function returns the first child window of the desktop window.
Return Value	The return value is the handle of the top-level child window in a parent window's linked list of child windows. The return value is NULL if no child windows exist.
See Also	EnumWindows, GetParent, IsChild

GetUpdateRect

BOOL GetUpdateRe	ect(hwnd, lprc, fErase)	
HWND hwnd;	/* handle of window	*/
RECT FAR* <i>lprc</i> ;	/* address of structure for update rectangle	*/
BOOL fErase;	/* erase flag	*/

3.1

2.x

The **GetUpdateRect** function retrieves the coordinates of the smallest rectangle that completely encloses the update region of the given window. If the window was created with the CS_OWNDC style and the mapping mode is not MM_TEXT, **GetUpdateRect** gives the rectangle in logical coordinates; otherwise, **GetUpdateRect** gives the rectangle in client coordinates. If there is no update region, **GetUpdateRect** makes the rectangle empty (sets all coordinates to zero).

Parameters

hwnd

Identifies the window whose update region is to be retrieved.

lprc

Points to the **RECT** structure that receives the client coordinates of the enclosing rectangle. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

An application can set this parameter to NULL to determine whether an update region exists for the window. If this parameter is NULL, the **GetUpdateRect** function returns nonzero if an update region exists, and zero if one does not. This provides a simple and efficient means of determining whether a WM_PAINT message resulted from an invalid area.

fErase

Specifies whether to erase the background in the update region. If this parameter is TRUE and the update region is not empty, the background is erased. To erase the background, the **GetUpdateRect** function sends a WM_ERASEBKGND message to the given window.

Return Value The return value is nonzero if the update region is not empty. Otherwise, it is zero.

Comments The update rectangle retrieved by the **BeginPaint** function is identical to that retrieved by the **GetUpdateRect** function.

BeginPaint automatically validates the update region, so any call to **Get-UpdateRect** made immediately after the call to **BeginPaint** retrieves an empty update region.

See Also BeginPaint, GetUpdateRgn, InvalidateRect, UpdateWindow, ValidateRect

GetUpdateRgn

int GetUpdateRgr HWND hwnd; HRGN hrgn; BOOL fErase;	(hwnd, hrgn, fErase)/* handle of window*//* handle of region*//* erase flag*/
	The GetUpdateRgn function retrieves the update region of a window. The coordinates of the update region are relative to the upper-left corner of the window (that is, they are client coordinates).
Parameters	 hwnd Identifies the window whose update region is to be retrieved. hrgn Identifies the update region. <i>fErase</i> Specifies whether the window background should be erased and whether non- client areas of child windows should be drawn. If this parameter is FALSE, no drawing is done.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.
Comments	The BeginPaint function automatically validates the update region, so any call to the GetUpdateRgn function made immediately after the call to BeginPaint retrieves an empty update region.
See Also	BeginPaint, GetUpdateRect, InvalidateRgn, UpdateWindow, ValidateRgn

GetVersion

2.x

DWORD GetVersion(void)

The GetVersion function retrieves the current version numbers of the Windows
and MS-DOS operation systems.ParametersThis function has no parameters.Return ValueThe return value specifies the major and minor version numbers of Windows and
of MS-DOS, if the function is successful.

Comments	The low-order word of the return value contains the version of Windows, if the function is successful. The high-order byte contains the minor version (revision) number as a two-digit decimal number. For example, in Windows 3.1, the minor version number is 10. The low-order byte contains the major version number.
	The high-order word contains the version of MS-DOS, if the function is successful. The high-order byte contains the major version; the low-order byte contains the minor version (revision) number.
Example	The following example uses the GetVersion function to display the Windows and MS-DOS version numbers:
	int len; char szBuf[80]; DWORD dwVersion;
	<pre>dwVersion = GetVersion();</pre>
	<pre>len = sprintf(szBuf, "Windows version %d.%d\n", LOBYTE(LOWORD(dwVersion)), HIBYTE(LOWORD(dwVersion)));</pre>
	<pre>sprintf(szBuf + len, "MS-DOS version %d.%d", HIBYTE(HIWORD(dwVersion)), LOBYTE(HIWORD(dwVersion)));</pre>
	<pre>MessageBox(NULL, szBuf, "GetVersion", MB_ICONINFORMATION);</pre>
	Note that the major and minor version information is reversed between the Win- dows version and MS-DOS version.

GetViewportExt

DWORD GetViewportExt(*hdc*)

HDC hdc; /* handle of device context */

The **GetViewportExt** function retrieves the x- and y-extents of the device context's viewport.

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The low-order word of the return value contains the x-extent, in device units, if the function is successful; the high-order word contains the y-extent.

Example The following example uses the **GetViewportExt** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-extents for a device context:

HDC hdc; DWORD dw; int xViewExt, yViewExt; hdc = GetDC(hwnd); dw = GetViewportExt(hdc); ReleaseDC(hwnd, hdc); xViewExt = LOWORD(dw); yViewExt = HIWORD(dw);

See Also

SetViewportExt

GetViewportExtEx

BOOL GetViewportExtEx(*hdc*, *lpSize*) **HDC** *hdc*; **SIZE FAR*** *lpSize*;

The **GetViewportExtEx** function retrieves the x- and y-extents of the device context's viewport.

Parameters	<i>hdc</i> Identifies the device context.
	<i>lpSize</i> Points to a SIZE structure. The x- and y-extents (in device units) are placed in this structure.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

GetViewportOrg

DWORD GetViewportOrg(*hdc*)

HDC hdc; /* handle of device context */

The **GetViewportOrg** function retrieves the x- and y-coordinates of the origin of the viewport associated with the given device context.

2.x

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The low-order word of the return value contains the viewport origin's x-coordi- nate, in device coordinates, if the function is successful; the high-order word con- tains the y-coordinate of the viewport origin.
Example	The following example uses the GetViewportOrg function and the LOWORD and HIWORD macros to retrieve the x- and y-coordinates of the viewport origin:
	HDC hdc; DWORD dw; int xViewOrg, yViewOrg;
	<pre>hdc = GetDC(hwnd); dw = GetViewportOrg(hdc); ReleaseDC(hwnd, hdc); xViewOrg = LOWORD(dw); yViewOrg = HIWORD(dw);</pre>
See Also	GetWindowOrg, SetViewportOrg

GetViewportOrgEx

BOOL GetViewportOrgEx(hdc, lpPoint)
HDC hdc;
POINT FAR* lpPoint;
The GetViewportOrgEx function retrieves the x- and y-coordinates of the origin of the viewport associated with the specified device context.
Parameters
hdc

Identifies the device context.
lpPoint
Points to a POINT structure. The origin of the viewport (in device coordinates) is placed in this structure.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

GetWinDebugInfo

BOOL GetWinDel WINDEBUGINFO UINT flags;		s of WINDEBUGINFO structure */ or returned information */	
		unction retrieves current system-debugging information of the Windows 3.1 operating system.	
Parameters	<i>lpwdi</i> Points to a WINDEBUGINFO structure that is filled with debugging informa- tion. The WINDEBUGINFO structure has the following form:		
	<pre>typedef struct tagWINDEBUGINF0 { UINT flags; DWORD dwOptions; DWORD dwFilter; char achAllocModule[8]; DWORD dwAllocBreak; DWORD dwAllocCount; } WINDEBUGINF0; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>		
	<i>flags</i> Specifies which members of the WINDEBUGINFO structure should be filled in. This parameter can be one or more of the following values:		
	Value	Meaning	
	WDI_OPTIONS WDI_FILTER WDI_ALLOCBREAK	Fill in the dwOptions member of WINDEBUGINFO . Fill in the dwFilter member of WINDEBUGINFO . Fill in the achAllocModule , dwAllocBreak , and dwAllocCount members of WINDEBUGINFO .	
Return Value	The return value is nonzero if the function is successful. It is zero if the pointer specified in the <i>lpwdi</i> parameter is invalid or if the function is not called in the debugging version of Windows 3.1.		
Comments	The flags member of the returned WINDEBUGINFO structure is set to the values supplied in the <i>flags</i> parameter of this function.		
See Also	SetWinDebugInfo		

GetWindow

HWND GetWind HWND hwnd; UINT fuRel;	dow (<i>hwnd</i> , <i>fuRel</i>) /* handle of original wind /* relationship flag	low */ */	
	relationship to the gives level windows, their as	ion retrieves the handle of a window that has the specified n window. The function searches the system's list of top- sociated child windows, the child windows of any child ngs of the owner of a window.	
Parameters	<i>hwnd</i> Identifies the origina	al window.	
	<i>fuRel</i> Specifies the relationship between the original window and the returned window. This parameter can be one of the following values:		
	Value	Meaning	
	GW_CHILD	Identifies the window's first child window.	
	GW_HWNDFIRST	Returns the first sibling window for a child window; other- wise, it returns the first top-level window in the list.	
	GW_HWNDLAST	Returns the last sibling window for a child window; other- wise, it returns the last top-level window in the list.	
	GW_HWNDNEXT	Returns the sibling window that follows the given window in the list.	
	GW_HWNDPREV	Returns the previous sibling window in the list.	
	GW_OWNER	Identifies the window's owner.	
Return Value		The return value is the handle of the window if the function is successful. Otherwise, it is NULL, indicating either the end of the system's list or an invalid <i>fuRel</i> parameter.	
See Also	EnumWindows, Find	Window	

GetWindowDC

2.x

2.x

HDC GetWindowDC(hwnd)

HWND hwnd; /* handle of window */

The **GetWindowDC** function retrieves a device context for the entire window, including title bar, menus, and scroll bars. A window device context permits

2.x

See Also	BeginPaint, GetDC, GetSystemMetrics, ReleaseDC
	After painting is complete, the ReleaseDC function must be called to release the device context. Failure to release a window device context will have serious effects on painting requested by applications.
	The GetSystemMetrics function can be used to retrieve the dimensions of various parts of the nonclient area, such as the title bar, menu, and scroll bars.
Comments	The GetWindowDC function is intended to be used for special painting effects within a window's nonclient area. Painting in nonclient areas of any window is not recommended.
Return Value	The return value is the handle of the device context for the given window, if the function is successful. Otherwise, it is NULL, indicating an error or an invalid <i>hwnd</i> parameter.
Parameters	<i>hwnd</i> Identifies the window whose device context is to be retrieved.
	GetWindowDC assigns default attributes to the device context each time it re- trieves the context. Previous attributes are lost.
	painting anywhere in the window, because the origin of the context is the upper- left corner of the window instead of the client area.

GetWindowExt

DWORD GetWindowExt(*hdc*)

HDC *hdc*; /* handle of device context */

The **GetWindowExt** function retrieves the x- and y-extents of the window associated with the given device context.

Parameters	<i>hdc</i> Identifies the device context.
Return Value	The return value specifies the x- and y-extents, in logical units, if the function is successful. The x-extent is in the low-order word; the y-extent is in the high-order word.

Example The following example uses the **GetWindowExt** function and the **LOWORD** and **HIWORD** macros to retrieve the x- and y-extents of a window:

HDC hdc; DWORD dw; int xWindExt, yWindExt; hdc = GetDC(hwnd); dw = GetWindowExt(hdc); ReleaseDC(hwnd, hdc); xWindExt = LOWORD(dw); yWindExt = HIWORD(dw);

See Also SetWindowExt

GetWindowExtEx

BOOL GetWindowExtEx(*hdc*, *lpSize*) **HDC** *hdc*; **SIZE FAR*** *lpSize*;

The **GetWindowExtEx** function retrieves the x- and y-extents of the window associated with the specified device context.

 Parameters
 hdc

 Identifies the device context.
 Identifies the device context.

 lpSize
 Points to a SIZE structure. The x- and y-extents (in logical units) are placed in this structure.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

GetWindowLong

LONG GetWindowLong(hwnd, nOffset)

HWND hwnd;	/* handle of window	*/
int nOffset;	/* offset of value to retrieve	*/

The **GetWindowLong** function retrieves a long value at the specified offset into the extra window memory of the given window. Extra window memory is re-

3.1

served by specifying a nonzero value in the **cbWndExtra** member of the **WNDCLASS** structure used with the **RegisterClass** function.

Parameters

Identifies the window.

nOffset

hwnd

Specifies the zero-based byte offset of the value to be retrieved. Valid values are in the range zero through the number of bytes of extra window memory, minus four (for example, if 12 or more bytes of extra memory was specified, a value of 8 would be an index to the third long integer), or one of the following values:

Value	Meaning
GWL_EXSTYLE	Extended window style
GWL_STYLE	Window style
GWL_WNDPROC	Long pointer to the window procedure

The following values are also available when the *hwnd* parameter identifies a dialog box:

	Value	Meaning
	DWL_DLGPROC	Specifies the address of the dialog box procedure.
	DWL_MSGRESULT	Specifies the return value of a message processed in the dialog box procedure.
	DWL_USER	Specifies extra information that is private to the applica- tion, such as handles or pointers.
Return Value	The return value specifies information about the given window if the function is successful.	
Comments	To access any extra 4-byte values allocated when the window-class structure was created, use a positive byte offset as the index specified by the <i>nOffset</i> parameter, starting at 0 for the first 4-byte value in the extra space, 4 for the next 4-byte value, and so on.	
See Also	GetWindowWord, SetWindowLong, SetWindowWord	

GetWindowOrg

DWORD Ge HDC hdc;	tWindowOrg(hdc) /* handle of device context */
	The GetWindowOrg function retrieves the x- and y-coordinates of the origin of the window associated with the given device context.
Parameters	<i>hdc</i> Identifies the device context.
Return Value	The low-order word of the return value contains the logical x-coordinate of the window's origin, if the function is successful; the high-order word contains the y-coordinate.
Example	The following example uses the GetWindowOrg function and the LOWORD and HIWORD macros to retrieve the x- and y-coordinates for the window origin:
	HDC hdc; DWORD dw; int xWindOrg, yWindOrg;
	<pre>hdc = GetDC(hwnd); dw = GetWindowOrg(hdc); ReleaseDC(hwnd, hdc); xWindOrg = LOWORD(dw); yWindOrg = HIWORD(dw);</pre>
See Also	GetViewportOrg, SetWindowOrg

GetWindowOrgEx

BOOL GetWindowOrgEx(hdc, lpPoint) HDC hdc; POINT FAR* lpPoint;

hdc

This function retrieves the x- and y-coordinates of the origin of the window associated with the specified device context.

Parameters

Identifies the device context.

3.1

lpPoint Points to a **POINT** structure. The origin of the window (in logical coordinates) is placed in this structure.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

GetWindowPlacement

HWND hwnd;	vPlacement(hwnd, lpwndpl) /* handle of window */ CMENT FAR* lpwndpl; /* address of structure for position data */
	The GetWindowPlacement function retrieves the show state and the normal (restored), minimized, and maximized positions of a window.
Parameters	hwnd Identifies the window.
	<i>lpwndpl</i> Points to the WINDOWPLACEMENT structure that receives the show state and position information. The WINDOWPLACEMENT structure has the fol- lowing form:
	<pre>typedef struct tagWINDOWPLACEMENT { /* wndpl */ UINT length; UINT flags; UINT showCmd; POINT ptMinPosition; POINT ptMaxPosition; RECT rcNormalPosition; } WINDOWPLACEMENT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
See Also	SetWindowPlacement

GetWindowRect

void GetWindowRe	ct(hwnd, lprc)	
HWND hwnd;	/* handle of window	*/
RECT FAR* <i>lprc</i> ;	/* address of structure for window coordinates	*/
	The GetWindowRect function retrieves the dimension of a given window. The dimensions are given in screen upper-left corner of the display screen, and include the bars, if present.	n coordinates, relative to the
Parameters	<i>hwnd</i> Identifies the window.	
	<i>lprc</i> Points to a RECT structure that receives the screen left and lower-right corners of the window. The RE ing form:	
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>	
	For a full description of this structure, see the Micro mer's Reference, Volume 3.	osoft Windows Program-
Return Value	This function does not return a value.	
Example	The following example calls the GetWindowRect fun sions of the desktop window, and uses the dimensions the right third of the desktop window:	
	RECT rc; WORD wWidth;	
	<pre>GetWindowRect(GetDesktopWindow(), &rc);</pre>	
	/* Set the width to be 1/3 of the desktop window	w's width. */
	wWidth = (rc.right - rc.left) / 3;

GetWindowsDir

#include -	<ver.h></ver.h>
------------	-----------------

	Dir(lpszAppDir, lpszPath, cbPath) ir; /* address of Windows directory */ /* address of buffer for path */ /* size of buffer for path */
	The GetWindowsDir function retrieves the path of the Windows directory. This directory contains such files as Windows applications, initialization files, and help files.
	GetWindowsDir is used by MS-DOS applications that set up Windows applica- tions; it exists only in the static-link version of the File Installation library. Win- dows applications should use the GetWindowsDirectory function to determine the Windows directory.
Parameters	<i>lpszAppDir</i> Specifies the current directory in a search for Windows files. If the Windows directory is not on the path, the application must prompt the user for its location and pass that string to the GetWindowsDir function in the <i>lpszAppDir</i> parameter.
	<i>lpszPath</i> Points to the buffer that will receive the null-terminated string containing the path.
	<i>cbPath</i> Specifies the size, in bytes, of the buffer pointed to by the <i>lpszPath</i> parameter.
Return Value	The return value is the length of the string copied to the <i>lpszPath</i> parameter, including the terminating null character, if the function is successful. If the return

value is greater than the *cbPath* parameter, it is the size of the buffer required to hold the path. The return value is zero if the function fails.

Comments The path that this function retrieves does not end with a backslash unless the Windows directory is the root directory. For example, if the Windows directory is named WINDOWS on drive C, the path retrieved by this function is C:\WINDOWS. If Windows is installed in the root directory of drive C, the path retrieved is C:\.

After the **GetWindowsDir** function locates the Windows directory, it caches the location for use by subsequent calls to the function.

See Also GetSystemDir, GetWindowsDirectory

GetWindowsDirectory

UINT GetWindowsl LPSTR lpszSysPath; UINT cbSysPath;	Directory(<i>lpszSysPath</i> , <i>cbSysPath</i>) ; /* address of buffer for Windows directory */ /* size of directory buffer */
	The GetWindowsDirectory function retrieves the path of the Windows directory. The Windows directory contains such files as Windows applications, initialization files, and help files.
Parameters	<i>lpszSysPath</i> Points to the buffer that will receive the null-terminated string containing the path.
	<i>cbSysPath</i> Specifies the maximum size, in bytes, of the buffer. This value should be set to at least 144 to allow sufficient room in the buffer for the path.
Return Value	The return value is the length, in bytes, of the string copied to the <i>lpszSysPath</i> parameter, not including the terminating null character. If the return value is greater than the number specified in the <i>cbSysPath</i> parameter, it is the size of the buffer required to hold the path. The return value is zero if the function fails.
Comments	The Windows directory is the <i>only</i> directory where an application should create files. If the user is running a shared version of Windows, the Windows directory is the only directory guaranteed private to the user.
	The path this function retrieves does not end with a backslash unless the Windows directory is the root directory. For example, if the Windows directory is named

2.x

	WINDOWS on drive C, the path retrieved by this function is C:\WINDOWS. If Windows is installed in the root directory of drive C, the path retrieved is C:\.
	A similar function, GetWindowsDir , is intended for use by MS-DOS applications that set up Windows applications. Windows applications should use Get-WindowsDirectory , not GetWindowsDir .
Example	The following example uses the GetWindowsDirectory function to determine the path of the Windows directory:
	WORD wReturn; char szBuf[144];
	<pre>wReturn = GetWindowsDirectory((LPSTR)szBuf, sizeof(szBuf));</pre>
	<pre>if (wReturn == 0) MessageBox(hwnd, "function failed", "GetWindowsDirectory", MB_ICONEXCLAMATION);</pre>
	else if (wReturn > sizeof(szBuf)) MessageBox(hwnd, "buffer is too small", "GetWindowsDirectory", MB_ICONEXCLAMATION);
	else MessageBox(hwnd, szBuf, "GetWindowsDirectory", MB_OK);
See Also	GetSystemDirectory

GetWindowTask

HTASK GetWindowTask(hwnd)

HWND *hwnd*; /* handle of window */

The **GetWindowTask** function searches for the handle of a task associated with a window. A task is any program that executes as an independent unit. All applications are executed as tasks. Each instance of an application is a task.

Parameters	<i>hwnd</i> Identifies the window for which to retrieve a task handle.
Return Value	The return value is the handle of the task associated with a particular window, if the function is successful. Otherwise, it is NULL.
See Also	EnumTaskWindows, GetCurrentTask

GetWindowText

int GetWindow]	ext (<i>hwnd</i> , <i>lpsz</i> , <i>cbMax</i>)
	/* handle of window */
LPSTR lpsz;	/* address of buffer for text */
int cbMax;	/* maximum number of bytes to copy */
	The GetWindowText function copies text of the given window's title bar (if it has one) into a buffer. If the given window is a control, the text within the control is copied.
Parameters	hwnd
	Identifies the window or control containing the title bar or text.
	<i>lpsz</i> Points to a buffer that will receive the title bar or text.
	<i>cbMax</i> Specifies the maximum number of characters to copy to the buffer. The title bar or text is truncated if it is longer than the number of characters specified in <i>cbMax</i> .
Return Value	The return value specifies the length, in bytes, of the copied string, not including the terminating null character. It is zero if the window has no title bar, the title bar is empty, or the <i>hwnd</i> parameter is invalid.
Comments	This function causes a WM_GETTEXT message to be sent to the given window or control.
See Also	GetWindowTextLength

GetWindowTextLength

2.x

2.x

int GetWindowTextLength(hwnd)
HWND hwnd; /* handle of window with text */

The **GetWindowTextLength** function retrieves the length, in bytes, of the text in the given window's title bar. If the window is a control, the length of the text within the control is retrieved.

Parameters

hwnd

Identifies the window or control.

Return Value	The return value specifies the text length, in bytes, not including any null terminat- ing character, if the function is successful. Otherwise, it is zero.
Comments	This function causes the WM_GETTEXTLENGTH message to be sent to the given window or control.
See Also	GetWindowText

GetWindowWord

WORD GetWine HWND hwnd; int nOffset;	lowWord(<i>hwnd</i> , <i>nOffset</i>) /* handle of window /* offset of value to retrieve	*/ */
	the extra window memory o served by specifying a nonz	ction retrieves a word value at the specified offset into f the given window. Extra window memory is re- ero value in the cbWndExtra member of the l with the RegisterClass function.
Parameters	<i>hwnd</i> Identifies the window.	
	are in the range zero thro minus two (for example,	byte offset of the value to be retrieved. Valid values ugh the number of bytes of extra window memory, if 10 or more bytes of extra memory was specified, a dex to the fifth integer), or one of the following values:
	Value	Meaning
	Value GWW_HINSTANCE	Meaning Specifies the instance handle of the module that owns the window.
		Specifies the instance handle of the module that owns
	GWW_HINSTANCE	Specifies the instance handle of the module that owns the window. Specifies the handle of the parent window, if any. The SetParent function changes the parent window of a child window. An application should not call the SetWindowWord function to change the parent of a
Return Value	GWW_HINSTANCE GWW_HWNDPARENT GWW_ID	Specifies the instance handle of the module that owns the window. Specifies the handle of the parent window, if any. The SetParent function changes the parent window of a child window. An application should not call the SetWindowWord function to change the parent of a child window.

parameter, starting at 0 for the first two-byte value in the extra space, 2 for the next two-byte value, and so on.

GetWindowLong, SetParent, SetWindowLong, SetWindowWord

GetWinFlags

3.0

DWORD GetWinFlags(void)

The **GetWinFlags** function retrieves the current Windows system and memory configuration.

Parameters This function has no parameters.

Return Value The return value specifies the current system and memory configuration if the function is successful.

Comments The configuration returned by **GetWinFlags** can be a combination of the following values:

Value	Meaning
WF_80x87	System contains an Intel math coprocessor.
WF_CPU086	System CPU is an 8086. Windows 3.1 will not return this flag.
WF_CPU186	System CPU is an 80186. Windows 3.1 will not return this flag.
WF_CPU286	System CPU is an 80286.
WF_CPU386	System CPU is an 80386.
WF_CPU486	System CPU is an i486.
WF_ENHANCED	Windows is running in 386-enhanced mode. The WF_PMODE flag is always set when WF_ENHANCED is set.
WF_PAGING	Windows is running on a system with paged memory.
WF_PMODE	Windows is running in protected mode. In Windows 3.1, this flag is always set.
WF_STANDARD	Windows is running in standard mode. The WF_PMODE flag is always set when WF_STANDARD is set.
WF_WIN286	Same as WF_STANDARD.
WF_WIN386	Same as WF_ENHANCED.
WF_WLO	Identifies an application running Windows-emulation libraries in a non-Windows operating system.

```
Example The following example uses the GetWinFlags function to display information about the current Windows system configuration:
```

```
int len:
char szBuf[80];
DWORD dwFlags;
dwFlags = GetWinFlags();
len = sprintf(szBuf, "system %s a coprocessor",
    (dwFlags & WF_80x87) ? "contains" : "does not contain");
TextOut(hdc, 10, 15, szBuf, len);
len = sprintf(szBuf, "processor is an %s",
    (dwFlags & WF_CPU286) ? "80286" :
    (dwFlags & WF_CPU386) ? "80386" :
    (dwFlags & WF_CPU486) ? "i486" : "unknown");
TextOut(hdc, 10, 30, szBuf, len);
len = sprintf(szBuf, "running in %s mode",
    (dwFlags & WF_ENHANCED) ? "enhanced" : "standard");
TextOut(hdc, 10, 45, szBuf, len);
len = sprintf(szBuf, "%s WLO",
    (dwFlags & WF_WLO) ? "using" : "not using");
TextOut(hdc, 10, 60, szBuf, len);
```

GetWinMem32Version

#include <winmem32.h>

WORD GetWinMem32Version(void)

	The GetWinMem32Version function retrieves the application programming inter- face (API) version implemented by the WINMEM32.DLL dynamic-link library. This is not the version number of the library itself.
Parameters	This function has no parameters.
Return Value	The return value specifies the version of the 32-bit memory API implemented by WINMEM32.DLL. The high-order 8 bits contain the major version number, and the low-order 8 bits contain the minor version number.

Global16PointerAlloc

#include <winmem32.h>

WORD Global16PG WORD wSelector; DWORD dwOffset; LPDWORD lpBuffe DWORD dwSize; WORD wFlags;	DinterAlloc(wSelector, dwOffset, lpBuffer, dwSize, wFlags) /* selector of object */ /* offset of first byte for alias */ /* address of location for alias */ /* size of region */ /* reserved, must be zero */
	The Global16PointerAlloc function converts a 16:32 pointer into a 16:16 pointer alias that the application can pass to a Windows function or to other 16:16 functions.
Parameters	<i>wSelector</i> Specifies the selector of the object for which an alias is to be created. This must be the selector returned by a previous call to the Global32Alloc function.
	<i>dwOffset</i> Specifies the offset of the first byte for which an alias is to be created. The offset is from the first byte of the object specified by the <i>wSelector</i> parameter. Note that <i>wSelector:dwOffset</i> forms a 16:32 address of the first byte of the region for which an alias is to be created.
	<i>lpBuffer</i> Points to a four-byte location in memory that receives the 16:16 pointer alias for the specified region.
	<i>dwSize</i> Specifies the addressable size, in bytes, of the region for which an alias is to be created. This value must be no larger than 64K.
	<i>wFlags</i> Reserved; must be zero.
Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func
Comments	When this function returns successfully, the location pointed to by the <i>lpBuffer</i> parameter contains a 16:16 pointer to the first byte of the region. This is the same byte to which <i>wSelector:dwOffset</i> points.

3.0

The returned selector identifies a descriptor for a data segment that has the following attributes: read-write, expand up, and small (B bit clear). The descriptor privilege level (DPL) and the granularity (the G bit) are set at the system's discretion, so you should make no assumptions regarding their settings. The DPL and requestor privilege level (RPL) are appropriate for a Windows application.

Note An application must not change the setting of any bits in the DPL or the RPL selector. Doing so can result in a system crash and will prevent the application from running on compatible platforms.

Because of tiling schemes implemented by some systems, the offset portion of the returned 16:16 pointer is not necessarily zero.

When writing your application, you should not assume the size limit of the returned selector. Instead, assume that at least dwSize bytes can be addressed starting at the 16:16 pointer created by this function.

See Also Global16PointerFree

Global16PointerFree

#include <winmem32.h>

WORD Global16P	ointerFree(wSelector, dwAlias	, wFlags)
WORD wSelector;	/* selector of object	*/
DWORD <i>dwAlias</i> ;	/* pointer alias to free	*/
WORD wFlags;	/* reserved, must be zero	*/
	The Global16PointerFree fur created by a call to the Globa	nction frees the 16:16 pointer alias previously I16PointerAlloc function.
Parameters		e object for which the alias is to be freed. This must a previous call to the Global32Alloc function.
		r alias to be freed. This must be the alias (including d by a previous call to the Global16PointerAlloc
	<i>wFlags</i> Reserved; must be zero.	

Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func
Comments	An application should free a 16:16 pointer alias as soon as it is no longer needed. Freeing the alias releases space in the descriptor table, a limited system resource.
See Also	Global16PointerAlloc

Global32Alloc

#include <winmem32.h>

DWORD dwSize;	loc(dwSize, lpSelector, dwMaxSize, wFlags)/* size of block to allocate*/r;/* address of location for selectore;/* maximum size of object/* sharing flag*/
	The Global32Alloc function allocates a memory object to be used as a 16:32 (USE32) code or data segment and retrieves the selector portion of the 16:32 address of the memory object. The first byte of the object is at offset 0 from this selector.
Parameters	<i>dwSize</i> Specifies the initial size, in bytes, of the object to be allocated. This value must be in the range 1 through (16 megabytes – 64K).
	<i>lpSelector</i> Points to a 2-byte location in memory that receives the selector portion of the 16:32 address of the allocated object.
	<i>dwMaxSize</i> Specifies the maximum size, in bytes, that the object will reach when it is reallocated by the Global32Realloc function. This value must be in the range 1 through (16 megabytes – 64 K). If the application will never reallocate this memory object, the <i>dwMaxSize</i> parameter should be set to the same value as the <i>dwSize</i> parameter.

	<i>wFlags</i> Depends on the return value of the GetWinMem32Version function. If the return value is less than 0x0101, this parameter must be zero. If the return value is greater than or equal to 0x0101, this parameter can be set to GMEM_DDESHARE (to make the object shareable). Otherwise, this parame- ter should be zero. For more information about GMEM_DDESHARE, see the description of the GlobalAlloc function.
Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func
Comments	If the Global32Alloc function fails, the value to which the <i>lpSelector</i> parameter points is zero. If the function succeeds, <i>lpSelector</i> points to the selector of the object. The valid range of offsets for the object referenced by this selector is 0 through (but not including) <i>dwSize</i> .
	In Windows 3.0 and later, the largest object that can be allocated is $0x00FF0000$ (16 megabytes – 64K). This is the limitation placed on WINMEM32.DLL by the current Windows kernel.
	The returned selector identifies a descriptor for a data segment that has the follow- ing attributes: read-write, expand-up, and big (B bit set). The descriptor privilege level (DPL) and the granularity (the G bit) are set at the system's discretion, so you should make no assumptions regarding these settings. Because the system sets the granularity, the size of the object (and the selector size limit) may be greater than the requested size by up to 4095 bytes (4K minus 1). The DPL and requestor privilege level (RPL) will be appropriate for a Windows application.
	Note An application must not change the setting of any bits in the DPL or the RPL selector. Doing so can result in a system crash and will prevent the application from running on compatible platforms.
	The allocated object is neither movable nor discardable but can be paged. An appli- cation should not page-lock a 32-bit memory object. Page-locking an object is use- ful only if the object contains code or data that is used at interrupt time, and 32-bit memory cannot be used at interrupt time.
See Also	Global32Free, Global32Realloc

Global32CodeAlias

#include <winmem32.h>

WORD Global32Co WORD wSelector; LPWORD lpAlias; WORD wFlags;	odeAlias(wSelector, lpAlias, wFlags) /* selector of object for alias */ /* address of location for alias selector */ /* reserved, must be zero */	
	The Global32CodeAlias function creates a 16:32 (USE32) code-segment alias selector for a 32-bit memory object previously created by the Global32Alloc function. This allows the application to execute code contained in the memory object.	
Parameters	<i>wSelector</i> Specifies the selector of the object for which an alias is to be created. This must be the selector returned by a previous call to the Global32Alloc function.	
	<i>lpAlias</i> Points to a 2-byte location in memory that receives the selector portion of the 16:32 code-segment alias for the specified object.	
	<i>wFlags</i> Reserved; must be zero.	
Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:	
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func	
Comments	If the function fails, the value pointed to by the <i>lpAlias</i> parameter is zero. If the function is successful, <i>lpAlias</i> points to a USE32 code-segment alias for the object specified by the <i>wSelector</i> parameter. The first byte of the object is at offset 0 from the selector returned in <i>lpAlias</i> . Valid offsets are determined by the size of the object as set by the most recent call to the Global32Alloc or Global32Realloc function.	
	The returned selector identifies a descriptor for a code segment that has the follow- ing attributes: read-execute, nonconforming, and USE32 (D bit set). The descrip- tor privilege level (DPL) and the granularity (the G bit) are set at the system's discretion, so you should make no assumptions regarding their settings. The granu- larity will be consistent with the current data selector for the object. The DPL and requestor privilege level (RPL) are appropriate for a Windows application.	

Note An application must not change the setting of any bits in the DPL or the RPL selector. Doing so can result in a system crash and will prevent the application from running on compatible platforms.

An application should not call this function more than once for an object. Depending on the system, the function might fail if an application calls it a second time for a given object without first calling the **Global32CodeAliasFree** function for the object.

Global32Free

#include <winmem32.h>

WORD Global32Fi WORD wSelector; WORD wFlags;	ree(wSelector, wFlags) /* selector of object to free */ /* reserved, must be zero */	
	The Global32Free function frees an object previously allocated by the Global32Alloc function.	
Parameters	<i>wSelector</i> Specifies the selector of the object to be freed. This must be the selector re- turned by a previous call to the Global32Alloc function.	
	<i>wFlags</i> Reserved; must be zero.	
Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:	
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func	
Comments	The Global32Alloc function frees the object itself; it also frees all aliases created for the object by the 32-bit memory application programming interface (API).	
	Note Before terminating, an application must call this function to free each object allocated by the Global32Alloc function to ensure that all aliases created for the object are freed.	
See Also	Global32Alloc, Global32Realloc	

Global32Realloc

#include <winmem32.h>

WORD Global32Res WORD wSelector; DWORD dwNewSize WORD wFlags;	alloc(wSelector, dwNewSize, wFlags) /* selector of object to reallocate /* new size of object /* reserved, must be zero
	The Global32Realloc function changes the size of a 32-bit memory object pre- viously allocated by the Global32Alloc function.
G	<i>wSelector</i> Specifies the selector of the object to be changed. This must be the selector re- turned by a previous call to the Global32Alloc function.
	<i>dwNewSize</i> Specifies the new size, in bytes, of the object. This value must be greater than zero and less than or equal to the size specified by the <i>dwMaxSize</i> parameter of the Global32Alloc function call that created the object.
	<i>wFlags</i> Reserved; must be zero.
Return Value	The return value is zero if the function is successful. Otherwise, it is an error value, which can be one of the following:
	WM32_Insufficient_Mem WM32_Insufficient_Sels WM32_Invalid_Arg WM32_Invalid_Flags WM32_Invalid_Func
Comments	If this function fails, the previous state of the object is unchanged. If the function succeeds, it updates the state of the object and the state of all aliases to the object created by the 32-bit memory application programming interface (API) functions. For this reason, an application must call the the Global32Realloc function to change the size of the object. Using other Windows functions to manipulate the object results in corrupted aliases.
	This function does not change the selector specified by the <i>wSelector</i> parameter. If this function succeeds, the new valid range of offsets for the selector is zero through (but not including) <i>dwNewSize</i> .

The system determines the appropriate granularity of the object. As a result, the size of the object (and the selector size limit) may be greater than the requested size by up to 4095 bytes (4K minus 1).

2.x

GlobalAddAtom

ATOM GlobalAddAtom(*lpszString*) LPCSTR lpszString; /* address of string to add */ The **GlobalAddAtom** function adds a string to the system atom table and returns a unique value identifying the string. **Parameters** lpszString Points to the null-terminated string to be added. The case of the first string added is preserved and returned by the **GlobalGetAtomName** function. Strings that differ only in case are considered identical. **Return Value** The return value identifies the string if the function is successful. Otherwise, it is zero. Comments If the string exists already in the system atom table, the atom for the existing string will be returned and the atom's reference count will be incremented (increased by one). The string associated with the atom will not be deleted from memory until its reference count is zero. For more information, see the description of the Global-DeleteAtom function. Global atoms are not deleted automatically when the application terminates. For every call to the **GlobalAddAtom** function, there must be a corresponding call to the GlobalDeleteAtom function. Example The following example adds the string "This is a global atom" to the system atom table: ATOM atom: char szMsg[80]; atom = GlobalAddAtom("This is a global atom"); if (atom == 0)MessageBox(hwnd, "GlobalAddAtom failed", "", MB ICONSTOP);

```
else {
    wsprintf(szMsg, "GlobalAddAtom returned %u", atom);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

AddAtom, GlobalDeleteAtom, GlobalGetAtomName

GlobalAlloc

HGLOBAL Global UINT fuAlloc; DWORD cbAlloc;	Alloc(fuAlloc, cbAlloc) /* how to allocate object /* size of object	*/ */	
	The GlobalAlloc function allocates the specified number of bytes from the global heap.		
Parameters	<i>fuAlloc</i> Specifies how to allocate memory. This parameter can be a combination of the following values:		
	Value	Meaning	
	GHND	Combines the GMEM_MOVEABLE and GMEM_ZEROINIT flags.	
	GMEM_DDESHARE	Allocates sharable memory. This flag is used for dy- namic data exchange (DDE) only. This flag is equiv- alent to GMEM_SHARE.	
	GMEM_DISCARDABLE	Allocates discardable memory. This flag can only be used with the GMEM_MOVEABLE flag.	
	GMEM_FIXED	Allocates fixed memory. The GMEM_FIXED and GMEM_MOVEABLE flags cannot be combined.	
	GMEM_LOWER	Same as GMEM_NOT_BANKED. This flag is ignored in Windows 3.1.	
	GMEM_MOVEABLE	Allocates movable memory. The GMEM_FIXED and GMEM_MOVEABLE flags cannot be combined.	
	GMEM_NOCOMPACT	Does not compact or discard memory to satisfy the al- location request.	
	GMEM_NODISCARD	Does not discard memory to satisfy the allocation re- quest.	
	GMEM_NOT_BANKED	Allocates non-banked memory (memory is not within the memory provided by expanded memory). This flag cannot be used with the GMEM_NOTIFY	

flag. This flag is ignored in Windows 3.1.

	Value	Meaning
	GMEM_NOTIFY	Calls the notification routine if the memory object is discarded.
	GMEM_SHARE	Allocates memory that can be shared with other applications. This flag is equivalent to GMEM_DDESHARE.
	GMEM_ZEROINIT	Initializes memory contents to zero.
	GPTR	Combines the GMEM_FIXED and GMEM_ZEROINIT flags.
	<i>cbAlloc</i> Specifies the number of by	rtes to be allocated.
Return Value	The return value is the handle of the newly allocated global memory object, if the function is successful. Otherwise, it is NULL.	
Comments	To convert the handle returned by the GlobalAlloc function into a pointer, an a plication should use the GlobalLock function.	
	amount allocated is greater th	it allocates at least the amount requested. If the an the amount requested, the application can use the the size of a global memory object, an application on.
		ect, an application should use the GlobalFree func- ributes of an allocated memory object, an application unction.
		at an application can allocate on an 80286 processor The largest block on an 80386 processor is 16 mega-
	If the <i>cbAlloc</i> parameter is zer memory object that is marked	ro, the GlobalAlloc function returns a handle of a l as discarded.
Example		he GlobalAlloc and GlobalLock functions to Ils the GlobalUnlock and GlobalFree functions

```
HGLOBAL hglb;
void FAR* lpvBuffer;
hglb = GlobalAlloc(GPTR, 1024);
lpvBuffer = GlobalLock(hglb);
.
.
.
.
GlobalUnlock(hglb);
GlobalFree(hglb);
```

See Also

GlobalFree, GlobalLock, GlobalNotify, GlobalReAlloc, GlobalSize, LocalAlloc

GlobalCompact

	ompact(dwMinFree) ee; /* amount of memory requested */
	The GlobalCompact function rearranges memory currently allocated to the global heap so that the specified amount of memory is free. If the function cannot free the requested amount of memory, it frees as much as possible.
Parameters	<i>dwMinFree</i> Specifies the number of contiguous free bytes desired. If this parameter is zero, the function does not discard memory, but the return value is valid.
Return Value	The return value specifies the number of bytes in the largest free global memory object in the global heap. If the <i>dwMinFree</i> parameter is zero, the return value specifies the number of bytes in the largest free object that Windows can generate if it removes all discardable objects.
Comments	If an application passes the return value to the GlobalAlloc function, the GMEM_NOCOMPACT or GMEM_NODISCARD flag should not be used. This function always rearranges movable memory objects before checking for free memory. Then it checks the memory currently allocated to the global heap for the number of contiguous free bytes specified by the <i>dwMinFree</i> parameter. If the specified amount of memory is not available, the function discards unlocked discardable objects, until the requested space is generated (if possible).
See Also	GlobalAlloc

GlobalDeleteAtom

ATOM GlobalDeleteAtom(atm)

ATOM *atm*; /* atom to delete */

The **GlobalDeleteAtom** function decrements (decreases by one) the reference count of a global atom. If the atom's reference count reaches zero, the string associated with the atom is removed from the system atom table.

- Parameters *atm* Identifies the atom to be deleted.
- **Return Value** The return value is zero if the function is successful. The return value is equal to the *atm* parameter if the function failed to decrement the reference count for the specified atom.
- **Comments** An atom's reference count specifies the number of times the string has been added to the atom table. The **GlobalAddAtom** function increments (increases by one) the reference count each time it is called with a string that already exists in the system atom table.

The only way to ensure that an atom has been deleted from the atom table is to call this function repeatedly until it fails. When the count is decremented to zero, the next **GlobalFindAtom** or **GlobalDeleteAtom** function call will fail.

Example

The following example repeatedly calls the **GlobalDeleteAtom** function to decrement the reference count for the atom until the atom is deleted and the **Global-DeleteAtom** function does not return zero:

int cRef; ATOM atom; char szMsg[80];

wsprintf(szMsg, "reference count was %d", cRef); MessageBox(hwnd, szMsg, "GlobalDeleteAtom", MB_OK);

DeleteAtom, GlobalAddAtom, GlobalFindAtom

3.0

GlobalDosAl	IOC 3.0
DWORD GlobalDo DWORD cbAlloc;	sAlloc(<i>cbAlloc</i>) /* number of bytes to allocate */
	The GlobalDosAlloc function allocates global memory that can be accessed by MS-DOS running in real mode. The memory is guaranteed to exist in the first megabyte of linear address space.
	An application should not use this function unless it is absolutely necessary, be- cause the memory pool from which the object is allocated is a scarce system re- source.
Parameters	<i>cbAlloc</i> Specifies the number of bytes to be allocated.
Return Value	The return value contains a paragraph-segment value in its high-order word and a selector in its low-order word. An application can use the paragraph-segment value to access memory in real mode and the selector to access memory in protected mode. If Windows cannot allocate a block of memory of the requested size, the return value is zero.
Comments	Memory allocated by using the GlobalDosAlloc function does not need to be locked by using the GlobalLock function.
See Also	GlobalDosFree

GlobalDosFree

UINT GlobalDosFree(uSelector) UINT uSelector; /* memory to free */

The **GlobalDosFree** function frees a global memory object previously allocated by the **GlobalDosAlloc** function.

ParametersuSelectorIdentifies the memory object to be freed.

Return Value The return value is zero if the function is successful. Otherwise, it is equal to the uSelector parameter.

See Also GlobalDosAlloc

lpge

GlobalEntryHandle

#include <toolhelp.h> **BOOL GlobalEntryHandle**(*lpge*, *hglb*) **GLOBALENTRY FAR*** *lpge*; /* address of structure for object /* handle of item **HGLOBAL** hglb; The GlobalEntryHandle function fills the specified structure with information that describes the given global memory object.

Parameters

Points to a GLOBALENTRY structure that receives information about the global memory object. The GLOBALENTRY structure has the following form:

*/

*/

3.1

#include <toolhelp.h> typedef struct tagGLOBALENTRY { /* ge */ DWORD dwSize: DWORD dwAddress: DWORD dwBlockSize; HGLOBAL hBlock; WORD wcLock; WORD wcPageLock; WORD wFlags: BOOL wHeapPresent; HGLOBAL hOwner; WORD wType; WORD wData; DWORD dwNext; DWORD dwNextAlt; } GLOBALENTRY;

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

3.1

	hglb Identifies the global memory object to be described.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero. The function fails if the $hglb$ value is an invalid handle or selector.
Comments	This function retrieves information about a global memory handle or selector. De- buggers use this function to obtain the segment number of a segment loaded from an executable file.
	Before calling the GlobalEntryHandle function, an application must initialize the GLOBALENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	GlobalEntryModule, GlobalFirst, GlobalInfo, GlobalNext

GlobalEntryModule

#include <toolhelp.h>

BOOL GlobalEntry			
GLOBALENTRY	AR* lpge; /	* address of structure for segment	*/
HMODULE hmod;		* handle of module	*/
WORD wSeg;	/	* segment to describe	*/
		ryModule function fills the specified e specified module segment.	d structure by <i>lpge</i> with infor-
Parameters	lpge		
	Points to a G ment specific following for		
	#include <to< th=""><th>oolnelp.n></th><th></th></to<>	oolnelp.n>	
	typedef stru	uct tagGLOBALENTRY { /* ge */	
	DWORD	dwSize;	
	DWORD	•	
		dwBlockSize; hBlock:	
	WORD	wcLock;	
	WORD		
	WORD	wFlags;	
	BOOL	wHeapPresent;	
	HGLOBAL	hOwner;	

	WORD wType; WORD wData; DWORD dwNext; DWORD dwNextAlt; } GLOBALENTRY;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>hmod</i> Identifies the module that owns the segment.
	<i>wSeg</i> Specifies the segment to be described in the GLOBALENTRY structure. The number of the first segment in the module is 1. Segment numbers are always contiguous, so if the last valid segment number is 10, all segment numbers 1 through 10 are also valid.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero. This function fails if the segment in the <i>wSeg</i> parameter does not exist in the module specified in the <i>hmod</i> parameter.
Comments	Debuggers can use the GlobalEntryModule function to retrieve global heap infor- mation about a specific segment loaded from an executable file. Typically, the de- bugger will have symbols that refer to segment numbers; this function translates the segment numbers to heap information.
	Before calling GlobalEntryModule , an application must initialize the GLOBALENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	GlobalEntryHandle, GlobalFirst, GlobalInfo, GlobalNext

GlobalFindAtom

2.x

ATOM GlobalFind LPCSTR lpszString	Atom(<i>lpszString</i>) ; /* address of string to find	*/
		arches the system atom table for the specified obal atom associated with that string. (A global all Windows applications.)
Parameters	lpszString	

Points to the null-terminated character string to search for.

Return Value	The return value identifies the global atom associated with the given string, if the function is successful. Otherwise, if the string is not in the table, the return value is
	zero.

Example The following example repeatedly calls the **GlobalFindAtom** function to retrieve the atom associated with the string "This is a global atom". The example uses the **GlobalDeleteAtom** function to decrement (decrease by one) the reference count for the atom until the atom is deleted and **GlobalFindAtom** returns zero.

See Also FindAtom, GlobalAddAtom, GlobalDeleteAtom

GlobalFirst

#include <toolhelp.h>

BOOL GlobalFirst GLOBALENTRY I WORD wFlags;		/* address of structure for object /* specifies the heap to use	*/ */
		irst function fills the specified struct st object on the global heap.	ure with information that de-
Parameters	lpge		

Points to a **GLOBALENTRY** structure that receives information about the global memory object. The **GLOBALENTRY** structure has the following form:

#include <toolhelp.h>
typedef struct tagGLOBALENTRY { /* ge */
 DWORD dwSize;
 DWORD dwAddress;
 DWORD dwBlockSize;
 HGLOBAL hBlock;

3.1

WORD wcLock: WORD wcPageLock; WORD wFlags: BOOL wHeapPresent; HGLOBAL hOwner: WORD wType: WORD wData: DWORD dwNext: DWORD dwNextAlt: } GLOBALENTRY;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

wFlags

Specifies the heap to use. This parameter can be one of the following values:

Value	Meaning
GLOBAL_ALL	Structure pointed to by <i>lpge</i> will receive information about the first object on the complete global heap.
GLOBAL_FREE	Structure will receive information about the first object on the free list.
GLOBAL_LRU	Structure will receive information about the first object on the least-recently-used (LRU) list.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments The **GlobalFirst** function can be used to begin a global heap walk. An application can examine subsequent objects on the global heap by using the **GlobalNext** function. Calls to **GlobalNext** must have the same *wFlags* value as that specified in **GlobalFirst**.

Before calling **GlobalFirst**, an application must initialize the **GLOBALENTRY** structure and specify its size, in bytes, in the **dwSize** member.

See Also GlobalEntryHandle, GlobalEntryModule, GlobalInfo, GlobalNext

GlobalFix

3.0

void GlobalFix(hglb)
HGLOBAL hglb;

/* handle of object to fix

The **GlobalFix** function prevents the given global memory object from moving in linear memory.

*/

2.x

See Also	GlobalFlags, GlobalReAlloc, GlobalUnfix
	Each time an application calls the GlobalFix function for a memory object, it must eventually call the GlobalUnfix function, which decrements (decreases by one) the lock count for the object. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the Global-Flags function.
Comments	The object is locked into linear memory at its current address, and its lock count is incremented (increased by one). Locked memory is not subject to moving or discarding except when the memory object is being reallocated by the Global-ReAlloc function. The object remains locked in memory until its lock count is decreased to zero.
Return Value	This function does not return a value.
Parameters	hglb Identifies the global memory object to be fixed in linear memory.
	This function interferes with effective Windows memory management and can re- sult in linear-address fragmentation. Few applications need to fix memory in linear address space.

GlobalFlags

UINT GlobalFlags(HGLOBAL hglb;	hglb) /* handle of global memory object */
	The GlobalFlags function returns information about the given global memory object.
Parameters	hglb Identifies the global memory object.
Return Value	The return value specifies the memory-allocation flag and the lock count for the memory object, if the function is successful.
Comments	When an application masks out the lock count in the low-order byte of the return value, the return value contains one of the following allocation flags:

Value	Meaning	
GMEM_DISCARDABLE	Object can be discarded.	
GMEM_DISCARDED	Object has been discarded.	

The low-order byte of the return value contains the lock count of the object. Use the GMEM_LOCKCOUNT mask to retrieve the lock count from the return value.

The following functions can affect the lock count of a global memory object:

Increments lock count	Decrements lock count	
GlobalFix	GlobalUnfix	
GlobalLock	GlobalUnlock	

2.x

See Also

GlobalFix, GlobalLock, GlobalUnfix, GlobalUnlock

GlobalFree

See Also	GlobalDiscard, GlobalFlags, GlobalLock		
	Once freed, the handle of the memory object must not be used again. Attempting to free the same memory object more than once can cause Windows to terminate abnormally.		
Comments	The GlobalFree function cannot be used to free a locked memory object—that is, a memory object with a lock count greater than zero. For a list of the functions that affect the lock count, see the description of the GlobalFlags function.		
Return Value	The return value is NULL if the function is successful. Otherwise, it is equal to the $hglb$ parameter.		
Parameters	hglb Identifies the global memory object to be freed.		
	The GlobalFree function frees the given global memory object (if the object is not locked) and invalidates its handle.		
HGLOBAL Global HGLOBAL hglb;	Free(<i>hglb</i>) /* handle of object to free */		

2.x

GlobalGetAtomName

UINT GlobalGetAt ATOM atom; LPSTR lpszBuffer; int cbBuffer;	omName(atom, lpszBuffer, cbBuffer)/* atom identifier*//* address of buffer for atom string*//* size of buffer*/	
	The GlobalGetAtomName function retrieves a copy of the character string associated with the given global atom. (A global atom is an atom that is available to all Windows applications.)	
Parameters	<i>atom</i> Identifies the global atom associated with the character string to be retrieved.	
	<i>lpszBuffer</i> Points to the buffer for the character string.	
	<i>cbBuffer</i> Specifies the size, in bytes, of the buffer.	
Return Value	The return value specifies the number of bytes copied to the buffer, not including the terminating null character, if the function is successful.	
Example	The following example uses the GlobalGetAtomName function to retrieve the character string associated with a global atom:	
	char szBuf[80];	
	<pre>GlobalGetAtomName(atGlobal, szBuf, sizeof(szBuf));</pre>	
	<pre>MessageBox(hwnd, szBuf, "GlobalGetAtomName", MB_OK);</pre>	
	Messagebox(nwhu, szbar, arobaraetxtomname, hb_ok),	

GlobalHandle

DWORD GlobalHa UINT uGlobalSel;	
	The GlobalHandle function retrieves the handle of the specified global memory object.
Parameters	<i>uGlobalSel</i> Specifies the selector of a global memory object.

Return Value The low-order word of the return value contains the handle of the global memory object, and the high-order word contains the selector of the memory object, if the function is successful. The return value is NULL if no handle exists for the memory object.

GlobalHandleToSel

#include <toolhelp.h>

WORD GlobalHandleToSel(*hglb*) **HGLOBAL** *hglb*;

The **GlobalHandleToSel** function converts the given handle to a selector.

Parameters	hglb Identifies the global memory object to be converted.
Return Value	The return value is the selector of the given object if the function is successful. Otherwise, it is zero.
Comments	The GlobalHandleToSel function converts a global handle to a selector appropriate for Windows, version 3.0 or 3.1, depending on which version is running. A debugging application might use this selector to access a global memory object if the object is not discardable or if the object's attributes are irrelevant.
See Also	GlobalAlloc

GlobalInfo

3.1

3.1

#include <toolhelp.h>

BOOL GlobalInfo(*lpgi*) **GLOBALINFO FAR*** *lpgi*;

/* address of global-heap structure */

The **GlobalInfo** function fills the specified structure with information that describes the global heap.

Parameters	<i>lpgi</i> Points to a GLOBALINFO structure that receives information about the global heap. The GLOBALINFO structure has the following form:		
	#include <toolhelp.h></toolhelp.h>		
	<pre>typedef struct tagGLOBALINFO { /* gi */ DWORD dwSize; WORD wcItems; WORD wcItemsFree; WORD wcItemsLRU; } GLOBALINFO;</pre>		
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.		
Return Value	The return value is nonzero if the function successful. Otherwise, it is zero.		
Comments	The information in the structure can be used to determine how much memory to a locate for a global heap walk.		
	Before calling the GlobalInfo function, an application must initialize the GLOBALINFO structure and specify its size, in bytes, in the dwSize member.		
See Also	GlobalEntryHandle, GlobalEntryModule, GlobalFirst, GlobalNext		

GlobalLock

void FAR* GlobalL HGLOBAL hglb;	ock(hglb) /* handle of memory object to lock */
	The GlobalLock function returns a pointer to the given global memory object. GlobalLock increments (increases by one) the lock count of movable objects and locks the memory. Locked memory will not be moved or discarded unless the memory object is reallocated by the GlobalReAlloc function. The object remains locked in memory until its lock count is decreased to zero.
Parameters	hglb Identifies the global memory object to be locked.
Return Value	The return value points to the first byte of memory in the global object, if the func- tion is successful. It is NULL if the object has been discarded or an error occurs.

Comments Each time an application calls the **GlobalLock** function for an object, it must eventually call the **GlobalUnlock** function for the object.

This function will return NULL if an application attempts to lock a memory object with a zero-byte size.

If **GlobalLock** incremented the lock count for the object, **GlobalUnlock** decrements the lock count for the object. Other functions can also affect the lock count of a memory object. For a list of these functions, see the description of the **Get-GlobalFlags** function.

Discarded objects always have a lock count of zero.

See Also GlobalFlags, GlobalReAlloc, GlobalUnlock

GlobalLRUNewest

HGLOBAL Global	
HGLOBAL hglb;	/* handle of memory object to move */
	The GlobalLRUNewest function moves a global memory object to the newest least-recently-used (LRU) position in memory. This greatly reduces the likelihood that the object will be discarded soon, but does not prevent the object from eventually being discarded.
Parameters	hglb Identifies the global memory object to be moved.
Return Value	The return value is NULL if the <i>hglb</i> parameter is not a valid handle.
Comments	The GlobalLRUNewest function is useful only if the given object is discardable.
See Also	GlobalLRUOldest

3.1

GlobalLRUOIdest 2.x		
LRUOldest(hglb) /* handle of memory object to move */		
The GlobalLRUOldest function moves a global memory object to the oldest least-recently-used (LRU) position in memory. This makes the memory object the next candidate for discarding.		
hglb Identifies the global memory object to be moved.		
The return value is NULL if the <i>hglb</i> parameter does not identify a valid handle.		
The GlobalLRUOldest function is useful only if the <i>hglb</i> object is discardable.		
GlobalLRUNewest		

GlobalNext

#include <toolhelp.h>

_ _ _ _ _

-

-

-- -

BOOL GlobalNext GLOBALENTRY I WORD flags;	
	The GlobalNext function fills the specified structure with information that describes the next object on the global heap.
Parameters	<i>lpge</i> Points to a GLOBALENTRY structure that receives information about the global memory object. The GLOBALENTRY structure has the following form:
	<pre>#include <toolhelp.h> typedef struct tagGLOBALENTRY { /* ge */ DWORD dwSize; DWORD dwAddress; DWORD dwBlockSize; HGLOBAL hBlock; WORD wcLock; WORD wcPageLock;</toolhelp.h></pre>

```
WORD wFlags;
BOOL wHeapPresent;
HGLOBAL hOwner;
WORD wType;
WORD wData;
DWORD dwNext;
DWORD dwNextAlt;
} GLOBALENTRY;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

flags

Specifies heap to use. This parameter can be one of the following values:

	Value	Meaning	
	GLOBAL_ALL	Structure pointed by the <i>lpge</i> parameter will receive informa- tion about the first object on the complete global heap.	
	GLOBAL_FREE	Structure will receive information about the first object on the free list.	
	GLOBAL_LRU	Structure will receive information about the first object on the least-recently-used (LRU) list.	
Return Value	The return value is no	onzero if the function is successful. Otherwise, it is zero.	
Comments	The GlobalNext function can be used to continue a global heap walk started by the GlobalFirst , GlobalEntryHandle , or GlobalEntryModule functions.		
	If GlobalFirst starts a heap walk, the <i>flags</i> value used in GlobalNext must be the same as the value used in GlobalFirst .		
See Also	GlobalEntryHandle	GlobalEntryHandle, GlobalEntryModule, GlobalFirst, GlobalInfo	

GlobalNotify

2.x

void GlobalNotify(lpNotifyProc)
GNOTIFYPROC lpNotifyProc;

/* instance address of callback function

*/

The **GlobalNotify** function installs a notification procedure for the current task. A notification procedure is a library-defined callback function that the system calls whenever a global memory object allocated with the GMEM_NOTIFY flag is about to be discarded.

Parameters	<i>lpNotifyProc</i> Specifies the address of the current task's notification procedure. For more information, see the description of the NotifyProc callback function.
Return Value	This function does not return a value.
Comments	An application must not call the GlobalNotify function more than once per instance.
	The system does not call the notification procedure when discarding memory that belongs to a dynamic-link library (DLL).
	If the object is discarded, the application must use the GMEM_NOTIFY flag when it calls the GlobalRealloc function to recreate the object. Otherwise, the application will not be notified when the object is discarded again.
	If the notification procedure returns a nonzero value, Windows discards the global memory object. If the procedure returns zero, the block is not discarded.
	The address of the NotifyProc callback function (specified in the <i>lpNotifyProc</i> parameter) must be in a fixed code segment of a dynamic-link library.
See Also	GlobalReAlloc, NotifyProc

GlobalPageLock

3.0

UINT GlobalPageLock(hglb)		
HGLOBAL hglb;	/* selector of global memory to lock */	
	The GlobalPageLock function increments (increases by one) the page-lock count for the memory associated with the given global selector. As long as its page-lock count is nonzero, the data that the selector references is guaranteed to remain in memory at the same physical address.	
Parameters	hglb Specifies the selector of the memory to be page-locked.	
Return Value	The return value specifies the page-lock count after the function has incremented it. If the function fails, the return value is zero.	
Comments	Because using this function violates preferred Windows programming practices, an application should not use it unless absolutely necessary. The function is	

intended to be used for dynamically allocated data that must be accessed at interrupt time. For this reason, it must be called only from a dynamic-link library (DLL).

The **GlobalPageLock** function increments the page-lock count for the block of memory, and the **GlobalPageUnlock** function decrements (decreases by one) the page-lock count. Page-locking operations can be nested, but each page-locking must be balanced by a corresponding unlocking.

3.0

See Also GlobalPageUnlock

GlobalPageUnlock

See Also	GlobalPageLock
	The GlobalPageLock function increments the page-lock count for the block of memory, and the GlobalPageUnlock function decrements the page-lock count. Page-locking operations can be nested, but each page-locking must be balanced by a corresponding unlocking.
Comments	Because using this function violates preferred Windows programming practices, an application should not use it unless absolutely necessary. The function is in- tended to be used for dynamically allocated data that must be accessed at interrupt time. For this reason, it must only be called from a dynamic-link library (DLL).
Return Value	The return value specifies the page-lock count after the function has decremented it. If the function fails, the return value is zero.
Parameters	hglb Specifies the selector of the memory to be page-unlocked.
	The GlobalPageLock function decrements (decreases by one) the page-lock count for the memory associated with the specified global selector. When the page-lock count reaches zero, the data that the selector references is no longer guaranteed to remain in memory at the same physical address.
UINT GlobalPageU HGLOBAL hglb;	Inlock(<i>hglb</i>) /* selector of global memory to unlock */

GlobalReAlloc

HGLOBAL	GlobalReAlloc (<i>hglb</i> , <i>cbNewSize</i> , <i>fuAlloc</i>)

HGLOBAL hglb;	/* handle of memory object to reallocate	*/
DWORD <i>cbNewSize</i> ;	/* new size of object	*/
UINT fuAlloc;	/* how object is reallocated	*/

The **GlobalReAlloc** function changes the size or attributes of the given global memory object.

Parameters

hglb

Identifies the global memory object to be reallocated.

cbNewSize

Specifies the new size of the memory object.

fuAlloc

Specifies how to reallocate the global object. If this parameter includes GMEM_MODIFY, the **GlobalReAlloc** function ignores the *cbNewSize* parameter.

Value	Meaning
GMEM_DISCARDABLE	Causes a previously movable object to become discardable. This flag can be used only with GMEM_MODIFY.
GMEM_MODIFY	Modifies the object's memory flags. This flag can be used with GMEM_DISCARDABLE and GMEM_MOVEABLE.
GMEM_MOVEABLE	Causes a previously movable and discardable object to be discarded, if the <i>cbNewSize</i> parameter is zero and the object's lock count is zero. If <i>cbNewSize</i> is zero and the object is not movable and discardable, this flag causes the GlobalReAlloc function to fail.
	If <i>cbNewSize</i> is nonzero and the object identified by the <i>hglb</i> parameter is fixed, this flag allows the reallocated object to be moved to a new fixed location.
	If a movable object is locked, this flag allows the object to be moved to a new locked location without invalidating the handle. This may occur even if the object is currently locked by a previous call to the GlobalLock function.
	If this flag is used with GMEM_MODIFY, the GlobalReAlloc function changes a fixed memory object to a movable memory object.
GMEM_NODISCARD	Prevents memory from being discarded to satisfy the allocation request. This flag cannot be used with GMEM_MODIFY.

	Value	Meaning	
	GMEM_ZEROINIT	Causes the additional memory to be initialized to zero if the object is growing. This flag cannot be used with GMEM_MODIFY.	
Return Value		dle of the reallocated global memory if the function is ne object cannot be reallocated as specified.	
Comments	memory. To access the men	If GlobalReAlloc reallocates a movable object, the return value is a handle to the memory. To access the memory, an application must use the GlobalLock function to convert the handle to a pointer.	
	To free a global memory ol tion.	bject, an application should use the GlobalFree func-	
	The GMEM_ZEROINIT fl in the following sequence:	ag will cause applications to fail if it is used as shown	
	hMem = GlobalAlloc(GMEM_	_ZEROINIT (<i>other flags</i>), dwSize1);	
	hMem = GlobalReAlloc(hMe	em, dwSize2, GMEM_ZEROINIT (<i>other flags</i>));	
	/* where dwSize2 > dwSiz	zel. */	
	hMem = GlobalReAlloc(hMe	em, dwSize3, GMEM_ZEROINIT (<i>other flags</i>));	
	/* where dwSize3 < dwSiz	ze2. */	
	hMem = GlobalReAlloc(hMe	em, dwSize4, GMEM_ZEROINIT (<i>other flags</i>));	
	/* GMEM_ZEROINIT fails w	when dwSize4 > dwSize3. */	
	ternal allocation boundary	ding example, the memory between dwSize3 and the in- is not set to zero. After the last step, the contents of the ior to the call to GlobalReAlloc that specified dwSize3.

GlobalAlloc, GlobalDiscard, GlobalFree, GlobalLock

2.x

3.0

GlobalSize **DWORD GlobalSize**(*hglb*) **HGLOBAL** hglb; */ /* handle of memory object to return size of The GlobalSize function retrieves the current size, in bytes, of the given global memory object. **Parameters** hglb Identifies the global memory object. **Return Value** The return value specifies the size, in bytes, of the memory object. It is zero if the specified handle is not valid or if the object has been discarded. Comments The size of a memory object is sometimes larger than the size requested at the time the memory was allocated. An application should call the GlobalFlags function prior to calling the Global-Size function, to verify that the specified memory object was not discarded. If the memory object has been discarded, the return value for GlobalSize is meaningless.

See Also GlobalAlloc, GlobalFlags

GlobalUnfix

void GlobalUnfix(/ HGLOBAL hglb;	<i>aglb</i>) /* handle of global memory to unlock */
	The GlobalUnfix function cancels the effects of the GlobalFix function and allows a global memory object to be moved in linear memory.
Parameters	hglb Identifies the global memory object to be unlocked.
Return Value	This function does not return a value.
Comments	This function interferes with effective Windows memory management and can re- sult in linear-address fragmentation. Few applications need to fix memory in linear address space.
	Each time an application calls the GlobalFix function for an object, it must eventu- ally call the GlobalUnfix function for the object.

GlobalUnfix decrements (decreases by one) the object's lock count and returns the new lock count in the CX register. The object is completely unlocked and subject to moving or discarding if the lock count is decremented to zero. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

See Also GlobalFix, GlobalFlags

GlobalUnlock

BOOL GlobalUnlo HGLOBAL hglb;	ck (<i>hglb</i>) /* handle of global memory to unlock */
	The GlobalUnlock function unlocks the given global memory object. This func- tion has no effect on fixed memory.
Parameters	<i>hglb</i> Identifies the global memory object to be unlocked.
Return Value	The return value is zero if the object's lock count was decremented (decreased by one) to zero. Otherwise, the return value is nonzero.
Comments	With movable or discardable memory, this function decrements the object's lock count. The object is completely unlocked and subject to moving or discarding if the lock count is decreased to zero.
	This function returns nonzero if the given memory object is not movable. An appli- cation should not rely on the return value to determine the number of times it must subsequently call the GlobalUnlock function for the memory object.
	Other functions can also affect the lock count of a memory object. For a list of the functions that affect the lock count, see the description of the GlobalFlags function.
	Each time an application calls GlobalLock for an object, it must eventually call the GlobalUnlock function for the object.

GrayString

BOOL GrayString (<i>hdc</i> , <i>hbr</i> , <i>gsp</i>	rc, lParam, cch, x, y, cx, cy)	
HDC hdc;	/* handle of device context	*/
HBRUSH hbr;	/* handle of brush for graying	*/
GRAYSTRINGPROC gsprc;	/* address of callback function	*/
LPARAM lParam;	/* address of application-defined data	*/
int cch;	/* number of characters to output	*/
int x;	/* horizontal position	*/
int y;	/* vertical position	*/
int cx;	/* width	*/
int cy;	/* height	*/
the text in a the display.	tring function draws gray (dim) text at the memory bitmap, graying the bitmap, and The function grays the text regardless of the ayString uses the font currently selected for	then copying the bitmap to he selected brush and back-
Parameters hdc		

Identifies the device context.

2.x

2.x

hbr

Identifies the brush to be used for graying.

gsprc

Specifies the procedure-instance address of the application-supplied callback function that will draw the string. The address must be created by the **Make-ProcInstance** function. For more information about the callback function, see the description of the **GrayStringProc** callback function.

If this parameter is NULL, the system uses the **TextOut** function to draw the string, and the *lParam* parameter is assumed to be a long pointer to the character string to be output.

lParam

Points to data to be passed to the output function. If the *gsprc* parameter is NULL, the *lParam* parameter must point to the string to be output.

cch

Specifies the number of characters to be output. If this parameter is zero, the **GrayString** function calculates the length of the string (assuming that the *lParam* parameter is a pointer to the string). If *cch* is -1 and the function pointed to by the *gsprc* parameter returns zero, the image is shown but not grayed.

х

Specifies the logical x-coordinate of the starting position of the rectangle that encloses the string.

y

Specifies the logical y-coordinate of the starting position of the rectangle that encloses the string.

cx

Specifies the width, in logical units, of the rectangle that encloses the string. If this parameter is zero, the **GrayString** function calculates the width of the area, assuming the *lParam* parameter is a pointer to the string.

су

Specifies the height, in logical units, of the rectangle that encloses the string. If this parameter is zero, the **GrayString** function calculates the height of the area, assuming the *lParam* parameter is a pointer to the string.

Return Value The return value is nonzero if the function is successful. It is zero if either the **TextOut** function or the application-supplied output function returns zero, or if there is insufficient memory to create a memory bitmap for graying.

Comments An application must select the MM_TEXT mapping mode before using this function.

If **TextOut** cannot handle the string to be output (for example, if the string is stored as a bitmap), the *gsprc* parameter must point to a callback function that will draw the string.

An application can draw grayed strings on devices that support a solid gray color without calling the **GrayString** function. The system color COLOR_GRAYTEXT is the solid-gray system color used to draw disabled text. The application can call the **GetSysColor** function to retrieve the color value of COLOR_GRAYTEXT. If the color is other than zero (black), the application can call the **SetTextColor** function to set the text color to the color value and then draw the string directly. If the retrieved color is black, the application must call **GrayString** to gray the text.

GetSysColor, MakeProcInstance, SetTextColor, TextOut

GrayStringProc

BOOL CALLBACK GrayStringProc(*hdc*, *lpData*, *cch*) HDC hdc: /* handle of device context */ */ /* address of string to be drawn LPARAM lpData; int cch: /* length of string to be drawn */ The GrayStringProc function is an application-defined callback function that draws a string as a result of a call to the GravString function. **Parameters** hdc Identifies a device context with a bitmap of at least the width and height specified by the cx and cy parameters passed to the **GrayString** function. lpData Points to the string to be drawn. cchSpecifies the length, in characters, of the string. **Return Value** The callback function should return TRUE to indicate success. Otherwise it should return FALSE. Comments The callback function must draw an image relative to the coordinates (0,0). **GrayStringProc** is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition (.DEF) file. See Also GrayString

HardwareProc

LRESULT CALLB int code; WPARAM wParam; LPARAM lParam;	ACK HardwareProc(code, wParam, lParam) /* hook code */ ; /* undefined */ /* address of structure with event information */
	The HardwareProc function is an application-defined callback function that the system calls whenever the application calls the GetMessage or PeekMessage function and there is a hardware event to process. Mouse events and keyboard events are not processed by this hook.
Parameters	<i>code</i> Specifies whether the callback function should process the message or call the CallNextHookEx function. If this value is less than zero, the callback function should pass the message to CallNextHookEx without further processing. If this value is HC_NOREMOVE, the application is using the PeekMessage function with the PM_NOREMOVE option, and the message will not be removed from the system queue.
	wParam Specifies a NULL value.
	<i>lParam</i> Points to a HARDWAREHOOKSTRUCT structure. The HARDWARE-HOOKSTRUCT structure has the following form:
	typedef struct tagHARDWAREHOOKSTRUCT { /* hhs */ HWND hWnd; UINT wMessage; WPARAM wParam; LPARAM 1Param; } HARDWAREHOOKSTRUCT;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The callback function should return zero to allow the system to process the mes- sage; it should be 1 if the message is to be discarded.
Comments	This callback function should not install a playback hook because the function can not use the GetMessageExtraInfo function to get the extra information associated with the message.
	The callback function must use the Pascal calling convention and must be declared FAR . An application must install the callback function by specifying the WH_HARDWARE filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.

3.1

HardwareProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition (.DEF) file.

See Also CallNextHookEx, GetMessageExtraInfo, SetWindowsHookEx

hardware_event

```
3.1
```

extrn hardware_event :far

mov	ax, Msg	;	message
mov	cx, ParamL	;	low-order word of lParam of the message
mov	dx, ParamH	;	high-order word of 1Param of the message
mov	si, hwnd	;	handle of the destination window
mov	di, wParam	;	wParam of the message
cCall	hardware_event		

The **hardware_event** function places a hardware-related message into the system message queue. This function allows a driver for a non-standard hardware device to place a message into the queue.

Parameters

Msg

Specifies the message to place in the system message queue.

ParamL

Specifies the low-order word of the *lParam* parameter of the message.

lParamH

Specifies the high-order word of the *lParam* parameter of the message.

hwnd

Identifies the window to which the message is directed. This parameter also becomes the low-order word of the *dwExtraInfo* parameter associated with the message. An application can determine the value of this parameter by calling the **GetMessageExtraInfo** function.

wParam

Specifies the *wParam* parameter of the message.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments An application should not use this function to place keyboard or mouse messages into the system message queue.

An application may only call the **hardware_event** function from an assembly language routine. The application must declare the function as follows:

extrn hardware_event :far

If the application includes CMACROS.INC, the application can declare the function as follows:

extrnFP hardware_event.

See Also GetMessageExtraInfo

.

void HideCaret(hwnd)
HWND hwnd;	/* handle of window with caret */
	The HideCaret function hides the caret by removing it from the screen. Although the caret is no longer visible, it can be displayed again by using the ShowCaret function. Hiding the caret does not destroy its current shape.
Parameters	<i>hwnd</i> Identifies the window that owns the caret. This parameter can be set to NULL to specify indirectly the window in the current task that owns the caret.
Return Value	This function does not return a value.
Comments	The HideCaret function hides the caret only if the given window owns the caret. If the <i>hwnd</i> parameter is NULL, the function hides the caret only if a window in the current task owns the caret.
	Hiding is cumulative. If HideCaret has been called five times in a row, Show-Caret must be called five times before the caret will be shown.
See Also	CreateCaret, ShowCaret

HiliteMenultem

BOOL HiliteMenuItem(*hwnd*, *hmenu*, *idHiliteItem*, *fuHilite*)

HWND hwnd;	/* handle of window with menu	*/
HMENU hmenu;	/* handle of menu	*/
UINT <i>idHiliteItem</i> ;	/* menu-item identifier	*/
UINT fuHilite;	/* highlight flags	*/

The **HiliteMenuItem** function highlights or removes the highlighting from a toplevel (menu-bar) menu item.

Parameters

hwnd Identifies the window that contains the menu.

hmenu

Identifies the top-level menu that contains the item to be highlighted.

idHiliteItem

Specifies the menu item to be highlighted, as determined by the *fuHilite* parameter.

fuHilite

Specifies whether the menu item is highlighted or the highlight is removed. It can be a combination of the MF_HILITE or MF_UNHILITE value with the MF_BYCOMMAND or MF_BYPOSITION value. These values have the following meanings:

	Value	Meaning	
	MF_BYCOMMAND	Menu-item identifier is specified by the <i>idHiliteItem</i> parameter (the default interpretation).	
	MF_BYPOSITION	Zero-based position of the menu item is specified by the <i>idHiliteItem</i> parameter.	
	MF_HILITE	Menu item is highlighted. If this value is not given, highlighting is removed from the menu item.	
	MF_UNHILITE	Highlighting is removed from the menu item.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	The MF_HILITE and MF_UNHILITE flags can be used only with the Hilite- MenuItem function; they cannot be used with the ModifyMenu function.

long cbBuffer;		/* size of data	*/	
		e function writes data to the specified f ects (that is, objects larger than 64K, al		
Parameters	<i>hf</i> Identifies	s the file to be written to.		
<i>hpvBuffer</i> Points to a buffer that contains the data to be written to the file.			itten to the file.	
	<i>cbBuffer</i> Specifies	the number of bytes to be written to th	e file.	
Return Value	Urn Value The return value indicates the number of bytes written to the file, if the function successful. Otherwise, the return value is $-1L$.			
Comments	MS-DOS error values are not available when an application calls this function.			
See Also hmemcpy, _hread, _lwrite				

InflateRect

<pre>void InflateRect(lpr RECT FAR* lprc; int xAmt; int yAmt;</pre>	c, xAmt, yAmt)*//* address of rectangle*//* amount to increase or decrease width*//* amount to increase or decrease height*/			
	The InflateRect function increases or decreases the width and height of a rectangle. The InflateRect function adds <i>xAmt</i> units to the left and right ends of the rectangle and adds <i>yAmt</i> units to the top and bottom. The <i>xAmt</i> and <i>yAmt</i> parameters are signed values; positive values increase the width and height, and negative values decrease them.			
Parameters	<i>lprc</i> Points to the RECT structure that increases or decreases in size. The RECT structure has the following form:			
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>			
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.			
	<i>xAmt</i> Specifies the amount to increase or decrease the rectangle width. It must be negative to decrease the width.			
	<i>yAmt</i> Specifies the amount to increase or decrease the rectangle height. It must be negative to decrease the height.			
Return Value	This function does not return a value.			
Comments	The width and height of a rectangle must not be greater than $32,767$ units or less than $-32,768$ units.			
See Also	IntersectRect, OffsetRect, UnionRect			

InitAtomTable

BOOL InitAtomTal int <i>cTableEntries</i> ;	ble(<i>cTableEntries</i>) /* size of atom table */
	The InitAtomTable function initializes the local atom hash table and sets it to the specified size.
	An application need not use this function to use a local atom table. The default size of the local and global atom hash tables is 37 table entries. If an application uses InitAtomTable , however, it should call the function before any other atommanagement function.
Parameters	<i>cTableEntries</i> Specifies the size, in table entries, of the atom hash table. This value should be a prime number.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	If an application uses a large number of local atoms, it can increase the size of the local atom table, reducing the time required to add an atom to the local atom table or to find an atom in the table. However, this increases the amount of memory required to maintain the table.
	The size of the global atom table cannot be changed from its default size of 37 entries.
Example	The following example uses the InitAtomTable function to change the size of the local atom table to 73:
	BOOL fSuccess;
	<pre>fSuccess = InitAtomTable(73);</pre>
	<pre>if (fSuccess) MessageBox(hwnd, "table initialization succeeded", "InitAtomTable", MB_OK); else</pre>
	MessageBox(hwnd, "table initialization failed", "InitAtomTable", MB_ICONEXCLAMATION);

InSendMessage

BOOL InSendMessage(void)

The **InSendMessage** function specifies whether the current window procedure is processing a message that was sent from another task by a call to the **Send-Message** function.

- **Parameters** This function has no parameters.
- **Return Value** The return value is nonzero if the window procedure is processing a message sent to it from another task by the **SendMessage** function. Otherwise, the return value is zero.
- **Comments** Applications use the **InSendMessage** function to determine how to handle errors that occur when an inactive window processes messages. For example, if the active window uses the **SendMessage** function to send a request for information to another window, the other window cannot become active until it returns control from the **SendMessage** call. The only method an inactive window has to inform the user of an error is to create a message box.

See Also PostAppMessage, SendMessage

InsertMenu

BOOL InsertMenu(h	menu, idIte	m, fuFlags,	, idNewItem,	lpNewItem)

HMENU hmenu;	/* handle of menu	*/
UINT idItem;	/* menu item that new menu item is to precede	*/
UINT fuFlags;	/* menu flags	*/
UINT idNewItem;	/* item identifier or pop-up menu handle	*/
LPCSTR lpNewItem;	/* item content	*/

The **InsertMenu** function inserts a new menu item into a menu, moving other items down the menu. The function also sets the state of the menu item.

Parameters

hmenu

Identifies the menu to be changed.

idItem

Specifies the menu item before which the new menu item is to be inserted, as determined by the *fuFlags* parameter.

3.0

fuFlags

Return Value

Comments

Specifies how the *idItem* parameter is interpreted and information about the state of the new menu item when it is added to the menu. This parameter consists of a combination of one of the following values and the values listed in the Comments section.

Value	Meaning
MF_BYCOMMAND MF_BYPOSITION	The <i>idItem</i> parameter specifies the menu-item identifier. The <i>idItem</i> parameter specifies the zero-based position of the menu item. If <i>idItem</i> is -1 , the new menu item is ap-
	pended to the end of the menu.
dNewItem	
	entifier of the new menu item or, if <i>fuFlags</i> is set to u handle of the pop-up menu.
pNewItem	f de a company item If CELLER is act to ME OTDINIC
(the default value), this	of the new menu item. If <i>fuFlags</i> is set to MF_STRING is parameter points to a null-terminated string. If <i>fuFlags</i> P instead, <i>lpNewItem</i> contains a bitmap handle in its low-
	s is set to MF_OWNERDRAW, <i>lpNewItem</i> specifies an
application-defined 32	2-bit value, which the application can use to maintain add
	with the menu item. This 32-bit value is available to the nData member of the structure pointed to by the <i>lParam</i>
parameter of the WM	_MEASUREITEM and WM_DRAWITEM messages.
These messages are se changed.	ent when the menu item is initially displayed or is
The return value is nonze	ero if the function is successful. Otherwise, it is zero.
	cument interface (MDI) child window is maximized and
	op-up menu into the MDI application's menu by calling
	ing the MF_BYPOSITION flag, the menu is inserted on expected. This occurs because the System menu of the a
ive MDI child window i	is inserted into the first position of the MDI frame win-
	id this behavior, the application must add 1 to the

position value that would otherwise be used. An application can use the WM_MDIGETACTIVE message to determine whether the currently active child window is maximized.

Whenever a menu changes (whether or not the menu is in a window that is displayed), the application should call the **DrawMenuBar** function.

Each of the following groups lists flags that should not be used together:

- MF_BYCOMMAND and MF_BYPOSITION
- MF_DISABLED, MF_ENABLED, and MF_GRAYED

- MF_BITMAP, MF_STRING, MF_OWNERDRAW, and MF_SEPARATOR
- MF_MENUBARBREAK and MF_MENUBREAK
- MF_CHECKED and MF_UNCHECKED

The following list describes the flags that may be set in the *fuFlags* parameter:

Value	Meaning
MF_BITMAP	Uses a bitmap as the item. The low-order word of the <i>lpNewItem</i> parameter contains the handle of the bitmap.
MF_BYCOMMAND	Specifies that the <i>idItem</i> parameter gives the menu-item identifier (default).
MF_BYPOSITION	Specifies that the <i>idItem</i> parameter gives the position of the menu item rather than the menu-item identifier.
MF_CHECKED	Places a check mark next to (selects) the menu item. If the application has supplied check-mark bitmaps (see the SetMenuItemBitmaps function), setting this flag dis- plays the check-mark bitmap next to the menu item.
MF_DISABLED	Disables the menu item so that it cannot be selected, but does not gray (dim) it.
MF_ENABLED	Enables the menu item so that it can be selected, and re- stores it from its grayed state.
MF_GRAYED	Disables the menu item so that it cannot be selected, and grays it.
MF_MENUBARBREAK	Same as MF_MENUBREAK except, for pop-up menus, separates the new column from the old column by using a vertical line.
MF_MENUBREAK	Places the menu item on a new line for static menu-bar items. For pop-up menus, places the menu item in a new column, with no dividing line between the columns.
MF_OWNERDRAW	Specifies that the item is an owner-drawn item. The window that owns the menu receives a WM_MEASUREITEM message (when the menu is dis- played for the first time) to retrieve the height and width of the menu item. The WM_DRAWITEM message is then sent to the owner whenever the owner must update the visual appearance of the menu item. This option is not valid for a top-level menu item.
MF_POPUP	Specifies that the menu item has a pop-up menu as- sociated with it. The <i>idNewItem</i> parameter specifies a handle of a pop-up menu to be associated with the item. Use the MF_OWNERDRAW flag to add either a top- level pop-up menu or a hierarchical pop-up menu to a pop-up menu item.

3.1

Value	Meaning
MF_SEPARATOR	Draws a horizontal dividing line. You can use this flag in a pop-up menu. This line cannot be grayed, disabled, or highlighted. Windows ignores the <i>lpNewItem</i> and <i>idNewItem</i> parameters.
MF_STRING	Specifies that the menu item is a character string; the <i>lpNewItem</i> parameter points to the string for the item.
MF_UNCHECKED	Does not place a check mark next to the item (default value). If the application has supplied check-mark bit- maps (see SetMenuItemBitmaps), setting this flag dis- plays the check-mark-off bitmap next to the menu item.

AppendMenu, CreateMenu, DrawMenuBar, RemoveMenu, SetMenuItemBitmaps

InterruptRegister

#include <toolhelp.h>

HTASK htask;	gister(htask, lpfnIntCallback) /* handle of task*/allback;/* address of callback function		
	The InterruptRegister function installs a callback function to handle all system interrupts.		
Parameters	<i>htask</i> Identifies the task that is registering the callback function. The <i>htask</i> value is for registration purposes, not for filtering interrupts. Typically, this value is NULL, indicating the current task. The only time this value is not NULL is when an application requires more than one interrupt handler.		
	<i>lpfnIntCallback</i> Points to the interrupt callback function that will handle interrupts. The Tool Helper library calls this function whenever a task receives an interrupt.		
	The <i>lpfnIntCallback</i> value is normally the return value of a call to the Make-ProcInstance function. This causes the interrupt callback function to be entered with the AX register set to the selector of the application's data segment. Usually, an exported function prolog contains the following code:		
	mov ds,ax		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		

Comments The syntax of the function pointed to by *lpfnIntCallback* is as follows:

void InterruptRegisterCallback(void)

InterruptRegisterCallback is a placeholder for the application-defined function name. The actual name must be exported by including it an **EXPORTS** in the application's module-definition file.

An interrupt callback function must be reentrant, must be page-locked, and must explicitly preserve all register values. When the Tool Helper library calls the function, the stack will be organized as shown in the following illustration.

:	
SS (fault)	SP + 12h
SP (fault)	SP + 10h
Flags (fault)	SP + OEh
CS (fault)	SP + OCh
IP (fault)	SP + OAh
Handle (internal)	SP + 08h
Interrupt number	SP + 06h
AX	SP + 04h
CS (TOOLHELP.DLL)	SP + 02h
IP (TOOLHELP.DLL)	SP + 00h

The SS and SP values will not be on the stack unless a low-stack fault occurred. This fault is indicated by the high bit of the interrupt number being set.

When Windows calls a callback function, the AX register contains the DS value for the instance of the application that contains the callback function. For more information about this process, see the **MakeProcInstance** function.

Typically, an interrupt callback function is exported. If it is not exported, the developer should verify that the appropriate stack frame is generated, including the correct DS value.

An interrupt callback function must save and restore all register values. The function must also do one of the following:

- Execute an **retf** instruction if it does not handle the interrupt. The Tool Helper library will pass the interrupt to the next appropriate handler in the interrupt handler list.
- Terminate the application by using the TerminateApp function.
- Correct the problem that caused the interrupt, clear the first 10 bytes of the stack, and execute an **iret** instruction. This action will restart execution at the specified address. An application may change this address, if necessary.
- Execute a nonlocal goto to a known position in the application by using the **Catch** and **Throw** functions. This type of interrupt handling can be hazardous; the system may be in an unstable state and another fault may occur. Applications that handle interrupts in this way must verify that the fault was a result of the application's code.

Name	Number	Meaning
INT_DIV0	0	Divide-error exception
INT_1	1	Debugger interrupt
INT_3	3	Breakpoint interrupt
INT_UDINSTR	6	Invalid-opcode exception
INT_STKFAULT	12	Stack exception
INT_GPFAULT	13	General protection violation
INT_BADPAGEFAULT	14	Page fault not caused by normal virtual- memory operation
INT_CTLALTSYS RQ	256	User pressed CTRL+ALT+SYS RQ

The Tool Helper library supports the following interrupts:

The Tool Helper library returns interrupt numbers as word values. Normal software interrupts and processor faults are represented by numbers in the range 0 through 255. Interrupts specific to Tool Helper are represented by numbers greater than 255.

Some developers may wish to use CTRL+ALT+SYS RQ (Interrupt 256) to break into the debugger. Be cautious about implementing this interrupt, because the point at which execution stops will probably be in a sensitive part of the Windows kernel. All **InterruptRegisterCallback** functions must be page-locked to prevent problems when this interrupt is used. In addition, the debugger probably will not be able to perform user-interface functions. However, the debugger can use Tool Helper functions to set breakpoints and gather information. The debugger may also be able to use a debugging terminal or secondary screen to display information.

Low-stack Faults

A low-stack fault occurs when inadequate stack space is available on the faulting application's stack. For example, if any fault occurs when there is less than 128 bytes of stack space available or if runaway recursion depletes the stack, a low-stack fault occurs. The Tool Helper library processes a low-stack fault differently than it processes other faults.

A low-stack fault is indicated by the high-order bit of the interrupt number being set. For example, if a stack fault occurs and the SP value becomes invalid, the Tool Helper library will return the fault number as 0x800C rather than 0x000C.

Interrupt handlers designed to process low-stack faults must be aware that the Tool Helper library has passed a fault frame on a stack other that the faulting application's stack. The SS:SP value is on the stack because it was pushed before the rest of the information in the stack frame. The SS:SP value is available only for advisory purposes.

An interrupt handler should never restart the faulting instruction, because this will cause the system to crash. The handler may terminate the application with **TerminateApp** or pass the fault to the next handler in the interrupt-handler list.

Interrupt handlers should not assume that all stack faults are low-stack faults. For example, if an application accesses a stack-relative variable that is out of range, a stack fault will occur. This type of fault can be processed in the same manner as any general protection (GP) fault. If the high-order bit of the interrupt number is not set, the instruction can be restarted.

Interrupt handlers also should not assume that all low-stack faults are stack faults. Any fault that occurs when there is less than 128 bytes of stack available will cause a low-stack fault.

Interrupt callback functions that are not designed to process low-stack faults should execute an **retf** instruction so that the Tool Helper library will pass the fault to the next appropriate handler in the interrupt-handler list.

3.1

See Also Catch, InterruptUnRegister, NotifyRegister, NotifyUnRegister, TerminateApp, Throw

InterruptUnRegister

#include <toolhelp.h>

BOOL InterruptUnRegister(*htask*) **HTASK** *htask*; /* handle of task

*/

2.x

	The InterruptUnRegister function restores the default interrupt handle for system interrupts.
Parameters	htask Identifies the task. If this value is NULL, it identifies the current task.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	After this function is executed, the Tool Helper library will pass all interrupts it re- ceives to the system's default interrupt handler.
See Also	InterruptRegister, NotifyRegister, NotifyUnRegister, TerminateApp

IntersectClipRect

int IntersectClipR	ect(hdc, nLeftRect, nTopRect, nRightRect, nBottomRect)
HDC hdc;	/* handle of device context */
int nLeftRect;	/* x-coordinate top-left corner of rectangle */
int nTopRect;	/* y-coordinate top-left corner of rectangle */
int nRightRect;	/* x-coordinate bottom-right corner of rectangle */
int nBottomRect;	/* y-coordinate bottom-right corner of rectangle */
	The IntersectClipRect function creates a new clipping region from the intersec- tion of the current region and a specified rectangle.
Parameters	hdc
	Identifies the device context.
	<i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left corner of the rectangle.
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the rectangle.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the rectangle.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the rectangle.
Return Value	The return value specifies that the resulting region has overlapping borders (COMPLEXREGION), is empty (NULLREGION), or has no overlapping borders (SIMPLEREGION). Otherwise, the return value is ERROR.

Comments	An application uses the IntersectClipRect function to create a clipping region from the intersection of the current region and a specified rectangle. An applica- tion can also create a clipping region that is the intersection of two regions, by specifying RGN_AND in a call to the CombineRgn function and then making this combined region the clipping region by calling the SelectClipRgn function.
	The width of the rectangle, specified by the absolute value of $nRightRect - nLeftRect$, must not exceed 32,767 units. This limit applies to the height of the rectangle as well.
Example	The following example creates a square clipping region and colors it red by using a red brush to fill the client area. The IntersectClipRect function is called with coordinates that overlap the region, and the client area is filled with a yellow brush. The only region colored yellow is the overlap between the region and the coordinates specified in the call to IntersectClipRect .
	RECT rc; HRGN hrgn; HBRUSH hbrRed, hbrYellow;
	GetClientRect(hwnd, &rc); hrgn = CreateRectRgn(10, 10, 110, 110); SelectClipRgn(hdc, hrgn); hbrRed = CreateSolidBrush(RGB(255, 0, 0)); FillRect(hdc, &rc, hbrRed);
	IntersectClipRect(hdc, 100, 100, 200, 200);
	hbrYellow = CreateSolidBrush(RGB(255, 255, 0)); FillRect(hdc, &rc, hbrYellow);
	DeleteObject(hbrRed); DeleteObject(hbrYellow); DeleteObject(hrgn);

See Also

CombineRgn, SelectClipRgn

IntersectRect

BOOL IntersectRect (<i>lprcDst</i> , <i>lprcSrc1</i> , <i>lprcSrc2</i>)			
RECT FAR* <i>lprcDst</i> ;	/* address of structure for intersection	*/	
<pre>const RECT FAR* lprcSrc1;</pre>	/* address of structure with 1st rectangle	*/	
const RECT FAR* lprcSrc2;	/* address of structure with 2nd rectangle	*/	

The **IntersectRect** function calculates the intersection of two source rectangles and places the coordinates of the intersection rectangle into the destination rectangle. If the rectangles do not intersect, an empty rectangle (0, 0, 0, 0) is placed into the destination rectangle.

Parameters	<i>lprcDst</i> Points to a RECT structure that receives the intersection of the rectangles pointed to by the <i>lprcSrc1</i> and <i>lprcSrc2</i> parameters. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lprcSrc1</i> Points to the RECT structure that contains the first source rectangle.
	<i>lprcSrc2</i> Points to the RECT structure that contains the second source rectangle.
Return Value	The return value is nonzero if the rectangles intersect. Otherwise, it is zero.
See Also	InflateRect, SubtractRect, UnionRect

2.x

void InvalidateRect(hwnd, lprc, fErase)			
HWND hwnd;	/* handle of window with changed update region	*/	
<pre>const RECT FAR* lprc;</pre>	/* address of structure with rectangle	*/	
BOOL <i>fErase</i> ;	/* erase-background flag	*/	

The **InvalidateRect** function adds a rectangle to a window's update region. The update region represents the client area of the window that must be redrawn.

Parameters

hwnd

Identifies the window whose update region has changed.

lprc

Points to a **RECT** structure that contains the client coordinates of the rectangle to be added to the update region. If the *lprc* parameter is NULL, the entire client area is added to the update region.

The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

fErase

Specifies whether the background within the update region is to be erased when the update region is processed. It this parameter is TRUE, the background is erased when the **BeginPaint** function is called. If this parameter is FALSE, the background remains unchanged.

Return Value This function does not return a value.

Comments The invalidated areas accumulate in the update region until the region is processed when the next WM_PAINT message occurs, or until the region is validated by using the **ValidateRect** or **ValidateRgn** function.

Windows sends a WM_PAINT message to a window whenever its update region is not empty and there are no other messages in the application queue for that window.

If the *fErase* parameter is TRUE for any part of the update region, the background is erased in the entire region, not just in the given part.

See Also BeginPaint, InvalidateRgn, ValidateRect, ValidateRgn

InvalidateRgn

void InvalidateRgi	n(hwnd, hrgn, fErase)	
HWND hwnd;	/* handle of window with changed update region	*/
HRGN hrgn;	/* handle of region to add	*/
BOOL <i>fErase</i> ;	/* erase-background flag	*/

	The InvalidateRgn function adds a region to a window's update region. The update region represents the client area of the window that must be redrawn.
Parameters	<i>hwnd</i> Identifies the window whose update region has changed.
	<i>hrgn</i> Identifies the region to be added to the update region. The region is assumed to have client coordinates. If this parameter is NULL, the entire client area is added to the update region.
	<i>fErase</i> Specifies whether the background within the update region is to be erased when the update region is processed. If this parameter is TRUE, the background is erased when the BeginPaint function is called. If the parameter is FALSE, the background remains unchanged.
Return Value	This function does not return a value.
Comments	The invalidated regions accumulate in the update region until the region is processed when the next WM_PAINT message occurs, or until the region is validated by using the ValidateRect or ValidateRgn function.
	Windows sends a WM_PAINT message to a window whenever its update region is not empty and there are no other messages in the application queue for that window.
	If the <i>fErase</i> parameter is TRUE for any part of the update region, the background is erased in the entire region, not just in the given part.
See Also	BeginPaint, InvalidateRect, ValidateRect, ValidateRgn

InvertRect

2.x

void InvertRect (<i>hdc</i> , <i>lprc</i>)		
HDC hdc;	/* handle of device context	*/
<pre>const RECT FAR* lprc;</pre>	/* address of structure with rectangle	*/

The **InvertRect** function inverts a rectangular area. Inversion is a logical NOT operation and flips the bits of each pixel.

Parameters

Identifies the device context.

hdc

lprc

Points to a **RECT** structure that contains the logical coordinates of the rectangle to be inverted. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Return Value This function does not return a value.

Comments On monochrome screens, the **InvertRect** function makes white pixels black and black pixels white. On color screens, the inversion depends on how colors are generated for the screen. Calling **InvertRect** twice, specifying the same rectangle, restores the display to its previous colors.

The **InvertRect** function compares the values of the **top**, **bottom**, **left**, and **right** members of the specified rectangle. If **bottom** is less than or equal to **top**, or if **right** is less than or equal to **left**, the function does not draw the rectangle.

See Also FillRect

InvertRgn

BOOL InvertRgn(hdc, hrgn)

HDC hdc;	/* handle of device context	*/
HRGN hrgn;	/* handle of region	*/

The InvertRgn function inverts the colors in a given region.

Parameters	<i>hdc</i> Identifies the device context.
	<i>hrgn</i> Identifies the region for which colors are to be inverted.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

3.1

Comments	On monochrome screens, the InvertRgn function makes white pixels black and black pixels white. On color screens, the inversion depends on how the colors are generated for the screen.
Example	The following example sets the device coordinates of and creates a rectangular re- gion, selects the region into a device context, and then calls the InvertRgn func- tion to display the region in inverted colors:
	hrgn = CreateRectRgn(10, 10, 110, 110); SelectObject(hdc, hrgn); InvertRgn(hdc, hrgn);
	<pre>DeleteObject(hrgn);</pre>
See Also	FillRgn, PaintRgn

IsBadCodePtr

BOOL IsBadCode FARPROC lpfn;	Ptr(<i>lpfn</i>) /* pointer to test */
	The IsBadCodePtr function determines whether a pointer to executable code is valid.
Parameters	<i>lpfn</i> Points to a function.
Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to ex- ecutable code). The return value is zero if the pointer is good.
See Also	IsBadHugeReadPtr, IsBadHugeWritePtr, IsBadReadPtr, IsBadStringPtr, IsBadWritePtr

IsBadHugeReadPtr

BOOL IsBadHugel const void _huge* i DWORD cb;	ReadPtr(lp, cb)lp; /* pointer to test*//* number of allocated bytes*/		
	The IsBadHugeReadPtr function determines whether a huge pointer to readable memory is valid.		
Parameters	 <i>lp</i> Points to the beginning of a block of allocated memory. The data object may reside anywhere in memory and may exceed 64K in size. <i>cb</i> 		
	Specifies the number of bytes of memory that were allocated.		
Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to read- able memory of the specified size). The return value is zero if the pointer is good.		
See Also	IsBadCodePtr, IsBadHugeWritePtr, IsBadReadPtr, IsBadStringPtr, IsBadWritePtr		

IsBadHugeWritePtr

BOOL IsBadHugeWritePtr (<i>lp</i> , <i>cb</i>)			
void _huge* <i>lp</i> ;	/* pointer to test	*/	
DWORD <i>cb</i> ;	/* number of allocated bytes	*/	

The **IsBadHugeWritePtr** function determines whether a huge pointer to writable memory is valid.

Parameters

lp

Points to the beginning of a block of allocated memory. The data object may reside anywhere in memory and may exceed 64K in size.

cb

Specifies the number of bytes of memory that were allocated.

3.1

Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to writable memory of the specified size). The return value is zero if the pointer is good.
See Also	IsBadCodePtr, IsBadHugeReadPtr, IsBadReadPtr, IsBadStringPtr, IsBadWritePtr

IsBadReadPtr

3.1

BOOL IsBadReadP const void FAR* <i>lp</i> ; UINT <i>cb</i> ;	
	The IsBadReadPtr function determines whether a pointer to readable memory is valid.
Parameters	 <i>lp</i> Points to the beginning of a block of allocated memory. <i>cb</i> Specifies the number of bytes of memory that were allocated.
Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to read- able memory of the specified size). The return value is zero if the pointer is good.
See Also	IsBadCodePtr, IsBadHugeReadPtr, IsBadHugeWritePtr, IsBadStringPtr, IsBadWritePtr

IsBadStringPtr

3.1

BOOL IsBadStringPtr (<i>lpsz</i> , <i>cchMax</i>)			
const void FAR* <i>lpsz</i> ;	/* pointer to test	*/	
UINT cchMax;	/* maximum size of string	*/	

The IsBadStringPtr function determines whether a pointer to a string is valid.

Parameters

lpsz

Points to a null-terminated string.

	<i>cchMax</i> Specifies the maximum size of the string, in bytes.
Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to a string of the specified size). The return value is zero if the pointer is good.
See Also	IsBadCodePtr, IsBadHugeReadPtr, IsBadHugeWritePtr, IsBadReadPtr, IsBadWritePtr

IsBadWritePtr

3.1

BOOL IsBadWri void FAR* <i>lp</i> ; UINT <i>cb</i> ;	tePtr(lp, cb)/* pointer to test*//* number of allocated bytes*/
	The IsBadWritePtr function determines whether a pointer to writable memory is valid.
Parameters	 <i>lp</i> Points to the beginning of a block of allocated memory. <i>cb</i> Specifies the number of bytes of memory that were allocated.
Return Value	The return value is nonzero if the pointer is bad (that is, if it does not point to wri- table memory of the specified size). The return value is zero if the pointer is good.
See Also	IsBadCodePtr, IsBadHugeReadPtr, IsBadHugeWritePtr, IsBadReadPtr, IsBadStringPtr

IsCharAlpha

BOOL IsCharAlpha(chTest) /* character to test **char** *chTest*; */

> The IsCharAlpha function determines whether a character is in the set of language-defined alphabetic characters.

3.0

3.0

Parameters	<i>chTest</i> Specifies the character to be tested.
Return Value	The return value is nonzero if the character is in the set of alphabetic characters. Otherwise, it is zero.
Comments	The language driver for the current language (the language the user selected at setup or by using Control Panel) determines whether the character is in the set. If no language has been set, Windows uses an internal function.
Example	The following example uses the IsCharAlpha function to find the first nonalphabetic character in a string:
	<pre>for (lpszNon = lpsz; IsCharAlpha(*lpszNon); lpszNon = AnsiNext(lpszNon));</pre>
See Also	IsCharAlphaNumeric

IsCharAlphaNumeric

BOOL IsChar char chTest;	•AlphaNumeric(chTest) /* character to test */
	The IsCharAlphaNumeric function determines whether a character is in the set of language-defined alphabetic or numeric characters.
Parameters	<i>chTest</i> Specifies the character to be tested.
Return Value	The return value is nonzero if the character is in either the set of alphabetic charac- ters or the set of numeric characters. Otherwise, it is zero.
Comments	The language driver for the current language (the language the user selected at setup or by using Control Panel) determines whether the character is in the set. If no language driver is selected, Windows uses an internal function.
Example	The following example uses the IsCharAlphaNumeric function to find the first nonalphanumeric character in a string:

See Also IsCharAlpha

IsCharLower

3.0

BOOL IsCharLower(chTest) char chTest; /* character to test */		
	The IsCharLower function determines whether a character is in the set of language-defined lowercase characters.	
Parameters	<i>chTest</i> Specifies the character to be tested.	
Return Value	The return value is nonzero if the character is lowercase. Otherwise, it is zero.	
Comments	The language driver for the current language (the language selected at setup or by using Control Panel) determines whether the character is in the set. If no language driver is selected, Windows uses an internal function.	
Example	The following example uses the IsCharLower function to find the first lowercase character in a string:	
	/* Look through string for a lowercase character. */	
	for (lpszLower = lpsz; !IsCharLower(*lpszLower) && lpszLower != '\0'; lpszLower = AnsiNext(lpszLower));	
	/* Return NULL if no lowercase character is found. */	
	<pre>if (lpszLower == '\0') lpszLower = NULL;</pre>	
See Also	IsCharUpper	

IsCharUpper

BOOL IsCharUpp char chTest; /*	er(chTest) character to test */
	The IsCharUpper function determines whether a character is in the set of language-defined uppercase characters.
Parameters	<i>chTest</i> Specifies the character to be tested.
Return Value	The return value is nonzero if the character is uppercase. Otherwise, it is zero.
Comments	The language driver for the current language (the language the user selected at setup or by using Control Panel) determines whether the character is in the set. If no language driver is selected, Windows uses an internal function.
Example	The following example uses the IsCharUpper function to find the first uppercase character in a string:
	/* Look through the string for an uppercase character. */
	for (lpszUpper = lpsz; !IsCharUpper(*lpszUpper) && lpszUpper != '\0'; lpszUpper = AnsiNext(lpszUpper));
	/* Return NULL if no uppercase character is found. */
	<pre>if (lpszUpper == '\0') lpszUpper = NULL;</pre>
See Also	IsCharLower

lsChild

2.x

BOOL IsChild(hwndPa	arent, hwndChild)	
HWND hwndParent;	/* handle of parent window	*/
HWND hwndChild;	/* handle of child window	*/

The **IsChild** function tests whether a given window is a child or other direct descendant of a given parent window. A child window is the direct descendant of a given parent window if that parent window is in the chain of parent windows leading from the original pop-up window to the child window.

3.0

Parameters	hwndParent Identifies the parent window.
	<i>hwndChild</i> Identifies the child window to be tested.
Return Value	The return value is nonzero if the child window is a descendant of the parent window. Otherwise, it is zero.
See Also	SetParent

IsClipboardFormatAvailable

BOOL IsClipboar	rdFormatAvailable(uFormat)
UINT uFormat;	/* registered clipboard format */
	The IsClipboardFormatAvailable function specifies whether data of a certain format exists on the clipboard.
Parameters	<i>uFormat</i> Specifies a registered clipboard format. For information about clipboard for- mats, see the description of the SetClipboardData function .
Return Value	The return value is nonzero if data of the specified format is on the clipboard. Otherwise, the return value is zero.
Comments	This function is typically called during processing of the WM_INITMENU or WM_INITMENUPOPUP message to determine whether the clipboard contains data that the application can paste. If such data is present, the application typically enables the Paste command (in its Edit menu).
See Also	CountClipboardFormats, EnumClipboardFormats, GetClipboardFormat- Name, GetPriorityClipboardFormat, RegisterClipboardFormat, SetClipboardData

IsDBCSLeadByte

BOOL IsDBCSLeadByte(*bTestChar*) BYTE *bTestChar*; /* character to test

*/

3.1

2.x

	The IsDBCSLeadByte function determines whether a character is a lead byte, the first byte of a character in a double-byte character set (DBCS).
Parameters	<i>bTestChar</i> Specifies the character to be tested.
Return Value	The return value is nonzero if the character is a DBCS lead byte. Otherwise, it is zero.
Comments	The language driver for the current language (the language the user selected at setup or by using Control Panel) determines whether the character is in the set. If no language driver is selected, Windows uses an internal function.
	Each double-byte character set has a unique set of lead-byte values. By itself, a lead byte has no character value; together, the lead byte and the following byte represent a single character. The second, or following, byte is called a trailing byte.
See Also	GetKeyboardType

IsDialogMessage

BOOL IsDialogMessage(*hwndDlg*, *lpmsg*) */ **HWND** hwndDlg; /* handle of dialog box MSG FAR* lpmsg; /* address of structure with message */ The IsDialogMessage function determines whether the specified message is intended for the given modeless dialog box and, if it is, processes the message. **Parameters** hwndDlg Identifies the dialog box. lpmsg Points to an MSG structure that contains the message to be checked. The MSG structure has the following form: typedef struct tagMSG { /* msq */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

Return Value The return value is nonzero if the message has been processed. Otherwise, it is zero.

Comments Although **IsDialogMessage** is intended for modeless dialog boxes, it can be used with any window that contains controls, enabling such windows to provide the same keyboard selection as in a dialog box.

When **IsDialogMessage** processes a message, it checks for keyboard messages and converts them into selection commands for the corresponding dialog box. For example, the TAB key, when pressed, selects the next control or group of controls, and the DOWN ARROW key, when pressed, selects the next control in a group.

If a message is processed by **IsDialogMessage**, it must not be passed to the **TranslateMessage** or **DispatchMessage** function. This is because **IsDialog-Message** performs all necessary translating and dispatching of messages.

IsDialogMessage sends WM_GETDLGCODE messages to the dialog box procedure to determine which keys should be processed.

IsDialogMessage can send DM_GETDEFID and DM_SETDEFID messages to the window. These messages are defined in the WINDOWS.H header file as WM_USER and WM_USER+1, so conflicts are possible with application-defined messages having the same values.

See Also DispatchMessage, SendDlgItemMessage, TranslateMessage

IsDIgButtonChecked

UINT IsDlgButton(HWND hwndDlg; int idButton;	hecked(hwndDlg, idButton) /* handle of dialog box */ /* button identifier */
	The IsDlgButtonChecked function determines whether a button has a check mark next to it and whether a three-state button is grayed, checked, or neither.
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the button.
	<i>idButton</i> Specifies the identifier of the button.

Return Value	The return value is nonzero if the specified button is checked, 0 if it is not, or -1 if the <i>hwndDlg</i> parameter is invalid. For three-state buttons, the return value is 2 if the button is grayed, 1 if the button is checked, 0 if it is unchecked, or -1 if <i>hwndDlg</i> is invalid.
Comments	The IsDlgButtonChecked function sends a BM_GETCHECK message to the button.
See Also	CheckDlgButton, CheckRadioButton

IsGDIObject

BOOL IsGDIObject(*hobj*) **HGDIOBJ** hobj; /* handle of a menu */ The **IsGDIObject** function determines whether the specified handle is not the handle of a graphics device interface (GDI) object. **Parameters** hobj Specifies a handle to test. **Return Value** The return value is nonzero if the handle may be the handle of a GDI object. It is zero if the handle is not the handle of a GDI object. **Comments** An application cannot use IsGDIObject to guarantee that a given handle is to a GDI object. However, this function can be used to guarantee that a given handle is not to a GDI object. See Also GetObject

Islconic

2.x

3.1

BOOL IsIconic(*hwnd*) HWND *hwnd*; /* handle of window */

The IsIconic function determines whether the given window is minimized (iconic).

Parameters	<i>hwnd</i> Identifies the window.
Return Value	The return value is nonzero if the window is minimized. Otherwise, it is zero.
See Also	CloseWindow, IsZoomed

IsMenu

3.1

BOOL IsMenu(hma HMENU hmenu;	enu) /* handle of menu */
	The IsMenu function determines whether the given handle is a menu handle.
Parameters	hmenu Identifies the handle to be tested.
Return Value	The return value is zero if the handle is definitely <i>not</i> a menu handle. A nonzero return value does not guarantee that the handle is a menu handle, however; for non-zero return values, the application should conduct further tests to verify the handle.
Comments	An application should use this function only to ensure that a given handle is <i>not</i> a menu handle.
See Also	CreateMenu, CreatePopupMenu, DestroyMenu, GetMenu

IsRectEmpty

BOOL IsRectEmpt const RECT FAR*	
	The IsRectEmpty function determines whether the specified rectangle is empty. A rectangle is empty if its width or height is zero, or if both are zero.
Parameters	<i>lprc</i> Points to a RECT structure that contains the coordinates of the rectangle. The RECT structure has the following form:

	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>
Return Value	The return value is nonzero if the rectangle is empty. Otherwise, it is zero.
Example	The following example uses the IsRectEmpty function to determine whether a rectangle is empty and then displays a message box giving the status of the rectangle:
	RECT rc;
	if (IsRectEmpty((LPRECT) &rc)) MessageBox(hwnd, "Rectangle is empty.", "Rectangle Status", MB_OK);
	else MessageBox(hwnd, "Rectangle is not empty.", "Rectangle Status", MB_OK);

lsTask

3.1

BOOL IsTask(htash	k)
HTASK htask;	/* handle of task */
	The IsTask function determines whether the given task handle is valid.
Parameters	htask Identifies a task.
Return Value	The return value is nonzero if the task handle is valid. Otherwise, it is zero.

IsWindow

BOOL IsWindow	
HWND hwnd;	/* handle of window */
	The IsWindow function determines whether the given window handle is valid.
Parameters	<i>hwnd</i> Identifies a window.
Return Value	The return value is nonzero if the window handle is valid. Otherwise, it is zero.
See Also	IsWindowEnabled, IsWindowVisible

IsWindowEnabled

BOOL IsWindowEnabled(*hwnd*)

HWND *hwnd*; /* handle of window to test */

The **IsWindowEnabled** function determines whether the given window is enabled for mouse and keyboard input.

Parameters	hwnd Identifies the window.
Return Value	The return value is nonzero if the window is enabled. Otherwise, it is zero.
Comments	A child window receives input only if it is both enabled and visible.
See Also	IsWindow, IsWindowVisible

IsWindowVisible

BOOL IsWindowVisible(*hwnd*)

HWND *hwnd*; /* handle of window to test */

The **IsWindowVisible** function determines the visibility state of the given window.

2.x

2.x

2.x

3.1

Parameters	hwnd Identifies the window.
Return Value	The return value is nonzero if the specified window is visible on the screen (has the WS_VISIBLE style bit set). The return value is zero if the window is not visible. Because the return value reflects the value of the window's WS_VISIBLE flag, it may be nonzero even if the window is totally obscured by other windows.
Comments	A window possesses a visibility state indicated by the WS_VISIBLE style bit. When this style bit is set, the window is displayed and subsequent drawing into the window is displayed as long as the window has the style bit set.
	Any drawing to a window that has the WS_VISIBLE style will not be displayed if the window is covered by other windows or is clipped by its parent window.
See Also	ShowWindow

IsZoomed

BOOL IsZoomed	l(hwnd)
HWND hwnd;	/* handle of window */
	The IsZoomed function determines whether the given window is maximized.
Parameters	hwnd Identifies the window.
Return Value	The return value is nonzero if the window is maximized. Otherwise, it is zero.
See Also	IsIconic

JournalPlaybackProc

LRESULT CALLBACK JournalPlaybackProc (code, wParam, lParam)		
int code;	/* process-message flag	*/
WPARAM wParam;	/* undefined	*/
LPARAM lParam;	/* address of structure for message	*/

The **JournalPlaybackProc** function is a library-defined callback function that a library can use to insert mouse and keyboard messages into the system message queue. Typically, a library uses this function to play back a series of mouse and keyboard messages that were recorded earlier by using the **JournalRecordProc** function. Regular mouse and keyboard input is disabled as long as a **Journal-PlaybackProc** function is installed.

Parameters

Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this parameter is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.

wParam

code

Specifies a NULL value.

lParam

Points to an **EVENTMSG** structure that represents the message being processed by the callback function. The **EVENTMSG** structure has the following form:

```
typedef struct tagEVENTMSG { /* em */
  UINT message;
  UINT paramL;
  UINT paramH;
  DWORD time;
} EVENTMSG;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

Return Value The callback function should return a value that represents the amount of time, in clock ticks, that the system should wait before processing the message. This value can be computed by calculating the difference between the **time** members of the current and previous input messages. If the function returns zero, the message is processed immediately.

Comments The **JournalPlaybackProc** function should copy an input message to the *lParam* parameter. The message must have been recorded by using a **JournalRecordProc** callback function, which should not modify the message.

Once the function returns control to the system, the message continues to be processed. If the *code* parameter is HC_SKIP, the filter function should prepare to return the next recorded event message on its next call.

This callback function should reside in a dynamic-link library.

An application must install the callback function by specifying the WH_JOURNALPLAYBACK filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

3.1

JournalPlaybackProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also CallNextHookEx, JournalRecordProc, SetWindowsHookEx

JournalRecordProc

LRESULT CALLBACK JournalRecordProc(code, wParam, lParam) /* process-message flag int code: */ WPARAM wParam; /* undefined */ LPARAM lParam; /* address of structure for message */ The JournalRecordProc function is a library-defined callback function that records messages that the system removes from the system message queue. Later, a library can use a **JournalPlaybackProc** function to play back the messages. **Parameters** code Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this parameter is less than zero, the callback function should pass the message to CallNextHookEx without further processing. wParam Specifies a NULL value. **lParam** Points to an MSG structure. The MSG structure has the following form: typedef struct tagMSG { /* msg */ HWND hwnd; UINT message: WPARAM wParam: LPARAM 1Param: DWORD time: POINT pt; } MSG; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3. **Return Value** The callback function should return zero. Comments A JournalRecordProc callback function should copy but not modify the messages. After control returns to the system, the message continues to be processed. The callback function does not require a return value.

This callback function must be in a dynamic-link library.

An application must install the callback function by specifying the WH_JOURNALRECORD filter type and the procedure-instance address of the callback function in a call to the **SetWindowsHookEx** function.

JournalRecordProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

See Also CallNextHookEx, JournalPlaybackProc, SetWindowsHookEx

KeyboardProc

LRESULT CALLBACI	K KeyboardProc(code, wParam, lPa	ram)
int code;	/* process-message flag	*/
WPARAM wParam;	/* virtual-key code	*/
LPARAM lParam;	/* keyboard-message information	*/

The **KeyboardProc** function is a library-defined callback function that the system calls whenever the application calls the **GetMessage** or **PeekMessage** function and there is a WM_KEYUP or WM_KEYDOWN keyboard message to process.

Parameters

code

Specifies whether the callback function should process the message or call the **CallNextHookEx** function. If this value is HC_NOREMOVE, the application is using the **PeekMessage** function with the PM_NOREMOVE option, and the message will not be removed from the system queue. If this value is less than zero, the callback function should pass the message to **CallNextHookEx** without further processing.

wParam

Specifies the virtual-key code of the given key.

lParam

Specifies the repeat count, scan code, extended key, previous key state, context code, and key-transition state, as shown in the following table. (Bit 0 is the low-order bit):

Bit	Description
0–15	Specifies the repeat count. The value is the number of times the keystroke is repeated as a result of the user holding down the key.
16–23	Specifies the scan code. The value depends on the original equipment manufacturer (OEM).

3.1

	Bit	Description	
	24	Specifies whether the key is an extended key, such as a function key or a key on the numeric keypad. The value is 1 if it is an extended key; otherwise, it is 0.	
	25-26	Not used.	
	27-28	Used internally by Windows.	
	29	Specifies the context code. The value is 1 if the ALT key is held down while the key is pressed; otherwise, the value is 0.	
	30	Specifies the previous key state. The value is 1 if the key is down before the message is sent, or it is 0 if the key is up.	
	31	Specifies the key-transition state. The value is 1 if the key is being re- leased, or it is 0 if the key is being pressed.	
Return Value	The callback function should return 0 if the message should be processed by the system; it should return 1 if the message should be discarded.		
Comments	This callback function must be in a dynamic-link library.		
	An application must install the callback function by specifying the WH_KEYBOARD filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.		
	KeyboardProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library module-definition file.		
See Also	CallNextH	lookEx, GetMessage, PeekMessage, SetWindowsHookEx	

KillTimer 2.x **BOOL KillTimer**(*hwnd*, *idTimer*) /* handle of window that installed timer HWND hwnd: */ */ **UINT** *idTimer*; /* timer identifier The KillTimer function removes the specified timer. Any pending WM_TIMER messages associated with the timer are removed from the message queue. **Parameters** hwnd Identifies the window associated with the timer to be removed. This must be the same value passed as the hwnd parameter of the SetTimer function that created the timer.

	<i>idTimer</i> Identifies the timer to be removed. If the application called SetTimer with the <i>hwnd</i> parameter set to NULL, this parameter must be the timer identifier returned by SetTimer . If the <i>hwnd</i> parameter of SetTimer was a valid window handle, this parameter must be the value of the <i>idTimer</i> parameter passed to SetTimer .
Return Value	The return value is nonzero if the function is successful. It is zero if the KillTimer function could not find the specified timer.
See Also	SetTimer

_lclose

HFILE _lclose(<i>hf</i>) HFILE <i>hf</i> ; /* ha	andle of file to close */
	The _lclose function closes the given file. As a result, the file is no longer available for reading or writing.
Parameters	<i>hf</i> Identifies the file to be closed. This handle is returned by the function that created or last opened the file.
Return Value	The return value is zero if the function is successful. Otherwise, it is HFILE_ERROR.
Example	The following example copies a file to a temporary file, then closes both files:
	int cbRead; PBYTE pbBuf;
	/* Allocate a buffer for file I/0. */
	<pre>pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);</pre>
	/* Copy the input file to the temporary file. */
	<pre>do { cbRead = _lread(hfReadFile, pbBuf, 2048); _lwrite(hfTempFile, pbBuf, cbRead); } while (cbRead != 0);</pre>
	/* Free the buffer and close the files. */

LocalFree((HLOCAL) pbBuf); _lclose(hfReadFile); _lclose(hfTempFile);

See Also _lopen, OpenFile

_lcreat

HFILE _lcreat(lpszFilename, fnALPCSTR lpszFilename;/* adint fnAttribute;/* fil				
	The _lcreat function creates or opens a specified file. If the file does not exist, the function creates a new file and opens it for writing. If the file does exist, the function truncates the file size to zero and opens it for reading and writing. When the function opens the file, the pointer is set to the beginning of the file.			
Parameters	<i>lpszFilename</i> Points to a null-terminated string that names the file to be opened. The string must consist of characters from the Windows character set.			
	<i>fnAttribute</i> Specifies the file attributes. This parameter must be one of the following values:			
	Value	Meaning		
	0	Normal; can be read or written without restriction.		
	1	Read-only; cannot be opened for writing.		
	2	Hidden; not found by directory search.		
	3	System; not found by directory search.		
Return Value	The return value is a file handle if the function is successful. Otherwise, it is HFILE_ERROR.			
Comments	Use this function carefully. It is possible to open any file, even one that has al- ready been opened by another function.			
Example	The following example uses the _lcreat function to open a temporary file:			
	HFILE hfTempFile; char szBuf[144];			

```
/* Create a temporary file. */
GetTempFileName(0, "tst", 0, szBuf);
hfTempFile = _lcreat(szBuf, 0);
if (hfTempFile == HFILE_ERROR) {
    ErrorHandler();
}
```

LibMain

int CALLBACK Li HINSTANCE hinst WORD wDataSeg; WORD cbHeapSize LPSTR lpszCmdLin	/* library data segment */ /* default heap size */		
	The LibMain function is called by the system to initialize a dynamic-link library (DLL). A DLL must contain the LibMain function if the library is linked with the file LIBENTRY.OBJ.		
Parameters	<i>hinst</i> Identifies the instance of the DLL.		
	<i>wDataSeg</i> Specifies the value of the data segment (DS) register.		
	<i>cbHeapSize</i> Specifies the size of the heap defined in the module-definition file. (The LibEntry routine in LIBENTRY.OBJ uses this value to initialize the local heap.)		
	<i>lpszCmdLine</i> Points to a null-terminated string specifying command-line information. This parameter is rarely used by DLLs.		
Return Value	The function should return 1 if it is successful. Otherwise, it should return 0.		
Comments	The LibMain function is called by LibEntry, which is called by Windows when the DLL is loaded. The LibEntry routine is provided in the LIBENTRY.OBJ mod- ule. LibEntry initializes the DLL's heap (if a HEAPSIZE value is specified in the DLL's module-definition file) before calling the LibMain function.		

```
Example
                   The following example shows a typical LibMain function:
                   int CALLBACK LibMain(HINSTANCE hinst, WORD wDataSeg, WORD cbHeap,
                       LPSTR lpszCmdLine )
                   ſ
                       HGLOBAL
                                  hgblClassStruct:
                       LPWNDCLASS lpClassStruct:
                       static HINSTANCE hinstLib;
                       /* Has the library been initialized yet? */
                       if (hinstLib == NULL) {
                           hgblClassStruct = GlobalAlloc(GHND, sizeof(WNDCLASS));
                           if (hgb]ClassStruct != NULL) {
                               lpClassStruct = (LPWNDCLASS) GlobalLock(hgblClassStruct);
                               if (lpClassStruct != NULL) {
                                   /* Define the class attributes. */
                                   lpClassStruct->style = CS_HREDRAW | CS_VREDRAW |
                                       CS_DBLCLKS | CS_GLOBALCLASS;
                                   lpClassStruct->lpfnWndProc = DllWndProc;
                                   lpClassStruct->cbWndExtra = 0;
                                   lpClassStruct->hInstance = hinst;
                                   lpClassStruct->hIcon = NULL;
                                   lpClassStruct->hCursor = LoadCursor(NULL, IDC_ARROW);
                                   lpClassStruct->hbrBackground =
                                        (HBRUSH) (COLOR WINDOW + 1):
                                   lpClassStruct->lpszMenuName = NULL;
                                   lpClassStruct->lpszClassName = "MyClassName";
                                   hinstLib = (RegisterClass(lpClassStruct)) ?
                                       hinst : NULL;
                                   GlobalUnlock(hgblClassStruct):
                               }
                               GlobalFree(hgblClassStruct);
                           }
                       }
                       return (hinstLib ? 1 : 0); /* return 1 = success; 0 = fail */
                   }
```

LineTo

BOOL LineTe	Fo(hdc, nXEnd, nYEnd)	
HDC hdc;	/* handle of device context */	
int nXEnd;	/* x-coordinate of line endpoint */	
int nYEnd;	/* y-coordinate of line endpoint */	
	The LineTo function draws a line from the current position up to, but not ing, the specified endpoint. The function uses the selected pen to draw th sets the current position to the coordinates (<i>nXEnd</i> , <i>nYEnd</i>).	
Parameters	<i>hdc</i> Identifies the device context.	
	<i>nXEnd</i> Specifies the logical x-coordinate of the line's endpoint.	
	<i>nYEnd</i> Specifies the logical y-coordinate of the line's endpoint.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is	zero.
Example	The following example sets the current position by using the MoveTo fu before calling the LineTo function. The example uses POINT structures the coordinates.	
	HDC hdc;	
	POINT ptStart = { 12, 12 }; POINT ptEnd = { 128, 135 };	
	MoveTo(hdc, ptStart.x, ptStart.y); LineTo(hdc, ptEnd.x, ptEnd.y);	

_llseek			2. x
LONG _llseek(hf, HFILE hf; LONG lOffset; int nOrigin;	/* file handle /* number of /* position to	bytes to move move from	*/ */ */ ons the pointer in a previously opened file.
Parameters	hf Identifies lOffset Specifies nOrigin		rtes the pointer is to be moved.
	Specifies	the starting posit the following va Meaning	ion and direction of the pointer. This parameter must lues:
	0 1 2	Move the file po	inter <i>lOffset</i> bytes from the beginning of the file. inter <i>lOffset</i> bytes from its current position. inter <i>lOffset</i> bytes from the end of the file.
Return Value		file, if the function	new offset, in bytes, of the pointer from the begin- is successful. Otherwise, the return value is
Comments	When a file is initially opened, the file pointer is positioned at the beginning of the file. The _llseek function permits random access to a file's contents by moving the pointer an arbitrary amount without reading data.		
Example	end of an ex	isting file:	he _llseek function to move the file pointer to the

LoadAccelerators

_lopen

 HACCEL LoadAccelerators(hinst, lpszTableName)

 HINSTANCE hinst;
 /* handle of module to load from */

 LPCSTR lpszTableName;
 /* address of table name
 */

The LoadAccelerators function loads the specified accelerator table.

Parameters	<i>hinst</i> Identifies an instance of the module whose executable file contains the accelera- tor table to be loaded.
	<i>lpszTableName</i> Points to a null-terminated string that names the accelerator table to be loaded.
Return Value	The return value is the handle of the loaded accelerator table if the function is successful. Otherwise, it is NULL.
Comments	If the accelerator table has not yet been loaded, the function loads it from the given executable file.
	Accelerator tables loaded from resources are freed automatically when the applica-

Accelerator tables loaded from resources are freed automatically when the application terminates.

2.x

LoadBitmap

HBITMAP LoadBit HINSTANCE hinst; LPCSTR lpszBitmap	map(hinst, lpszBitmap)/* handle of application instance*/;/* address of bitmap name*/
	The LoadBitmap function loads the specified bitmap resource from the given module's executable file.
Parameters	<i>hinst</i> Identifies the instance of the module whose executable file contains the bitmap to be loaded.
	<i>lpszBitmap</i> Points to a null-terminated string that contains the name of the bitmap resource to be loaded. Alternatively, this parameter can consist of the resource identifier in the low-order word and zero in the high-order word. The MAKEINT- RESOURCE macro can be used to create this value.
Return Value	The return value is the handle of the specified bitmap if the function is successful. Otherwise, it is NULL.
Comments	If the bitmap pointed to by <i>lpszBitmap</i> does not exist or if there is insufficient memory to load the bitmap, the function fails.
	The application must call the DeleteObject function to delete each bitmap handle returned by the LoadBitmap function. This also applies to the following predefined bitmaps.
	An application can use the LoadBitmap function to access the predefined bitmaps used by Windows. To do so, the application must set the <i>hinst</i> parameter to NULL and the <i>lpszBitmap</i> parameter to one of the following values:
	OBM_BTNCORNERS OBM_BTSIZE OBM_CHECK OBM_CHECKBOXES OBM_CLOSE OBM_COMBO OBM_DNARROW OBM_DNARROWD OBM_DNARROWI OBM_LFARROW OBM_LFARROWI OBM_LFARROWI OBM_LFARROWI OBM_MNARROW

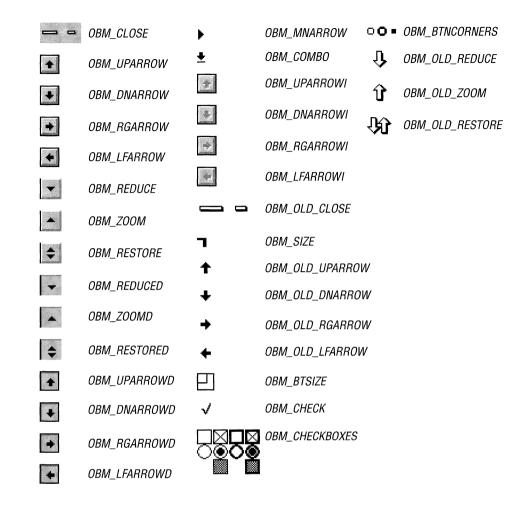

OBM OLD DNARROW OBM_OLD_LFARROW OBM_OLD_REDUCE OBM_OLD_RESTORE OBM OLD RGARROW OBM OLD UPARROW OBM OLD ZOOM **OBM REDUCE OBM REDUCED OBM RESTORE OBM RESTORED OBM RGARROW OBM RGARROWD OBM RGARROWI** OBM_SIZE **OBM UPARROW OBM UPARROWD OBM UPARROWI** OBM ZOOM **OBM ZOOMD**

Bitmap names that begin with OBM_OLD represent bitmaps used by Windows versions earlier than 3.0.

The bitmaps identified by OBM_DNARROWI, OBM_LFARROWI, OBM_RGARROWI, and OBM_UPARROWI are new for Windows 3.1. These bitmaps are not found in device drivers for previous versions of Windows.

Note that for an application to use any of the OBM_ constants, the constant OEMRESOURCE must be defined before the WINDOWS.H header file is included.

The following shows the appearance of each of the OBM_bitmaps.

DeleteObject

LoadCursor

2.x

HCURSOR LoadCursor(hinst, pszCursor)

HINSTANCE hinst;/* handle of application instance*/LPCSTR pszCursor;/* cursor-name string or cursor resource identifier*/

The **LoadCursor** function loads the specified cursor resource from the executable file associated with the given application instance.

Parameters	<i>hinst</i> Identifies an instance of the module whose executable file contains the cursor to be loaded.		
	<i>pszCursor</i> Points to a null-terminated string that contains the name of the cursor resource to be loaded. Alternatively, this parameter can consist of the resource identifier in the low-order word and zero in the high-order word. The MAKEINT- RESOURCE macro can be used to create this value.		
Return Value	The return value is ful. Otherwise, it is	the handle of the newly loaded cursor if the function is success- NULL.	
Comments	The function loads the cursor resource only if it has not been loaded; otherwise, it retrieves a handle of the existing resource. The LoadCursor function returns a valid cursor handle only if the <i>pszCursor</i> parameter points to a cursor resource. If <i>pszCursor</i> points to any type of resource other than a cursor (such as an icon), the return value will not be NULL, even though it is not a valid cursor handle.		
	used by Windows.	use the LoadCursor function to access the predefined cursors Fo do this, the application must set the <i>hinst</i> parameter to <i>Cursor</i> parameter to one the following values:	
	Value	Meaning	
	IDC_ARROW IDC_CROSS IDC_IBEAM	Standard arrow cursor. Crosshair cursor. Text I-beam cursor.	

IDC_ICON	Empty icon.
IDC_SIZE	A square with a smaller square inside its lower-right corner.
IDC_SIZENESW	Double-pointed cursor with arrows pointing northeast and south-west.
IDC_SIZENS	Double-pointed cursor with arrows pointing north and south.
IDC_SIZENWSE	Double-pointed cursor with arrows pointing northwest and south- east.
IDC_SIZEWE	Double-pointed cursor with arrows pointing west and east.
IDC_UPARROW	Vertical arrow cursor.
IDC_WAIT	Hourglass cursor.

It is not necessary to destroy these system cursors. An application should use the DestroyCursor function to destroy any private cursors it loads.

LoadLibrary

See Also

HINSTANCE LoadLibrary (<i>lpszLibFileName</i>)		
LPCSTR lpszLibFileName;	/* address of name of library file	*/

The LoadLibrary function loads the specified library module.

Parameters	<i>lpszLibFileName</i> Points to a null-terminated string that names the library file to be loaded. If the string does not contain a path, Windows searches for the library in this order:
	1. The current directory.
,	 The Windows directory (the directory containing WIN.COM); the Get- WindowsDirectory function retrieves the path of this directory.
	3. The Windows system directory (the directory containing such system files as GDI.EXE); the GetSystemDirectory function retrieves the path of this directory.
	 The directory containing the executable file for the current task; the Get- ModuleFileName function retrieves the path of this directory.
	5. The directories listed in the PATH environment variable.
	6. The list of directories mapped in a network.
Return Value	The return value is the instance handle of the loaded library module if the function is successful. Otherwise, it is an error value less than HINSTANCE_ERROR.

Errors

If the function fails, it returns one of the following error values:

	Value	Meaning
	0	System was out of memory, executable file was corrupt, or relocations were invalid.
	2	File was not found.
	3	Path was not found.
	5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.
	6	Library required separate data segments for each task.
	8	There was insufficient memory to start the application.
	10	Windows version was incorrect.
	11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.
	12	Application was designed for a different operating system.
	13	Application was designed for MS-DOS 4.0.
	14	Type of executable file was unknown.
	15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).
	16	Attempt was made to load a second instance of an executable file contain- ing multiple data segments that were not marked read-only.
	19	Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.
	20	Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application was corrupt.
	21	Application requires Microsoft Windows 32-bit extensions.
Comments	module's	dule has been loaded, LoadLibrary increments (increases by one) the reference count. If the module has not been loaded, the function loads it specified file.
	plication	rary increments the reference count for a library module each time an ap- calls the function. When it has finished using the module, the application se the FreeLibrary function to decrement (decrease by one) the reference
		cation can use the GetProcAddress function to access functions in a at was loaded using LoadLibrary .
Example		wing example uses the LoadLibrary function to load the Tool Helper OOLHELP.DLL and the FreeLibrary function to free it:
	HINSTANC	E hinstToolHelp = LoadLibrary("TOOLHELP.DLL");

LoadMenu

HMENU LoadMen HINSTANCE hinst; LPCSTR lpszMenu?	
	The LoadMenu function loads the specified menu resource from the executable file associated with the given application instance.
Parameters	<i>hinst</i> Identifies an instance of the module whose executable file contains the menu to be loaded.
	<i>lpszMenuName</i> Points to a null-terminated string that contains the name of the menu resource to be loaded. Alternatively, this parameter can consist of the resource identifier in the low-order word and zero in the high-order word. The MAKEINT- RESOURCE macro can be used to create this value.
Return Value	The return value is the handle of the menu resource if the function is successful. Otherwise, it is NULL.
Comments	Before exiting, an application must free system resources associated with a menu if the menu is not assigned to a window. An application frees a menu by calling the DestroyMenu function.
Example	The following example loads a menu resource, and then assigns the menu to a window:

HMENU hmenu;

hmenu = LoadMenu(hinst, "ColorMenu"); SetMenu(hwnd, hmenu);

LoadMenuIndirect

```
        HMENU LoadMenuIndirect(lpmith)

        const void FAR* lpmith;
        /* address of menu template
        */
```

The **LoadMenuIndirect** function loads the specified menu template in memory. A menu template is a header followed by a collection of one or more **MENU-ITEMTEMPLATE** structures, each of which may contain one or more menu items and pop-up menus.

Parameters

lpmith

Points to a menu template, which consists of a menu-template header and one or more menu item templates. The menu template header consists of a **MENU-ITEMTEMPLATEHEADER** structure, which has the following form:

```
typedef struct { /* mith */
   UINT versionNumber;
   UINT offset;
} MENUITEMTEMPLATEHEADER;
```

Each menu item template consists of a **MENUITEMTEMPLATE** structure. The **MENUITEMTEMPLATE** structure has the following form:

```
typedef struct { /* mit */
    UINT mtOption;
    UINT mtID;
    char mtString[1];
} MENUITEMTEMPLATE;
```

For a full description of these two structures, see the *Microsoft Windows Pro*grammer's Reference, Volume 3.

Return Value The return value is the handle of a menu if the function is successful. Otherwise, it is NULL.

Comments	Before exiting, an application must free system resources associated with a menu if the menu is not assigned to a window. An application frees a menu by calling the DestroyMenu function.
Example	The following example retrieves a menu handle for a menu template resource that has been loaded into memory, gives the menu handle to a window, and then unlocks and frees the resource:
	HRSRC hrsrcResInfo; HGLOBAL hglbResMenu; char FAR* lpResMenu; HMENU hmenu;
	case IDM_NEWMENU: hrsrcResInfo = FindResource(hinst, "DynaMenu", RT_MENU); hglbResMenu = LoadResource(hinst, hrsrcResInfo); lpResMenu = LockResource(hglbResMenu); hmenu = LoadMenuIndirect(lpResMenu);
	DestroyMenu(GetMenu(hwnd)); SetMenu(hwnd, hmenu);
	UnlockResource(hglbResMenu); FreeResource(hglbResMenu);
	break;
See Also	DestroyMenu, LoadMenu, SetMenu

LoadModule

 HINSTANCE LoadModule(lpszModuleName, lpvParameterBlock)

 LPCSTR lpszModuleName;
 /* address of filename to load
 */

 LPVOID lpvParameterBlock;
 /* address of parameter block for new module
 */

The **LoadModule** function loads and executes a Windows application or creates a new instance of an existing Windows application.

3.0

Parameters

lpszModuleName

Points to a null-terminated string that contains the complete filename (including the file extension) of the application to be run. If the string does not contain a path, Windows searches for the executable file in this order:

1. The current directory.

- 2. The Windows directory (the directory containing WIN.COM), whose path the **GetWindowsDirectory** function retrieves.
- 3. The Windows system directory (the directory containing such system files as GDI.EXE), whose path the **GetSystemDirectory** function retrieves.
- 4. The directory containing the executable file for the current task; the **Get-ModuleFileName** function obtains the path of this directory.
- 5. The directories listed in the PATH environment variable.
- 6. The list of directories mapped in a network.
- *lpvParameterBlock*

Points to an application-defined LOADPARMS structure that defines the new application's parameter block. The LOADPARMS structure has the following form:

st	ruct _LOADP/	ARMS {			
	WORD	segEnv;	/*	child environment	*/
	LPSTR	lpszCmdLine;	/*	child command tail	*/
	UINT FAR*	lpShow;	/*	how to show child	*/
	UINT FAR*	<pre>lpReserved;</pre>	/*	must be NULL	*/
}	LOADPARMS;				

Member	Description
segEnv	Specifies whether the child application receives a copy of the parent application's environment or a new environment created by the parent application. If this member is zero, the child application receives an exact duplicate of the parent ap plication's environment block. If the member is nonzero, the value entered must be the segment address of a memory ob- ject containing a copy of the new environment for the child application.
lpszCommandLine	Points to a null-terminated string that specifies the command line (excluding the child application name). This string must not exceed 120 characters. If there is no command line, this member must point to a zero-length string (it cannot be set to NULL).
lpShow	Points to an array containing two 16-bit values. The first value must always be set to two. The second value specifies how the application window is to be shown. For a list of the acceptable values, see the description of the <i>nCmdShow</i> parameter of the ShowWindow function.
lpReserved	Reserved; must be NULL.

Return Value The return value is the instance handle of the loaded module if the function is successful. If the function fails, it returns an error value less than HINSTANCE_ERROR.

	Value	Meaning		
	0	System was out of memory, invalid.	executable file was corrupt, or relocations were	
	2	File was not found.		
	3	Path was not found.		
	5	Attempt was made to dynam network-protection error.	nically link to a task, or there was a sharing or	
	6	Library required separate da	ta segments for each task.	
	8	There was insufficient mem-	ory to start the application.

LoadProc

HGLOBAL CALLE	BACK LoadProc(hglbMem, hinst, hrsrcResInfo)	
HGLOBAL hglbMer	<i>n</i> ; /* handle of object containing resource	*/
HINSTANCE <i>hinst</i> ;	/* handle of application instance	*/
HRSRC hrsrcResInfe	<i>b</i> ; /* handle of a resource	*/
	The LoadProc function is an application-defined information about a resource to be locked and ca needed.	
Parameters	<i>hglbMem</i> Identifies a memory object that contains a res the resource has not yet been loaded.	ource. This parameter is NULL if
	<i>hinst</i> Identifies the instance of the module whose exsource.	xecutable file contains the re-
	<i>hrsrcResInfo</i> Identifies the resource. The resource must hav FindResource function.	ve been created by using the
Return Value	The return value is a global memory handle for the GMEM_DDESHARE flag in the GlobalAlle	

CommentsIf an attempt to lock the memory object identified by the *hglbMem* parameter fails,
this means the resource has been discarded and must be reloaded.LoadProc is a placeholder for the application-defined function name. The actual
name must be exported by including it in an EXPORTS statement in the applica-
tion's module-definition file.See AlsoFindResource, GlobalAlloc, SetResourceHandler

LoadResource

HGLOBAL LoadRe HINSTANCE hinst; HRSRC hrsrc;	
	The LoadResource function loads the specified resource in global memory.
Parameters	 <i>hinst</i> Identifies an instance of the module whose executable file contains the resource to be loaded. <i>hrsrc</i> Identifies the resource to be loaded. This handle must have been created by
Return Value	using the FindResource function. The return value is the instance handle of the global memory object containing the
	data associated with the resource. It is NULL if no such resource exists.
Comments	When finished with a resource, an application should free the global memory associated with it by using the FreeResource function.
	If the specified resource has been loaded, this function simply increments the reference count for the resource.
	The resource is not loaded until the LockResource function is called to translate the handle returned by LoadResource into a far pointer to the resource data.
See Also	FindResource, FreeResource, LockResource

2.x

LoadString		2. x
HINSTANCE <i>hinst</i> ;	<i>c, idResource, lpszBuffer, cbBuffer)</i> /* handle of module containing string resource /* resource identifier /* address of buffer for resource /* size of buffer	*/ */ */
	The LoadString function loads the specified string res	source.
Parameters	<i>hinst</i> Identifies an instance of the module whose executal source to be loaded.	ble file contains the string re-
	<i>idResource</i> Specifies the integer identifier of the string to be los	aded.
	<i>lpszBuffer</i> Points to the buffer that will receive the null-termin	ated string.
	<i>cbBuffer</i> Specifies the buffer size, in bytes. The buffer should string and its terminating null character. The string than the number of bytes specified.	
Return Value	The return value specifies the number of bytes copied tion is successful. It is zero if the string resource does	

LocalAlloc

HLOCAL LocalAll UINT fuAllocFlags; UINT fuAlloc;	oc(fuAllocFlags, fuAlloc) /* allocation attributes */ /* number of bytes to allocate */
	The LocalAlloc function allocates the specified number of bytes from the local heap.
Parameters	<i>fuAllocFlags</i> Specifies how to allocate memory. This parameter can be a combination of the following values:

	Value	Meaning
	LHND	Combines the LMEM_MOVEABLE and LMEM_ZEROINIT flags.
	LMEM_DISCARDABLE	Allocates discardable memory.
	LMEM_FIXED	Allocates fixed memory. The LMEM_FIXED and LMEM_MOVEABLE flags cannot be combined.
	LMEM_MOVEABLE	Allocates movable memory. The LMEM_FIXED and LMEM_MOVEABLE flags cannot be combined.
	LMEM_NOCOMPACT	Does not compact or discard memory to satisfy the al- location request.
	LMEM_NODISCARD	Does not discard memory to satisfy the allocation re- quest.
	LMEM_ZEROINIT	Initializes memory contents to zero.
	LPTR	Combines the LMEM_FIXED and LMEM_ZEROINIT flags.
	NONZEROLHND	Same as the LMEM_MOVEABLE flag.
	NONZEROLPTR	Same as the LMEM_FIXED flag.
Return Value	The return value is the instan ject, if the function is success	ce handle of the newly allocated local memory ob- ful. Otherwise, it is NULL.
Comments	If LocalAlloc allocates mova	ble memory, the return value is a local handle of the
	to convert the handle to a poi	ory, an application must use the LocalLock function nter.
		memory, the return value is a pointer to the memory. plication can simply cast the return value to a pointer.

	amount allocated is greater th	it allocates at least the amount requested. If the nan the amount requested, the application can use the the size of a local memory object, an application can
		et, an application should use the LocalFree function. tes of an allocated memory object, an application can on.
See Also	LocalFree, LocalLock, Loc	alReAlloc, LocalSize, LocalUnlock

LocalCompact **UINT LocalCompact**(*uMinFree*) **UINT** *uMinFree*: */ /* amount of memory requested The LocalCompact function rearranges the local heap so that the specified amount of memory is free. **Parameters** uMinFree Specifies the number of contiguous free bytes requested. If this parameter is zero, the function does not compact memory, but the return value is valid. **Return Value** The return value specifies the number of bytes in the largest free local memory object. If the *uMinFree* parameter is zero, the return value specifies the number of bytes in the largest free object that Windows can generate if it removes all discardable objects. Comments The function first checks the local heap for the specified number of contiguous free bytes. If the bytes do not exist, the function compacts local memory by moving all unlocked, movable objects into high memory. If this does not generate the requested amount of space, the function discards movable and discardable objects that are not locked, until the requested amount of space is generated (if possible). See Also LocalAlloc, LocalLock

LocalFirst

#include <toolhelp.h>

BOOL LocalFirst(lple, hglbHea	(p)	
LOCALENTRY FAR* lple;	/* address of LOCALENTRY structure	*/
HGLOBAL hglbHeap;	/* handle of local heap	*/

The LocalFirst function fills the specified structure with information that describes the first object on the local heap.

Parameters

lple

Points to a LOCALENTRY structure that will receive information about the local memory object. The LOCALENTRY structure has the following form:

2.x

3.1

	<pre>#include <toolhelp.h></toolhelp.h></pre>		
	<pre>typedef struct tagLOCALENTRY { /* le */ DWORD dwSize; HLOCAL hHandle; WORD wAddress; WORD wSize; WORD wFlags; WORD wcLock; WORD wcLock; WORD mType; WORD hHeap; WORD hHeap; WORD wHeapType; WORD wNext; } LOCALENTRY; For a full description of this structure, see the Microsoft Windows Program-</pre>		
	mer's Reference, Volume 3.		
	hglbHeap Identifies the local heap.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	The LocalFirst function can be used to begin a local heap walk. An application can examine subsequent objects on the local heap by using the LocalNext function.		
	Before calling LocalFirst, an application must initialize the LOCALENTRY structure and specify its size, in bytes, in the dwSize member.		
See Also	LocalInfo, LocalNext		

LocalFlags

2.x

UINT LocalFlags(*hloc*) HLOCAL *hloc*; /* handle of local memory object */

The **LocalFlags** function retrieves information about the given local memory object.

Parameters

hloc Identifies the los

Identifies the local memory object.

Return Value	The low-order byte of the return value contains the lock count of the object; the high-order byte contains either LMEM_DISCARDABLE (object has been marked as discardable) or LMEM_DISCARDED (object has been discarded).
Comments	To retrieve the lock count from the return value, use the LMEM_LOCKCOUNT mask.
See Also	LocalAlloc, LocalLock, LocalReAlloc, LocalUnlock

LocalFree

2.x

HLOCAL LocalFr	ree(hloc)
HLOCAL hloc;	/* handle of local memory object */
	The LocalFree function frees the given local memory object (if the object is not locked) and invalidates its handle.
Parameters	<i>hloc</i> Identifies the local memory object to be freed.
Return Value	The return value is NULL if the function is successful. Otherwise, it is equal to the <i>hloc</i> parameter.
Comments	An application cannot use the LocalFree function to free a locked memory object—that is, a memory object with a lock count greater than zero.
	After freeing the handle of the memory object, an application cannot use the handle again. An attempt to free the same memory object more than once can cause Windows to terminate abnormally.
See Also	LocalFlags, LocalLock

LocalHandle

2.x

HLOCAL LocalHandle(pvMem)

void NEAR* *pvMem*; /* address of local memory object */

The **LocalHandle** function retrieves the handle of the specified local memory object.

Parameters	<i>pvMem</i> Specifies the address of the local memory object.
Return Value	The return value is the handle of the specified local memory object if the function is successful. It is NULL if the specified address has no handle.
See Also	LocalAlloc

LocalInfo

3.1

#include <toolhelp.h>

BOOL LocalInfo (<i>lpli</i> , <i>hglbH</i>	Ieap)	
LOCALINFO FAR* lpli;	/* address of LOCALINFO structure	*/
HGLOBAL hglbHeap;	/* handle of local heap	*/

The **LocalInfo** function fills the specified structure with information that describes the local heap.

Parameters

Points to a **LOCALINFO** structure that will receive information about the local heap. The **LOCALINFO** structure has the following form:

#include <toolhelp.h>

```
typedef struct tagLOCALINFO { /* li */
   DWORD dwSize;
   WORD wcItems;
} LOCALINF0;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

hglbHeap

lpli

Identifies the local heap to be described.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments The information in the **LOCALINFO** structure can be used to determine how much memory to allocate for a local heap walk.

Before calling **LocalInfo**, an application must initialize the **LOCALINFO** structure and specify its size, in bytes, in the **dwSize** member.

See Also LocalFirst, LocalNext

LocalInit

2.x

BOOL LocalInit(uSegment, uStartAddr, uEndAddr)			
UINT uSegment;	/* segment to contain local heap */		
UINT uStartAddr;	/* starting address for heap */		
UINT uEndAddr;	/* ending address for heap */		
	The LocalInit function initializes a local heap in the specified segment.		
Parameters	<i>uSegment</i> Identifies the segment that is to contain the local heap.		
	<i>uStartAddr</i> Specifies the starting address of the local heap within the segment.		
	<i>uEndAddr</i> Specifies the ending address of the local heap within the segment.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	The first 16 bytes of the segment containing a local heap must be reserved for use by the system.		
See Also	GlobalLock, LocalAlloc, LocalReAlloc		

LocalLock

void NEAR* LocalLock(hloc)			
HLOCAL hloc;	/* handle of local memory object */		
	The LocalLock function retrieves a pointer to the given local memory object. LocalLock increments (increases by one) the lock count of movable objects and locks the memory.		
Parameters	<i>hloc</i> Identifies the local memory object to be locked.		

Return Value	The return value points to the first byte of memory in the local object, if the func- tion is successful. It is NULL if the object has been discarded or an error occurs.
Comments	Each time an application calls LocalLock for an object, it must eventually call LocalUnlock for the object.
	This function will return NULL if an application attempts to lock a memory object with a size of 0 bytes.
	The LocalUnlock function decrements (decreases by one) the lock count for the object if LocalLock incremented the count. Other functions can also affect the lock count of a memory object.
	Locked memory will not be moved or discarded unless the memory object is reallocated by the LocalReAlloc function. The object remains locked in memory until its lock count is decreased to zero.
	Discarded objects always have a lock count of zero.
See Also	LocalFlags, LocalReAlloc, LocalUnlock

LocalNext

<pre>#include <toolhelp.h< pre=""></toolhelp.h<></pre>		
BOOL LocalNext(lp LOCALENTRY FA		
	The LocalNext function fills the specified structure with information that describes the next object on the local heap.	
Parameters lple Points to a LOCALENTRY structure that will receive information about local memory object. The LOCALENTRY structure has the following for		
	<pre>#include <toolhelp.h></toolhelp.h></pre>	
	<pre>typedef struct tagLOCALENTRY { /* le */ DWORD dwSize; HLOCAL hHandle; WORD wAddress; WORD wSize; WORD wFlags; WORD wcLock;</pre>	

WORD

wType;

3.1

	WORD hHeap; WORD wHeapType; WORD wNext; } LOCALENTRY;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The LocalNext function can be used to continue a local heap walk started by the LocalFirst function.
See Also	LocalFirst, LocalInfo

LocalReAlloc

HLOCAL LocalRe	Alloc(hloc, fuNewSize, fuFlags	r)	
HLOCAL hloc;	/* handle of local memory o	bject */	
UINT fuNewSize;	/* new size of object	*/	
UINT fuFlags;	/* new allocation attributes	*/	
	The LocalReAlloc function c memory object.	hanges the size or attributes of the given local	
Parameters	y object to be reallocated.		
	 fuNewSize Specifies the new size of the local memory object. fuFlags Specifies how to reallocate the local memory object. If this parameter incl the LMEM_MODIFY and LMEM_DISCARDABLE flags, LocalReAlloo nores the fuNewSize parameter. The fuFlags parameter can be a combinati the following values. 		
	Value	Meaning	
	LMEM_DISCARDABLE	Causes a previously movable object to become discardable. This flag can be used only with LMEM_MODIFY.	
	LMEM_MODIFY	Modifies the object's memory flags. This flag can be used only with LMEM_DISCARDABLE.	

	Value	Meaning	
	LMEM_MOVEABLE	If <i>fuNewSize</i> is zero, this flag causes a previously fixed object to be freed or a previously movable object to be discarded (if the object's lock count is zero). This flag cannot be used with LMEM_MODIFY.	
		If <i>fuNewSize</i> is nonzero and the object identified by the <i>hloc</i> parameter is fixed, this flag allows the reallocated object to be moved to a new fixed location.	
	LMEM_NOCOMPACT	Prevents memory from being compacted or discarded to satisfy the allocation request. This flag cannot be used with LMEM_MODIFY.	
	LMEM_ZEROINIT	If the object is growing, this flag causes the addi- tional memory contents to be initialized to zero. This flag cannot be used with LMEM_MODIFY.	
Return Value	The return value is the handle of the reallocated local memory object, if the func- tion is successful. Otherwise, it is NULL.		
Comments	entsIf LocalReAlloc reallocates a movable object, the return value is a local handle of the memory. To access the memory, an application must use the LocalLock func- tion to convert the handle to a pointer.If LocalReAlloc reallocates a fixed object, the return value is a pointer to the memory. To access the memory, an application can simply cast the return value to a pointer.		
	To free a local memory objec	t, an application should use the LocalFree function.	
See Also	LocalAlloc, LocalDiscard, I	localFree, LocalLock	

LocalShrink

2.x

UINT LocalShrink(hloc, cbNewSize)			
HLOCAL hloc;	/* segment containing local heap	*/	
UINT cbNewSize;	/* new size of local heap	*/	

The LocalShrink function shrinks the local heap in the given segment.

Parameters

hloc

Identifies the segment that contains the local heap. If this parameter is zero, the function shrinks the heap in the current data segment.

2.x

	<i>cbNewSize</i> Specifies the new size, in bytes, of the local heap.
Return Value	The return value specifies the new size of the local heap if the function is successful.
Comments	Windows will not shrink the portion of the data segment that contains the stack and the static variables.
	Use the GlobalSize function to determine the new size of the data segment.
See Also	GlobalSize

LocalSize

UINT LocalSize(hlo	<i>c</i>)
HLOCAL hloc;	/* handle of local memory object */
	The LocalSize function returns the current size, in bytes, of the given local memory object.
Parameters	<i>hloc</i> Identifies the local memory object.
Return Value	The return value specifies the size, in bytes, of the memory object, if the function is successful. It is zero if the specified handle is invalid or if the object has been discarded.
Comments	The size of a memory object sometimes is larger than the size requested when the memory was allocated.
	To verify that the memory object has not been discarded, an application should call the LocalFlags function prior to calling the LocalSize function. If the memory object has been discarded, the return value for LocalSize is meaningless.
See Also	LocalAlloc, LocalFlags

LocalUnlock

BOOL LocalUnloc HLOCAL hloc;	k(<i>hloc</i>) /* handle of local memory object */	
	The LocalUnlock function unlocks the given local memory object. This function has no effect on fixed memory.	
Parameters	<i>hloc</i> Identifies the local memory object to be unlocked.	
Return Value	The return value is zero if the function is successful. Otherwise, it is nonzero.	
Comments	With discardable memory, this function decrements (decreases by one) the object's lock count. The object is completely unlocked, and subject to discarding, if the lock count is decreased to zero.	
See Also	LocalLock	

Lockinput

BOOL LockInput(h	Reserved, hwndInput, fLock)	
HANDLE hReserved	/* reserved, must be NULL	*/
HWND hwndInput;	/* handle of window to receive all input	*/
BOOL fLock;	/* the lock/unlock flag	*/
	The LockInput function locks input to all tasks <i>fLock</i> parameter is TRUE. The given window is receive all input. If <i>fLock</i> is FALSE, LockInput tem to its unlocked state.	made system modal; that is, it will
Parameters	<i>hReserved</i> This parameter is reserved and must be NULI	L.
	<i>hwndInput</i> Identifies the window that is to receive all inp current task. If <i>fLock</i> is FALSE, this parameter	
	<i>fLock</i> Indicates whether to lock or unlock input. A value of FALSE unlocks input.	value of TRUE locks input; a
Return Value	The return value is nonzero if the function is suc	ccessful. Otherwise, it is zero.

2.x

3.1

Comments	Before entering hard mode, a Windows-based debugger calls LockInput , specifying TRUE for the <i>fLock</i> parameter. This action saves the current global state. To exit hard mode, the debugger calls LockInput , specifying FALSE for <i>fLock</i> . This restores the global state to the conditions that existed when the debugger entered hard mode. A debugger must restore the global state before exiting. Calls to Lock-Input cannot be nested.

See Also Directed Yield

LockResource

void FAR* LockRe HGLOBAL hglb;	esource(hglb) /* handle of resource */
	The LockResource function locks the given resource. The resource is locked in memory and its reference count is incremented (increased by one). The locked resource is not subject to discarding.
Parameters	<i>hglb</i> Identifies the resource to be locked. This handle must have been created by using the LoadResource function.
Return Value	The return value points to the first byte of the loaded resource if the function is successful. Otherwise, it is NULL.
Comments	The resource remains locked in memory until its reference count is decreased to zero by calls to the FreeResource function.
	If the resource identified by the <i>hglb</i> parameter has been discarded, the resource- handler function (if any) associated with the resource is called before the Lock- Resource function returns. The resource-handler function can recalculate and reload the resource if necessary. After the resource-handler function returns, LockResource makes another attempt to lock the resource and returns with the result.
	Using the handle returned by the FindResource function for the <i>hglb</i> parameter causes an error.
	Use the UnlockResource macro to unlock a resource that was locked by Lock-Resource .
See Also	FindResource, FreeResource, SetResourceHandler

LockSegment

HGLOBAL LockS UINT uSegment;	egment(uSegment) /* segment to lock */
	The LockSegment function locks the specified discardable segment. The segment is locked into memory at the given address and its lock count is incremented (increased by one).
Parameters	<i>uSegment</i> Specifies the segment address of the segment to be locked. If this parameter is -1, the LockSegment function locks the current data segment.
Return Value	The return value specifies the data segment if the function is successful. It is NULL if the segment has been discarded or an error occurs.
Comments	Locked memory is not subject to discarding except when a portion of the segment is being reallocated by the GlobalReAlloc function. The segment remains locked in memory until its lock count is decreased to zero by the UnlockSegment function.
	Each time an application calls LockSegment for a segment, it must eventually call UnlockSegment for the segment. The UnlockSegment function decrements the lock count for the segment. Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the Global-Flags function.
See Also	GlobalFlags, GlobalReAlloc, LockData, UnlockSegment

LockWindowUpdate

BOOL LockWindowUpdate(*hwndLock*)

HWND hwndLock; /* handle of window */

> The LockWindowUpdate function disables or reenables drawing in the given window. A locked window cannot be moved. Only one window can be locked at a time.

Parameters hwndLock

Identifies the window in which drawing will be disabled. If this parameter is NULL, drawing in the locked window is enabled.

3.1

Return Value The return value is nonzero if the function is successful. It is zero if a failure occurs or if the **LockWindowUpdate** function has been used to lock another window.

Comments If an application with a locked window (or any locked child windows) calls the **GetDC**, **GetDCEx**, or **BeginPaint** function, the called function returns a device context whose visible region is empty. This will occur until the application unlocks the window by calling **LockWindowUpdate**, specifying a value of NULL for *hwndLock*.

While window updates are locked, the system keeps track of the bounding rectangle of any drawing operations to device contexts associated with a locked window. When drawing is reenabled, this bounding rectangle is invalidated in the locked window and its child windows to force an eventual WM_PAINT message to update the screen. If no drawing has occurred while the window updates were locked, no area is invalidated.

The **LockWindowUpdate** function does not make the given window invisible and does not clear the WS_VISIBLE style bit.

LogError		3.1
void LogError(uErr UINT uErr; void FAR* lpvInfo;	r, <i>lpvInfo</i>) /* error type /* address of error information	*/)n */
	The LogError function identifies the most recent system error. An application's interrupt callback function typically calls LogError to return error information to the user.	
Parameters	<i>uErr</i> Specifies the type of error that occurred. The <i>lpvInfo</i> parameter may point to more information about the error, depending on the value of <i>uErr</i> . This parameter may be one or more of the following values:	
	Value	Meaning
	ERR_ALLOCRES	AllocResource failed.
	ERR_BADINDEX	Bad index to GetClassLong, GetClassWord, GetWindowLong, GetWindowWord, Set- ClassLong, SetClassWord, SetWindowLong, or SetWindowWord.
	ERR_BYTE	Invalid 8-bit parameter.

Value	Meaning
ERR_CREATEDC	CreateCompatibleDC, CreateDC, or CreateIC failed.
ERR_CREATEDLG	Could not create dialog box because LoadMenu failed.
ERR_CREATEDLG2	Could not create dialog box because Create- Window failed.
ERR_CREATEMENU	Could not create menu.
ERR_CREATEMETA	CreateMetaFile failed.
ERR_CREATEWND	Could not create window because the class was not found.
ERR_DCBUSY	Device context (DC) cache is full.
ERR_DELOBJSELECTED	Program is trying to delete a bitmap that is selected into the DC.
ERR_DWORD	Invalid 32-bit parameter.
ERR_GALLOC	GlobalAlloc failed.
ERR_GLOCK	GlobalLock failed.
ERR_GREALLOC	GlobalReAlloc failed.
ERR_LALLOC	LocalAlloc failed.
ERR_LLOCK	LocalLock failed.
ERR_LOADMENU	LoadMenu failed.
ERR_LOADMODULE	LoadModule failed.
ERR_LOADSTR	LoadString failed.
ERR_LOCKRES	LockResource failed.
ERR_LREALLOC	LocalReAlloc failed.
ERR_NESTEDBEGINPAINT	Program contains nested BeginPaint calls.
ERR_REGISTERCLASS	RegisterClass failed because the class is already registered.
ERR_SELBITMAP	Program is trying to select a bitmap that is al- ready selected.
ERR_SIZE_MASK	Identifies which 2 bits of <i>uErr</i> specify the size of the invalid parameter.
ERR_STRUCEXTRA	Program is using unallocated space.
ERR_WARNING	A non-fatal error occurred.
ERR_WORD	Invalid 16-bit parameter.

lpvInfo

Points to more information about the error. The value of *lpvInfo* depends on the value of *uErr*. If the value of (*uErr* & ERR_SIZE_MASK) is 0, *lpvInfo* is undefined. Currently, no *uErr* code has defined meanings for *lpvInfo*.

Return Value

This function does not return a value.

Comments	The errors identified by LogError may be trapped by the callback function that NotifyRegister installs.	
	Error values whose low 12 bits are less than 0x07FF are reserved for use by Windows.	
See Also	LogParamError, NotifyRegister	

LogParamError

3.1

void LogParamError(uErr, lpfn, lpvParam)			
UINT uErr;	/* error type	*/	
FARPROC lpfn;	/* address where error occurred	*/	
<pre>void FAR* lpvParam;</pre>	/* address of more error information	*/	

The **LogParamError** function identifies the most recent parameter validation error. An application's interrupt callback function typically calls **LogParamError** to return information about an invalid parameter to the user.

Parameters

uErr

Specifies the type of parameter validation error that occurred. The *lpvParam* parameter may point to more information about the error, depending on the value of *uErr*. This parameter may be one or more of the following values:

Value	Meaning
ERR_BAD_ATOM	Invalid atom.
ERR_BAD_CID	Invalid communications identifier (CID).
ERR_BAD_COORDS	Invalid x,y coordinates.
ERR_BAD_DFLAGS	Invalid 32-bit flags.
ERR_BAD_DINDEX	Invalid 32-bit index or index out-of-range.
ERR_BAD_DVALUE	Invalid 32-bit signed or unsigned value.
ERR_BAD_FLAGS	Invalid bit flags.
ERR_BAD_FUNC_PTR	Invalid function pointer.
ERR_BAD_GDI_OBJECT	Invalid graphics device interface (GDI) object.
ERR_BAD_GLOBAL_HANDLE	Invalid global handle.
ERR_BAD_HANDLE	Invalid generic handle.
ERR_BAD_HBITMAP	Invalid bitmap handle.
ERR_BAD_HBRUSH	Invalid brush handle.
ERR_BAD_HCURSOR	Invalid cursor handle.

Value	Meaning	
ERR_BAD_HDC	Invalid device context (DC) handle.	
ERR_BAD_HDRVR	Invalid driver handle.	
ERR_BAD_HDWP	Invalid handle of a window-position structure.	
ERR_BAD_HFILE	Invalid file handle.	
ERR_BAD_HFONT	Invalid font handle.	
ERR_BAD_HICON	Invalid icon handle.	
ERR_BAD_HINSTANCE	Invalid instance handle.	
ERR_BAD_HMENU	Invalid menu handle.	
ERR_BAD_HMETAFILE	Invalid metafile handle.	
ERR_BAD_HMODULE	Invalid module handle.	
ERR_BAD_HPALETTE	Invalid palette handle.	
ERR_BAD_HPEN	Invalid pen handle.	
ERR_BAD_HRGN	Invalid region handle.	
ERR_BAD_HWND	Invalid window handle.	
ERR_BAD_INDEX	Invalid index or index out-of-range.	
ERR_BAD_LOCAL_HANDLE	Invalid local handle.	
ERR_BAD_PTR	Invalid pointer.	
ERR_BAD_SELECTOR	Invalid selector.	
ERR_BAD_STRING_PTR	Invalid zero-terminated string pointer.	
ERR_BAD_VALUE	Invalid 16-bit signed or unsigned value.	
ERR_BYTE	Invalid 8-bit parameter.	
ERR_DWORD	Invalid 32-bit parameter.	
ERR_PARAM	A parameter validation error occurred. This flag is always set.	
ERR_SIZE_MASK	Identifies which 2 bits of <i>uErr</i> specify the size of the invalid parameter.	
ERR_WARNING	An invalid parameter was detected, but the error is not serious enough to cause the func- tion to fail. The invalid parameter is reported, but the call runs as usual.	
ERR_WORD	Invalid 16-bit parameter.	

lpfn

Specifies the address at which the parameter error occurred. This value is NULL if the address is unknown.

lpvParam

Points to more information about the error. The value of *lpvParam* depends on the value of *uErr*. If the value of (*uErr* & ERR_SIZE_MASK) is 0, *lpvParam* is undefined. Currently, no *uErr* code has defined meanings for *lpvParam*.

Return Value This function does not return a value.

Comments The errors identified by LogParamError may be trapped by the callback function that NotifyRegister installs.

> Error values whose low 12 bits are less than 0x07FF are reserved for use by Windows.

The size of the value passed in *lpvParam* is determined by the values of the bits selected by ERR_SIZE_MASK, as follows:

```
switch (err & ERR_SIZE_MASK)
ſ
case ERR_BYTE:
                        /* 8-bit invalid parameter */
    b = LOBYTE(param);
    break;
case ERR WORD:
                        /* 16-bit invalid parameter */
    w = LOWORD(param);
    break:
case ERR DWORD:
                        /* 32-bit invalid parameter */
    1 = (DWORD)param;
    break:
default:
                        /* invalid parameter value is unknown */
    break;
}
```

lopen

HFILE _lopen(lpszFilena LPCSTR lpszFilename; int fnOpenMode;	<i>ume, fnOpenMode</i>) /* address of file to open /* file access	*/ */
The _lopen function opens an existing file and sets the file pointer to the begin- ning of the file.		
P	Filename oints to a null-terminated string oust consist of characters from t	g that names the file to be opened. The string the Windows character set.

fnOpenMode Specifies the modes in which to open the file. This parameter consists of one access mode and an optional share mode.

	Value	Access mo	de
	READ	Opens the f	file for reading only.
	READ_WRITE	Opens the f	file for reading and writing.
	WRITE	Opens the file for writing only.	
	Value		Share mode (optional)
	OF_SHARE_COM	IPAT	Opens the file in compatibility mode, allowing any process on a given machine to open the file any number of times. If the file has been opened by using any of the other sharing modes, _lopen fails.
	OF_SHARE_DEN	Y_NONE	Opens the file without denying other programs read or write access to the file. If the file has been opened in compatibility mode by any other program, _lopen fails.
	OF_SHARE_DEN	Y_READ	Opens the file and denies other programs read access to the file. If the file has been opened in compatibility mode or for read access by any other program, _lopen fails.
	OF_SHARE_DEN	Y_WRITE	Opens the file and denies other programs write access to the file. If the file has been opened in compatibility mode or for write access by any other program, _lopen fails.
	OF_SHARE_EXC	LUSIVE	Opens the file in exclusive mode, denying other programs both read and write access to the file. If the file has been opened in any other mode for read or write access, even by the current program, _lopen fails.
Return Value	The return value is a file handle if the function is successful. Otherwise, it is HFILE_ERROR.		
Example	The following exam	ple uses the	_lopen function to open an input file:
	HFILE hfReadFile; /* Open the input file (read only). */		
	hfReadFile = _lopen("testfile", READ);		
	if (hfReadFile == ErrorHandler(}	_)R) {

LPtoDP		2.x	(
BOOL LPtoDP(hdc HDC hdc; POINT FAR* lppt; int cPoints;	<i>, lppt, cPoints</i>) /* handle of device context /* address of array with points /* number of points in array	*/ */ */	
	The LPtoDP function converts logic	cal coordinates (points) into device coordinate	s.
Parameters	<i>hdc</i> Identifies the device context.		
		ctures. The coordinates in each structure are of the current device context. The POINT	
	<pre>typedef struct tagPOINT { / int x; int y; } POINT;</pre>	* pt */	
	For a full description of this struc <i>mer's Reference, Volume 3</i> .	ture, see the Microsoft Windows Program-	
	<i>cPoints</i> Specifies the number of points in	the array.	
Return Value	The return value is nonzero if the fu	nction is successful. Otherwise, it is zero.	
Comments	The conversion depends on the curre origins and extents of the device's w	ent mapping mode and the settings of the vindow and viewport.	
	through 32,767. In cases where the r	re 2-byte signed integers in the range –32,768 napping mode would result in values larger values to –32,768 and 32,767, respectively.	3
Example		ping mode to MM_LOENGLISH and then t the coordinates of a rectangle into device	

RECT rc;

SetMapMode(hdc, MM_LOENGLISH); SetRect(&rc, 100, -100, 200, -200); LPtoDP(hdc, (LPPOINT) &rc, 2);

See Also

DPtoLP

_lread

UINT _lread(hf, hp HFILE hf; void _huge* hpvBuj UINT cbBuffer;	/* file handle */
	The _lread function reads data from the specified file.
Parameters	<i>hf</i> Identifies the file to be read.
	<i>hpvBuffer</i> Points to a buffer that is to receive the data read from the file.
	<i>cbBuffer</i> Specifies the number of bytes to be read from the file. This value cannot be greater than 0xFFFE (65,534).
Return Value	The return value indicates the number of bytes that the function read from the file, if the function is successful. If the number of bytes read is less than the number specified in <i>cbBuffer</i> , the function reached the end of the file (EOF) before reading the specified number of bytes. The return value is HFILE_ERROR if the function fails.
Example	The following example uses the _lread and _lwrite functions to copy data from one file to another:
	HFILE hfReadFile; int cbRead; PBYTE pbBuf;
	/* Allocate a buffer for file I/0. */
	<pre>pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);</pre>
	/* Copy the input file to the temporary file. */

2.x

2.x

```
do {
    cbRead = _lread(hfReadFile, pbBuf, 2048);
    _lwrite(hfTempFile, pbBuf, cbRead);
} while (cbRead != 0);
/* Free the buffer and close the files. */
LocalFree((HLOCAL) pbBuf);
_lclose(hfReadFile);
_lclose(hfTempFile);
```

See Also

_hread, _lwrite

Istrcat

	String1, lpszString2)*//* address of buffer for concatenated strings*/2;/* address of string to add to string1*/The lstrcat function appends one string to another.
Parameters	<i>lpszString1</i> Points to a byte array containing a null-terminated string. The byte array containing the string must be large enough to contain both strings.
	<i>lpszString2</i> Points to the null-terminated string to be appended to the string specified in the <i>lpszString1</i> parameter.
Return Value	The return value points to <i>lpszString1</i> if the function is successful.
Comments	Both strings must be less than 64K in size.
Example	<pre>The following example uses the lstrcat function to append a test string to a buffer: char szBuf[80] = { "the test string is " }; lstrcat(szBuf, lpsz); MessageBox(hwnd, szBuf, "lstrcat", MB_OK);</pre>

Istrcmp

int lstrcmp(lpszStrin LPCSTR lpszString LPCSTR lpszString	<i>I</i> ; /* address of first string */
	The lstrcmp function compares two character strings. The comparison is case-sensitive.
Parameters	<i>lpszString1</i> Points to the first null-terminated string to be compared.
	<i>lpszString2</i> Points to the second null-terminated string to be compared.
Return Value	The return value is less than zero if the string specified in <i>lpszString1</i> is less than the string specified in <i>lpszString2</i> , is greater than zero if <i>lpszString1</i> is greater than <i>lpszString2</i> , and is zero if the two strings are equal.
Comments	The lstrcmp function compares two strings by checking the first characters against each other, the second characters against each other, and so on, until it finds an inequality or reaches the ends of the strings. The function returns the difference of the values of the first unequal characters it encounters. For example, lstrcmp determines that "abcz" is greater than "abcdefg" and returns the difference of "z" and "d".
	The language driver for the language selected by the user determines which string is greater (or whether the strings are the same). If no language driver is selected, Windows uses an internal function. With the Windows United States language functions, uppercase characters have lower values than lowercase characters.
	With a double-byte character set (DBCS) version of Windows, this function can compare two DBCS strings.
	Both strings must be less than 64K in size.
See Also	lstrcmpi

Istrcmpi

int lstrcmpi(lpszString1, lpszString2) LPCSTR lpszString1; /* address of first string */ LPCSTR lpszString2; /* address of second string */ 3.0

	The lstrcmpi function compares the two strings. The comparison is not case- sensitive.
Parameters	<i>lpszString1</i> Points to the first null-terminated string to be compared.
	<i>lpszString2</i> Points to the second null-terminated string to be compared.
Return Value	The return value is less than zero if the string specified in <i>lpszString1</i> is less than the string specified in <i>lpszString2</i> , is greater than zero if <i>lpszString1</i> is greater than <i>lpszString2</i> , and is zero if the two strings are equal.
Comments	The lstrcmpi function compares two strings by checking the first characters against each other, the second characters against each other, and so on, until it finds an inequality or reaches the ends of the strings. The function returns the difference of the values of the first unequal characters it encounters. For example, lstrcmpi determines that "abcz" is greater than "abcdefg" and returns the difference of "z" and "d".
	The language driver for the language selected by the user determines which string is greater (or whether the strings are the same). If no language driver is selected, Windows uses an internal function.
	With a double-byte character set (DBCS) version of Windows, this function can compare two DBCS strings.
	Both strings must be less than 64K in size.
See Also	lstrcmp

Istrcpy

2.x

LPSTR lstrcpy(lpszStrin	ng1, lpszString2)	
LPSTR <i>lpszString1</i> ;	/* address of buffer	*/
LPCSTR lpszString2;	/* address of string to copy	*/

The **lstrcpy** function copies a string to a buffer.

Parameters*lpszString1*Points to a buffer that will receive the contents of the string pointed to by the
lpszString2 parameter. The buffer must be large enough to contain the string, in-
cluding the terminating null character.

	<i>lpszString2</i> Points to the null-terminated string to be copied.
Return Value	The return value is a pointer to <i>lpszString1</i> if the function is successful. Otherwise, it is NULL.
Comments	This function can be used to copy a double-byte character set (DBCS) string.
	Both strings must be less than 64K in size.
See Also	lstrlen

Istrlen

2.x

2.x

int lstrlen(lpszString LPCSTR lpszString	
	The lstrlen function returns the length, in bytes, of the specified string (not including the terminating null character).
Parameters	<i>lpszString</i> Points to a null-terminated string. This string must be less than 64K in size.
Return Value	The return value specifies the length, in bytes, of the string pointed to by the <i>lpszString</i> parameter. There is no error return.
See Also	lstrcpy

_lwrite

UINT _lwrite(<i>hf</i> , <i>hpvBuffer</i> , <i>cbBu</i>	uffer)	
HFILE hf;	/* file handle	*/
<pre>const void _huge* hpvBuffer;</pre>	/* address of buffer for write data	*/
UINT cbBuffer;	/* size of data	*/

The _lwrite function writes data to the specified file.

Parameters	<i>hf</i> Identifies the file to be written to.
	<i>hpvBuffer</i> Points to a buffer that contains the data to be written to the file.
	<i>cbBuffer</i> Specifies the number of bytes to be written to the file. If this parameter is zero, the file is expanded or truncated to the current file-pointer position.
Return Value	The return value indicates the number of bytes written to the file, if the function is successful. Otherwise, the return value is HFILE_ERROR.
Comments	The buffer specified by <i>hpvBuffer</i> cannot extend past the end of a segment.
Example	The following example uses the _lread and _lwrite functions to copy data from one file to another:
	int cbRead; PBYTE pbBuf;
	/* Allocate a buffer for file I/0. */
	<pre>pbBuf = (PBYTE) LocalAlloc(LMEM_FIXED, 2048);</pre>
	/* Copy the input file to the temporary file. */
	<pre>do { cbRead = _lread(hfReadFile, pbBuf, 2048); _lwrite(hfTempFile, pbBuf, cbRead); } while (cbRead != 0);</pre>
	/* Free the buffer and close the files. */
	LocalFree((HLOCAL) pbBuf);
	<pre>_lclose(hfReadFile); _lclose(hfTempFile);</pre>
See Also	_hwrite, _lread

LZClose

#include <lzexpand.h>

void LZClose(<i>hf</i>) HFILE <i>hf</i> ; /* h	andle of file to be closed */
	The LZClose function closes a file that was opened by the LZOpenFile or Open-File function.
Parameters	<i>hf</i> Identifies the source file.
Return Value	This function does not return a value.
Comments	If the file was compressed by Microsoft File Compression Utility (COMPRESS.EXE) and opened by the LZOpenFile function, LZClose frees any global heap space that was required to expand the file.
Example	The following example uses LZClose to close a file opened by LZOpenFile:
	<pre>char szSrc[] = {"readme.txt"}; char szDst[] = {"readme.bak"}; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest; HFILE hfSrcFile, hfDstFile;</pre>
	/* Open the source file. */
	hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ);
	/* Create the destination file. */
	hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE);
	/* Copy the source file to the destination file. */
	LZCopy(hfSrcFile, hfDstFile);
	/* Close the files. */
	LZClose(hfSrcFile); LZClose(hfDstFile);
See Also	OpenFile, LZOpenFile

LZCopy

#include <lzexpand.h>

LONG LZCopy(hf. HFILE hfSource;	/* handle of source file	*/
HFILE hfDest;	/* handle of destination file	*/
	was compressed by Microsoft Fil	ource file to a destination file. If the source file le Compression Utility (COMPRESS.EXE), this destination file. If the source file was not com- the original file.
Parameters	hfSource Identifies the source file. (This when a compressed file is open hfDest Identifies the destination file.	s handle is returned by the LZOpenFile function ned.)
Return Value	The return value is the size, in bytes, of the destination file if the function is successful. Otherwise, it is an error value that is less than zero and may be one of the following:	
	Value	Meaning
	LZERROR_BADINHANDLE	The handle identifying the source file was not valid.
	LZERROR_BADOUTHANDLE	The handle identifying the destination file was not valid.
	LZERROR_GLOBALLOC	There is insufficient memory for the required buffers.
	LZERROR_GLOBLOCK	The handle identifying the internal data structures is invalid.
	LZERROR_READ	The source file format was not valid.
	LZERROR_UNKNOWNALG	The source file was compressed with an unrecog- nized compression algorithm.
	LZERROR_WRITE	There is insufficient space for the output file.
Comments	This function is designed for sing function for multiple-file copy op	ele-file copy operations. (Use the CopyLZFile berations.)
	If the function is successful, the f	ile identified by hfDest is uncompressed.
	If the source or destination file is	opened by a C run-time function (rather than the

_lopen or **OpenFile** function), it must be opened in binary mode.

Example The following example uses the LZCopy function to copy a file: char szSrc[] = {"readme.txt"}; char szDst[] = {"readme.bak"}; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest: HFILE hfSrcFile, hfDstFile; /* Open the source file. */ hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ); /* Create the destination file. */ hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE); /* Copy the source file to the destination file. */ LZCopy(hfSrcFile, hfDstFile); /* Close the files. */ LZClose(hfSrcFile); LZClose(hfDstFile); See Also CopyLZFile, _lopen, LZOpenFile, OpenFile

LZDone

#include <lzexpand.h>

void LZDone(void)

	The LZDone function frees buffers that the LZStart function allocated for multiple-file copy operations.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
Comments	Applications that copy multiple files should call LZStart before copying the files with the CopyLZFile function. LZStart allocates buffers for the file copy operations.
Example	The following example uses LZDone to free buffers allocated by LZStart:

```
#define NUM FILES
                  4
char *szSrc[NUM_FILES] =
    {"readme.txt", "data.txt", "update.txt", "list.txt"};
char *szDest[NUM_FILES] =
    {"readme.bak", "data.bak", "update.bak", "list.bak"};
OFSTRUCT ofStrSrc:
OFSTRUCT ofStrDest;
HFILE hfSrcFile, hfDstFile;
int i:
/* Allocate internal buffers for the CopyLZFile function. */
LZStart();
/* Open, copy, and then close the files. */
for (i = 0; i < NUM_FILES; i++) {</pre>
   hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ);
   hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE);
   CopyLZFile(hfSrcFile, hfDstFile);
   LZClose(hfSrcFile);
   LZClose(hfDstFile):
}
LZDone(); /* free the internal buffers */
```

See Also

CopyLZFile, LZCopy, LZStart

LZInit

#include <lzexpand.h>

HFILE LZInit(hfSi HFILE hfSrc; /	rc) ** handle of source file */
	The LZInit function allocates memory for, creates, and initializes the internal data structures that are required to decompress files.
Parameters	<i>hfSrc</i> Identifies the source file.
Return Value	The return value is the original file handle if the function is successful and the file is not compressed. If the function is successful and the file is compressed, the re- turn value is a new file handle. If the function fails, the return value is an error value that is less than zero and may be one of the following:

	Value	Meaning		
	LZERROR_BADINHANDLE	The handle identifying the source file is invalid.		
	LZERROR_GLOBALLOC	There is insufficient memory for the required inter- nal data structures. This value is returned when an application attempts to open more than 16 files.		
	LZERROR_GLOBLOCK	The handle identifying global memory is invalid. (The internal call to the GlobalLock function failed.)		
	LZERROR_READ	The source file format is invalid.		
	LZERROR_UNKNOWNALG	The file was compressed with an unrecognized compression algorithm.		
Comments	A maximum of 16 compressed	files can be open at any given time.		
Example	The following example uses LZInit to initialize the internal structures that are re- quired to decompress a file:			
	<pre>char szSrc[] = {"readme.cmp"}; char szFileName[128]; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest; HFILE hfSrcFile, hfDstFile, hfCompFile; int cbRead; BYTE abBuf[512];</pre>			
	/* Open the compressed source file. */			
	hfSrcFile = OpenFile(szSrc, &ofStrSrc, OF_READ);			
	/* * Initialize internal data structures for the decompression * operation. */			
	hfCompFile = LZInit(hfSrcFile);			
	/* Retrieve the original name for the compressed file. */			
	<pre>GetExpandedName(szSrc, szFileName);</pre>			
	/* Create the destination file using the original name. */			
	hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);			
	/* Copy the compressed source file to the destination file. */			
	do { if ((cbRead = LZRead(hf _lwrite(hfDstFile,	CompFile, abBuf, sizeof(abBuf))) > 0) abBuf, cbRead);		

LZOpenFile

#include <lzexpand.h>

HFILE LZOpenFile	e(lpszFil	e, lpof, style)		
LPCSTR lpszFile;	-	/* address of filename		*/
OFSTRUCT FAR*	lpof;	/* address of structure for	or file info	*/
UINT style;		/* action to be taken		*/
		OpenFile function create of to which <i>lpszFile</i> point		as, or deletes the file specified by
Parameters	<i>lpszFile</i> Poin	ts to a string that specifies	s the name of a f	ïle.
	 <i>lpof</i> Points to the OFSTRUCT structure that is to receive information about the file when the file is opened. The structure can be used in subsequent calls to LZOpenFile to refer to the open file. The szPathName member of this structure contains characters from the OEM character set. For more information about the OEM character set, see the Microsoft Windows Guide to Programming. 		be used in subsequent calls to ntains characters from the ut the OEM character set, see	
<i>style</i> Specifies the action to be taken. These styles can be combined by bitwise OR operator:		~		
	Valu	e	Meaning	
	OF_C	CANCEL	box. Choosing t	button to the OF_PROMPT dialog he Cancel button directs LZOpen - file-not-found error message.
	OF_C	CREATE		nFile to create a new file. If the ts, it is truncated to zero length.

Return Value

Comments

Example

Value	Meaning
OF_DELETE	Deletes the file.
OF_EXIST	Opens the file, and then closes it. This action is used to test for file existence.
OF_PARSE	Fills the OFSTRUCT structure, but carries out no other action.
OF_PROMPT	Displays a dialog box if the requested file does not exist. The dialog box informs the user that Windows cannot find the file and prompts the user to insert the disk containing the file in drive A.
OF_READ	Opens the file for reading only.
OF_READWRITE	Opens the file for reading and writing.
OF_REOPEN	Opens the file using information in the reopen buffer.
OF_SHARE_DENY_NONE	Opens the file without denying other programs read access or write access to the file. LZOpen- File fails if the file has been opened in compati- bility mode by any other program.
OF_SHARE_DENY_READ	Opens the file and denies other programs read access to the file. LZOpenFile fails if the file has been opened in compatibility mode or for read access by any other program.
OF_SHARE_DENY_WRITE	Opens the file and denies other programs write access to the file. LZOpenFile fails if the file has been opened in compatibility mode or for write access by any other program.
OF_SHARE_EXCLUSIVE	Opens the file in exclusive mode, denying other programs both read access and write access to the file. LZOpenFile fails if the file has been opened in any other mode for read access or write access, even by the current program.
OF_WRITE	Opens the file for writing only.
value specified by <i>style</i> is not OI with <i>style</i> set to the OF_READ with function fails, the return value If <i>style</i> is OF_READ (or OF_READ)	AD and any of the OF_SHARE_ flags) and the calls the LZInit function, which performs the re-
The following example uses LZ nation file into which the source	OpenFile to open a source file and create a destifile can be copied:

3.1

char szSrc[] = {"readme.txt"}; char szDst[] = {"readme.bak"}; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest; HFILE hfSrcFile, hfDstFile; /* Open the source file. */ hfSrcFile = LZOpenFile(szSrc, &ofStrSrc, OF_READ); /* Create the destination file. */ hfDstFile = LZOpenFile(szDst, &ofStrDest, OF_CREATE); /* Copy the source file to the destination file. */ LZCopy(hfSrcFile, hfDstFile); /* Close the files. */ LZClose(hfSrcFile); LZClose(hfDstFile);

LZInit

LZRead

#include <lzexpand.h>

int LZRead(hf, lpvB	uf, cb)	
HFILE hf;	/* handle of the file	*/
<pre>void FAR* lpvBuf;</pre>	/* address of buffer for file data	*/
int cb;	/* number of bytes to read	*/
	The LZRead function reads into a buff	fer bytes from a file.
Parameters	<i>hf</i> Identifies the source file.	
	<i>lpvBuf</i> Points to a buffer that is to receive the	ne bytes read from the file.
	<i>cb</i> Specifies the maximum number of b	bytes to be read.

Return Value The return value is the actual number of bytes read if the function is successful. Otherwise, it is an error value that is less than zero and may be any of the following:

	Value	Meaning	
	LZERROR_BADINHANDLE	The handle identifying the source file was invalid.	
	LZERROR_BADVALUE	The <i>cb</i> parameter specified a negative value.	
	LZERROR_GLOBLOCK	The handle identifying required initialization data is invalid.	
	LZERROR_READ	The format of the source file was invalid.	
	LZERROR_UNKNOWNALG	The file was compressed with an unrecognized com- pression algorithm.	
Comments	If the file is not compressed, L2 the read operation.	ZRead calls the _lread function, which performs	
	If the file is compressed, LZRead emulates _lread on an expanded image of the file and copies the bytes of data into the buffer to which <i>lpvBuf</i> points.		
		ed by Microsoft File Compression Utility penFile, LZSeek, and LZRead functions can be _llseek, and _lread functions.	
Example	The following example uses L2	ZRead to copy and decompress a compressed file:	
	<pre>char szSrc[] = {"readme.cmp char szFileName[128]; OFSTRUCT ofStrSrc; OFSTRUCT ofStrDest; HFILE hfSrcFile, hfDstFile, int cbRead; BYTE abBuf[512];</pre>		
	brit abbar[J12],		
	/* Open the compressed sour	ce file. */	
	hfSrcFile = OpenFile(szSrc,	&ofStrSrc, OF_READ);	
	/* * Initialize internal data * operation. */	structures for the decompression	
	hfCompFile = LZInit(hfSrcFi	le);	
	/* Retrieve the original na	me for the compressed file. */	
	GetExpandedName(szSrc, szFi	leName);	

3.1

```
/* Create the destination file using the original name. */
hfDstFile = LZOpenFile(szFileName, &ofStrDest, OF_CREATE);
/* Copy the compressed source file to the destination file. */
do {
    if ((cbRead = LZRead(hfCompFile, abBuf, sizeof(abBuf))) > 0)
        __lwrite(hfDstFile, abBuf, cbRead);
    else {
        . .
        /* handle error condition */
        .
        /* handle error condition */
        .
        /* Close the files. */
LZClose(hfSrcFile);
LZClose(hfDstFile);
__llseek, __lread, LZOpenFile, LZRead, LZSeek
```

See Also	_llseek				

LZStart

#include <lzexpand.h>

int LZStart(void)

The **LZStart** function allocates the buffers that the **CopyLZFile** function uses to copy a source file to a destination file.

- Parameters This function has no parameters.
- **Return Value** The return value is nonzero if the function is successful. Otherwise, it is LZERROR_GLOBALLOC.
- **Comments** Applications that copy (or copy and decompress) multiple consecutive files should call the **LZStart**, **CopyLZFile**, and **LZDone** functions. Applications that copy a single file should call the **LZCopy** function.

2.x

```
Example
                   The following example uses LZStart to allocate buffers used by CopyLZFile:
                   #define NUM_FILES
                                        4
                   char *szSrc[NUM FILES] =
                       {"readme.txt", "data.txt", "update.txt", "list.txt"};
                   char *szDest[NUM FILES] =
                       {"readme.bak", "data.bak", "update.bak", "list.bak"};
                   OFSTRUCT ofStrSrc:
                   OFSTRUCT ofStrDest:
                   HFILE hfSrcFile, hfDstFile;
                   int i:
                   /* Allocate internal buffers for the CopyLZFile function. */
                   LZStart();
                   /* Open, copy, and then close the files. */
                   for (i = 0; i < NUM_FILES; i++) {</pre>
                       hfSrcFile = LZOpenFile(szSrc[i], &ofStrSrc, OF_READ);
                       hfDstFile = LZOpenFile(szDest[i], &ofStrDest, OF_CREATE);
                       CopyLZFile(hfSrcFile, hfDstFile);
                       LZClose(hfSrcFile):
                       LZClose(hfDstFile);
                   }
                   LZDone(); /* free the internal buffers */
See Also
                   CopyLZFile, LZCopy, LZDone
```

MakeProcInstance

FARPROC MakePr FARPROC lpProc; HINSTANCE hinst;	
	The MakeProcInstance function returns the address of the prolog code for an exported function. The prolog code binds an instance data segment to an exported function. When the function is called, it has access to variables and data in that instance data segment.
Parameters	<i>lpProc</i> Specifies the address of an exported function.

	<i>hinst</i> Identifies the instance associated with the desired data segment.
Return Value	The return value points to the prolog code for the specified exported function, if MakeProcInstance is successful. Otherwise, it is NULL.
Comments	The MakeProcInstance function is used to retrieve a calling address for a func- tion that must be called by Windows, such as an About procedure. This function must be used only to access functions from instances of the current module. If the address specified in the <i>lpProc</i> parameter identifies a procedure in a dynamic-link library, MakeProcInstance returns the same address specified in <i>lpProc</i> .
	After MakeProcInstance has been called for a particular function, all calls to that function should be made through the retrieved address.
	The FreeProcInstance function frees the function from the data segment bound to it by the MakeProcInstance function.
	MakeProcInstance will create more than one procedure instance. To avoid wast- ing memory, an application should not call MakeProcInstance more than once using the same function and instance handle.
See Also	FreeProcInstance, GetProcAddress

MapDialogRect

void MapDialogRe	ct(hwndDlg, lprc)	
HWND hwndDlg;	/* handle of dialog box	*/
RECT FAR* <i>lprc</i> ;	/* address of structure with rectangle	*/
	The MapDialogRect function converts (m screen units (pixels).	aps) the specified dialog box units to
Parameters	<i>hwndDlg</i> Identifies a dialog box. This dialog box CreateDialog or DialogBox function.	must have been created by using the
	lprc	- 4h - 1/-1 1

Points to a **RECT** structure that contains the dialog box coordinates to be converted. The **RECT** structure has the following form:

2.x

3.0

	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.</pre>	
Return Value	This function does not return a value.	
Comments	The MapDialogRect function converts the dialog box units of a rectangle to screen units. Dialog box units are defined in terms of the current dialog base unit, which is derived from the average width and height of characters in the font used for dialog box text. Typically, dialog boxes use the System font, but an application can specify a different font by using the DS_SETFONT style in the resource-definition file.	
	One horizontal unit is one-fourth of the dialog box base width unit, and one verti- cal unit is one-eighth of the dialog box base height unit. The GetDialogBaseUnits function retrieves the dialog box base units in pixels.	
See Also	CreateDialog, DialogBox, GetDialogBaseUnits	

MapVirtualKey

UINT MapVirtualk UINT uKeyCode; UINT fuMapType;	ey(uKeyCode, fuMapType)/* virtual-key code or scan code*//* translation to perform*/	
	The MapVirtualKey function translates (maps) a virtual-key code into a scan code or ASCII value, or it translates a scan code into a virtual-key code.	
Parameters	<i>uKeyCode</i> Specifies the virtual-key code or scan code for a key. How this parameter is in- terpreted depends on the value of the <i>fuMapType</i> parameter.	
	<i>fuMapType</i> Specifies the translation to perform. If this parameter is 0, the <i>uKeyCode</i> parameter is a virtual-key code and is translated into its corresponding scan cod If <i>fuMapType</i> is 1, <i>uKeyCode</i> is a scan code and is translated to a virtual-key code. If <i>fuMapType</i> is 2, <i>uKeyCode</i> is a virtual-key code and is translated to a unshifted ASCII value. Other values are reserved.	

Return Value The return value depends on the value of the *uKeyCode* and *fuMapType* parameters. For more information, see the description of the *fuMapType* parameter.

3.1

See Also OemKeyScan, VkKeyScan

MapWindowPoints

	oints(hwndFrom, hwndTo, lppt, cPoints)
HWND hwndFrom; HWND hwndTo; POINT FAR* lppt;	/* handle of window to be mapped from*//* handle of window to be mapped to*//* address of structure array with points to map*/
UINT cPoints;	/* number of structures in array */
	The MapWindowPoints function converts (maps) a set of points from a coordinate space relative to one window to a coordinate space relative to another window.
Parameters	<i>hwndFrom</i> Identifies the window from which points are converted. If this parameter is NULL or HWND_DESKTOP, the points are assumed to be in screen coordinates.
	<i>hwndTo</i> Identifies the window to which points are converted. If this parameter is NULL or HWND_DESKTOP, the points are converted to screen coordinates.
	<i>lppt</i> Points to an array of POINT structures that contain the set of points to be converted. This parameter can also point to a RECT structure, in which case the <i>cPoints</i> parameter should be set to 2. The POINT structure has the following form:
	typedef struct tagPOINT { /* pt */ int x; int y; } POINT;
	The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>

3.1

For a full description of these structures, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

cPoints

Specifies the number of **POINT** structures in the array pointed to by the *lppt* parameter.

Return Value This function does not return a value.

See Also ClientToScreen, ScreenToClient

MemManInfo

#include <toolhelp.h>

BOOL MemManIı MEMMANINFO I	
	The MemManInfo function fills the specified structure with status and perform- ance information about the memory manager. This function is most useful in 386 enhanced mode but can also be used in standard mode.
Parameters	<i>lpmmi</i> Points to a MEMMANINFO structure that will receive information about the memory manager. The MEMMANINFO structure has the following form:
	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagMEMMANINFO { /* mmi */ DWORD dwSize; DWORD dwLargestFreeBlock; DWORD dwMaxPagesAvailable; DWORD dwMaxPagesLockable; DWORD dwTotalLinearSpace; DWORD dwTotalUnlockedPages; DWORD dwFreePages; DWORD dwTrotalPages; DWORD dwFreeLinearSpace; DWORD dwSwapFilePages; WORD wPageSize; } MEMMANINF0;</pre>
) HERITALITO,

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments This function is included for advisory purposes.

Before calling **MemManInfo**, an application must initialize the **MEM-MANINFO** structure and specify its size, in bytes, in the **dwSize** member.

MemoryRead

#include <toolhelp.h>

DWORD MemoryR	kead (<i>wSel</i> , <i>dwOffset</i> , <i>lpvBuf</i> , <i>dwcb</i>) /* selector of global heap object */
WORD wSel; DWORD dwOffset;	/* selector of global heap object */ /* offset to object */
void FAR* lpvBuf;	/* address of buffer to read to */
DWORD dwcb;	/* number of bytes to read */
	The MemoryRead function copies memory from the specified global heap object to the specified buffer.
Parameters	wSel
	Specifies the global heap object from which to read. This value must be a selector on the global heap; if the value is an alias selector or a selector in a tiled selector array, MemoryRead will fail.
	<i>dwOffset</i> Specifies the offset in the object specified in the <i>wSel</i> parameter at which to begin reading. The <i>dwOffset</i> value may point anywhere within the object; it may be greater than 64K if the object is larger than 64K.
	<i>lpvBuf</i> Points to the buffer to which MemoryRead will copy the memory from the object. This buffer must be large enough to contain the entire amount of memory copied to it. If the application is running under low memory conditions, <i>lpvBuf</i> should be in a fixed object while MemoryRead copies data to it.
	<i>dwcb</i> Specifies the number of bytes to copy from the object to the buffer pointed to by <i>lpvBuf</i> .
Return Value	The return value is the number of bytes copied from <i>wSel</i> to <i>lpvBuf</i> . If <i>wSel</i> is invalid or if <i>dwOffset</i> is out of the selector's range, the return value is zero.
Comments	The MemoryRead function enables developers to examine memory without consideration for selector tiling and aliasing. MemoryRead reads memory in

3.1

read-write or read-only objects. This function can be used in any size object owned by any task. It is not necessary to compute selector array offsets.

The **MemoryRead** and **MemoryWrite** functions are designed to read and write objects loaded by the **LoadModule** function or allocated by the **GlobalAlloc** function. Developers should *not* split off the selector portion of a far pointer and use this as the value for *wSel*, unless the selector is known to be on the global heap.

See Also

MemoryWrite

MemoryWrite

#include <toolhelp.h>

DWORD MemoryV WORD wSel; DWORD dwOffset; void FAR* lpvBuf; DWORD dwcb;	Vrite(wSel, dwOffset, lpvBuf, dwcb) /* selector of global heap object /* offset to object /* address of buffer to write from /* number of bytes to write	*/ */ */
	The MemoryWrite function copies met specified global heap object.	mory from the specified buffer to the
Parameters	<i>wSel</i> Specifies the global heap object to which MemoryWrite will write. This value must be a selector on the global heap; if the value is an alias selector or a selec- tor in a tiled selector array, MemoryWrite will fail.	
	<i>dwOffset</i> Specifies the offset in the object at which to begin writing. The <i>dwOffset</i> value may point anywhere within the object; it may be greater than 64K if the object is larger than 64K.	
		horyWrite will copy the memory to the ob- er low memory conditions, <i>lpvBuf</i> should rite copies data from it.
	<i>dwcb</i> Specifies the number of bytes to copy by <i>lpvBuf</i> .	to the object from the buffer pointed to
Return Value	The return value is the number of bytes is invalid or if <i>dwOffset</i> is out of the sele	copied from <i>lpvBuf</i> to <i>wSel</i> . If the selector ector's range, the return value is zero.

Comments	The MemoryWrite function enables developers to modify memory without con- sideration for selector tiling and aliasing. MemoryWrite writes memory in read- write or read-only objects. This function can be used in any size object owned by any task. It is not necessary to make alias objects writable or to compute selector array offsets.
	The MemoryRead and MemoryWrite functions are designed to read and write objects loaded by the LoadModule function or allocated by the GlobalAlloc function. Developers should <i>not</i> split off the selector portion of a far pointer and use this as the value for <i>wSel</i> , unless the selector is known to be on the global heap.
See Also	MemoryRead
MessageBeep 2.x	

void MessageBeep(uAlert) UINT uAlert; /* alert level */

The **MessageBeep** function plays a waveform sound corresponding to a given system alert level. The sound for each alert level is identified by an entry in the [sounds] section of the WIN.INI initialization file.

Parameters

uAlert

Specifies the alert level. This parameter can be one of the following values:

Value	Meaning
-1	Produces a standard beep sound by using the computer speaker.
MB_ICONASTERISK	Plays the sound identified by the SystemAsterisk entry in the [sounds] section of WIN.INI.
MB_ICONEXCLAMATION	Plays the sound identified by the System- Exclamation entry in the [sounds] section of WIN.INI.
MB_ICONHAND	Plays the sound identified by the SystemHand entry in the [sounds] section of WIN.INI.
MB_ICONQUESTION	Plays the sound identified by the SystemQuestion entry in the [sounds] section of WIN.INI.
MB_OK	Plays the sound identified by the SystemDefault entry in the [sounds] section of WIN.INI.

Return Value This function does not return a value.

Comments MessageBeep returns control to the caller after queuing the sound and plays the sound asynchronously.

If it cannot play the specified alert sound, **MessageBeep** attempts to play the system default sound. If it cannot play the system default sound, the function produces a standard beep sound by using the computer speaker.

The user can disable the warning beep by using the Windows Control Panel application Sounds.

See Also FlashWindow, MessageBox

MessageBox

2.x

	ndParent, lpszText, lpszTitle, fuStyl		
HWND hwndParent			
LPCSTR lpszText;	/* address of text in message		
LPCSTR lpszTitle;	/* address of title of message		
UINT fuStyle;	/* style of message box	*/	
	The message box contains an app	s, displays, and operates a message-box window. lication-defined message and title, plus any com- nd push buttons described in the <i>fuStyle</i> parame-	
Parameters	<i>hwndParent</i> Identifies the parent window of the message box to be created. If this parameter is NULL, the message box will have no parent window.		
	<i>lpszText</i> Points to a null-terminated strip	ng containing the message to be displayed.	
	<i>lpszTitle</i> Points to a null-terminated strin rameter is NULL, the default t	ng to be used for the dialog box title. If this pa- tle Error is used.	
	<i>fuStyle</i> Specifies the contents and behavior of the dialog box. This parameter can be a combination of the following values:		
	Value	Meaning	
	MB_ABORTRETRYIGNORE	The message box contains three push buttons: Abort, Retry, and Ignore.	

Value	Meaning
MB_APPLMODAL	The user must respond to the message box before continuing work in the window identified by the <i>hwndParent</i> parameter. However, the user can move to the windows of other applications and work in those windows. MB_APPLMODAL is the default if neither MB_SYSTEMMODAL nor MB_TASKMODAL is specified.
MB_DEFBUTTON1	The first button is the default. Note that the first button is always the default unless MB_DEFBUTTON2 or MB_DEFBUTTON3 is specified.
MB_DEFBUTTON2	The second button is the default.
MB_DEFBUTTON3	The third button is the default.
MB_ICONASTERISK	Same as MB_ICONINFORMATION.
MB_ICONEXCLAMATION	An exclamation-point icon appears in the mes- sage box.
MB_ICONHAND	Same as MB_ICONSTOP.
MB_ICONINFORMATION	An icon consisting of a lowercase letter "I" in a circle appears in the message box.
MB_ICONQUESTION	A question-mark icon appears in the message box.
MB_ICONSTOP	A stop-sign icon appears in the message box.
MB_OK	The message box contains one push button: OK.
MB_OKCANCEL	The message box contains two push buttons: OK and Cancel.
MB_RETRYCANCEL	The message box contains two push buttons: Retry and Cancel.
MB_SYSTEMMODAL	All applications are suspended until the user re- sponds to the message box. Unless the applica- tion specifies MB_ICONHAND, the message box does not become modal until after it is created; consequently, the parent window and other windows continue to receive messages re- sulting from its activation. System-modal mes- sage boxes are used to notify the user of serious, potentially damaging errors that require immedi- ate attention (for example, running out of memory).

Value	Meaning
MB_TASKMODAL	Same as MB_APPLMODAL except that all the top-level windows belonging to the current task are disabled if the <i>hwndParent</i> parameter is NULL. This flag should be used when the calling application or library does not have a window handle available but still needs to pre- vent input to other windows in the current appli- cation without suspending other applications.
MB_YESNO	The message box contains two push buttons: Yes and No.
MB_YESNOCANCEL	The message box contains three push buttons: Yes, No, and Cancel.

Return Value

The return value is zero if there is not enough memory to create the message box. Otherwise, it is one of the following menu-item values returned by the dialog box:

Value	Meaning
IDABORT	Abort button was selected.
IDCANCEL	Cancel button was selected.
IDIGNORE	Ignore button was selected.
IDNO	No button was selected.
IDOK	OK button was selected.
IDRETRY	Retry button was selected.
IDYES	Yes button was selected.

If a message box has a Cancel button, the IDCANCEL value will be returned if either the ESC key is pressed or the Cancel button is selected. If the message box has no Cancel button, pressing ESC has no effect.

Comments

When a system-modal message box is created to indicate that the system is low on memory, the strings pointed to by the *lpszText* and *lpszTitle* parameters should not be taken from a resource file, because an attempt to load the resource may fail.

When an application calls the **MessageBox** function and specifies the MB_ICONHAND and MB_SYSTEMMODAL flags for the *fuStyle* parameter, Windows displays the resulting message box regardless of available memory. When these flags are specified, Windows limits the length of the message-box text to three lines. Windows does *not* automatically break the lines to fit in the message box, however, so the message string must contain carriage returns to break the lines at the appropriate places.

If a message box is created while a dialog box is present, use the handle of the dialog box as the *hwndParent* parameter. The *hwndParent* parameter should not identify a child window, such as a control in a dialog box.

Following are the various system icons that can be used in a message box:

MB_ICONHAND and MB_ICONSTOP

MB_ICONQUESTION

MB_ICONEXCLAMATION

MB_ICONASTERISK and MB_ICONINFORMATION

FlashWindow, MessageBeep

MessageProc

3.1

LRESULT CALLBA	ACK MessageProc(code,	wParam, lParam)
int code;	/* message type	*/
WPARAM wParam		*/
LPARAM lParam;	/* address of structure	e with message data */
Parameters	that the system calls after	on is an application- or library-defined callback function a dialog box, message box, or menu has retrieved a mes- age is processed. The callback function can process or
Specifies the type of message being processed. This parameter ca the following values:		
	Value	Meaning
	MSGF_DIALOGBOX	Messages inside a dialog box or message box procedure are being processed.
	MSGF_MENU	Keyboard and mouse messages in a menu are being processed.
		s less than zero, the callback function must pass the mes- Ex without further processing and return the value re- okEx.
	wParam	

Specifies a NULL value.

	<i>lParam</i> Points to an MSG structure. The MSG structure has the following form:
	<pre>typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The callback function should return a nonzero value if it processes the message; it should return zero if it does not process the message.
Comments	The WH_MSGFILTER filter type is the only task-specific filter. A task may in- stall this filter.
	An application must install the callback function by specifying the WH_MSGFILTER filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.
	MessageProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.
See Also	CallNextHookEx, SetWindowsHookEx

ModifyMenu

3.0

BOOL ModifyMenu (<i>hmenu</i> , <i>idItem</i> , <i>fuFlags</i> , <i>idNewItem</i> , <i>lpNewItem</i>)			
HMENU hmenu;	/* handle of menu	*/	
UINT idItem;	/* menu-item identifier	*/	
UINT fuFlags;	/* menu-item flags	*/	
UINT <i>idNewItem</i> ;	/* new menu-item identifier	*/	
LPCSTR lpNewItem;	/* menu-item content	*/	

The **ModifyMenu** function changes an existing menu item.

Parameters

hmenu

Identifies the menu to change.

idItem

Specifies the menu item to change, as determined by the *fuFlags* parameter. When the *fuFlags* parameter is MF_BYCOMMAND, the *idItem* parameter specifies the menu-item identifier. When the *fuFlags* parameter is MF_BY-POSITION, the *idItem* parameter specifies the zero-based position of the menu item.

fuFlags

Specifies how the *idItem* parameter is interpreted and information about the changes to be made to the menu item. It consists of one or more values listed in the following Comments section.

idNewItem

Specifies either the identifier of the modified menu item or, if *fuFlags* is set to MF_POPUP, the menu handle of the pop-up menu.

lpNewItem

Specifies the content of the changed menu item. If *fuFlags* is set to MF_STRING (the default), *lpNewItem* is a long pointer to a null-terminated string. If *fuFlags* is set to MF_BITMAP instead, *lpNewItem* contains a bitmap handle in its low-order word. If *fuFlags* is set to MF_OWNERDRAW, *lpNewItem* specifies an application-defined 32-bit value that the application can use to maintain additional data associated with the menu item. This 32-bit value is available to the application in the **itemData** member of the **MEASUREITEMSTRUCT** or **DRAWITEMSTRUCT** structure pointed to by the *lParam* parameter of the WM_MEASUREITEM or WM_DRAWITEM message. These messages are sent when the menu item is initially displayed or is changed.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments If the **ModifyMenu** function replaces a pop-up menu associated with the menu item, it destroys the old pop-up menu and frees the memory used by the pop-up menu.

Whenever a menu changes (whether or not it is in a window that is displayed), the application should call **DrawMenuBar**. To change the attributes of existing menu items, it is much faster to use the **CheckMenuItem** and **EnableMenuItem** functions.

Each of the following groups lists flags that should not be used together:

- MF_BYCOMMAND and MF_BYPOSITION
- MF_DISABLED, MF_ENABLED, and MF_GRAYED
- MF_BITMAP, MF_STRING, MF_OWNERDRAW, and MF_SEPARATOR

• MF_MENUBARBREAK and MF_MENUBREAK

MF_CHECKED and MF_UNCHECKED

The following list describes the flags that may be set in the *fuFlags* parameter:

Value	Meaning
MF_BITMAP	Uses a bitmap as the menu item. The low-order word of the <i>lpNewItem</i> parameter contains the handle of the bitmap.
MF_BYCOMMAND	Specifies that the <i>idItem</i> parameter gives the menu-item identifier. This is the default if neither MF_BYCOMMAND nor MF_POSITION is set.
MF_BYPOSITION	Specifies that the <i>idItem</i> parameter gives the position of the menu item to be changed rather than the menu-item identifier.
MF_CHECKED	Places a check mark next to the menu item. If the appli- cation has supplied check-mark bitmaps (see SetMenu- ItemBitmaps), setting this flag displays the check-mark bitmap next to the menu item.
MF_DISABLED	Disables the menu item so that it cannot be selected, but does not gray (dim) it.
MF_ENABLED	Enables the menu item so that it can be selected and re- stores it from its grayed state.
MF_GRAYED	Disables the menu item so that it cannot be selected and grays it.
MF_MENUBARBREAK	Same as MF_MENUBREAK except, for pop-up menus, separates the new column from the old column with a vertical line.
MF_MENUBREAK	Places the menu item on a new line for static menu-bar items. For pop-up menus, this flag places the item in a new column, with no dividing line between the columns.
MF_OWNERDRAW	Specifies that the menu item is an owner-drawn item. The window that owns the menu receives a WM_MEASUREITEM message when the menu is dis- played for the first time to retrieve the height and width of the menu item. The WM_DRAWITEM message is then sent whenever the owner must update the visual ap- pearance of the menu item. This option is not valid for a top-level menu item.
MF_POPUP	Specifies that the item has a pop-up menu associated with it. The <i>idNewItem</i> parameter specifies a handle of a pop-up menu to be associated with the menu item. Use this flag for adding either a top-level pop-up menu or a hierarchical pop-up menu to a pop-up menu item.

Value	Meaning
MF_SEPARATOR	Draws a horizontal dividing line. This line cannot be grayed, disabled, or highlighted. You can use this flag only in a pop-up menu. The <i>lpNewItem</i> and <i>idNewItem</i> parameters are ignored.
MF_STRING	Specifies that the menu item is a character string; the <i>lpNewItem</i> parameter points to the string for the menu item.
MF_UNCHECKED	Does not select (place a check mark next to) the menu item. No check mark is the default condition if neither MF_CHECKED nor MF_UNCHECKED is set. If the ap- plication has supplied check-mark bitmaps (see the Set- MenuItemBitmaps function), setting this flag displays the "check mark off" bitmap next to the menu item.

3.1

ModuleFindHandle

#include <toolhelp.h>

HMODULE ModuleFindHandle(*lpme*, *hmod*) /* address of MODULEENTRY structure **MODULEENTRY FAR*** *lpme*; */ **HMODULE** hmod: /* handle of module */ The ModuleFindHandle function fills the specified structure with information that describes the given module. **Parameters** lpme Points to a MODULEENTRY structure that will receive information about the module. The **MODULEENTRY** structure has the following form: #include <toolhelp.h> typedef struct tagMODULEENTRY { /* me */ DWORD dwSize:

typedef struct tagMODULEENTRY { /* me */
 DWORD dwSize;
 char szModule[MAX_MODULE_NAME + 1];
 HMODULE hModule;
 WORD wcUsage;
 char szExePath[MAX_PATH + 1];
 WORD wNext;
} MODULEENTRY:

3.1

	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>hmod</i> Identifies the module to be described.
Return Value	The return value is the handle of the given module if the function is successful. Otherwise, it is NULL.
Comments	The ModuleFindHandle function returns information about a currently loaded module whose module handle is known.
	This function can be used to begin a walk through the list of all currently loaded modules. An application can examine subsequent items in the module list by using the ModuleNext function.
	Before calling ModuleFindHandle , an application must initialize the MODULEENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	ModuleFindName, ModuleFirst, ModuleNext

ModuleFindName

#include <toolhelp.h>

HMODULE ModuleFindName(lpme, lpszName)			
MODULEENTRY FAR* <i>lpme</i> ;	/* address of MODULEENTRY structure	*/	
LPCSTR lpszName;	/* address of module name	*/	

The **ModuleFindName** function fills the specified structure with information that describes the module with the specified name.

Parameters

lpme

Points to a **MODULEENTRY** structure that will receive information about the module. The **MODULEENTRY** structure has the following form:

	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagMODULEENTRY { /* me */ DWORD dwSize; char szModule[MAX_MODULE_NAME + 1]; HMODULE hModule; WORD wcUsage; char szExePath[MAX_PATH + 1]; WORD wNext; } MODULEENTRY;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lpszName</i> Specifies the name of the module to be described.
Return Value	The return value is the handle named in the lpszName parameter, if the function is successful. Otherwise, it is NULL.
Comments	The ModuleFindName function returns information about a currently loaded module by looking up the module's name in the module list.
	This function can be used to begin a walk through the list of all currently loaded modules. An application can examine subsequent items in the module list by using the ModuleNext function.
	Before calling ModuleFindName , an application must initialize the MODULEENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	ModuleFindHandle, ModuleFirst, ModuleNext

ModuleFirst

3.1

#include <toolhelp.h>

BOOL ModuleFirst(*lpme*) **MODULEENTRY FAR*** *lpme*;

/* address of MODULEENTRY structure

*/

The **ModuleFirst** function fills the specified structure with information that describes the first module in the list of all currently loaded modules.

3.1

Parameters	<i>lpme</i> Points to a MODULEENTRY structure that will receive information about the first module. The MODULEENTRY structure has the following form:
	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagMODULEENTRY { /* me */ DWORD dwSize; char szModule[MAX_MODULE_NAME + 1]; HMODULE hModule; WORD wcUsage; char szExePath[MAX_PATH + 1]; WORD wNext; } MODULEENTRY;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The ModuleFirst function can be used to begin a walk through the list of all cur- rently loaded modules. An application can examine subsequent items in the mod- ule list by using the ModuleNext function.
	Before calling ModuleFirst , an application must initialize the MODULEENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	ModuleFindHandle, ModuleFindName, ModuleNext

ModuleNext

#include <toolhelp.h>

lpme

BOOL ModuleNext(lpme) MODULEENTRY FAR* lpme;	/* address of MODULEENTRY structure	*/
	Next function fills the specified structure with i ext module in the list of all currently loaded mo	

Parameters

Points to a **MODULEENTRY** structure that will receive information about the next module. The **MODULEENTRY** structure has the following form:

	<pre>#include <toolhelp.h></toolhelp.h></pre>
	<pre>typedef struct tagMODULEENTRY { /* me */ DWORD dwSize; char szModule[MAX_MODULE_NAME + 1]; HMODULE hModule; WORD wcUsage; char szExePath[MAX_PATH + 1]; WORD wNext; } MODULEENTRY;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The ModuleNext function can be used to continue a walk through the list of all currently loaded modules. The walk must have been started by the ModuleFirst , ModuleFindName , or ModuleFindHandle function.
See Also	ModuleFindHandle, ModuleFindName, ModuleFirst

MouseProc

LRESULT CALLB	ACK MouseProc(code, wParam, lParam)	
int code;	/* process-message flag	*/
WPARAM wParam	; /* message identifier	*/
LPARAM lParam;	/* address of MOUSEHOOKSTRUCT structure	*/
	The MouseProc function is a library-defined callback fu calls whenever an application calls the GetMessage or H there is a mouse message to be processed.	
Parameters	<i>code</i> Specifies whether the callback function should proces CallNextHookEx function. If this value is less than z should pass the message to CallNextHookEx without value is HC_NOREMOVE, the application is using a with the PM_NOREMOVE option, and the message the system queue. <i>wParam</i> Specifies the identifier of the mouse message.	zero, the callback function t further processing. If this PeekMessage function

	<i>lParam</i> Points to a MOUSEHOOKSTRUCT structure containing information about the mouse. The MOUSEHOOKSTRUCT structure has the following form:
	<pre>typedef struct tagMOUSEHOOKSTRUCT { /* ms */ POINT pt; HWND hwnd; UINT wHitTestCode; DWORD dwExtraInfo; } MOUSEHOOKSTRUCT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	The callback function should return 0 to allow the system to process the message; it should return 1 to discard the message.
Comments	This callback function should not install a JournalPlaybackProc callback func- tion.
	An application must install the callback function by specifying the WH_MOUSE filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.
	MouseProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.
See Also	CallNextHookEx, GetMessage, PeekMessage, SetWindowsHookEx
T o	
MoveTo	2.x
DWORD M HDC <i>hdc</i> ; int <i>nXPos</i> ; int <i>nYPos</i> :	oveTo(hdc, nXPos, nYPos) /* handle of device context */ /* x-coordinate of new position */ /* y-coordinate of new position */

The MoveTo function moves the current position to the specified coordinates.

Parameters

Identifies the device context.

nXPos

hdc

Specifies the logical x-coordinate of the new position.

	<i>nYPos</i> Specifies the logical y-coordinate of the new position.
Return Value	The low-order word of the return value contains the logical x-coordinate of the pre- vious position, if the function is successful; the high-order word contains the logi- cal y-coordinate.
Example	The following example uses the MoveTo function to set the current position and then calls the LineTo function. The example uses POINT structures to store the coordinates.
	HDC hdc;
	POINT ptStart = { 12, 12 }; POINT ptEnd = { 128, 135 };
	MoveTo(hdc, ptStart.x, ptStart.y); LineTo(hdc, ptEnd.x, ptEnd.y);
See Also	GetCurrentPosition, LineTo

MoveToEx

BOOL MoveToEx(hdc, n	X, nY, lpPoint)	
HDC hdc;	/* handle of device context	*/
int nX ;	/* x-coordinate of new position	*/
int nY ;	/* y-coordinate of new position	*/
POINT FAR* <i>lpPoint</i> ;	/* pointer to structure for previous position	*/

The **MoveToEx** function moves the current position to the point specified by the nX and nY parameters, optionally returning the previous position.

Parameters

hdc

Identifies the device context.

nХ

Specifies the logical x-coordinate of the new position.

nY

Specifies the logical y-coordinate of the new position.

lpPoint

Points to a **POINT** structure in which the previous current position will be stored. If this parameter is NULL, no previous position is returned. The **POINT** structure has the following form:

2.x

	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.
Return Value	The return value is nonzero if the call is successful. Otherwise, it is zero.
See Also	MoveTo

•

MoveWindow

BOOL MoveWindo HWND hwnd; int nLeft; int nTop; int nWidth; int nHeight; BOOL fRepaint;	w(hwnd, nLeft, nTop, nWidth, nHeight, fRepaint) /* handle of window */ /* left coordinate */ /* top coordinate */ /* width */ /* neight */ /* repaint flag */
	The MoveWindow function changes the position and dimensions of a window. For top-level windows, the position and dimensions are relative to the upper-left corner of the screen. For child windows, they are relative to the upper-left corner of the parent window's client area.
Parameters	hwnd Identifies the window to be changed. <i>nLeft</i> Specifies the new position of the left side of the window. <i>nTop</i> Specifies the new position of the top of the window. <i>nWidth</i> Specifies the new width of the window. <i>nHeight</i> Specifies the new height of the window. <i>fRepaint</i> Specifies whether the window is to be repainted. If this parameter is TRUE, the window receives a WM_PAINT message. If this parameter is FALSE, no repainting of any kind occurs. This applies to the client area, the nonclient area

	(including the title and scroll bars), and any part of the parent window un- covered as a result of the moved window. When this parameter is FALSE, the application must explicitly invalidate or redraw any parts of the window and parent window that must be redrawn.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The MoveWindow function sends a WM_GETMINMAXINFO message to the window being moved, giving it an opportunity to modify the default values for the largest and smallest possible windows. If the MoveWindow parameters exceed these values, they will be replaced by the minimum or maximum values specified in the WM_GETMINMAXINFO message.
Example	<pre>The following example changes the dimensions of a child window in response to a WM_SIZE message. In this example, the child window would always fill the client area of the parent window. case WM_SIZE: MoveWindow(hwndChild, 0, 0, LOWORD(lParam), HIWORD(lParam), TRUE); break;</pre>
See Also	ClientToScreen, GetWindowRect, ScreenToClient, SetWindowPos

MulDiv

<pre>int MulDiv(nMultip int nMultiplicand; int nMultiplier; int nDivisor;</pre>	licand, nMultiplier, nDivisor) /* 16-bit signed multiplicand */ /* 16-bit signed multiplier */ /* 16-bit signed divisor */
	The MulDiv function multiplies two 16-bit values and then divides the 32-bit result by a third 16-bit value. The return value is the 16-bit result of the division, rounded up or down to the nearest integer.
Parameters	<i>nMultiplicand</i> Specifies the multiplicand.
	<i>nMultiplier</i> Specifies the multiplier.
	<i>nDivisor</i> Specifies the number by which the result of the multiplication (<i>nMultiplicand</i> * <i>nMultiplier</i>) is to be divided.

Return Value	The return value is the result of the multiplication and division if the function is successful. The return value is $-32,768$ if either an overflow occurs or the <i>nDivisor</i> parameter is 0.

See Also CreateFontIndirect, GetDeviceCaps

NetBIOSCall

	The NetBIOSCall function allows an application to issue the NETBIOS Interrupt 5Ch. This function can be called only from assembly-language routines. It is exported from KRNL286.EXE and KRNL386.EXE and is not defined in any Windows header files.
Parameters	Registers must be set up as required by Interrupt 5Ch before the application calls the NetBIOSCall function.
Return Value	The register contents are preserved as they are returned by Interrupt 5Ch.
Comments	Applications should use this function instead of directly issuing a NETBIOS Interrupt 5Ch.
Example	To use this function, an application should declare it in an assembly-language routine, as follows:
	extrn NETBIOSCALL: far
	If the application includes CMACROS.INC, the function is declared as follows:
	externFP NetBIOSCall
	Following is an example of how to use the NetBIOSCall function:
	extrn NETBIOSCALL: far
	;set registers
	cCall NetBIOSCall

NotifyProc

BOOL CALLBACI HGLOBAL hglbl;	K NotifyProc(<i>hglbl</i>) /* handle of global memory object */
	The NotifyProc function is a library-defined callback function that the system calls whenever it is about to discard a global memory object allocated with the GMEM_NOTIFY flag.
Parameters	<i>hglbl</i> Identifies the global memory object being discarded.
Return Value	The callback function should return nonzero if the system is to discard the memory object, or zero if it should not.
Comments	The callback function is not necessarily called in the context of the application that owns the routine. For this reason, the callback function should not assume it is using the stack segment of the application. The callback function should not call any routine that might move memory.
	The callback function must be in a fixed code segment of a dynamic-link library.
	NotifyProc is a placeholde [·] for the application-defined function name. The actual name must be exported by 'ncluding it in an EXPORTS statement in the library's module-definition statement.
See Also	GlobalNotify

NotifyRegister

#include <toolhelp.h>

BOOL NotifyRegister (<i>htask</i> , <i>lpfnCallback</i> , <i>wFlags</i>)			
HTASK htask;	/* handle of task	*/	
LPFNNOTIFYCALLBACK <i>lpfnCallback</i> ;	/* address of callback function	*/	
WORD wFlags;	/* notification flags	*/	

The **NotifyRegister** function installs a notification callback function for the given task.

Parameters

htask

Identifies the task associated with the callback function. If this parameter is NULL, it identifies the current task.

lpfnCallback

Points to the notification callback function that is installed for the task. The kernel calls this function whenever it sends a notification to the task.

The callback-function address is normally the return value of a call to **Make-ProcInstance**. This causes the callback function to be entered with the AX register set to the selector of the application's data segment. Usually, an exported function prolog contains the following code:

mov ds,ax

wFlags

Specifies the optional notifications that the application will receive, in addition to the default notifications. This parameter can be NF_NORMAL or any combination of the following values:

	Value Meaning		
none of the notifications of t		The application will receive the default notifications but none of the notifications of task switching, system debug- ging errors, or debug strings.	
	NF_TASKSWITCH	The application will receive task-switching notifications. To avoid poor performance, an application should not re- ceive these notifications unless absolutely necessary.	
	NF_RIP	The application will receive notifications of system debug- ging errors.	
Return Value	The return value is nonzero if the function was successful. Otherwise, it is zero.		
Callback Function	The syntax of the function pointed to by <i>lpfnCallback</i> is as follows:		
	BOOL NotifyRegisterCallback(wID, dwData) WORD wID; DWORD dwData;		
Parameters	<i>wID</i> Indicates the type of notification and the value of the <i>dwData</i> parameter. The <i>wID</i> parameter may be one of the following values in Windows versions 3.0 and later:		
	Value	Meaning	
	NFY_DELMODULE	The low-order word of <i>dwData</i> is the handle of the module to be freed.	

Return Value

Comments

Value	Meaning
NFY_EXITTASK	The low-order byte of <i>dwData</i> contains the program exit code.
NFY_FREESEG	The low-order word of <i>dwData</i> is the selector of the segment to be freed.
NFY_INCHAR	The <i>dwData</i> parameter is not used. The notification call- back function should return either the ASCII value for the keystroke or NULL.
NFY_LOADSEG	The <i>dwData</i> parameter points to an NFYLOADSEG structure.
NFY_OUTSTR	The <i>dwData</i> parameter points to the string to be displayed
NFY_RIP	The <i>dwData</i> parameter points to an NFYRIP structure.
NFY_STARTDLL	The <i>dwData</i> parameter points to an NFYSTARTDLL structure.
NFY_STARTTASK	The <i>dwData</i> parameter is the CS:IP of the starting addres of the task.
NFY_UNKNOWN	The kernel returned an unknown notification.
NFY_LOGERROR	Meaning The <i>dwData</i> parameter points to an NFYLOG-
	ERROR structure.
NFY_LOGPARAM	ERROR The <i>dwData</i> parameter points to an NFYLOG - PARAMERROR structure.
NFY_TASKIN	The <i>dwData</i> parameter is undefined. The callback function should call the GetCurrentTask function
NFY_TASKOUT	The <i>dwData</i> parameter is undefined. The callback function should call GetCurrentTask .
<i>wData</i> Specifies data, or value of <i>wID</i> .	specifies a pointer to data, or is undefined, depending on t
	he callback function is nonzero if the callback function ion. Otherwise, it is zero and the notification is passed to ons.
alue. Typically, the	ck function must be able to ignore any unknown notification notification callback function cannot use any Windows fution of the Tool Helper functions and PostMessage .
otifyRegisterCall	back is a placeholder for the application-defined function ne must be exported by including it in an EXPORTS state

See Also InterruptRegister, InterruptUnRegister, MakeProcInstance, NotifyUnRegister, TerminateApp

NotifyUnRegister

#include <toolhelp.h>

3.1

3.0

BOOL NotifyUnl HTASK htask;	Register(htask)/* handle of task*/
	The NotifyUnRegister function restores the default notification handler.
Parameters	<i>htask</i> Identifies the task. If <i>htask</i> is NULL, it identifies the current task.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	After this function is executed, the given task no longer receives notifications from the kernel.
See Also	InterruptRegister, InterruptUnRegister, NotifyRegister, TerminateApp

OemKeyScan

DWORD OemKeyScan(*uOemChar*) **UINT** *uOemChar*; /* OEM ASCII character

The **OemKeyScan** function translates (maps) OEM ASCII codes 0 through 0xFF to their corresponding OEM scan codes and shift states.

*/

Parameters	<i>uOemChar</i> Specifies the ASCII value of the OEM character.
Return Value	The low-order word of the return value contains the scan code of the specified OEM character; the high-order word contains flags that indicate the shift state: If bit 1 is set, a SHIFT key is pressed; if bit 2 is set, a CTRL key is pressed. Both the low-order and high-order words of the return value contain -1 if the character is not defined in the OEM character tables.

Comments	The OemKeyScan function does not translate characters that require CTRL+ALT or dead keys. Characters not translated by this function must be copied by simulating input, using the ALT+ keypad mechanism. For this to work, the NUM LOCK key must be off.
	This function calls the VkKeyScan function in recent versions of the keyboard device drivers.
	OemKeyScan allows an application to send OEM text to another application by simulating keyboard input. It is used specifically for this purpose by Windows in 386 enhanced mode.
See Also	VkKeyScan

OemToAnsi

void OemToAnsi(hp	pszOemStr, hpszWindowsStr)
const char _huge* /	
char _huge* hpszWi	<i>ndowsStr</i> ; /* address of translated string buffer */
	The OemToAnsi function translates a string from the OEM-defined character set into the Windows character set.
Parameters	<i>hpszOemStr</i> Points to a null-terminated string of characters from the OEM-defined character set.
	<i>hpszWindowsStr</i> Points to the location where the translated string is to be copied. To translate the string in place, the <i>hpszWindowsStr</i> parameter can be the same as the <i>hpszOemStr</i> parameter.
Return Value	This function does not return a value.
See Also	AnsiToOem, OemToAnsiBuff

2.x

2.x

2.x

OemToAnsiBuff

void OemToAnsiBut	ff(lpszOemStr, lpszWindowsStr, cbOemStr)		
LPCSTR lpszOemSt	<i>r</i> ; /* address of OEM character string	*/	
	Str; /* address of buffer for Windows string	*/	
UINT cbOemStr;	/* length of OEM string	*/	
	The OemToAnsiBuff function translates a string set into the Windows character set.	from the OEM-defined character	
Parameters	<i>lpszOemStr</i> Points to a buffer containing one or more characters from the OEM-defined character set.		
	<i>lpszWindowsStr</i> Points to the location where the translated strin the string in place, the <i>lpszWindowsStr</i> parame <i>lpszOemStr</i> parameter.		
	<i>cbOemStr</i> Specifies the length, in bytes, of the buffer poin <i>cbOemStr</i> is 0, the length is 64K.	nted to by <i>lpszOemStr</i> . If	
Return Value	This function does not return a value.		
See Also	AnsiToOem, OemToAnsi		

OffsetClipRgn

int OffsetClipRgn(hdc, nXOffset, nYOffset) HDC hdc; /* device-context handle

int nXOffset;	/* offset along x-axis	*/
int nYOffset;	/* offset along y-axis	*/

The **OffsetClipRgn** function moves the clipping region of the given device by the specified offsets.

Parameters

Identifies the device context.

nXOffset

hdc

Specifies the number of logical units to move left or right.

*/

	<i>nYOffset</i> Specifies the number of logical units to move up or down.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.
Example	The following example creates an elliptical region and selects it as the clipping re- gion for a device context. The OffsetClipRgn function is called repeatedly to move the clipping region from left to right across the screen. Because only the new clipping region is redrawn each time the Rectangle function is called, the left side of each ellipse remains on the screen when the clipping region moves. When the loop has finished, a wide blue line with rounded ends stretches from one side of the client area to the other.
	RECT rc; HRGN hrgn; HBRUSH hbr, hbrPrevious; int i;
	GetClientRect(hwnd, &rc); hrgn = CreateEllipticRgn(0, 100, 100, 200); SelectClipRgn(hdc, hrgn); hbr = CreateSolidBrush(RGB(0, 0, 255)); hbrPrevious = SelectObject(hdc, hbr);
	<pre>for (i = 0; i < rc.right - 100; i++) { OffsetClipRgn(hdc, 1, 0); Rectangle(hdc, rc.left, rc.top, rc.right, rc.bottom); }</pre>
	SelectObject(hdc, hbrPrevious); DeleteObject(hbr); DeleteObject(hrgn);

See Also

CreateEllipticRgn, SelectClipRgn

OffsetRect

void OffsetRect(lprc	(x, y)	
RECT FAR* <i>lprc</i> ;	/* address of structure with rectangle	*/
int x;	/* horizontal offset	*/
int y;	/* vertical offset	*/

The **OffsetRect** function moves the given rectangle by the specified offsets.

Parameters	<i>lprc</i> Points to a RECT structure that contains the coordinates of the rectangle to be moved. The RECT structure has the following form:		
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>		
	For a full description of this structure, see the <i>Microsoft Windows Program-</i> mer's Reference, Volume 3.		
	<i>x</i> Specifies the amount to move left or right. It must be negative to move left.		
	<i>y</i> Specifies the amount to move up or down. It must be negative to move up.		
Return Value	This function does not return a value.		
Comments	The coordinate values of a rectangle must not be greater than 32,767 or less than $-32,768$. The <i>x</i> and <i>y</i> parameters must be chosen carefully to prevent invalid rectangles.		
See Also	InflateRect, IntersectRect, UnionRect		

OffsetRgn

int OffsetRgn(hrgn, nXOffset, nYOffset)

HRGN hrgn;	/* handle of region	*/
int nXOffset;	/* offset along x-axis	*/
<pre>int nYOffset;</pre>	/* offset along y-axis	*/

The **OffsetRgn** function moves the given region by the specified offsets.

Parameters	<i>hrgn</i> Identifies the region to be moved.
	<i>nXOffset</i> Specifies the number of logical units to move left or right.
	<i>nYOffset</i> Specifies the number of logical units to move up or down.

2.x

Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.
Comments	The coordinate values of a region must not be greater than 32,767 or less than $-32,768$. The <i>nXOffset</i> and <i>nYOffset</i> parameters must be carefully chosen to prevent invalid regions.
Example	The following example creates a rectangular region, uses the OffsetRgn function to move the region 50 positive units in the x- and y-directions, selects the offset re- gion into the device context, and then fills it by using a blue brush: HDC hdcLocal; HRGN hrgn; HBRUSH hbrBlue; int RgnType; hdcLocal = GetDC(hwnd); hrgn = CreateRectRgn(100, 10, 210, 110); SelectObject(hdc, hrgn); PaintRgn(hdc, hrgn); RgnType = OffsetRgn(hrgn, 50, 50);
	<pre>SelectObject(hdc, hrgn); if (RgnType == ERROR) TextOut(hdcLocal, 10, 135, "ERROR", 5); else if (RgnType == SIMPLEREGION) TextOut(hdcLocal, 10, 135, "SIMPLEREGION", 12); else if (RgnType == NULLREGION) TextOut(hdcLocal, 10, 135, "NULLREGION", 10); else TextOut(hdcLocal, 10, 135, "Unrecognized value.", 19); hbrBlue = CreateSolidBrush(RGB(0, 0, 255)); FillRgn(hdc, hrgn, hbrBlue); DeleteObject(hrgn); DeleteObject(hbrBlue); ReleaseDC(hwnd, hdcLocal);</pre>

OffsetViewportOrg

HDC hdc;	etViewportOrg(hdc, nXOffset, nYOffset) /* handle of device context */ /* offset along x-axis */
<pre>int nXOffset; int nYOffset;</pre>	/* offset along x-axis */ /* offset along y-axis */
	The OffsetViewportOrg function modifies the coordinates of the viewport origin relative to the coordinates of the current viewport origin.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXOffset</i> Specifies the value, in device units, to add to the x-coordinate of the current origin.
	<i>nYOffset</i> Specifies the value, in device units, to add to the y-coordinate of the current origin.
Return Value	The low-order word of the return value contains the x-coordinate, in device units, of the previous viewport origin, if the function is successful; the high-order word contains the y-coordinate.
Comments	The viewport origin is the origin of the device coordinate system for a window. By changing the viewport origin, an application can change the way the graphics device interface (GDI) maps points from the logical coordinate system. GDI maps all points in the logical coordinate system to the viewport in the same way as it maps the origin.
	To map points to the right, specify a negative value for the <i>nXOffset</i> parameter. Similarly, to map points down (in the MM_TEXT mapping mode), specify a nega- tive value for the <i>nYOffset</i> parameter.
Example	The following example uses the OffsetWindowOrg and OffsetViewportOrg functions to reposition the output of the PlayMetaFile function on the screen:
	HDC hdcMeta; HANDLE hmf;
	<pre>hdcMeta = CreateMetaFile((LPSTR) NULL);</pre>
	. /* Record the metafile. */
	<pre>PlayMetaFile(hdc, hmf);</pre>

2.x

```
OffsetWindowOrg(hdc, -200, -200);
PlayMetaFile(hdc, hmf); /* MM_TEXT screen output +200 x, +200 y */
OffsetViewportOrg(hdc, 0, -200);
PlayMetaFile(hdc, hmf); /* outputs -200 y from last PlayMetaFile */
DeleteMetaFile(hmf);
```

See Also GetViewportOrg, OffsetWindowOrg, SetViewportOrg

OffsetViewportOrgEx

BOOL OffsetViewy HDC hdc; int nX; int nY; POINT FAR* lpPo	<pre>portOrgEx(hdc, nX, nY, lpPoint)</pre>	*/ */ */
	The OffsetViewportOrgEx function modifies the current values. The formulas are written as follow	
	<pre>xNewV0 = x0ldV0 + X yNewV0 = y0ldV0 + Y</pre>	
	The new origin is the sum of the current origin an	d the nX and nY values.
Parameters	<i>hdc</i> Identifies the device context.	
nX Specifies the number of device units to add to the current origin's x-co		
	<i>nY</i> Specifies the number of device units to add to t	the current origin's y-coordinate.
	<i>lpPoint</i> Points to a POINT structure. The previous vie nates) is placed in this structure. If <i>lpPoint</i> is N origin in not returned.	
Return Value	The return value is nonzero if the function is succ	essful. Otherwise, it is zero.

OffsetWindowOrg

DWORD Offset HDC hdc; int nXOffset; int nYOffset;	WindowOrg(hdc, nXOffset, nYOffset)/* handle of device context*//* offset along x-axis*//* offset along y-axis*/		
	The OffsetWindowOrg function modifies the window origin relative to the coordinates of the current window origin.		
Parameters	<i>hdc</i> Identifies the device context.		
	<i>nXOffset</i> Specifies the value, in logical units, to add to the x-coordinate of the current origin.		
	<i>nYOffset</i> Specifies the value, in logical units, to add to y-coordinate of the current origin.		
Return Value	The low-order word of the return value contains the logical x-coordinate of the pre- vious window origin, if the function is successful; the high-order word contains the logical y-coordinate.		
Comments	The window origin is the origin of the logical coordinate system for a window. By changing the window origin, an application can change the way the graphics device interface (GDI) maps logical points to the physical coordinate system (the viewport). GDI maps all points in the logical coordinate system to the viewport in the same way as it maps the origin.		
	To map points to the right, specify a negative value for the <i>nXOffset</i> parameter. Similarly, to map points down (in the MM_TEXT mapping mode), specify a nega- tive value for the <i>nYOffset</i> parameter.		
Example	The following example uses the OffsetWindowOrg and OffsetViewportOrg functions to reposition the output of the PlayMetaFile function on the screen:		
	HDC hdcMeta; HANDLE hmf;		
	<pre>hdcMeta = CreateMetaFile((LPSTR) NULL);</pre>		
	. /* Record the metafile. */		
	<pre>PlayMetaFile(hdc, hmf);</pre>

OffsetWindowOrg(hdc, -200, -200); PlayMetaFile(hdc, hmf); /* MM_TEXT screen output +200 x, +200 y */	
OffsetViewportOrg(hdc, 0, -200); PlayMetaFile(hdc, hmf); /* outputs -200 y from last PlayMetaFile */	
<pre>DeleteMetaFile(hmf);</pre>	
GetWindowOrg, OffsetViewportOrg, SetWindowOrg	

OffsetWindowOrgEx

BOOL OffsetWind HDC hdc; int nX; int nY; POINT FAR* lpPot	<pre>owOrgEx(hdc, nX, nY, lpPoint)</pre>	*/ */ */ */
	The OffsetWindowOrgEx function modifies the current values. The formulas are written as follows:	
	xNewWO = x01dWO + X yNewWO = y01dWO + Y	
	The new origin is the sum of the current origin a	and the nX and nY values.
Parameters	<i>hdc</i> Identifies the device context.	
	<i>nX</i> Specifies the number of logical units to add t	o the current origin's x-coordinate.
	<i>nY</i> Specifies the number of logical units to add t	o the current origin's y-coordinate.
	<i>lpPoint</i> Points to a POINT structure. The previous w nates) is placed in this structure. If <i>lpPoint</i> is returned.	
Return Value	The return value is nonzero if the function is suc	ccessful. Otherwise, it is zero.

OleActivate

#include <ole.h>

OLESTATUS OleActivate (<i>lpObjet</i>	ct, verb, fShow, fTakeFocus, hwnd, lprcBound)	
LPOLEOBJECT <i>lpObject</i> ;	/* address of object to activate	*/
UINT verb;	/* operation to perform	*/
BOOL fShow;	/* whether to show window	*/
BOOL fTakeFocus;	/* whether server gets focus	*/
HWND hwnd;	/* window handle of destination document	*/
<pre>const RECT FAR* lprcBound;</pre>	/* bounding rectangle for object display	*/

The **OleActivate** function opens an object for an operation. Typically, the object is edited or played.

Parameters

lpObject Points to the object to activate.

verb

Specifies which operation to perform (0 = the primary verb, 1 = the secondary verb, and so on).

fShow

Specifies whether the window is to be shown. If the window is to be shown, this value is TRUE; otherwise, it is FALSE.

fTakeFocus

Specifies whether the server should get the focus. If the server should get the focus, this value is TRUE; otherwise, it is FALSE. This parameter is relevant only if the *fShow* parameter is TRUE.

hwnd

Identifies the window of the document containing the object.

lprcBound

Points to a **RECT** structure containing the coordinates of the bounding rectangle in which the destination document displays the object. The mapping mode of the device context determines the units for these coordinates.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE

Comments Typically, a server is launched in a separate window; editing then occurs asynchronously. The client is notified of changes to the object through the callback function.

A client application might set the *fShow* parameter to FALSE if a server needed to remain active without being visible on the display. (In this case, the application would also use the **OleSetData** function.)

Client applications typically specify the primary verb when the user double-clicks an object. The server can take any action in response to the specified verb. If the server supports only one action, it takes that action no matter which value is passed in the *verb* parameter.

In future releases of the object linking and embedding (OLE) protocol, the *hwnd* and *lprcBound* parameters will be used to help determine the placement of the server's editing window.

See Also OleQueryOpen, OleSetData

OleBlockServer

#include <ole.h>

OLESTATUS OleBl LHSERVER lhSrvr;	
	The OleBlockServer function causes requests to the server to be queued until the server calls the OleUnblockServer function.
Parameters	<i>lhSrvr</i> Identifies the server for which requests are to be queued.
	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.
Comments	The server must call the OleUnblockServer function after calling the OleBlock-Server function.
	A server application can use the OleBlockServer and OleUnblockServer func- tions to control when the server library processes requests from client applications. Because only messages from the client to the server are blocked, a blocked server can continue to send messages to client applications.

3.1

A server application receives a handle when it calls the **OleRegisterServer** function.

See Also OleRegisterServer, OleUnblockServer

OleClone

#include <ole.h>

OLESTATUS OleCl LPOLEOBJECT <i>lp</i>	one(lpObject, lpClient, lhC Dbiect: /* addt	<i>lientDoc</i> , <i>lpszObjname</i> , <i>lplpObject</i>) ess of object to copy	*/

LPOLEOBJECT FA		ess of pointer to new object	*/
	The OleClone function ma source object, but it is not c	kes a copy of an object. The copy is id onnected to the server.	entical to the
Parameters	<i>lpObject</i> Points to the object to co	ру.	
	<i>lpClient</i> Points to an OLECLIE	NT structure for the new object.	
	<i>lhClientDoc</i> Identifies the client docu	ment in which the object is to be creat	ted.
		ed string specifying the client's name are with respect to the names of any oth name a slash mark (/).	
	<i>lplpObject</i> Points to a variable when ject.	e the library will store the long pointe	r to the new ob-
Return Value	The return value is OLE_O value, which may be one of	K if the function is successful. Otherw the following:	vise, it is an error
	OLE_BUSY OLE_ERROR_HANDLE OLE_ERROR_OBJECT OLE_WAIT_FOR_RELE/	ASE	

666	OleClose	
Comm	ients	Client applications often use the OleClone function to support the Undo command.
		A client application can supply a new OLECLIENT structure for the cloned object, if required.
See A	lso	OleEqual

OleClose

3.1

#include <ole.h>

OLESTATUS OleClose(*lpObject*) **LPOLEOBJECT** *lpObject*; /* address of object to close */

The **OleClose** function closes the specified open object. Closing an object terminates the connection with the server application.

Parameters	lpObject
	Points to the object to

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

close.

OLE_BUSY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE

See Also OleActivate, OleDelete, OleReconnect

OleCopyFromLink

#include <ole.h>

OLESTATUS OleCopyFromLink(lpObject, lpszProtocol, lpClient, lhClientDoc, lpszObjname, lplpObject) LPOLEOBJECT lpObject; /* address of object to embed */ LPCSTR lpszProtocol; /* address of protocol name */ LPOLECLIENT lpClient; /* address of client structure */

LHCLIENTDOC <i>lhClientDoc</i> ;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to new object	*/

The OleCopyFromLink function makes an embedded copy of a linked object.

Parameters	<i>lpObject</i> Points to the linked object that is to be embedded.
	<i>lpszProtocol</i> Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).
	<i>lpClient</i> Points to an OLECLIENT structure for the new object.
	<i>lhClientDoc</i> Identifies the client document in which the object is to be created.
	<i>lpszObjname</i> Points to a null-terminated string specifying the client's name for the object.
	<i>lplpObject</i> Points to a variable where the long pointer to the new object will be stored.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY OLE_ERROR_HANDLE OLE_ERROR_NAME OLE_ERROR_OBJECT OLE_ERROR_PROTOCOL OLE_WAIT_FOR_RELEASE

Comments Making an embedded copy of a linked object may involve starting the server application.

See Also OleObjectConvert

OleCopyToClipboard

#include <ole.h>

OLESTATUS OleCopyToClipboard(*lpObject*) **LPOLEOBJECT** *lpObject*; /* address of object */

The OleCopyToClipboard function puts the specified object on the clipboard.

Parameters	<i>lpObject</i> Points to the object to copy to the clipboard.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.
Comments	A client application typically calls the OleCopyToClipboard function when a user chooses the Copy or Cut command from the Edit menu.
	The client application should open and empty the clipboard, call the OleCopyTo-Clipboard function, and close the clipboard.

OleCreate

#include <ole.h>

OLESTATUS OleCreate(*lpszProtocol*, *lpClient*, *lpszClass*, *lhClientDoc*, *lpszObjname*, *lplpObject*, *renderopt*, *cfFormat*)

renaeropi , eji orman)		
LPCSTR lpszProtocol;	/* address of string for protocol name	*/
LPOLECLIENT lpClient;	/* address of client structure	*/
LPCSTR lpszClass;	/* address of string for classname	*/
LHCLIENTDOC lhClientDoc;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to object	*/
OLEOPT_RENDER renderopt;	/* rendering options	*/
OLECLIPFORMAT cfFormat;	/* clipboard format	*/

The **OleCreate** function creates an embedded object of a specified class. The server is opened to perform the initial editing.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).

lpClient

Points to an OLECLIENT structure for the new object.

lpszClass

Points to a null-terminated string specifying the registered name of the class of the object to be created.

lhClientDoc

Identifies the client document in which the object is to be created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Return Value

Comments

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.
OleGetData . If thi CF_BITMAP, the does not support dr	t. This clipboard format is used in a subsequent call to s clipboard format is CF_METAFILEPICT, CF_DIB, or library manages the data and draws the object. The library rawing for any other formats. LE_OK if the function is successful. Otherwise, it is an error one of the following:
DLE_ERROR_HANI DLE_ERROR_NAM DLE_ERROR_PROT DLE_WAIT_FOR_R	E 'OCOL
	rendering option is typically used to support hyperlinks. client does not call OleDraw and calls OleGetData only for

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

OleCreateFromClip

#include <ole.h>

OLESTATUS OleCreateFromClip(*lpszProtocol*, *lpClient*, *lhClientDoc*, *lpszObjname*, *lplpObject*,

renderopt, cfFormat)		
LPCSTR lpszProtocol;	/* address of string for protocol name	*/
LPOLECLIENT lpClient;	/* address of client structure	*/
LHCLIENTDOC lhClientDoc;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to object	*/
OLEOPT_RENDER renderopt;	/* rendering options	*/
OLECLIPFORMAT cfFormat;	/* clipboard format	*/

The **OleCreateFromClip** function creates an object from the clipboard.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat

Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLIP OLE_ERROR_FORMAT OLE_ERROR_HANDLE OLE_ERROR_NAME OLE_ERROR_OPTION OLE_ERROR_PROTOCOL OLE_WAIT FOR_RELEASE

Comments The client application should open and empty the clipboard, call the **OleCreate-FromClip** function, and close the clipboard.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats. The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

OleCreateFromFile

#include <ole.h>

OLESTATUS OleCreateFromFile(*lpszProtocol*, *lpClient*, *lpszClass*, *lpszFile*, *lhClientDoc*, *lpszObjname*, *lplpObject*, *renderopt*, *cfFormat*) **LPCSTR** *lpszProtocol*; /* address of string for protocol name */ **LPOLECLIENT** *lpClient*; /* address of client structure */ **LPCSTR** *lpszClass*; /* address of string for class name */ **LPCSTR** *lpszClass*; /* address of string for filename */

/* address of string for filename	*/
/* long handle of client document	*/
/* address of string for object name	*/
/* address of pointer to object	*/
/* rendering options	*/
/* clipboard format	*/
	/* address of string for object name /* address of pointer to object /* rendering options

The **OleCreateFromFile** function creates an embedded object from the contents of a named file.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lpszClass

Points to a null-terminated string specifying the name of the class for the new object. If this value is NULL, the library uses the extension of the filename pointed to by the *lpszFile* parameter to find the class name for the object.

lpszFile

Points to a null-terminated string specifying the name of the file containing the object.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library obtains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat

Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS OLE_ERROR_HANDLE OLE_ERROR_MEMORY OLE_ERROR_NAME OLE_ERROR_PROTOCOL OLE_WAIT_FOR_RELEASE **Comments** When a client application calls the **OleCreateFromFile** function, the server is started to render the Native and presentation data and then is closed. (If the server and document are already open, this function simply retrieves the information, without closing the server.) The server does not show the object to the user for editing.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

If a client application accepts files dropped from File Manager, it should respond to the **WM_DROPFILES** message by calling **OleCreateFromFile** and specifying Packager for the *lpszClass* parameter to indicate Microsoft Windows Object Packager.

OleCreate, OleCreateFromTemplate, OleDraw, OleGetData

OleCreateFromTemplate

#include <ole.h>

OLESTATUS OleCreateFromTemplate(*lpszProtocol*, *lpClient*, *lpszTemplate*, *lhClientDoc*, *lpszObjname*, *lplpObject*, *renderopt*, *cfFormat*) LPCSTR lpszProtocol; /* address of string for protocol name */ **LPOLECLIENT** *lpClient*; /* address of client structure */ LPCSTR lpszTemplate; /* address of string for path of file */ **LHCLIENTDOC** *lhClientDoc*; /* long handle of client document */ LPCSTR lpszObjname; /* address of string for object name */ **LPOLEOBJECT FAR*** *lplpObject*; /* address of pointer to object */ **OLEOPT_RENDER** renderopt; /* rendering options */ **OLECLIPFORMAT** cfFormat; /* clipboard format */

The **OleCreateFromTemplate** function creates an object by using another object as a template. The server is opened to perform the initial editing.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).

lpClient

Points to an **OLECLIENT** structure for the new object.

lpsz.Template

Points to a null-terminated string specifying the path of the file to be used as a template for the new object. The server is opened for editing and loads the initial state of the new object from the named template file.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat

Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to the **OleGetData** function. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS OLE_ERROR_HANDLE OLE_ERROR_MEMORY OLE_ERROR_NAME OLE_ERROR_PROTOCOL OLE_WAIT_FOR_RELEASE

Comments

The client library uses the filename extension of the file specified in the *lpszTemplate* parameter to identify the server for the object. The association between the extension and the server is stored in the registration database.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls **OleGetData** only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

OLECLIPFORMAT cfFormat;	/* clipboard format	*/
BOOL <i>fActivate</i> ;	/* server activation flag	*/

The **OleCreateInvisible** function creates an object without displaying the server application to the user. The function either starts the server to create the object or creates a blank object of the specified class and format without starting the server.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol required for the new embedded object. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lpszClass

Points to a null-terminated string specifying the registered name of the class of the object to be created.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

	value	Meaning
	olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
	olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
	olerender_none	The client library does not obtain any presentation data and does not draw the object.
	olerender_format. OleGetData. If this CF_BITMAP, the li	ard format when the <i>renderopt</i> parameter is This clipboard format is used in a subsequent call to clipboard format is CF_METAFILEPICT, CF_DIB, or brary manages the data and draws the object. The library wing for any other formats.
	the server is started	o start the server for the object. If this parameter is TRUE (but not shown). If this parameter is FALSE, the server is unction creates a blank object of the specified class and for-
Return Value	The return value is OL value, which may be or	E_OK if the function is successful. Otherwise, it is an error ne of the following:

Value Meaning

OleCreateLinkFromClip

#include <ole.h>

OLESTATUS OleCreateLinkFromClip(*lpszProtocol*, *lpClient*, *lhClientDoc*, *lpszObjname*, *lplpObject*, *renderopt*, *cfFormat*)

(enderopit, eff official)		
LPCSTR lpszProtocol;	/* address of string for protocol name	*/
LPOLECLIENT lpClient;	/* address of client structure	*/
LHCLIENTDOC lhClientDoc;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to object	*/
OLEOPT_RENDER renderopt;	/* rendering options	*/
OLECLIPFORMAT cfFormat;	/* clipboard format	*/

The **OleCreateLinkFromClip** function typically creates a link to an object from the clipboard.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.

	Value	Meaning
	olerender_none	The client library does not obtain any presentation data and does not draw the object.
	olerender_format. OleGetData. If this CF_BITMAP, the li	ard format when the <i>renderopt</i> parameter is This clipboard format is used in a subsequent call to clipboard format is CF_METAFILEPICT, CF_DIB, or ibrary manages the data and draws the object. The library awing for any other formats.
Return Value	The return value is OL value, which may be o	E_OK if the function is successful. Otherwise, it is an error ne of the following:
	OLE_ERROR_CLIP OLE_ERROR_FORM OLE_ERROR_HAND OLE_ERROR_NAME OLE_ERROR_PROTO OLE_WAIT_FOR_RE	DLE E OCOL
Comments	With this option, the cl	rendering option is typically used to support hyperlinks. lient does not call the OleDraw function and calls OleGet - ink, OwnerLink, and Native formats.

OleCreateLinkFromFile

#include <ole.h>

OLESTATUS OleCreateLinkFromFile(*lpszProtocol*, *lpClient*, *lpszClass*, *lpszFile*, *lpszItem*, *lhClientDoc*, *lpszObiname*, *lplpObiect*, *renderopt*, *ctFormat*)

LPCSTR lpszProtocol;	/* address of string for protocol name	*/
LPOLECLIENT lpClient;	/* address of client structure	*/
LPCSTR lpszClass;	/* string for class name	*/
LPCSTR lpszFile;	/* address of string for filename	*/
LPCSTR lpszItem;	/* address of string for document part to link	*/
LHCLIENTDOC lhClientDoc;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to new object	*/
OLEOPT_RENDER renderopt;	/* rendering options	*/
OLECLIPFORMAT cfFormat;	/* clipboard format	*/

The **OleCreateLinkFromFile** function creates a linked object from a file that contains an object. If necessary, the library starts the server to render the presentation data, but the object is not shown in the server for editing.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lpszClass

Points to a null-terminated string specifying the name of the class for the new object. If this value is NULL, the library uses the extension of the filename pointed to by the *lpszFile* parameter to find the class name for the object.

lpszFile

Points to a null-terminated string specifying the name of the file containing the object.

lpszItem

Points to a null-terminated string identifying the part of the document to link to. If this value is NULL, the link is to the entire document.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

lplpObject

Points to a variable where the library will store the long pointer to the new object.

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The client calls the OleGetData function to retrieve data in a specific format. The library obtains and manages the data in the requested format, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat

Specifies the clipboard format when the *renderopt* parameter is **olerender_format**. This clipboard format is used in a subsequent call to **OleGetData**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_CLASS OLE_ERROR_HANDLE OLE_ERROR_MEMORY OLE_ERROR_NAME OLE_ERROR_PROTOCOL OLE WAIT FOR RELEASE

Comments The olerender_none rendering option is typically used to support hyperlinks. With this option, the client does not call OleDraw and calls OleGetData only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

See Also OleCreate, OleCreateFromFile, OleCreateFromTemplate, OleDraw, OleGetData

OleDelete

#include <ole.h>

OLESTATUS OleI LPOLEOBJECT <i>l</i> j	lete(<i>lpObject</i>) <i>Dbject</i> ; /* address of object to delete */
	The OleDelete function deletes an object and frees memory that was associated with that object. If the object was open, it is closed.
Parameters	<i>pObject</i> Points to the object to delete.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE
Comments	An application uses the OleDelete function when the object is no longer part of the client document.
	The OleDelete function, unlike OleRelease , indicates that the object has been per manently removed.
See Also	OleClose, OleRelease

OleDraw

#include <ole.h>

LPOLEOBJEC HDC hdc; const RECT FA	 <i>R* lprcBounds</i>; <i>R* lprcWBounds</i>; <i>k</i> + handle of DC for drawing object <i>k</i> + bounding rectangle for drawing object <i>k</i> + bounding rectangle for metafile DC 	*/ */ */ */	
	The OleDraw function draws a specified object into a boundindevice context.	ig rectangle in a	
Parameters	<i>lpObject</i> Points to the object to draw.		
	<i>hdc</i> Identifies the device context in which to draw the object.		
	<i>lprcBounds</i> Points to a RECT structure defining the bounding rectangle, in logical units fo the device context specified by the <i>hdc</i> parameter, in which to draw the object.		
	<i>lprcWBounds</i> Points to a RECT structure defining the bounding rectangle ter specifies a metafile. The left and top members of the RE should specify the window origin, and the right and botton specify the window extents.	ECT structure	
	<i>hdcFormat</i> Identifies a device context describing the target device for w object.	which to format the	
Return Value	The return value is OLE_OK if the function is successful. Other value, which may be one of the following:	erwise, it is an error	
	OLE_ERROR_ABORT OLE_ERROR_BLANK OLE_ERROR_DRAW OLE_ERROR_MEMORY OLE_ERROR_OBJECT		
Comments	This function returns OLE_ERROR_ABORT if the callback for FALSE during drawing.	unction returns	
	When the <i>hdc</i> parameter specifies a metafile device context, the specified by the <i>lprcWBounds</i> parameter contains the rectangle		

lprcBounds parameter. If *hdc* does not specify a metafile device context, the *lprcWBounds* parameter is ignored.

The library may use an object handler to render the object, and this object handler may need information about the target device. Therefore, the device-context handle specified by the *hdcFormat* parameter is required. The *lprcBounds* parameter identifies the rectangle on the device context (relative to its current mapping mode) that the object should be mapped onto. This may involve scaling the picture and can be used by client applications to impose a view scaling between the displayed view and the final printed image.

An object handler should format an object as if it were to be drawn at the size specified by a call to the **OleSetBounds** function for the device context specified by the *hdcFormat* parameter. Often this formatting will already have been done by the server application; in this case, the library simply renders the presentation data with suitable scaling for the required bounding rectangle. If cropping or banding is required, the device context in which the object is drawn may include a clipping region smaller than the specified bounding rectangle.

See Also OleSetBounds

OleEnumFormats

#include <ole.h>

LPOLEOBJECT lp	T OleEnumFormats(lpObject, cfFormat)oObject;/* address of object to query*/T cfFormat;/* format from previous function call*/
	The OleEnumFormats function enumerates the data formats that describe a specified object.
Parameters	<i>lpObject</i> Points to the object to be queried.
	<i>cfFormat</i> Specifies the format returned by the last call to the OleEnumFormats function. For the first call to this function, this parameter is zero.
Return Value	The return value is the next available format if any further formats are available. Otherwise, the return value is NULL.
Comments	When an application specifies NULL for the <i>cfFormat</i> parameter, the OleEnum-Formats function returns the first available format. Whenever an application

specifies a format that was returned by a previous call to **OleEnumFormats**, the function returns the next available format, in sequence. When no more formats are available, the function returns NULL.

See Also OleGetData

OleEnumObjects

#include <ole.h>

 OLESTATUS OleEnumObjects(lhDoc, lplpObject)

 LHCLIENTDOC lhDoc;
 /* document handle
 */

 LPOLEOBJECT FAR* lplpObject;
 /* address of pointer to object
 */

The **OleEnumObjects** function enumerates the objects in a specified document.

Parameters	 <i>lhDoc</i> Identifies the document for which the objects are enumerated. <i>lplpObject</i> Points to an object in the document when the function returns. For the first call to this function, this parameter should point to a NULL object.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following: OLE_ERROR_HANDLE
	OLE_ERROR_OBJECT
Comments	When an application specifies a NULL object for the <i>lplpObject</i> parameter, the OleEnumObjects function returns the first object in the document. Whenever an application specifies an object that was returned by a previous call to OleEnumObjects , the function returns the next object, in sequence. When there are no more objects in the document, the <i>lplpObject</i> parameter points to a NULL object.
	Only objects that have been loaded and not released are enumerated by this func- tion.
See Also	OleDelete, OleRelease

OleEqual

#include <ole.h>

OLESTATUS OleEqual (<i>lpObject1</i> , <i>lpObject2</i>)				
LPOLEOBJECT lp				
LPOLEOBJECT <i>lp</i>	<i>Object2</i> ; /* address of second object to compare */			
	The OleEqual function compares two objects for equality.			
Parameters	<i>lpObject1</i> Points to the first object to test for equality.			
	<i>lpObject2</i> Points to the second object to test for equality.			
Return Value	The return value is OLE_OK if the specified objects are equal. Otherwise, it is an error value, which may be one of the following:			
	OLE_ERROR_OBJECT OLE_ERROR_NOT_EQUAL			
Comments	Embedded objects are equal if their class, item, and native data are identical. Linked objects are equal if their class, document, and item are identical.			
See Also	OleClone, OleQueryOutOfDate			

OleExecute

#include <ole.h>

OLESTATUS OleExecute (<i>lp</i> (Object, hglbCmds, reserved)		
LPOLEOBJECT <i>lpObject</i> ;	/* address of object receiving DDE commands	*/	
HGLOBAL hglbCmds;	/* handle of memory with commands	*/	
UINT reserved;	/* reserved	*/	
The OleExecute function sends dynamic data exchange (DDE) execute			

e commands to the server for the specified object.

Parameters

lpObject

Points to an object identifying the server to which DDE execute commands are sent.

3.1

	<i>hglbCmds</i> Identifies the memory containing one or more DDE execute commands. <i>reserved</i> Reserved; must be zero.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_COMMAND OLE_ERROR_MEMORY OLE_ERROR_NOT_OPEN OLE_ERROR_OBJECT OLE_ERROR_PROTOCOL OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE
Comments	The client application should call the OleQueryProtocol function, specifying StdExecute, before calling the OleExecute function. The OleQueryProtocol function succeeds if the server for an object supports the OleExecute function.
See Also	OleQueryProtocol

OleGetData

#include <ole.h>

OLESTATUS OleGetData(lpObject, cfFormat, lphData)

 LPOLEOBJECT lpObject;
 /* address of object to query
 */

 OLECLIPFORMAT cfFormat;
 /* format for retrieved data
 */

 HANDLE FAR* lphData;
 /* address of memory to contain data
 */

The **OleGetData** function retrieves data in the requested format from the specified object and supplies the handle of a memory or graphics device interface (GDI) object containing the data.

3.1

Parameters

lpObject

Points to the object from which data is retrieved.

cfFormat

Specifies the format in which data is returned. This parameter can be one of the predefined clipboard formats or the value returned by the **RegisterClipboard-Format** function.

See Also	OleEnumFormats, OleSetData, RegisterClipboardFormat
	When the OleGetData function specifies CF_METAFILE or CF_BITMAP, the <i>lphData</i> parameter points to a GDI object, not a memory object, when the function returns. OleGetData supplies the handle of a memory object for all other formats.
	The OleGetData function typically returns OLE_WARN_DELETE_DATA if an object handler generates data for an object that the client library cannot interpret. In this case, the client application is responsible for controlling that data.
Comments	If the OleGetData function returns OLE_WARN_DELETE_DATA, the client application owns the data and should free the memory associated with the data when the client has finished using it. For other return values, the client should not free the memory or modify the data, because the data is controlled by the client library. If the application needs the data for long-term use, it should copy the data.
	OLE_ERROR_BLANK OLE_ERROR_FORMAT OLE_ERROR_OBJECT OLE_WARN_DELETE_DATA
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	<i>lphData</i> Points to the handle of a memory object that contains the data when the function returns.

OleGetLinkUpdateOptions

3.1

#include <ole.h>

OLESTATUS OleGetLinkUpdateOptions(lpObject, lpUpdateOpt)	
LPOLEOBJECT lpObject;	/* address of object to query	*/
OLEOPT_UPDATE FAR* <i>lpUpdateOpt</i> ;	/* address of update options	*/

The **OleGetLinkUpdateOptions** function retrieves the link-update options for the presentation of a specified object.

Parameters

lpObject

Points to the object to query.

lpUpdateOpt

Points to a variable in which the function stores the current value of the linkupdate option for the specified object. The link-update option setting may be one of the following values:

	Value	Meaning
	oleupdate_always	Update the linked object whenever possible. This option sup- ports the Automatic link-update radio button in the Links dialog box.
	oleupdate_oncall	Update the linked object only on request from the client ap- plication. This option supports the Manual link-update radio button in the Links dialog box.
	oleupdate_onsave	Update the linked object when the source document is saved by the server.
Return Value	The return value is OI value, which may be c	LE_OK if the function is successful. Otherwise, it is an error one of the following:
		CTT.

OLE_ERROR_OBJECT OLE_ERROR_STATIC

See Also OleSetLinkUpdateOptions

OlelsDcMeta

#include <ol< th=""><th>e.h></th></ol<>	e.h>
	DcMeta(hdc) /* device-context handle */
	The OleIsDcMeta function determines whether the specified device context is a metafile device context.
Parameters	<i>hdc</i> Identifies the device context to query.

Return Value The return value is a positive value if the device context is a metafile device context. Otherwise, it is NULL.

OleLoadFromStream

#include <ole.h>

lplpObject) LPOLESTREAM lpStream; /* address of stream for object */ LPCSTR lpszProtocol: /* address of string for protocol name */ **LPOLECLIENT** *lpClient*; /* address of client structure */ **LHCLIENTDOC** *lhClientDoc*: /* long handle of client document */ LPCSTR lpszObjname; /* address of string for object name */ **LPOLEOBJECT FAR*** *lplpObject*; /* address of pointer to object */

OLESTATUS OleLoadFromStream(*lpStream*, *lps2Protocol*, *lpClient*, *lhClientDoc*, *lps2Objname*,

The OleLoadFromStream function loads an object from the containing document.

Parameters

lpStream

Points to an **OLESTREAM** structure that was allocated and initialized by the client application. The library calls the **Get** function in the **OLESTREAMVTBL** structure to obtain the data for the object.

lpszProtocol

Points to a null-terminated string specifying the name of the required protocol. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).

lpClient

Points to an **OLECLIENT** structure allocated and initialized by the client application. This pointer is used to locate the callback function and is passed in callback notifications.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object.

lplpObject

Points to a variable in which the library stores a pointer to the loaded object.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_HANDLE OLE_ERROR_NAME OLE_ERROR_PROTOCOL OLE_ERROR_STREAM OLE_WAIT_FOR_RELEASE

CommentsTo load an object, the client application needs only the location of that object in a
file. A client typically loads an object only when the object is needed (for ex-
ample, when it must be displayed).If an object cannot be loaded when the *lpszProtocol* parameter specifies
StdFileEditing, the application can call the **OleLoadFromStream** function again,
specifying Static.If the object is linked and the server and document are open, the library automat-
ically makes the link between the client and server applications when an applica-
tion calls **OleLoadFromStream**.See AlsoOleQuerySize, OleSaveToStream

	OLE_ERROF OLE_ERROF OLE_ERROF	R_LAUNCH		
Comments	er is used for	OleLockServer to speed the a number of different objects. nlockServer function to relea	Before the client termin	nates, it must

When **OleLockServer** is called more than once for a given server, even by different client applications, the server's lock count is increased. Each call to **Ole-UnlockServer** decrements the lock count. The server remains locked until the lock count is zero. If the object identified by the *lpObject* parameter is deleted before calling the **OleUnlockServer** function, **OleUnlockServer** must still be called to decrement the lock count.

If necessary, a server can terminate even though a client has called the **OleLock-Server** function.

See Also OleUnlockServer

0	e	0	b	je	ct	C	0	n	V	e	rt
---	---	---	---	----	----	---	---	---	---	---	----

#include <ole.h>

OLESTATUS OleObjectConvert(*lpObject*, *lpszProtocol*, *lpClient*, *lhClientDoc*, *lpszObjname*, *lplpObject*)

LPÔLEOBJECT lpObject;	/* address of object to convert	*/
LPCSTR lpszProtocol;	/* address of string for protocol name	*/
LPOLECLIENT <i>lpClient</i> ;	/* address of client for new object	*/
LHCLIENTDOC lhClientDoc;	/* long handle of client document	*/
LPCSTR lpszObjname;	/* address of string for object name	*/
LPOLEOBJECT FAR* lplpObject;	/* address of pointer to new object	*/

The **OleObjectConvert** function creates a new object that supports a specified protocol by converting an existing object. This function neither deletes nor replaces the original object.

Parameters

lpObject

Points to the object to convert.

lpszProtocol

Points to a null-terminated string specifying the name of the required protocol. Currently this value can be Static (for uneditable pictures only).

lpClient

Points to an **OLECLIENT** structure for the new object.

lhClientDoc

Identifies the client document in which the object is being created.

lpszObjname

Points to a null-terminated string specifying the client's name for the object. This name must be unique with respect to the names of any other objects in the document and cannot contain a slash mark (/).

	<i>lplpObject</i> Points to a variable in which the library stores a pointer to the new object.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_HANDLE OLE_ERROR_NAME OLE_ERROR_OBJECT OLE_ERROR_STATIC
Comments	The only conversion currently supported is that of changing a linked or embedded object to a static object.
See Also	OleClone

3.1

OleQueryBounds

#include <ole.h>

"menude (ofem)			
OLESTATUS OleQ LPOLEOBJECT lp RECT FAR* lpBou	Object;	(<i>lpObject</i> , <i>lpBounds</i>) * address of object to query */ * address of structure for bounding rectangle */	
		eryBounds function retrieves the extents of the bounding rectangle on vice for the specified object. The coordinates are in MM_HIMETRIC	
Parameters	<i>lpObject</i> Points t	the object to query.	
		a RECT structure for the extents of the bounding rectangle. The men e RECT structure have the following meanings:	n-
	Member	Meaning	
	rect.left	0	
	rect.top	0	
	rect.rigł	x-extent	
	rect.bot	m y-extent	

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_BLANK OLE_ERROR_MEMORY OLE_ERROR_OBJECT

See Also OleSetBounds, SetMapMode

OleQueryClientVersion

#include <ole.h>

DWORD OleQueryClientVersion(void)

The **OleQueryClientVersion** function retrieves the version number of the client library.

- **Parameters** This function has no parameters.
- **Return Value** The return value is a doubleword value. The major version number is in the loworder byte of the low-order word, and the minor version number is in the highorder byte of the low-order word. The high-order word is reserved.

See Also OleQueryServerVersion

OleQueryCreateFromClip

#include <ole.h>

OLESTATUS OleQueryCreateFrom	mClip (<i>lpszProtocol</i> , <i>renderopt</i> , <i>cfFormat</i>)	
LPCSTR lpszProtocol;	/* address of string for protocol name	*/
OLEOPT_RENDER renderopt;	/* rendering options	*/
OLECLIPFORMAT cfFormat;	/* format for clipboard data	*/

The **OleQueryCreateFromClip** function checks whether the object on the clipboard supports the specified protocol and rendering options.

3.1

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol needed by the client. Currently, this value can be StdFileEditing (the name of the object linking and embedding protocol) or Static (for uneditable pictures only).

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.
olerender_format	The library obtains and manages the data in the requested for- mat, as specified by the <i>cfFormat</i> parameter.
olerender_none	The client library does not obtain any presentation data and does not draw the object.

cfFormat

Specifies the clipboard format. This parameter is used only when the *renderopt* parameter is **olerender_format**. If the clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_ERROR_FORMAT OLE_ERROR_PROTOCOL

Comments The **OleQueryCreateFromClip** function is typically used to check whether to enable a Paste command.

The **olerender_none** rendering option is typically used to support hyperlinks. With this option, the client does not call **OleDraw** and calls the **OleGetData** function only for ObjectLink, OwnerLink, and Native formats.

The **olerender_format** rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option the client does not call **OleDraw**. The client calls **OleGetData** to retrieve data in the specified format.

The **olerender_draw** rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls **OleDraw**), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object

linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.

See Also OleCreateFromClip, OleDraw, OleGetData

OleQueryLinkFromClip

#include <ole.h>

OLESTATUS OleQueryLinkFromClip (<i>lpszProtocol</i> , <i>renderopt</i> , <i>cfFormat</i>)			
LPCSTR lpszProtocol;	/* address of string for protocol name	*/	
OLEOPT_RENDER renderopt;	/* rendering options	*/	
OLECLIPFORMAT cfFormat;	/* format for clipboard data	*/	

The **OleQueryLinkFromClip** function checks whether a client application can use the data on the clipboard to produce a linked object that supports the specified protocol and rendering options.

Parameters

lpszProtocol

Points to a null-terminated string specifying the name of the protocol needed by the client. Currently this value can be StdFileEditing (the name of the object linking and embedding protocol).

renderopt

Specifies the client's preference for presentation data for the object. This parameter can be one of the following values:

Value	Meaning	
olerender_draw	The client calls the OleDraw function, and the library ob- tains and manages presentation data.	
olerender_format	The library obtains and manages the data in the requested for- mat, as specified by the <i>cfFormat</i> parameter.	
olerender_none	The client library does not obtain any presentation data and does not draw the object.	

cfFormat

Specifies the clipboard format. This parameter is used only when the *renderopt* parameter is **olerender_format**. If this clipboard format is CF_METAFILEPICT, CF_DIB, or CF_BITMAP, the library manages the data and draws the object. The library does not support drawing for any other formats.

Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:	
	OLE_ERROR_FORMAT OLE_ERROR_PROTOCOL	
Comments	The OleQueryLinkFromClip function is typically used to check whether to enable a Paste Link command.	
	The olerender_none rendering option is typically used to support hyperlinks. With this option, the client does not call OleDraw and calls the OleGetData func- tion only for ObjectLink, OwnerLink, and Native formats.	
	The olerender_format rendering option allows a client to compute data (instead of painting it), use an unusual data format, or modify a standard data format. With this option, the client does not call OleDraw . The client calls OleGetData to retrieve data in the specified format.	
	The olerender_draw rendering option is the most typical option. It is the easiest rendering option for the client to implement (the client simply calls OleDraw), and it allows the most flexibility. An object handler can exploit this flexibility to store no presentation data, a private presentation data format, or several different formats that it can choose among dynamically. Future implementations of object linking and embedding (OLE) may also exploit the flexibility that is inherent in this option.	
See Also	OleCreateLinkFromClip, OleDraw, OleGetData	

OleQueryName

#include <ole.h>

OLESTATUS OleQueryName (<i>lpObject</i> , <i>lpszObject</i> , <i>lpwBuffSize</i>)			
LPOLEOBJECT <i>lpObject</i> ;	/* address of object	*/	
LPSTR lpszObject;	/* address of string for object name	*/	
UINT FAR* <i>lpwBuffSize</i> ;	/* address of word for size of buffer	*/	

The OleQueryName function retrieves the name of a specified object.

Parameters

lpObject

Points to the object whose name is being queried.

	<i>lpszObject</i> Points to a character array that contains a null-terminated string. When the func- tion returns, this string specifies the name of the object.
	<i>lpwBuffSize</i> Points to a variable containing the size, in bytes, of the buffer pointed to by the <i>lpszObject</i> parameter. When the function returns, this value is the number of bytes copied to the buffer.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.
See Also	OleRename

OleQueryOpen

3.1

#include <ole.h>

OLESTATUS OleQueryOpen(lpObject)LPOLEOBJECT lpObject;/* address of object to query*/

The **OleQueryOpen** function checks whether the specified object is open.

Parameters	<i>lpObject</i> Points to the object to query.
Return Value	The return value is OLE_OK if the object is open. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_COMM OLE_ERROR_OBJECT OLE_ERROR_STATIC

See Also OleActivate

OleQueryOutOfDate

#include <ole.h>

OLESTATUS OleQueryOutOfDate(*lpObject*) LPOLEOBJECT lpObject; /* address of object to query */

The OleQueryOutOfDate function checks whether an object is out-of-date.

Parameters	<i>lpObject</i> Points to the object to query.
Return Value	The return value is OLE_OK if the object is up-to-date. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_OBJECT OLE_ERROR_OUTOFDATE
Comments	The OleQueryOutOfDate function has not been implemented for the current version of object linking and embedding (OLE). For linked objects, OleQueryOutOf-Date always returns OLE_OK.
	A linked object might be out-of-date if the document that is the source for the link has been updated. An embedded object that contains links to other objects might also be out-of-date.
See Also	OleEqual, OleUpdate

OleQueryProtocol

#include <ole.h>

void FAR* OleQueryProtocol(lpobj, lpszProtocol)			
LPOLEOBJECT lpobj;	/* address of object to query	*/	
LPCSTR lpszProtocol;	/* address of string for protocol to query	*/	

The OleQueryProtocol function checks whether an object supports a specified protocol.

Parameters

lpobj Points to the object to query. 3.1

3.1

	<i>lpszProtocol</i> Points to a null-terminated string specifying the name of the requested protocol. This value can be StdFileEditing or StdExecute.
Return Value	The return value is a void pointer to an OLEOBJECT structure if the function is successful, or it is NULL if the object does not support the requested protocol. The library can return OLE_WAIT_FOR_RELEASE when an application calls this function.
Comments	The OleQueryProtocol function queries whether the specified protocol is supported and returns a modified object pointer that allows access to the function table for the protocol. This modified object pointer points to a structure that has the same form as the OLEOBJECT structure; the new structure also points to a table of functions and may contain additional state information. The new pointer does not point to a different object—if the object is deleted, secondary pointers become invalid. If a protocol includes delete functions, calling a delete function invalidates all pointers to that object.
	A client application typically calls OleQueryProtocol , specifying StdExecute for the <i>lpszProtocol</i> parameter, before calling the OleExecute function. This allows the client application to check whether the server for an object supports dynamic data exchange (DDE) execute commands.
See Also	OleExecute

OleQueryReleaseError

#include <ole.h>

OLESTATUS OleQueryReleaseError(*lpobj*)**LPOLEOBJECT** *lpobj*;/* address of object to query*/

The **OleQueryReleaseError** function checks the error value for an asynchronous operation on an object.

Parameters	<i>lpobj</i> Points to an object for which the error value is to be queried.
Return Value	The return value, if the function is successful, is either OLE_OK if the asynchronous operation completed successfully or the error value for that operation. If the pointer passed in the <i>lpobj</i> parameter is invalid, the function returns OLE_ERROR_OBJECT.

Comments	A client application receives the OLE_RELEASE notification when an asynchro- nous operation has terminated. The client should then call OleQueryRelease - Error to check whether the operation has terminated successfully or with an error value.
See Also	OleQueryReleaseMethod, OleQueryReleaseStatus

OleQueryReleaseMethod

lpobj

#include <ole.h>

OLE_RELEASE_METHOD OleQueryReleaseMethod(*lpobj*) LPOLEOBJECT *lpobj*; /* address of object to query */

The **OleQueryReleaseMethod** function finds out the operation that finished for the specified object.

3.1

Parameters

Points to an object for which the operation is to be queried.

Return Value

The return value indicates the server operation (method) that finished. It can be one of the following values:

Value	Server operation
OLE_ACTIVATE	Activate
OLE_CLOSE	Close
OLE_COPYFROMLNK	CopyFromLink (autoreconnect)
OLE_CREATE	Create
OLE_CREATEFROMFILE	CreateFromFile
OLE_CREATEFROMTEMPLATE	CreateFromTemplate
OLE_CREATEINVISIBLE	CreateInvisible
OLE_CREATELINKFROMFILE	CreateLinkFromFile
OLE_DELETE	Object Delete
OLE_EMBPASTE	Paste and Update
OLE_LNKPASTE	PasteLink (autoreconnect)
OLE_LOADFROMSTREAM	LoadFromStream (autoreconnect)
OLE_NONE	No operation active
OLE_OTHER	Other miscellaneous asynchronous operations
OLE_RECONNECT	Reconnect

3.1

	Value	Server operation
	OLE_REQUESTDATA	OleRequestData
	OLE_RUN	Run
	OLE_SERVERUNLAUNCH	Server is stopping
	OLE_SETDATA	OleSetData
	OLE_SETUPDATEOPTIONS	Setting update options
	OLE_SHOW	Show
	OLE_UPDATE	Update
	If the pointer passed in the <i>lpobj</i> par OLE_ERROR_OBJECT.	rameter is invalid, the function returns
Comments	A client application receives the OLE_RELEASE notification when an asynchro- nous operation has ended. The client can then call OleQueryReleaseMethod to check which operation caused the library to send the OLE_RELEASE notification. The client calls OleQueryReleaseError to determine whether the operation termi- nated successfully or with an error value.	
See Also	OleQueryReleaseError, OleQuer	yReleaseStatus

OleQueryReleaseStatus

<pre>#include <ole.h></ole.h></pre>	
	QueryReleaseStatus (<i>lpobj</i>) <i>pobj</i> ; /* address of object to query */
	The OleQueryReleaseStatus function determines whether an operation has finished for the specified object.
Parameters	<i>lpobj</i> Points to an object for which the operation is queried.
Return Value	The return value, if the function is successful, is either OLE_BUSY if an operation is in progress or OLE_OK. If the pointer passed in the <i>lpobj</i> parameter is invalid, the function returns OLE_ERROR_OBJECT.
See Also	OleQueryReleaseError, OleQueryReleaseMethod

OleQueryServerVersion

#include <ole.h>

DWORD OleQueryServerVersion(void)

	The OleQueryServerVersion function retrieves the version number of the server library.
Parameters	This function has no parameters.
Return Value	The return value is a doubleword value. The major version number is in the low-order byte of the low-order word, and the minor version number is in the high-order byte of the low-order word. The high-order word is reserved.
See Also	OleQueryClientVersion

OleQuerySize

#include <ole.h>

OLESTATUS OleQ LPOLEOBJECT lp DWORD FAR* pdw	Object; i	/* address of object	to query f object	*/ */
	The OleQu	erySize function re	trieves the size	of the specified object.
Parameters	<i>lpObject</i> Points to	the object to query	7.	
		a variable for the s of when the function		ct. This variable contains the size of
Return Value		value is OLE_OK i h may be one of the		s successful. Otherwise, it is an error
	OLE_ERR	OR_BLANK OR_MEMORY OR_OBJECT		
See Also	OleLoadF	romStream		

3.1

OleQueryType

#include <ole.h>

	QueryType(lpObject, lppObject;/* addresse;/* address	
	The OleQueryType f linked, or static.	function checks whether a specified object is embedded,
Parameters	<i>lpObject</i> Points to the object	t for which the type is to be queried.
		riable that contains the type of the object when the function neter can be one of the following values:
	Value	Meaning
	OT_EMBEDDED	Object is embedded.
	OT_LINK	Object is a link.
	OT_STATIC	Object is a static picture.
Return Value	The return value is OI value, which may be c	LE_OK if the function is successful. Otherwise, it is an error one of the following:
	OLE_ERROR_GENE OLE_ERROR_OBJE	
See Also	OleEnumFormats	

OleReconnect

3.1

#include <ole.h>

OLESTATUS OleReconnect(*lpObject*) **LPOLEOBJECT** *lpObject*; /* address of object to reconnect to

The **OleReconnect** function reestablishes a link to an open linked object. If the specified object is not open, this function does not open it.

*/

Parameters	<i>lpObject</i> Points to the object to reconnect to.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_NOT_LINK OLE_ERROR_OBJECT OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE
Comments	A client application can use OleReconnect to keep the presentation for a linked object up-to-date.
See Also	OleActivate, OleClose, OleUpdate

OleRegisterClientDoc

#include <ole.h>

OLESTATUS OleRegisterClientDoc (<i>lpszClass</i> , <i>lpszDoc</i> , <i>reserved</i> , <i>lplhDoc</i>)		
LPCSTR lpszClass;	/* address of string for class name	*/
LPCSTR lpszDoc;	/* address of string for document name	*/
LONG reserved;	/* reserved	*/
LHCLIENTDOC FAR* lplhDoc;	/* address of handle of document	*/

The **OleRegisterClientDoc** function registers an open client document with the library and returns the handle of that document.

ø

3.1

Parameters

lpszClass

Points to a null-terminated string specifying the class of the client document.

lpszDoc

Points to a null-terminated string specifying the location of the client document. (This value should be a fully qualified path.)

reserved

Reserved. Must be zero.

lplhDoc

Points to the handle of the client document when the function returns. This handle is used to identify the document in other document-management functions.

Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_ALREADY_REGISTERED OLE_ERROR_MEMORY OLE_ERROR_NAME
Comments	When a document being copied onto the clipboard exists only because the client application is copying Native data that contains objects, the name specified in the <i>lpszDoc</i> parameter must be Clipboard.
	Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a changed state.
See Also	OleRenameClientDoc, OleRevertClientDoc, OleRevokeClientDoc, OleSavedClientDoc

OleRegisterServer

3.1

#include <ole.h>

OLESTATUS OleRegisterServer	(lpszClass, lpsrvr, lplhserver, hinst, srvruse)	
LPCSTR lpszClass;	/* address of string for class name	*/
LPOLESERVER lpsrvr;	/* address of OLESERVER structure	*/
LHSERVER FAR* lplhserver;	/* address of server handle	*/
HINSTANCE hinst;	/* instance handle	*/
OLE_SERVER_USE <i>srvruse</i> ;	/* single or multiple instances	*/

The **OleRegisterServer** function registers the specified server, class name, and instance with the server library.

Parameters

lpszClass

Points to a null-terminated string specifying the class name being registered.

lpsrvr

Points to an **OLESERVER** structure allocated and initialized by the server application.

lplhserver

Points to a variable of type **LHSERVER** in which the library stores the handle of the server. This handle is used in such functions as **OleRegisterServerDoc** and **OleRevokeServer**.

	 <i>hinst</i> Identifies the instance of the server application. This handle is used to ensure that clients connect to the correct instance of a server application. <i>srvruse</i> Specifies whether the server uses a single instance or multiple instances to support multiple objects. This value must be either OLE_SERVER_SINGLE or
Return Value	OLE_SERVER_MULTI. The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_CLASS OLE_ERROR_MEMORY OLE_ERROR_PROTECT_ONLY
Comments	When the server application starts, it creates an OLESERVER structure and calls the OleRegisterServer function. Servers that support several class names can allo- cate a structure for each or reuse the same structure. The class name is passed to server-application functions that are called through the library, so that servers supporting more than one class can check which class is being requested.
	The <i>srvruse</i> parameter is used when the libraries open an object. When OLE_SERVER_MULTI is specified for this parameter and all current instances are already editing an object, a new instance of the server is started. Servers that support the multiple document interface (MDI) typically specify OLE_SERVER_SINGLE.
See Also	OleRegisterServerDoc, OleRevokeServer

OleRegisterServerDoc

#include <ole.h>

OLESTATUS OleRegisterServerDoc (<i>lhsrvr</i> , <i>lpszDocName</i> , <i>lpdoc</i> , <i>lplhdoc</i>)		
LHSERVER lhsrvr;	/* server handle	*/
LPCSTR lpszDocName;	/* address of string for document name	*/
LPOLESERVERDOC lpdoc;	/* address of OLESERVERDOC structure	*/
LHSERVERDOC FAR* lplhdoc;	/* handle of registered document	*/

The **OleRegisterServerDoc** function registers a document with the server library in case other client applications have links to it. A server application uses this function when the server is started with the **/Embedding** *filename* option or when it creates or opens a document that is not requested by the library.

Parameters	<i>lhsrvr</i> Identifies the server. Server applications obtain this handle by calling the OleRegisterServer function.
	<i>lpszDocName</i> Points to a null-terminated string specifying the permanent name for the document. This parameter should be a fully qualified path.
	<i>lpdoc</i> Points to an OLESERVERDOC structure allocated and initialized by the server application.
	<i>lplhdoc</i> Points to a handle that will identify the document. This parameter points to the handle when the function returns.
Return Value	If the function is successful, the return value is OLE_OK. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_ADDRESS OLE_ERROR_HANDLE OLE_ERROR_MEMORY
Comments	If the document was created or opened in response to a request from the server library, the server should not register the document by using OleRegisterServer-Doc . Instead, the server should return a pointer to the OLESERVERDOC structure through the parameter to the relevant function.
See Also	OleRegisterServer, OleRevokeServerDoc
OleRelease	3.1

#include <ole.h>

OLESTATUS OleRelease(*lpObject*) **LPOLEOBJECT** *lpObject*; /* address of object to release */

The **OleRelease** function releases an object from memory and closes it if it was open. This function does not indicate that the object has been deleted from the client document.

Parameters*lpObject*
Points to the object to release.

Return Value	If the function is successful, the return value is OLE_OK. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE
Comments	The OleRelease function should be called for all objects when closing the client document.
See Also	OleDelete

OleRename

3.1

#include <ole.h>

OLESTATUS OleF LPOLEOBJECT l LPCSTR lpszNewn	
	The OleRename function renames an object.
Parameters	<i>lpObject</i> Points to the object that is being renamed.
	<i>lpszNewname</i> Points to a null-terminated string specifying the new name of the object.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_OBJECT.
Comments	Object names need not be seen by the user. They must be unique within the con- taining document and must be preserved when the document is saved.
See Also	OleQueryName

OleRenameClientDoc

#include <ole.h>

OLESTATUS OleRenameClientDoc (<i>lhClientDoc</i> , <i>lpszNewDocname</i>)			
LHCLIENTDOC lhClientDoc;		/* handle of client document	*/
LPCSTR lpszNewD	ocname;	/* address of string for new document name	*/
-	been renamed.	neClientDoc function informs the client library the A client application calls this function when a do example, when the user chooses the Save or Save nenu.	cument name has
Parameters	<i>lhClientDoc</i> Identifies th	e document that has been renamed.	
	<i>lpszNewDocna</i> Points to a r	<i>ume</i> null-terminated string specifying the new name of	the document.
Return Value		ue is OLE_OK if the function is successful. Other nay be OLE_ERROR_HANDLE.	wise, it is an error
Comments		tions should register open documents with the libra document is renamed, closed, saved, or restored t	
See Also	OleRegisterC OleSavedClie	lientDoc, OleRevertClientDoc, OleRevokeClier ntDoc	ntDoc,

OleRenameServerDoc

#include <ole.h>

OLESTATUS OleRenameServerDoc (<i>lhDoc</i> , <i>lpszDocName</i>)			
LHSERVERDOC lhDoc;		/* handle of document	*/
LPCSTR lpszDocName;		/* address of string for path and filename	*/
		e RenameServerDoc function informs the serve n renamed.	er library that a document
Parameters	lhDoc		

Identifies the document that has been renamed.

3.1

	<i>lpszDocName</i> Points to a null-terminated string specifying the new name of the document. This parameter is typically a fully qualified path.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_HANDLE OLE_ERROR_MEMORY
Comments	The OleRenameServerDoc function has the same effect as sending the OLE_RENAMED notification to the client application's callback function. The server application calls this function when it renames a document to which the active links need to be reconnected or when the user chooses the Save As command from the File menu while working with an embedded object.
	Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a changed state.
See Also	OleRegisterServerDoc, OleRevertServerDoc, OleRevokeServerDoc, OleSavedServerDoc

OleRequestData

#include <ole.h>

OLESTATUS OleRequestData(lpObject, cfFormat)LPOLEOBJECT lpObject;/* address of object to query*/OLECLIPFORMAT cfFormat;/* format for retrieved data*/

The **OleRequestData** function requests the library to retrieve data in a specified format from a server.

Parameters

lpObject

Points to the object that is associated with the server from which data is to be retrieved.

3.1

cfFormat

Specifies the format in which data is to be returned. This parameter can be one of the predefined clipboard formats or the value returned by the **Register-ClipboardFormat** function.

3.1

Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_NOT_OPEN OLE_ERROR_OBJECT OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE
Comments	The client application should be connected to the server application when the client calls the OleRequestData function. When the client receives the OLE_RELEASE notification, it can retrieve the data from the object by using the OleGetData function or query the data by using such functions as OleQuery-Bounds .
	If the requested data format is the same as the presentation data for the object, the library manages the data and updates the presentation.
	The OleRequestData function returns OLE_WAIT_FOR_RELEASE if the server is busy. In this case, the application should continue to dispatch messages until it receives a callback notification with the OLE_RELEASE argument.
See Also	OleEnumFormats, OleGetData, OleSetData, RegisterClipboardFormat

OleRevertClientDoc

#include <ole.h>

OLESTATUS OleRevertClientDoc(lhClientDoc) LHCLIENTDOC lhClientDoc; /* handle of client document */	
	The OleRevertClientDoc function informs the library that a document has been restored to a previously saved condition.
Parameters	<i>lhClientDoc</i> Identifies the document that has been restored to its saved state.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.
Comments	A client application should call the OleRevertClientDoc function when it reloads a document without saving changes to the document.

Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a saved state.

See Also

OleRegisterClientDoc, OleRenameClientDoc, OleRevokeClientDoc, OleSavedClientDoc

OleRevertServerDoc

#include <ole.h>

OLESTATUS OleRevertServerDoc(lhDoc) LHSERVERDOC lhDoc; /* handle of document */

The **OleRevertServerDoc** function informs the server library that the server has restored a document to its saved state without closing it.

3.1

3.1

Parameters	<i>lhDoc</i> Identifies the document that has been restored to its saved state.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.
Comments	Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a saved state.
See Also	OleRegisterServerDoc, OleRenameServerDoc, OleRevokeServerDoc, OleSavedServerDoc

OleRevokeClientDoc

#include <ole.h>

 OLESTATUS OleRevokeClientDoc(lhClientDoc)

 LHCLIENTDOC lhClientDoc;
 /* handle of client document
 */

The **OleRevokeClientDoc** function informs the client library that a document is no longer open.

3.1

Parameters	<i>lhClientDoc</i> Identifies the document that is no longer open. This handle is invalid following the call to OleRevokeClientDoc .
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_HANDLE OLE_ERROR_NOT_EMPTY
Comments	The client application should delete all the objects in a document before calling OleRevokeClientDoc .
	Client applications should register open documents with the library and notify the library when a document is renamed, closed, saved, or restored to a changed state.
See Also	OleRegisterClientDoc, OleRenameClientDoc, OleRevertClientDoc, OleSavedClientDoc

OleRevokeObject

#include <ole.h>

OLESTATUS O LPOLECLIENT	eRevokeObject(lpClient) > lpClient; /* address of OLECLIENT structure
	The OleRevokeObject function revokes access to an object. A server application typically calls this function when the user destroys an object.
Parameters	<i>lpClient</i> Points to the OLECLIENT structure associated with the object being revoked.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value.
See Also	OleRevokeServer, OleRevokeServerDoc

OleRevokeServer

#include <ole.h>

OLESTATUS OleR LHSERVER lhServ	er; /* server handle */
	The OleRevokeServer function is called by a server application to close any registered documents.
Parameters	<i>lhServer</i> Identifies the server to revoke. A server application obtains this handle in a call to the OleRegisterServer function.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_HANDLE OLE_WAIT_FOR_RELEASE
Comments	The OleRevokeServer function returns OLE_WAIT_FOR_RELEASE if com- munications between clients and the server are in the process of terminating. In this case, the server application should continue to send and dispatch messages until the library calls the server's Release function.
See Also	OleRegisterServer, OleRevokeObject, OleRevokeServerDoc

OleRevokeServerDoc

#include <ole.h>

OLESTATUS OleRevokeServerDoc(*lhdoc*) LHSERVERDOC *lhdoc*; /* document handle */

lhdoc

The **OleRevokeServerDoc** function revokes the specified document. A server application calls this function when a registered document is being closed or otherwise made unavailable to client applications.

Parameters

Identifies the document to revoke. This handle was returned by a call to the **OleRegisterServerDoc** function or was associated with a document by using one of the server-supplied functions that create documents.

3.1

Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_HANDLE OLE_WAIT_FOR_RELEASE
Comments	If this function returns OLE_WAIT_FOR_RELEASE, the server application should not free the OLESERVERDOC structure or exit until the library calls the server's Release function.
See Also	OleRegisterServerDoc, OleRevokeObject, OleRevokeServer

OleSavedClientDoc

<pre>#include <ole.h></ole.h></pre>	
	avedClientDoc(lhClientDoc) hClientDoc; /* handle of client document */
	The OleSavedClientDoc function informs the client library that a document has been saved.
Parameters	<i>lhClientDoc</i> Identifies the document that has been saved.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be OLE_ERROR_HANDLE.
Comments	Client applications should register open documents with the client library and notify the library when a document is renamed, closed, saved, or restored to a saved state.
See Also	OleRegisterClientDoc, OleRenameClientDoc, OleRevertClientDoc, OleRevokeClientDoc

OleSavedServerDoc

#include <ole.h>

OLESTATUS OleSavedServerDoc(*lhDoc*)

 LHSERVERDOC *lhDoc*;
 /* handle of document
 */

The **OleSavedServerDoc** function informs the server library that a document has been saved.

Parameters	<i>lhDoc</i> Identifies the document that has been saved.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_CANT_UPDATE_CLIENT OLE_ERROR_HANDLE
Comments	The OleSavedServerDoc function has the same effect as sending the OLE_SAVED notification to the client application's callback function. The server application calls this function when saving a document or when updating an embedded object without closing the document.
	When a server application receives OLE_ERROR_CANT_UPDATE_CLIENT as an error value, it should display a message box indicating that the user cannot up- date the document until the server terminates.
	Server applications should register open documents with the server library and notify the library when a document is renamed, closed, saved, or restored to a saved state.
See Also	OleRegisterServerDoc, OleRenameServerDoc, OleRevertServerDoc, OleRevokeServerDoc

OleSaveToStream

#include <ole.h>

LPOLEOBJECT lp	Object ;	m(<i>lpObject</i> , <i>lpStream</i>) /* address of object to save /* address of OLESTREAM structure	*/ */
	The OleSa	weToStream function saves an object to the	he stream.
Parameters	<i>lpObject</i> Points t	o the object to be saved to the stream.	
	plication	o an OLESTREAM structure allocated ar n. The library calls the Put function in the e data from the object.	
Return Value		value is OLE_OK if the function is succes ch may be one of the following:	ssful. Otherwise, it is an error
	OLE_ERR	ROR_BLANK ROR_MEMORY ROR_OBJECT ROR_STREAM	
Comments		tion can use the OleQuerySize function to r the object.	o find the number of bytes to
See Also	OleLoadF	'romStream, OleQuerySize	

OleSetBounds

3.1

#include <ole.h>

OLESTATUS OleSetBounds	(lpObject, lprcBound)	
LPOLEOBJECT <i>lpObject</i> ;	/* address of object	*/
RECT FAR* <i>lprcBound</i> ;	/* address of structure for bounding rectangle	*/

The **OleSetBounds** function sets the coordinates of the bounding rectangle for the specified object on the target device.

Parameters	<i>lpObject</i> Points to the object for which the bounding rectangle is set.
	<i>lprcBound</i> Points to a RECT structure containing the coordinates of the bounding rectangle. The coordinates are specified in MM_HIMETRIC units. Neither the width nor height of an object should exceed 32,767 MM_HIMETRIC units.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_MEMORY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE
	The OleSetBounds function returns OLE_ERROR_OBJECT when it is called for a linked object.
Comments	The OleSetBounds function is ignored for linked objects, because the size of a linked object is determined by the source document for the link.
	A client application uses OleSetBounds to change the bounding rectangle. The client does not need to call OleSetBounds every time a server is opened.
	The bounding rectangle specified in the OleSetBounds function does not neces- sarily have the same dimensions as the rectangle specified in the call to the Ole- Draw function. These dimensions may be different because of the view scaling used by the container application. An application can use OleSetBounds to cause the server to reformat the picture to fit the rectangle more closely.
	In the MM_HIMETRIC mapping mode, the positive y-direction is up.
See Also	OleDraw, OleQueryBounds, SetMapMode

OleSetColorScheme

#include <ole.h>

OLESTATUS OleSetColorScheme (<i>lpObj</i>	ect, lpPalette)	
LPOLEOBJECT <i>lpObject</i> ;	/* address of object	*/
<pre>const LOGPALETTE FAR* lpPalette;</pre>	/* address of preferred palette	*/

	The OleSetColorScheme function specifies the palette a client application recom- mends be used when the server application edits the specified object. The server application can ignore the recommended palette.
Parameters	<i>lpObject</i> Points to an OLEOBJECT structure describing the object for which a palette is recommended.
	<i>lpPalette</i> Points to a LOGPALETTE structure specifying the recommended palette.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_COMM OLE_ERROR_MEMORY OLE_ERROR_OBJECT OLE_ERROR_PALETTE OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE The OleSetColorScheme function returns OLE_ERROR_OBJECT when it is called for a linked object.
Comments	A client application uses OleSetColorScheme to change the color scheme. The client does not need to call OleSetColorScheme every time a server is opened.
	The first palette entry in the LOGPALETTE structure specifies the foreground color recommended by the client application. The second palette entry specifies the background color. The first half of the remaining palette entries are fill colors, and the second half are colors for lines and text.
	Client applications should specify an even number of palette entries. When there is an uneven number of entries, the server interprets the odd entry as a fill color; that is, if there are five entries, three are interpreted as fill colors and two as line and text colors.

When server applications render metafiles, they should use the suggested palette.

OleSetData

#include <ole.h>

OLESTATUS OleS LPOLEOBJECT <i>l</i> OLECLIPFORMA HANDLE <i>hData</i> ;	pObject;	/* address of object	*/ */ */
		ta function sends data in the spe specified object.	cified format to the server as-
Parameters	 <i>lpObject</i> Points to an object specifying the server to which data is to be sent. <i>cfFormat</i> Specifies the format of the data. <i>hData</i> Identifies a memory object containing the data in the specified format. 		
Return Value	 The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following: OLE_BUSY OLE_ERROR_BLANK OLE_ERROR_MEMORY OLE_ERROR_NOT_OPEN OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE If the specified object cannot accept the data, the function returns an error value. If the server is not open and the requested data format is different from the format of the presentation data, the return value is OLE_ERROR_NOT_OPEN. 		
See Also	OleGetData, (OleRequestData	

OleSetHostNames

#include <ole.h>

OLESTATUS OleSo LPOLEOBJECT lp LPCSTR lpszClient LPCSTR lpszClient	/* address of string with name of client app */		
	The OleSetHostNames function specifies the name of the client application and the client's name for the specified object. This information is used in window titles when the object is being edited in the server application.		
Parameters	<i>lpObject</i> Points to the object for which a name is to be set.		
	<i>lpszClient</i> Points to a null-terminated string specifying the name of the client application.		
	<i>lpszClientObj</i> Points to a null-terminated string specifying the client's name for the object.		
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:		
	OLE_BUSY OLE_ERROR_MEMORY OLE_ERROR_OBJECT OLE_WAIT_FOR_RELEASE		
	The OleSetHostNames function returns OLE_ERROR_OBJECT when it is called for a linked object.		
Comments	When a server application is started for editing of an embedded object, it displays in its title bar the string specified in the <i>lpszClientObj</i> parameter. The object name specified in this string should be the name of the client document containing the object.		
	A client application uses OleSetHostNames to set the name of an object the first time that object is activated or to change the name of an object. The client does not need to call OleSetHostNames every time a server is opened.		

OleSetLinkUpdateOptions

#include <ole.h>

OLESTATUS OleSetLinkUpdateOptions(lpObject, UpdateOpt)LPOLEOBJECT lpObject;/* address of object*/OLEOPT_UPDATE UpdateOpt;/* link-update options*/			
	The OleSetLinkUpdateOptions function sets the link-update options for the pre- sentation of the specified object.		
Parameters	<i>lpObject</i> Points to the object for which the link-update option is set.		
	<i>UpdateOpt</i> Specifies the link-up one of the following	pdate option for the specified object. This parameter can be g values:	
	Option	Description	
	oleupdate_always	Update the linked object whenever possible. This option sup- ports the Automatic link-update radio button in the Links dialog box.	
	oleupdate_oncall	Update the linked object only on request from the client ap- plication. This option supports the Manual link-update radio button in the Links dialog box.	
	oleupdate_onsave	Update the linked object when the source document is saved by the server.	
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:		
	OLE_BUSY OLE_ERROR_OBJECT OLE_ERROR_OPTION OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE		
See Also OleGetLinkUpdateOptions			

OleSetTargetDevice

opened.

#include <ole.h>

	etTargetDevice(<i>lpObject</i> , <i>hotd</i>)
LPOLEOBJECT lp HGLOBAL hotd;	Object; /* address of object */ /* handle of OLETARGETDEVICE structure */
	The OleSetTargetDevice function specifies the target output device for an object.
Parameters	<i>lpObject</i> Points to the object for which a target device is specified.
	<i>hotd</i> Identifies an OLETARGETDEVICE structure that describes the target device for the object.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_BUSY OLE_ERROR_MEMORY OLE_ERROR_OBJECT OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE
Comments	The OleSetTargetDevice function allows a linked or embedded object to be for- matted correctly for a target device, even when the object is rendered on a differ- ent device. A client application should call this function whenever the target device changes, so that servers can be notified to change the rendering of the ob- ject, if necessary. The client application should call the OleUpdate function to en- sure that the information is sent to the server, so that the server can make the necessary changes to the object's presentation. The client application should call the library to redraw the object if it receives a notification from the server that the object has changed.
	A client application uses the OleSetTargetDevice function to change the target device. The client does not need to call OleSetTargetDevice every time a server is

OleUnblockServer

#include <ole.h>

LHSERVER lhSrvr	InblockServer(lhSrvr, lpfRequest) ; /* handle of server quest; /* address of flag for more requests	*/ */
	The OleUnblockServer function processes a recalling the OleBlockServer function.	quest from a queue created by
Parameters	<i>lhSrvr</i> Identifies the server for which requests were <i>lpfRequest</i> Points to a flag indicating whether there are f there are further requests in the queue, this fla turns. Otherwise, it is FALSE when the funct	Turther requests in the queue. If ag is TRUE when the function re-
Return Value	The return value is OLE_OK if the function is structure, which may be one of the following:	uccessful. Otherwise, it is an error
	OLE_ERROR_HANDLE OLE_ERROR_MEMORY	
Comments	A server application can use the OleBlockServer tions to control when the server library processe It is best to use OleUnblockServer outside the loop, unblocking all blocked messages before ge ing message loops should not be run inside serve by the library.	es requests from client applications. GetMessage function in a message etting the next message. Unblock-
See Also	OleBlockServer	

OleUnlockServer

#include <ole.h>

OLESTATUS OleUnlockServer(*hServer*) LHSERVER *hServer*; /* handle of server to unlock */

The **OleUnlockServer** function unlocks a server that was locked by the **OleLock-Server** function.

Parameters	<i>hServer</i> Identifies the server to release from memory. This handle was retrieved by a call to the OleLockServer function.
Return Value	The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:
	OLE_ERROR_HANDLE OLE_WAIT_FOR_RELEASE
Comments	When the OleLockServer function is called more than once for a given server, the server's lock count is incremented. Each call to OleUnlockServer decrements the lock count. The server remains locked until the lock count is zero.
	If the OleUnlockServer function returns OLE_WAIT_FOR_RELEASE, the appli- cation should call the OleQueryReleaseStatus function to determine whether the unlocking process has finished. In the call to OleQueryReleaseStatus , the applica- tion can cast the server handle to a long pointer to an object linking and embed- ding (OLE) object (LPOLEOBJECT):
	<pre>OleQueryReleaseStatus((LPOLEOBJECT) lhserver);</pre>
	When OleQueryReleaseStatus no longer returns OLE_BUSY, the server has been unlocked.
See Also	OleLockServer, OleQueryReleaseStatus

OleUpdate

#include <ole.h>

OLESTATUS OleUpdate(*lpObject*) LPOLEOBJECT *lpObject*; /* address of object */

The **OleUpdate** function updates the specified object. This function updates the presentation of the object and ensures that the object is up-to-date with respect to any linked objects it contains.

Parameters

lpObject

Points to the object to be updated.

Return Value The return value is OLE_OK if the function is successful. Otherwise, it is an error value, which may be one of the following:

OLE_BUSY OLE_ERROR_OBJECT OLE_ERROR_STATIC OLE_WAIT_FOR_RELEASE

OleQueryOutOfDate

OpenClipboard

2.x

BOOL OpenClipboard(hwnd)HWND hwnd;/* handle of window to associate ownership with*/			
	The OpenClipboard function opens the clipboard. Other applications will not be able to modify the clipboard until the CloseClipboard function is called.		
Parameters	<i>hwnd</i> Identifies the window to be associated with the open clipboard.		
Return Value	The return value is nonzero if the function is successful. It is zero if another appli- cation or window has the clipboard opened.		
Comments	The window identified by the <i>hwnd</i> parameter will not become the owner of the clipboard until the EmptyClipboard function is called.		
See Also	CloseClipboard, EmptyClipboard		

OpenComm

int OpenComm(lpszDevControl, cbInQueue, cbOutQueue)			
LPCSTR lpszDevControl;	/* address of device-control information	*/	
UINT cbInQueue;	/* size of receiving queue	*/	
UINT <i>cbOutQueue</i> ;	/* size of transmission queue	*/	

The **OpenComm** function opens a communications device.

2.x

Parameters	 <i>lpszDevControl</i> Points to a null-terminated string that specifies the device in the form COMn or LPTn, where n is the device number. <i>cbInQueue</i> Specifies the size, in bytes, of the receiving queue. This parameter is ignored for LPT devices. 	
	<i>cbOutQueue</i> Specifies the size nored for LPT de	e, in bytes, of the transmission queue. This parameter is ig- vices.
Return Value	The return value ide it is less than zero.	entifies the open device if the function is successful. Otherwise,
Errors	If the function fails,	it may return one of the following error values:
	Value	Meaning
	IE_BADID	The device identifier is invalid or unsupported.
	IE_BAUDRATE	The device's baud rate is unsupported.
	IE_BYTESIZE	The specified byte size is invalid.
	IE_DEFAULT	The default parameters are in error.
	IE_HARDWARE	The hardware is not available (is locked by another device).
	IE_MEMORY	The function cannot allocate the queues.
	IE_NOPEN	The device is not open.
	IE_OPEN	The device is already open.
		lled with both queue sizes set to zero, the return value is rice is already open or IE_MEMORY if the device is not open.
Comments	Windows allows COM ports 1 through 9 and LPT ports 1 through 3. If the device driver does not support a communications port number, the OpenComm function will fail.	
		s device is initialized to a default configuration. The Set - on should be used to initialize the device to alternate values.
	drivers. LPT ports a	ransmission queues are used by interrupt-driven device re not interrupt driven—for these ports, the <i>cbInQueue</i> and eters are ignored and the queue size is set to zero.
Example	The following example uses the OpenComm function to open communications port 1:	

```
idComDev = OpenComm("COM1", 1024, 128);
if (idComDev < 0) {
    ShowError(idComDev, "OpenComm");
    return 0;
}
err = BuildCommDCB("COM1:9600,n,8,1", &dcb);
if (err < 0) {
    ShowError(err, "BuildCommDCB");
    return 0;
}
err = SetCommState(&dcb);
if (err < 0) {
    ShowError(err, "SetCommState");
    return 0;
}
```

CloseComm, SetCommState

OpenDriver

HDRVR OpenDriver(lpDriverName, lpSectionName, lParam)				
LPCSTR lpDriverN	ame; /* address of driver name */			
LPCSTR <i>lpSection</i> N	<i>Tame</i> ; /* address of .INI file section name */			
LPARAM ¹ Param;	/* address of driver-specific information */			
	The OpenDriver function performs necessary initialization operations such as setting members in installable-driver structures to their default values.			
Parameters	<i>lpDriverName</i> Points to a null-terminated string that specifies the name of an installable driver.			
	<i>lpSectionName</i> Points to a null-terminated string that specifies the name of a section in the SYSTEM.INI file.			
	<i>lParam</i> Specifies driver-specific information.			
Return Value	The return value is a handle of the installable driver, if the function is successful. Otherwise it is NULL.			
Comments	The string to which <i>lpDriverName</i> points must be identical to the name of the in- stallable driver as it appears in the SYSTEM.INI file.			

2.x

If the name of the installable driver appears in the [driver] section of the SYSTEM.INI file, the string pointed to by *lpSectionName* should be NULL. Otherwise this string should specify the name of the section in SYSTEM.INI that contains the driver name.

When an application opens a driver for the first time, Windows calls the **Driver-Proc** function with the DRV_LOAD, DRV_ENABLE, and DRV_OPEN messages. When subsequent instances of the driver are opened, only DRV_OPEN is sent.

The value specified in the *lParam* parameter is passed to the *lParam2* parameter of the **DriverProc** function.

See Also CloseDriver, DriverProc

OpenFile

HFILE OpenFile(InszFileName_InOpenRuff_fuMode)

in the open ne(ipst include, ipopendall, fundue)		
LPCSTR lpszFileName;	/* address of filename	*
OFSTRUCT FAR* <i>lpOpenBuff</i> ;	/* address of buffer for file information	*
UINT fuMode;	/* action and attributes	*

The **OpenFile** function creates, opens, reopens, or deletes a file.

Parameters

lpszFileName

Points to a null-terminated string that names the file to be opened. The string must consist of characters from the Windows character set and cannot contain wildcards.

lpOpenBuff

Points to the **OFSTRUCT** structure that will receive information about the file when the file is first opened. The structure can be used in subsequent calls to the **OpenFile** function to refer to the open file. The **OFSTRUCT** structure has the following form:

```
typedef struct tagOFSTRUCT { /* of */
  BYTE cBytes;
  BYTE fFixedDisk;
  UINT nErrCode;
  BYTE reserved[4];
  BYTE szPathName[128];
} OFSTRUCT;
```

The **szPathName** member of **OFSTRUCT** contains characters from the OEM character set.

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

fuMode

Specifies the action to take and the attributes for the file. This parameter can be a combination of the following values:

Value	Meaning
OF_CANCEL	Adds a Cancel button to the OF_PROMPT dialog box. Pressing the Cancel button directs OpenFile to return a file-not-found error message.
OF_CREATE	Creates a new file. If the file already exists, it is truncated to zero length.
OF_DELETE	Deletes the file.
OF_EXIST	Opens the file, and then closes it. This value is used to test for file existence. Using this value does not change the file date.
OF_PARSE	Fills the OFSTRUCT structure but carries out no other action.
OF_PROMPT	Displays a dialog box if the requested file does not exist. The dialog box informs the user that Windows cannot find the file and prompts the user to insert the file in drive A.
OF_READ	Opens the file for reading only.
OF_READWRITE	Opens the file for reading and writing.
OF_REOPEN	Opens the file using information in the reopen buffer.
OF_SEARCH	Windows searches in directories even when the file name includes a full path.
OF_SHARE_COMPAT	Opens the file with compatibility mode, allowing any program on a given machine to open the file any number of times. OpenFile fails if the file has been opened with any of the other sharing modes.
OF_SHARE_DENY_NONE	Opens the file without denying other programs read or write access to the file. OpenFile fails if the file has been opened in compatibility mode by any other program.
OF_SHARE_DENY_READ	Opens the file and denies other programs read access to the file. OpenFile fails if the file has been opened in compatibility mode or for read access by any other program.
OF_SHARE_DENY_WRITE	Opens the file and denies other programs write access to the file. OpenFile fails if the file has been opened in compatibility or for write access by any other program.

	Value	Meaning
	OF_SHARE_EXCLUSIVE	Opens the file with exclusive mode, denying other programs both read and write access to the file. OpenFile fails if the file has been opened in any other mode for read or write access, even by the current program.
	OF_VERIFY	Compares the time and date in the OF_STRUCT with the time and date of the specified file. The function returns HFILE_ERROR if the dates and times do not agree.
	OF_WRITE	Opens the file for writing only.
Return Value	The return value is an MS-DOS file handle if the function is successful. (This handle is not necessarily valid; for example, if the <i>fuMode</i> parameter is OF_EXIST, the handle does not identify an open file, and if the <i>fuMode</i> parameter is OF_DELETE, the handle is invalid.) The return value is HFILE_ERROR if an error occurs.	
Comments	If the <i>lpszFileName</i> parameter specifies a filename and extension only (or if the OF_SEARCH flag is specified), the OpenFile function searches for a matching file in the following directories (in this order):	
	1. The current directory.	
	 The Windows directory (the directory containing WIN.COM), whose path th GetWindowsDirectory function retrieves. The Windows system directory (the directory containing such system files a GDI.EXE), whose path the GetSystemDirectory function retrieves. The directory containing the executable file for the current task; the Get-ModuleFileName function obtains the path of this directory. 	
	5. The directories listed in the PA	ATH environment variable.
	6. The list of directories mapped	in a network.
	To close the file after use, the app	blication should call the _lclose function.
See Also	GetSystemDirectory, GetWind	owsDirectory

OpenIcon

BOOL OpenIcon(h HWND hwnd; /	wnd) * handle of window */
	The OpenIcon function activates and displays a minimized window. Windows restores the window to its original size and position.
Parameters	hwnd Identifies the window.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Using OpenIcon is the same as specifying the SW_SHOWNORMAL flag in a call to the ShowWindow function.
See Also	CloseWindow, IsIconic, ShowWindow

OpenSound

int OpenSound(void)

This function is obsolete. Use the Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Pro*grammer's Reference.

2.x

2.x

3.0

OutputDebugString

void OutputDebugString(lpszOutputString)
LPCSTR lpszOutputString; /* address of string to display

The **OutputDebugString** function displays the specified character string on the debugging terminal if a debugger is running.

*/

2.x

Parameters	<i>lpszOutputString</i> Points to a null-terminated string to be displayed.
Return Value	This function does not return a value.
Comments	This function preserves all registers.
Example	The following example uses the OutputDebugString function to display informa- tion on the debugging terminal:
	OutputDebugString("\n\rcalling ValidateCodeSegments");
	ValidateCodeSegments();
	OutputDebugString("\n\rdone");
See Also	DebugOutput

PaintRgn

· · · · · · · · · · · · · · · · · · ·	(hdc, hrgn)/* handle of device context/* handle of region*/
	The PaintRgn function fills a region by using the current brush for the given device context.
Parameters	 <i>hdc</i> Identifies the device context that contains the region to be filled. <i>hrgn</i> Identifies the region to be filled. The coordinates for the given region are specified in device units.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Example	The following example uses the current brush for a device context to fill an elliptical region:

CreateBrushIndirect CreateDIBPatternBrush (
<pre>DeleteObject(hrgn);</pre>
hrgn = CreateEllipticRgn(10, 10, 110, 110); SelectObject(hdc, hrgn); PaintRgn(hdc, hrgn);
HDC hdc; HRGN hrgn;

See AlsoCreateBrushIndirect, CreateDIBPatternBrush, CreateHatchBrush,
CreatePatternBrush, CreateSolidBrush, FillRgn

PatBlt

2.x

BOOL PatBlt(hdc,) HDC hdc; int nLeftRect; int nTopRect; int nwidth; int nheight; DWORD fdwRop;	<pre>nLeftRect, nTopRect, nwidth, nheight, fdwRop) /* handle of device context /* x-coordinate top-left corner destination rectangle /* y-coordinate top-left corner destination rectangle /* width of destination rectangle /* height of destination rectangle /* raster operation</pre>	*/ */ */ */
	The PatBlt function creates a bit pattern on the specified combination of the selected brush and the pattern already specified raster-operation code defines how the patterns a	on the device. The
Parameters	<i>hdc</i> Identifies the device context. <i>nLeftRect</i> Specifies the logical x-coordinate of the upper-left conreceives the pattern.	mer of the rectangle that
	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left correceives the pattern.	mer of the rectangle that
	<i>nwidth</i> Specifies the width, in logical units, of the rectangle the	nat will receive the pattern.
	<i>nheight</i> Specifies the height, in logical units, of the rectangle t pattern.	hat will receive the

fdwRop

Specifies the raster-operation code that determines how the graphics device interface (GDI) combines the colors in the output operation. This parameter can be one of the following values:

	Value	Meaning
	PATCOPY	Copies the pattern to the destination bitmap.
	PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
	PATPAINT	Paints the destination bitmap.
	DSTINVERT	Inverts the destination bitmap.
	BLACKNESS	Turns all output black.
	WHITENESS	Turns all output white.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The raster operations listed for this function are a limited subset of the full 256 te nary raster-operation codes; in particular, a raster-operation code that refers to a source cannot be used.	
		port the PatBlt function. To determine whether a device supplication can call the GetDeviceCaps function with the dex.
Example	The following example uses the CreateBitmap function to create a bitmap with a zig-zag pattern, and then uses the PatBlt function to fill the client area with that pattern:	
	HDC hdc; HBITMAP hbmp; HBRUSH hbr, hbrP RECT rc;	revious;
	int aZigzag[] =	{ 0xFF, 0xF7, 0xEB, 0xDD, 0xBE, 0x7F, 0xFF, 0xFF };
	hbmp = CreateBitr hbr = CreatePatte	nap(8, 8, 1, 1, aZigzag); ernBrush(hbmp);
	hdc = GetDC(hwnd UnrealizeObject(hbrPrevious = Se GetClientRect(hw	hbr); lectObject(hdc, hbr);

```
PatBlt(hdc, rc.left, rc.top,
    rc.right - rc.left, rc.bottom - rc.top, PATCOPY);
SelectObject(hdc, hbrPrevious);
ReleaseDC(hwnd, hdc);
DeleteObject(hbr);
DeleteObject(hbmp);
```

GetDeviceCaps

PeekMessage

2.x

BOOL PeekMessag MSG FAR* lpmsg; HWND hwnd; UINT uFilterFirst; UINT uFilterLast; UINT fuRemove;	ge(lpmsg, hwnd, uFilterFirst, uFilterLast, fuRemove)/* address of structure for message/* handle of filter window/* first message/* last message/* removal flags
	The PeekMessage function checks the application's message queue for a message and places the message (if any) in the specified MSG structure.
Parameters	<i>lpmsg</i> Points to an MSG structure that will receive message information from the application's message queue. The MSG structure has the following form:
	typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;
	For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.
	<i>hwnd</i> Identifies the window whose messages are to be examined.
	<i>uFilterFirst</i> Specifies the value of the first message in the range of messages to be examined.
	<i>uFilterLast</i> Specifies the value of the last message in the range of messages to be examined.

fuRemove

Specifies how messages are handled. This parameter can be a combination of the following values (PM_NOYIELD can be combined with either PM_NOREMOVE or PM_REMOVE):

	Value	Meaning
	PM_NOREMOVE	Messages are not removed from the queue after processing by PeekMessage .
	PM_NOYIELD	Prevents the current task from halting and yielding system re- sources to another task.
	PM_REMOVE	Messages are removed from the queue after processing by PeekMessage .
Return Value	The return value is non	nzero if a message is available. Otherwise, it is zero.
Comments	mmentsUnlike the GetMessage function, the PeekMessage function does not wait for a message to be placed in the queue before returning. It does, however, yield control to other tasks (if the PM_NOYIELD flag is not set).PeekMessage retrieves only messages associated with the window identified by the hwnd parameter, or any of its children as specified by the IsChild function, 	
	idle. Therefore, an app	on is in a PeekMessage loop, Windows cannot become lication should not remain in a PeekMessage loop after the and processing has completed.
	sage and then calls the the message is received	ses the PeekMessage function without removing the mes- WaitMessage function, WaitMessage does not return until d. Applications that use the PeekMessage function should nessages from the queue before calling WaitMessage .

Example	The following example checks the message queue for keystrokes that have special meaning to the application. Note that the CheckSpecialKeys function is application-defined.		
	MSG msg; BOOL fRetVal = TRUE;		
	while (PeekMessage(&msg, NULL, 0, 0, PM_REMOVE)) {		
	if (msg.message == WM_QUIT) fRetVal = FALSE;		
	if (CheckSpecialKeys(&msg)) /* application defined */ continue;		
	TranslateMessage(&msg); DispatchMessage(&msg);		
	, return fRetVal;		
See Also	GetMessage, IsChild, PostAppMessage, SetMessageQueue, WaitMessage		

Pie

BOOL Pie(hdc, nLeftRect, nTopRect, nRightRect, nBottomRect, nxStartArc, nyStartArc, nxEndArc, nyEndArc)

HDC hdc;	/* handle of device context	*/
int nLeftRect;	/* x-coordinate upper-left corner bounding rectangle	*/
int nTopRect;	/* y-coordinate upper-left corner bounding rectangle	*/
int nRightRect;	/* x-coordinate lower-right corner bounding rectangle	*/
int nBottomRect;	/* y-coordinate lower-right corner bounding rectangle	*/
int nxStartArc;	/* x-coordinate arc starting point	*/
int nyStartArc;	/* y-coordinate arc starting point	*/
int nxEndArc;	/* x-coordinate arc ending point	*/
int nyEndArc;	/* y-coordinate arc ending point	*/

The **Pie** function draws a pie-shaped wedge by drawing an elliptical arc whose center and two endpoints are joined by lines.

Parameters

Identifies the device context.

nLeftRect

hdc

Specifies the logical x-coordinate of the upper-left corner of the bounding rectangle.

2.x

	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the bounding rectangle.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the bounding rectangle.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the bounding rectangle.
	<i>nxStartArc</i> Specifies the logical x-coordinate of the arc's starting point. This point does not have to lie exactly on the arc.
	<i>nyStartArc</i> Specifies the logical y-coordinate of the arc's starting point. This point does not have to lie exactly on the arc.
	<i>nxEndArc</i> Specifies the logical x-coordinate of the arc's endpoint. This point does not have to lie exactly on the arc.
	<i>nyEndArc</i> Specifies the logical y-coordinate of the arc's endpoint. This point does not have to lie exactly on the arc.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The center of the arc drawn by the Pie function is the center of the bounding rectangle specified by the <i>nLeftRect</i> , <i>nTopRect</i> , <i>nRightRect</i> , and <i>nBottomRect</i> parameters. The starting and ending points of the arc are specified by the <i>nxStartArc</i> , <i>nyStartArc</i> , <i>nxEndArc</i> , and <i>nyEndArc</i> parameters. The function draws the arc by using the selected pen, moving in a counterclockwise direction. It then draws two additional lines from each endpoint to the arc's center. Finally, it fills the pie-shaped area by using the current brush.
	If <i>nxStartArc</i> equals <i>nxEndArc</i> and <i>nyStartArc</i> equals <i>nyEndArc</i> , the result is an ellipse with a single line from the center of the ellipse to the point (<i>nxStartArc</i> , <i>nyStartArc</i>) or (<i>nxEndArc</i> , <i>nyEndArc</i>).
	The figure drawn by this function extends up to but does not include the right and bottom coordinates. This means that the height of the figure is $nBottomRect - nTopRect$ and the width of the figure is $nRightRect - nLeftRect$.
	Dath the middle and the bail by a few structures the constant large 2 with an allow

Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.

ExampleThe following example uses a RECT structure to store the points that define the
bounding rectangle and uses POINT structures to store the coordinates that
specify the beginning and end of the wedge:
HDC hdc;
RECT rc = { 10, 10, 180, 140 };
POINT ptStart = { 12, 12 };
POINT ptEnd = { 128, 135 };
Pie(hdc, rc.left, rc.top, rc.right, rc.bottom,
ptStart.x, ptStart.y, ptEnd.x, ptEnd.y);See AlsoChord

PlayMetaFile

BOOL PlayMetaFil	e(hdc, hmf)		
HDC hdc;	/* handle of device context	*/	
HMETAFILE hmf;	/* handle of metafile	*/	
	The PlayMetaFile function plays given device. The metafile can be	s the contents of the specified metafile on the e played any number of times.	
Parameters	hdc		
	Identifies the device context of the output device.		
	hmf		
	Identifies the metafile to be pl	ayed.	
Return Value	The return value is nonzero if the	function is successful. Otherwise, it is zero.	
Example	The following example uses the CreateMetaFile function to create a device- context handle of a memory metafile, draws a line in the device context, retrieves a metafile handle by calling the CloseMetaFile function, plays the metafile by using the PlayMetaFile function, and finally deletes the metafile by using the DeleteMetaFile function:		
	HDC hdcMeta; HMETAFILE hmf;		

2.x

```
hdcMeta = CreateMetaFile(NULL);
MoveTo(hdcMeta, 10, 10);
LineTo(hdcMeta, 100, 100);
hmf = CloseMetaFile(hdcMeta);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
```

Polygon

BOOL Polygon (<i>hdc</i> , <i>lppt</i> , <i>c</i> .	Points)	
HDC hdc;	/* handle of device context	*/
const POINT FAR* <i>lppt</i> ;	/* address of array with points for vertices	*/
int cPoints;	/* number of points in array	*/
The P o	lygon function draws a polygon consisting of	two or more poi

The **Polygon** function draws a polygon consisting of two or more points (vertices) connected by lines. The system closes the polygon automatically, if necessary, by drawing a line from the last vertex to the first. Polygons are surrounded by a frame drawn by using the current pen and filled by using the current brush.

2.x

Parameters

hdc Identifies the device context.

lppt

Points to an array of **POINT** structures that specify the vertices of the polygon. Each structure in the array specifies a vertex. The **POINT** structure has the following form:

	<pre>typedef struct tagPOINT { /* pt */ int x; int y;</pre>		
	} POINT;		
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.		
	<i>cPoints</i> Specifies the number of vertices in the array.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	The current polygon-filling mode can be retrieved or set by using the GetPolyFill- Mode and SetPolyFillMode functions.		
Example	The following example assigns values to an array of points and then calls the Polygon function:		
	HDC hdc;		
	POINT aPoints[3];		
	aPoints[0].x = 50; aPoints[0].y = 10; aPoints[1].x = 250;		
	aPoints[1].y = 50;		
	aPoints[2].x = 125;		
	aPoints[2].y = 130;		
	<pre>Polygon(hdc, aPoints, sizeof(aPoints) / sizeof(POINT));</pre>		
See Also	GetPolyFillMode, Polyline, PolyPolygon, SetPolyFillMode		

Polyline

2.x

BOOL Polyline (<i>hdc</i> , <i>lppt</i> , <i>cP</i>)	oints)	
HDC hdc;	/* handle of device context	*/
<pre>const POINT FAR* lppt;</pre>	/* address of array with points to connect	*/
int cPoints;	/* number of points in array	*/

The **Polyline** function draws a set of line segments, connecting the specified points. The lines are drawn from the first point through subsequent points, using the current pen. Unlike the **LineTo** function, the **Polyline** function neither uses nor updates the current position.

Parameters	<i>hdc</i> Identifies the device context.		
	<i>lppt</i> Points to an array of POINT structures. Each structure in the array specifies a point. The POINT structure has the following form:		
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>		
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.		
	<i>cPoints</i> Specifies the number of points in the array. This value must be at least 2.		
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Example	The following example assigns values to an array of points and then calls the Polyline function:		
	HDC hdc;		
	POINT aPoints[3];		
	<pre>aPoints[0].x = 50; aPoints[0].y = 10; aPoints[1].x = 250; aPoints[1].y = 50; aPoints[2].x = 125; aPoints[2].y = 130;</pre>		
	<pre>Polyline(hdc, aPoints, sizeof(aPoints) / sizeof(POINT));</pre>		
· · · ·			

See Also LineTo, Polygon

PolyPolygon

BOOL PolyPolygon(hdc, lp)	pt, lpnPolyCounts, cPolygons)	
HDC hdc;	/* handle of device context	*/
<pre>const POINT FAR* lppt;</pre>	/* address of array with vertices	*/
int FAR* lpnPolyCounts;	/* address of array with point counts	*/
int cPolygons;	/* number of polygons to draw	*/

	The PolyPolygon function creates two or more polygons that are filled by using the current polygon-filling mode. The polygons may be disjoint or overlapping.
Parameters	<i>hdc</i> Identifies the device context.
	<i>lppt</i> Points to an array of POINT structures. Each structure in the array specifies a vertext of a polygon. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lpnPolyCounts</i> Points to an array of integers, each of which specifies the number of points in one of the polygons in the array pointed to by the <i>lppt</i> parameter.
	<i>cPolygons</i> Specifies the number of polygons to be drawn. This value must be at least 2.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Each polygon specified in a call to the PolyPolygon function must be closed. Un- like polygons created by the Polygon function, the polygons created by Poly- Polygon are not closed automatically.
	The PolyPolygon function creates two or more polygons. To create a single polygon, an application should use the Polygon function.
	The current polygon-filling mode can be retrieved or set by using the GetPolyFill-Mode and SetPolyFillMode functions.
Example	The following example draws two overlapping polygons by assigning values to an array of points and then calling the PolyPolygon function:
	HDC hdc;
	POINT aPolyPoints[8]; int aVertices[] = { 4, 4 };
	<pre>aPolyPoints[0].x = 50; aPolyPoints[0].y = 10; aPolyPoints[1].x = 250; aPolyPoints[1].y = 50; aPolyPoints[2].x = 125;</pre>

PostAppMessage

. .

BOOL PostAppivies	sage(htask, uMsg, wParam, lParam)	
HTASK htask;	/* handle of task to receive message	*/
UINT uMsg;	/* message to post	*/
WPARAM wParam;		*/
LPARAM lParam;	/* second message parameter	*/
	The PostAppMessage function posts (place the given application (task) and then returns process the message. The application to wh message by calling the GetMessage or Pee ber of the returned MSG structure is NULL	s without waiting for the application to ich the message is posted retrieves the kMessage function. The hwnd mem-
Parameters	<i>htask</i> Identifies the task to which the message tion returns this handle.	is posted. The GetCurrentTask func-
	<i>uMsg</i> Specifies the type of message to be posted	ed.
	wParam Specifies 16 bits of additional message-o	lependent information.
	<i>lParam</i> Specifies 32 bits of additional message-o	lependent information.
Return Value	The return value is nonzero if the function i	is successful. Otherwise, it is zero.

See Also GetCurrentTask, GetMessage, PeekMessage

PostMessage

2.x

BOOL PostMessage (hwnd, uMsg, wParam, lParam)			
HWND hwnd;	/* handle of the destination window	*/	
UINT uMsg;	/* message to post	*/	
WPARAM wParam;	/* first message parameter	*/	
LPARAM lParam;	/* second message parameter	*/	

The **PostMessage** function posts (places) a message in a window's message queue and then returns without waiting for the corresponding window to process the message. Messages in a message queue are retrieved by calls to the **GetMessage** or **PeekMessage** function.

hwnd

Identifies the window to which the message will be posted. If this parameter is HWND_BROADCAST, the message will be posted to all top-level windows, including disabled or invisible unowned windows.

uMsg

Specifies the message to be posted.

wParam

Specifies 16 bits of additional message-dependent information.

lParam

Specifies 32 bits of additional message-dependent information.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments An application should never use the **PostMessage** function to post a message to a control.

If the message is being posted to another application and the *wParam* or *lParam* parameter is used to pass a handle or pointer to a global memory object, the memory should be allocated by the **GlobalAlloc** function, using the GMEM_SHARE flag.

See Also GetMessage, PeekMessage, PostAppMessage, SendDlgItemMessage, SendMessage

PostQuitMessage

void PostQuitMessage(n.	ExitCode)
-------------------------	-----------

int nExitCode; /* exit code */

The **PostQuitMessage** function posts a message to Windows indicating that an application is requesting to terminate execution (quit). This function is typically used in response to a WM_DESTROY message.

Parameters	<i>nExitCode</i> Specifies an application-defined exit code. It must be the <i>wParam</i> parameter of the WM_QUIT message.
Return Value	This function does not return a value.
Comments	The PostQuitMessage function posts a WM_QUIT message to the application and returns immediately; the function simply indicates to the system that the application will request to quit some time in the future.
	When the application receives the WM_QUIT message, it should exit the message loop in the main function and return control to Windows.
See Also	GetMessage

PrestoChangoSelector

UINT PrestoChango UINT uSourceSelecto UINT uDestSelector;	
	The PrestoChangoSelector function generates a code selector that corresponds to a given data selector, or it generates a data selector that corresponds to a given code selector.
	An application should not use this function unless it is absolutely necessary, be- cause its use violates preferred Windows programming practices.
Parameters	<i>uSourceSelector</i> Specifies the selector to be converted.
	<i>uDestSelector</i> Specifies a selector previously allocated by the AllocSelector function. This previously allocated selector receives the converted selector.

3.1

Return Value	The return value is the copied and converted selector if the function is successful. Otherwise, it is zero.
Comments	Windows does not track changes to the source selector. Consequently, before any memory can be moved, the application should use the converted destination selector immediately after it is returned by this function.
	The PrestoChangoSelector function modifies the destination selector to have the same properties as the source selector, but with the opposite code or data attribute. This function changes only the attributes of the selector, not the value of the selector.
	This function was named ChangeSelector in the Windows 3.0 documentation.

PrintDlg

#include <commdlg.h>

BOOL PrintDlg(<i>l</i> PRINTDLG FAR	
	The PrintDlg function displays a Print dialog box or a Print Setup dialog box. The Print dialog box makes it possible for the user to specify the properties of a particular print job. The Print Setup dialog box makes it possible for the user to select additional job properties and configure the printer.
Parameters	<i>lppd</i> Points to a PRINTDLG structure that contains information used to initialize the dialog box. When the PrintDlg function returns, this structure contains in- formation about the user's selections. The PRINTDLG structure has the following form:
	<pre>#include <commdlg.h></commdlg.h></pre>
	<pre>typedef struct tagPD { /* pd */ DWORD lStructSize; HWND hwndOwner; HGLOBAL hDevMode; HGLOBAL hDevNames; HDC hDC; DWORD Flags; UINT nFromPage;</pre>

	UINT (CALLBACK* lpfn LPCSTR lpPrintTempla LPCSTR lpSetupTempla HGLOBAL hPrintTemplat HGLOBAL hSetupTemplat } PRINTDLG; For a full description of this str	teName; e;	
	mer's Reference, Volume 3.		
Return Value	The return value is nonzero if the function successfully configures the printer. The return value is zero if an error occurs, if the user chooses the Cancel button, or if the user chooses the Close command on the System menu to close the dialog box. (The return value is also zero if the user chooses the Setup button to display the Print Setup dialog box, chooses the OK button in the Print Setup dialog box, and then chooses the Cancel button in the Print dialog box.)		
Errors	Use the CommDlgExtendedError function to retrieve the error value, which may be one of the following:		
	CDERR_FINDRESFAILURE	PDERR_CREATEICFAILURE	
	CDERR_INITIALIZATION	PDERR_DEFAULTDIFFERENT	
	CDERR_LOADRESFAILURE	PDERR_DNDMMISMATCH	
	CDERR_LOADSTRFAILURE	PDERR_GETDEVMODEFAIL	
	CDERR_LOCKRESFAILURE	PDERR_INITFAILURE	
	CDERR_MEMALLOCFAILURE	PDERR_LOADDRVFAILURE	
	CDERR_MEMLOCKFAILURE	PDERR_NODEFAULTPRN

memset(&pd, 0, sizeof(PRINTDLG));
/* Initialize the necessary PRINTDLG structure fields. */
pd.lStructSize = sizeof(PRINTDLG);
pd.hwndOwner = hwnd:
pd.Flags = PD_RETURNDC;
/* Print a test page if successful */
if (PrintDlg(&pd) != 0) {
    Escape(pd.hDC, STARTDOC, 8, "Test-Doc", NULL);
    /* Print text and rectangle */
    TextOut(pd.hDC, 50, 50, "Common Dialog Test Page", 23);
    Rectangle(pd.hDC, 50, 90, 625, 105);
    Escape(pd.hDC, NEWFRAME, 0, NULL, NULL);
    Escape(pd.hDC, ENDDOC, 0, NULL, NULL);
    DeleteDC(pd.hDC);
    if (pd.hDevMode != NULL)
       GlobalFree(pd.hDevMode);
    if (pd.hDevNames != NULL)
       GlobalFree(pd.hDevNames);
}
else
    ErrorHandler();
```

ProfClear

void ProfClear(void)

The **ProfClear** function discards all Microsoft Windows Profiler samples currently in the sampling buffer.

- **Parameters** This function has no parameters.
- **Return Value** This function does not return a value.
- **Comments** For more information about using Profiler, see *Microsoft Windows Programming Tools*.

Example

The following example uses the **ProfClear** function to clear the Profiler sampling buffer before changing the sampling rate:

```
ProfClear(); /* clears existing buffer */
ProfSampRate(5, 1); /* changes sampling rate */
```

ProfFinish

3.0

void ProfFinish(void)

The ProfFinish function stops Microsoft Windows Profiler sampling and flushes the output buffer to disk. **Parameters** This function has no parameters. **Return Value** This function does not return a value. Comments If Profiler is running in 386 enhanced mode, the **ProfFinish** function also frees the buffer for system use. For more information about using Profiler, see *Microsoft Windows Programming* Tools. Example The following example uses the **ProfFinish** function to stop sampling and flush the output buffer during WM_DESTROY message processing: case WM_DESTROY: ProfFinish(); PostQuitMessage(0); break:

ProfFlush

3.0

void ProfFlush(void)

The **ProfFlush** function flushes the Microsoft Windows Profiler sampling buffer to disk.

Parameters This function has no parameters.

Return Value	This function does not return a value.		
Comments	Excessive use of the ProfFlush function can seriously impair application performance. An application should not use ProfFlush when MS-DOS may be unstable (inside an interrupt handler, for example).		
	For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i> .		
Example	The following example uses the ProfFlush function to flush the Profiler buffer before changing the buffer size:		
	ProfFlush(); ProfSetup(1024, 0);	/* flushes existing buffer */ /* uses a 1024K buffer	

ProfInsChk

3.0

int ProfInsChk(void)

	The ProfInsChk function determines whether Microsoft Windows Profiler is in- stalled.	
Parameters	This function has no parameters.	
Return Value	The return value is 1 if Profiler is installed for a mode other than 386 enhanced mode, or it is 2 if Profiler is installed for 386 enhanced mode. Otherwise, the return value is 0, indicating that Profiler is not installed.	
Comments	For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i> .	
Example	The following example uses the ProfInsChk function to determine whether the Profiler is installed:	
	int ick; char szMsg[80];	
	<pre>if ((ick = ProfInsChk()) == 0) MessageBox(hwnd, "Profiler is not installed!",</pre>	

```
else {
   strcpy(szMsg, "Profiler is installed");
   if (ick == 2) {
      strcat(szMsg, " in 386 enhanced mode");
      ProfSetup(128, 0); /* uses a 128K buffer */
   }
   MessageBox(hwnd, szMsg, "ProfInsChk", MB_OK);
}
```

ProfSampRate

3.0

void ProfSampRate(r	ıRate286, nRate386)
---------------------	---------------------

int nRate286;	/* sample rate for non–386 enhanced mode	*/
int nRate386;	/* sample rate for 386 enhanced mode	*/

The **ProfSampRate** function sets the Microsoft Windows Profiler code-sampling rate.

Parameters

nRate286

Specifies the sampling rate if the application is not running in 386 enhanced mode. The *nRate286* parameter can be one of the following values:

Value	Sampling rate
1	122.070 microseconds
2	244.141 microseconds
3	488.281 microseconds
4	976.562 microseconds
5	1.953125 milliseconds
6	3.90625 milliseconds
7	7.8125 milliseconds
8	15.625 milliseconds
9	31.25 milliseconds
10	62.5 milliseconds
11	125 milliseconds
12	250 milliseconds
13	500 milliseconds

nRate386

Specifies the sampling rate, in milliseconds if the application is running in 386 enhanced mode. This value is in the range 1 through 1000.

Return Value	This function does not return a value.	
Comments	 Only the rate parameter appropriate to the current mode is used; the other parameter is ignored. The default rate is 2 milliseconds in 386 enhanced mode; in any other mode, the value is 5, which specifies a rate of 1.953125 milliseconds. For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i>. 	
Example	The following example uses the ProfSampRate function to change the Profiler sampling rate to 1 millisecond in 386 enhanced mode:	
	ProfClear(); ProfSampRate(5, 1);	/* clears existing buffer */ /* changes sampling rate */

ProfSetup

	fferKB, nSamplesKB)
int nBufferKB; int nSamplesKB;	/* size of output buffer */ /* amount of sample data written to disk */
	The ProfSetup function specifies the size of the Microsoft Windows Profiler output buffer and how much sampling data Profiler is to write to the disk.
	Profiler ignores the ProfSetup function when running with Windows in any mode other than 386 enhanced mode.
Parameters	<i>nBufferKB</i> Specifies the size, in kilobytes, of the output buffer. This value is in the range 1 through 1064. The default value is 64.
	<i>nSamplesKB</i> Specifies the amount, in kilobytes, of sampling data Profiler writes to the disk. A value of zero (the default value) specifies unlimited sampling data.
Return Value	This function does not return a value.
Comments	Do not call the ProfSetup function after calling ProfStart . To resize memory after ProfStart has been called, first call the ProfStop function.
	For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i> .

Example The following example uses the **ProfSetup** function to set the output buffer size to 128K if Profiler is installed in 386 enhanced mode: int ick: char szMsg[80]; if ((ick = ProfInsChk()) == 0) MessageBox(hwnd, "Profiler is not installed!", "ProfInsChk", MB_ICONSTOP); else { strcpy(szMsg, "Profiler is installed"); if (ick == 2) { strcat(szMsg, " in 386 enhanced mode"); ProfSetup(128, 0); /* uses a 128K buffer */ } MessageBox(hwnd, szMsg, "ProfInsChk", MB_OK); }

See Also

ProfStart, ProfStop

ProfStart

void ProfStart(void	1)	
	The ProfStart function starts Microsoft Windows Profiler sampling.	
Parameters	This function has no parameters.	
Return Value	This function does not return a value.	
Comments	For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i> .	
Example	The following example uses the ProfStart and ProfStop functions to sample during the message-queue dispatch process:	
	/* Acquire and dispatch messages until WM_QUIT is received. */	
	<pre>while (GetMessage(&msg, /* message structure */</pre>	

```
{
    ProfStart();
    TranslateMessage(&msg); /* translates virtual-key codes */
    DispatchMessage(&msg); /* dispatches message to window */
    ProfStop();
}
See Also ProfStop
```

ProfStop	3.0]
void ProfStop(void)		
	The ProfStop function stops Microsoft Windows Profiler sampling.	
Parameters	This function has no parameters.	
Return Value	This function does not return a value.	
Comments	For more information about using Profiler, see <i>Microsoft Windows Programming Tools</i> .	
Example	The following example uses the ProfStart and ProfStop functions to sample during the message-queue dispatch process: /* Acquire and dispatch messages until WM_QUIT is received. */	
	<pre>while (GetMessage(&msg, /* message structure */ (HWND) NULL, /* handle of window receiving message */ 0, /* lowest message to examine */ 0)) /* highest message to examine */ { ProfStart(); } </pre>	
	TranslateMessage(&msg); /* translates virtual-key codes */ DispatchMessage(&msg); /* dispatches message to window */	
	<pre>ProfStop(); }</pre>	
See Also	ProfStart	

PtInRect

BOOL PtInRect (<i>lpi</i> const RECT FAR* POINT <i>pt</i> ;	
	The PtInRect function determines whether the specified point lies within a given rectangle. A point is within a rectangle if it lies on the left or top side or is within all four sides. A point on the right or bottom side is considered outside the rectangle.
Parameters	<i>lprc</i> Points to a RECT structure that contains the specified rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>pt</i> Specifies a POINT structure that contains the specified point. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the point lies within the given rectangle. Otherwise, it is zero.
See Also	EqualRect, IsRectEmpty

2.x

PtInRegion

BOOL PtInReg HRGN hrgn; int nXPos; int nYPos;	tion(hrgn, nXPos, nYPos)/* handle of region*//* x-coordinate of point*//* y-coordinate of point*/
	The PtInRegion function determines whether a specified point is in the given region.
Parameters	<i>hrgn</i> Identifies the region to be examined. <i>nXPos</i> Specifies the logical x-coordinate of the point.
	<i>nYPos</i> Specifies the logical y-coordinate of the point.
Return Value	The return value is nonzero if the point is in the region. Otherwise, it is zero.
Example	The following example uses the PtInRegion function to determine whether the point (50, 50) is in the specified region and prints the result:
	HRGN hrgn; BOOL fPtIn; LPSTR lpszInRegion = "Specified point is in region."; LPSTR lpszNotInRegion = "Specified point is not in region.";
	<pre>fPtIn = PtInRegion(hrgn, 50, 50); if (!fPtIn) TextOut(hdc, 10, 10, 1pszNotInRegion,</pre>
	TextOut(hdc, 10, 10, lpszInRegion, lstrlen(lpszInRegion));
See Also	RectInRegion

PtVisible

BOOL PtVis	sible(hdc, nXPos, nYPos)	
HDC hdc;	/* handle of device context	*/
int nXPos;	/* x-coordinate of point to query	*/
int nYPos;	/* y-coordinate of point to query	*/

	The PtVisible function determines whether the specified point is within the clipping region of the given device context.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXPos</i> Specifies the logical x-coordinate of the point.
	<i>nYPos</i> Specifies the logical y-coordinate of the point.
Return Value	The return is nonzero if the point is within the clipping region. Otherwise, it is zero.
Example	The following example creates a rectangular region, displays a message inside it, and selects the region as the clipping region. The PtVisible function is used to determine whether coordinates generated by a double-click are inside the region. If so, the message changes to "Thank you." If not, the CombineRgn function is used to create a clipping region that combines the first region with a new region that surrounds the specified coordinates, and the word "Missed!" is displayed at the coordinates.
	HDC hdcLocal; HRGN hrgnClick, hrgnMiss, hrgnCombine; HBRUSH hbr;
	hdcLocal = GetDC(hwnd); hbr = GetStockObject(BLACK_BRUSH);
	hrgnClick = CreateRectRgn(90, 95, 225, 120); FrameRgn(hdcLocal, hrgnClick, hbr, 1, 1); TextOut(hdcLocal, 100, 100, "Double-click here.", 18); SelectClipRgn(hdcLocal, hrgnClick);
	if (PtVisible(hdcLocal, XClick, YClick)) { PaintRgn(hdcLocal, hrgnClick); FrameRgn(hdcLocal, hrgnClick, hbr, 1, 1); TextOut(hdcLocal, 100, 100, "Thank you.", 10);
	<pre>} else if (XClick > 0) { hrgnMiss = CreateRectRgn(XClick - 5, YClick - 5, XClick + 60, YClick + 20); hrgnCombine = CreateRectRgn(0, 0, 0, 0); CombineRgn(hrgnCombine, hrgnClick, hrgnMiss, RGN_OR); SelectClipRgn(hdcLocal, hrgnCombine); FrameRgn(hdcLocal, hrgnCombine, hbr, 1, 1); TextOut(hdcLocal, XClick, YClick, "Missed!", 7); }</pre>
	InvalidateRect(hwnd, NULL, FALSE);

```
DeleteObject(hrgnClick);
DeleteObject(hrgnMiss);
DeleteObject(hrgnCombine);
ReleaseDC(hwnd, hdcLocal);
```

QueryAbort

3.1

3.1

HDC hdc;	bort(hdc, reserved)/* device-context handle*//* reserved; should be zero*/
	The QueryAbort function calls the AbortProc callback function for a printing application and queries whether the printing should be terminated.
Parameters	<i>hdc</i> Identifies the device context. <i>reserved</i> Specifies a reserved value. It should be zero.
Return Value	The return value is TRUE if printing should continue or if there is no abort proce- dure. It is FALSE if the print job should be terminated. The return value is sup- plied by the AbortProc callback function.
See Also	AbortDoc, AbortProc, SetAbortProc

QuerySendMessage

BOOL QuerySendMessag	ge(hreserved1, hreserved2, hreserved.	3, lpMessage)
HANDLE hreserved1;		
HANDLE hreserved2;		
HANDLE hreserved3;		
LPMSG lpMessage;	/* address of structure for message	*/

The **QuerySendMessage** function determines whether a message sent by **Send-Message** originated from within the current task. If the message is an intertask message, **QuerySendMessage** puts it into the specified **MSG** structure.

Parameters	<pre>hreserved1 Reserved; must be NULL. hreserved2 Reserved; must be NULL. hreserved3 Reserved; must be NULL. lpMessage Specifies the MSG structure in which to place an intertask message. The MSG structure has the following form: typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; } }</pre>	
	WPARAM WPAram; LPARAM 1Param; DWORD time; POINT pt; } MSG; For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.	
Return Value	The return value is zero if the message originated within the current task. Otherwise, it is nonzero.	
Comments	If the Windows debugger is entering soft mode, the application being debugged should reply to intertask messages by using the ReplyMessage function.	
	The NULL parameters are reserved for future use.	
See Also	SendMessage, ReplyMessage	

ReadComm

int ReadComm(idCon	nDev, lpvBuf, cbRead)	
int idComDev;	/* identifier of device to read from	*/
<pre>void FAR* lpvBuf;</pre>	/* address of buffer for read bytes	*/
int cbRead;	/* number of bytes to read	*/

The **ReadComm** function reads up to a specified number of bytes from the given communications device.

3.0

Parameters	<i>idComDev</i> Specifies the communications device to be read from. The OpenComm func- tion returns this value.
	<i>lpvBuf</i> Points to the buffer for the read bytes.
	<i>cbRead</i> Specifies the number of bytes to be read.
Return Value	The return value is the number of bytes read, if the function is successful. Otherwise, it is less than zero and its absolute value is the number of bytes read.
	For parallel I/O ports, the return value is always zero.
Comments	When an error occurs, the cause of the error can be determined by using the Get-CommError function to retrieve the error value and status. Since errors can occur when no bytes are present, if the return value is zero, the GetCommError function should be used to ensure that no error occurred.
	The return value is less than the number specified by the <i>cbRead</i> parameter only if the number of bytes in the receiving queue is less than that specified by <i>cbRead</i> . If the return value is equal to <i>cbRead</i> , additional bytes may be queued for the device. If the return value is zero, no bytes are present.
See Also	GetCommError, OpenComm

RealizePalette

UINT RealizePalette(*hdc*) HDC *hdc*; /* handle of device context

The **RealizePalette** function maps palette entries from the current logical palette to the system palette.

Parameters	<i>hdc</i> Identifies the device context containing a logical palette.
Return Value	The return value indicates how many entries in the logical palette were mapped to different entries in the system palette. This represents the number of entries that this function remapped to accommodate changes in the system palette since the logical palette was last realized.

*/

Comments	A logical color palette acts as a buffer between color-intensive applications and the system, allowing an application to use as many colors as necessary without in- terfering with either its own displayed color or with colors displayed by other win- dows. When a window has the input focus and calls the RealizePalette function, Windows ensures that the window will display all the requested colors (up to the maximum number simultaneously available on the screen) and Windows displays additional colors by matching them to available colors. In addition, Windows matches the colors requested by inactive windows that call RealizePalette as closely as possible to the available colors. This significantly reduces undesirable changes in the colors displayed in inactive windows.			
Example	The following example uses the SelectPalette function to select a palette into a device context and then calls the RealizePalette function to map the colors to the system palette:			
	HPALETTE hpal, hPalPrevious;			
	hdc = GetDC(hwnd);			
	hPalPrevious = SelectPalette(hdc, hpal, FALSE); if (RealizePalette(hdc) == NULL) MessageBox(hwnd, "Can't realize palette", "Error", MB_OK);			
	ReleaseDC(hwnd, hdc);			
See Also	SelectPalette			

Rectangle

BOOL Rectangle(h	ndc, nLeftRect, nTopRect, nRightRect, n	BottomRect)	
HDC hdc;	/* handle of device context */		
int nLeftRect;	/* x-coordinate upper-left corner	*/	
int nTopRect;	/* y-coordinate upper-left corner	*/	
int nRightRect;	/* x-coordinate lower-right corner	*/	
int nBottomRect;	/* y-coordinate lower-right corner	*/	
	The Rectangle function draws a recta the rectangle is filled by using the cur	ngle, using the current pen. The interior of rent brush.	
Parameters	hdc		
	Identifies the device context.		
	<i>nLeftRect</i> Specifies the logical x-coordinate of	of the upper-left corner of the rectangle.	

3.0

	<i>nTopRect</i> Specifies the logical y-coordinate of the upper-left corner of the rectangle.
	<i>nRightRect</i> Specifies the logical x-coordinate of the lower-right corner of the rectangle.
	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the rectangle.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The figure this function draws extends up to, but does not include, the right and bottom coordinates. This means that the height of the figure is $nBottomRect - nTopRect$ and the width of the figure is $nRightRect - nLeftRect$.
	Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.
Example	The following example uses a RECT structure to store the coordinates used by the Rectangle function:
	HDC hdc;
	<pre>RECT rc = { 10, 10, 180, 140 }; Rectangle(hdc, rc.left, rc.top, rc.right, rc.bottom);</pre>
See Also	PolyLine, RoundRect

RectInRegion

BOOL RectInRegie HRGN hrgn; const RECT FAR*	on(<i>hrgn</i> , <i>lprc</i>) /* handle of region */ <i>lprc</i> ; /* address of structure with rectangle */
	The RectInRegion function determines whether any part of the specified rectangle is within the boundaries of the given region.
Parameters	hrgn Identifies the region.
	<i>lprc</i> Points to a RECT structure containing the coordinates of the rectangle. The RECT structure has the following form:

	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>		
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.		
Return Value	The return value is nonzero if any part of the specified rectangle lies within the boundaries of the region. Otherwise, it is zero.		
Example	The following example uses the RectInRegion function to determine whether a specified rectangle is in a region and prints the result:		
	HRGN hrgn; RECT rc = { 100, 10, 130, 50 }; BOOL fRectIn; LPSTR lpszOverlap = "Some overlap between rc and region."; LPSTR lpszNoOverlap = "No common points in rc and region.";		
	fRectIn = RectInRegion(hrgn, &rc); if (!fRectIn) TextOut(hdc, 10, 10, lpszNoOverlap, lstrlen(lpszNoOverlap)); else TextOut(hdc, 10, 10, lpszOverlap, lstrlen(lpszOverlap));

PtInRegion

RectVisible				2. x
BOOL RectVisible HDC hdc; const RECT FAR*		 <i>prc</i>) /* handle of device context /* address of structure with rectangle 	*/ */	
		RectVisible function determines whether a vithin the clipping region of the given device	* 1	pecified rectangle
Parameters	<i>hdc</i> Id	entifies the device context.		
		bints to a RECT structure that contains the ctangle. The RECT structure has the follow		ates of the specified

```
typedef struct tagRECT { /* rc */
                          int left:
                          int top;
                          int right;
                          int bottom:
                       } RECT;
                       For a full description of this structure, see the Microsoft Windows Program-
                       mer's Reference, Volume 3.
Return Value
                    The return value is nonzero if some portion of the rectangle is within the clipping
                    region. Otherwise, it is zero.
Example
                    The following example paints a clipping region yellow by painting the client area.
                    The RectVisible function is called to determine whether a specified rectangle over-
                    laps the clipping region. If there is some overlap, the rectangle is filled by using a
                    red brush. If there is no overlap, text is displayed inside the clipping region. In this
                    case, the rectangle and the region do not overlap, even though they both specify
                    110 as a boundary on the y-axis, because regions are defined as including the pix-
                    els up to but not including the specified right and bottom coordinates.
                    RECT rc. rcVis:
                    HRGN hran:
                    HBRUSH hbrRed, hbrYellow;
                    GetClientRect(hwnd. &rc):
                    hrgn = CreateRectRgn(10, 10, 310, 110);
                    SelectClipRgn(hdc, hrgn);
                    hbrYellow = CreateSolidBrush(RGB(255, 255, 0));
                    FillRect(hdc, &rc, hbrYellow);
                    SetRect(&rcVis, 10, 110, 310, 300);
                    if (RectVisible(hdc, &rcVis)) {
                         hbrRed = CreateSolidBrush(RGB(255, 0, 0));
                         FillRect(hdc, &rcVis, hbrRed);
                         DeleteObject(hbrRed):
                    }
                    else {
                         SetBkColor(hdc, RGB(255, 255, 0));
                         TextOut(hdc, 20, 50, "Rectangle outside clipping region.", 34);
                    }
                    DeleteObject(hbrYellow);
                    DeleteObject(hrgn);

```

RedrawWindow

BOOL RedrawWindow(*hwnd*, *lprcUpdate*, *hrgnUpdate*, *fuRedraw*) /* handle of window */ */ **const RECT FAR*** *lprcUpdate*: /* address of structure with update rect. /* handle of update region */ **HRGN** *hrgnUpdate*; */ /* redraw flags

> The RedrawWindow function updates the specified rectangle or region in the given window's client area.

Parameters

HWND hwnd;

UINT fuRedraw;

hwnd

Identifies the window to be redrawn. If this parameter is NULL, the desktop window is updated.

lprcUpdate

Points to a **RECT** structure containing the coordinates of the update rectangle. This parameter is ignored if the *hrgnUpdate* parameter contains a valid region handle. The **RECT** structure has the following form:

```
typedef struct tagRECT {
                             /* rc */
   int left;
   int top;
   int right;
   int bottom;
} RECT:
```

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

hrgnUpdate

Identifies the update region. If both the *hrgnUpdate* and *lprcUpdate* parameters are NULL, the entire client area is added to the update region.

fuRedraw

Specifies one or more redraw flags. This parameter can be a combination of flags:

The following flags are used to invalidate the window:

Value	Meaning	
RDW_ERASE	Causes the window to receive a WM_ERASEBKGND message when the window is repainted. The RDW_INVALIDATE flag must also be specified; otherwise, RDW_ERASE has no effect.	

Value	Meaning
RDW_FRAME	Causes any part of the non-client area of the window that intersects the update region to receive a WM_NCPAINT message. The RDW_INVALIDATE flag must also be specified; otherwise, RDW_FRAME has no effect. The WM_NCPAINT message is typically not sent during the execution of the RedrawWindow function unless either RDW_UPDATENOW or RDW_ERASENOW is specified.
RDW_INTERNALPAINT	Causes a WM_PAINT message to be posted to the window regardless of whether the window contains an invalid region.
RDW_INVALIDATE	Invalidate <i>lprcUpdate</i> or <i>hrgnUpdate</i> (only one may be non-NULL). If both are NULL, the entire window is invalidated.

The following flags are used to validate the window:

Value	Meaning
RDW_NOERASE	Suppresses any pending WM_ERASEBKGND messages.
RDW_NOFRAME	Suppresses any pending WM_NCPAINT messages. This flag must be used with RDW_VALIDATE and is typically used with RDW_NOCHILDREN. This option should be used with care, as it could cause parts of a win- dow from painting properly.
RDW_NOINTERNALPAINT	Suppresses any pending internal WM_PAINT messages. This flag does not affect WM_PAINT messages resulting from invalid areas.
RDW_VALIDATE	Validates <i>lprcUpdate</i> or <i>hrgnUpdate</i> (only one may be non-NULL). If both are NULL, the entire window is validated. This flag does not affect internal WM_PAINT messages.

The following flags control when repainting occurs. No painting is performed by the **RedrawWindow** function unless one of these bits is specified.

Value	Meaning
RDW_ERASENOW	Causes the affected windows (as specified by the RDW_ALLCHILDREN and RDW_NOCHILDREN flags) to receive WM_NCPAINT and WM_ERASEBKGND messages, if necessary, before the function returns. WM_PAINT messages are deferred.

	Value	Meaning	
	RDW_UPDATENOW	Causes the affected windows (as specified by the RDW_ALLCHILDREN and RDW_NOCHILDREN flags) to receive WM_NCPAINT, WM_ERASEBKGND, and WM_PAINT messages, if necessary, before the function returns.	
	By default, the windows affected by the RedrawWindow function depend on whether the specified window has the WS_CLIPCHILDREN style. The child windows of WS_CLIPCHILDREN windows are not affected; however, non- WS_CLIPCHILDREN windows are recursively validated or invalidated until a WS_CLIPCHILDREN window is encountered. The following flags control which windows are affected by the RedrawWindow function:		
	Value	Meaning	
	RDW_ALLCHILDREN	Includes child windows, if any, in the repainting operation.	
	RDW_NOCHILDREN	Excludes child windows, if any, from the repainting operation.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.		
Comments	When the RedrawWindow function is used to invalidate part of the desktop win- dow, the desktop window does not receive a WM_PAINT message. To repaint the desktop, an application should use the RDW_ERASE flag to generate a WM_ERASEBKGND message.		
See Also	GetUpdateRect, GetUpdateRgn, InvalidateRect, InvalidateRgn, UpdateWindow		

RegCloseKey

3.1

#include <shellapi.h>

LONG RegCloseKey(*hkey*) HKEY *hkey*; /* handle of key to close */

> The **RegCloseKey** function closes a key. Closing a key releases the key's handle. When all keys are closed, the registration database is updated.

Parameters

hkey

Identifies the open key to close.

Return Value The return value is ERROR_SUCCESS if the function is successful. Otherwise, it is an error value.

Comments The **RegCloseKey** function should be called only if a key has been opened by either the **RegOpenKey** function or the **RegCreateKey** function. The handle for a given key should not be used after it has been closed, because it may no longer be valid. Key handles should not be left open any longer than necessary.

Example The following example uses the **RegCreateKey** function to create the handle of a protocol, uses the **RegSetValue** function to set up the subkeys of the protocol, and then calls **RegCloseKey** to save the information in the database:

HKEY hkProtocol;

	ES_ROOT, /* root ol\\StdFileEditing", /* protocol string UCCESS) /* protocol key handle	
RegSetValue(hkProtocol,	/* handle of protocol key	*/
"server",	/* name of subkey	*/
REG_SZ,	/* required	*/
"newapp.exe",	<pre>/* command to activate server</pre>	*/
10);	/* text string size	*/
RegSetValue(hkProtocol,	<pre>/* handle of protocol key</pre>	*/
"verb\\0",	/* name of subkey	*/
REG_SZ,	/* required	*/
"EDIT",	/* server should edit object	*/
4);	/* text string size	*/
<pre>RegCloseKey(hkProtocol);</pre>	/* closes protocol key and subkeys	*/

See Also RegCreateKey, RegDeleteKey, RegOpenKey, RegSetValue

RegCreateKey

3.1

#include <shellapi.h>

LONG RegCreateKey(hkey,	lpszSubKey, lphkResult)	
HKEY hkey;	/* handle of an open key	*/
LPCSTR lpszSubKey;	/* address of string for subkey to open	*/
HKEY FAR* lphkResult;	/* address of handle of open key	*/

	The RegCreateKey function c the registration database, RegC	reates the specified key. If the key already ex CreateKey opens it.	cists in
Parameters	opened or created by the Re	th can be HKEY_CLASSES_ROOT). The key gCreateKey function is a subkey of the key . This value should not be NULL.	
	<i>lpszSubKey</i> Points to a null-terminated s	tring specifying the subkey to open or create	×.
	<i>lphkResult</i> Points to the handle of the k	ey that is opened or created.	
Return Value	The return value is ERROR_SU is an error value.	UCCESS if the function is successful. Otherw	vise, it
Comments	by specifying HKEY_CLASSE can use the RegCreateKey fur an application could create a su	that are subordinate to the top level of the da ES_ROOT for the <i>hKey</i> parameter. An applic action to create several keys at once. For exam- bkey four levels deep and the three precedin he following form for the <i>lpszSubKey</i> parameters <i>ev4</i>	cation mple, 1g sub-
Example	protocol, uses the RegSetValu	e RegCreateKey function to create the hand e function to set up the subkeys of the protoc e the information in the database:	
	HKEY hkProtocol;		
	if (RegCreateKey(HKEY_CLASS "NewAppDocument\\protoc &hkProtocol) != ERROR_S return FALSE;	ol\\StdFileEditing", /* protocol string	
	RegSetValue(hkProtocol, "server", REG_SZ, "newapp.exe",	/* handle of protocol key /* name of subkey /* required /* command to activate server	*/ */ */
	10);	/* text string size	*/
	RegSetValue(hkProtocol, "verb\\0",	/* handle of protocol key /* name of subkey	*/ */
	REG_SZ,	/* required	*/
	"EDIT",	/* server should edit object	*/
	4);	/* text string size	*/
	<pre>RegCloseKey(hkProtocol);</pre>	/* closes protocol key and subkeys	*/

3.1

See Also RegCloseKey, RegOpenKey, RegSetValue

RegDeleteKey

#include <shellapi.h>

LONG RegDeleteKe HKEY hkey; LPCSTR lpszSubKey	/* handle of an open key */
	The RegDeleteKey function deletes the specified key. When a key is deleted, its value and all of its subkeys are deleted.
Parameters	hkey Identifies an open key (which can be HKEY_CLASSES_ROOT). The key de- leted by the RegDeleteKey function is a subkey of this key.
	<i>lpszSubKey</i> Points to a null-terminated string specifying the subkey to delete. This value should not be NULL.
Return Value	The return value is ERROR_SUCCESS if the function is successful. Otherwise, it is an error value.
	If the error value is ERROR_ACCESS_DENIED, either the application does not have delete privileges for the specified key or another application has opened the specified key.
Example	The following example uses the RegQueryValue function to retrieve the name of an object handler and then calls the RegDeleteKey function to delete the key if its value is nwappobj.dll:
	char szBuff[80]; LONG cb; HKEY hKStdFileEditing;
	<pre>if (RegOpenKey(HKEY_CLASSES_ROOT,</pre>
	<pre>cb = sizeof(szBuff);</pre>

RegEnumKey

#include <shellapi.h>

LONG RegEnumKe	ey(hkey, iSubkey, lpszBuffer, cbBuffer)	
HKEY hkey;	/* handle of key to query	*/
DWORD iSubkey;	/* index of subkey to query	*/
LPSTR lpszBuffer;	/* address of buffer for subkey string	*/
DWORD cbBuffer;	/* size of subkey buffer	*/
	The RegEnumKey function enumerates the	subkeys of a specified key.
Parameters	hkey	
	Identifies an open key (which can be HK) key information is retrieved.	EY_CLASSES_ROOT) for which sub-
	<i>iSubkey</i> Specifies the index of the subkey to retrie first call to the RegEnumKey function.	eve. This value should be zero for the
	<i>lpszBuffer</i> Points to a buffer that contains the name of returns. This function copies only the nam hierarchy, to the buffer.	
	<i>cbBuffer</i> Specifies the size, in bytes, of the buffer	pointed to by the <i>lpszBuffer</i> parameter.
Return Value	The return value is ERROR_SUCCESS if the is an error value.	e function is successful. Otherwise, it
Comments	The first parameter of the RegEnumKey fur plications typically precede the call to the R the RegOpenKey function and follow it wit	egEnumKey function with a call to

	Calling RegOpenKey and RegCloseKey is not necessary when the first parameter is HKEY_CLASSES_ROOT, because this key is always open and available; how- ever, calling RegOpenKey and RegCloseKey in this case is a time optimization. While an application is using the RegEnumKey function, it should not make calls to any registration functions that might change the key being queried. To enumerate subkeys, an application should initially set the <i>iSubkey</i> parameter to zero and then increment it on successive calls.
Example	The following example uses the RegEnumKey function to put the values associated with top-level keys into a list box:
	HKEY hkRoot; char szBuff[80], szValue[80]; static DWORD dwIndex; LONG cb;
	<pre>if (RegOpenKey(HKEY_CLASSES_ROOT, NULL, &hkRoot) == ERROR_SUCCESS) { for (dwIndex = 0; RegEnumKey(hkRoot, dwIndex, szBuff,</pre>

RegisterClass

ATOM RegisterCla const WNDCLASS	
	The RegisterClass function registers a window class for subsequent use in calls to the CreateWindow or CreateWindowEx function.
Parameters	<i>lpwc</i> Points to a WNDCLASS structure. The structure must be filled with the appropriate class attributes before being passed to the function. The WNDCLASS structure has the following form:

```
typedef struct tagWNDCLASS {
                                                           /* wc */
                            UINT
                                     style:
                            WNDPROC lpfnWndProc;
                            int
                                      cbClsExtra:
                                      cbWndExtra:
                            int
                            HINSTANCE hInstance:
                            HICON hIcon:
                            HCURSOR
                                      hCursor;
                            HBRUSH
                                       hbrBackground;
                            LPCSTR
                                      lpszMenuName:
                            LPCSTR
                                       lpszClassName;
                       } WNDCLASS;
                       For a full description of this structure, see the Microsoft Windows Program-
                       mer's Reference, Volume 3.
Return Value
                    The return value is an atom that uniquely identifies the class being registered. For
                     Windows versions 3.0 and earlier, the return value is nonzero if the function is
                     successful or zero if an error occurs.
Comments
                     An application cannot register a global class if either a global class or a task-
                     specific class already exists with the given name.
                     An application can register a task-specific class with the same name as a global
                     class. The task-specific class overrides the global class for the current task only. A
                     task cannot register two local classes with the same name. However, two different
                     tasks can register task-specific classes using the same name.
Example
                    The following example registers a window class, then creates a window of that
                    class:
                    WNDCLASS wc:
                    HINSTANCE hinst;
                    char szMyClass[] = "MyClass";
                    HWND hwndMyWindow:
                     /* Register the window class. */
                    wc.style
                                       = 0;
                                       = MyWndProc:
                    wc.lpfnWndProc
                    wc.cbClsExtra
                                       = 0:
                    wc.cbWndExtra
                                       = 0:
                    wc.hInstance
                                       = hinst:
                    wc.hIcon = LoadIcon(hinst, "MyIcon");
wc.hCursor = LoadCursor(NULL, IDC_ARROW);
                    wc.hbrBackground = (HBRUSH) (COLOR WINDOW + 1);
                    wc.lpszMenuName = (LPCSTR) NULL;
                     wc.lpszClassName = szMyClass;
```

```
if (!RegisterClass(&wc))
    return FALSE;
/* Create the window. */
hwndMyWindow = CreateWindow(szMyClass, "MyApp",
    WS_OVERLAPPED | WS_SYSMENU, CW_USEDEFAULT, 0,
    CW_USEDEFAULT, 0, NULL, NULL,
    hinst, NULL );
CreateWindow, CreateWindowEx, GetClassInfo, GetClassName, Unregister-
Class, WindowProc
```

RegisterClipboardFormat

See Also

UINT RegisterClipboardFormat (lpszFormatName) LPCSTR lpszFormatName;/* address of name string*/		
	The RegisterClipboardFormat function registers a new clipboard format. The registered format can be used in subsequent clipboard functions as a valid format in which to render data, and it will appear in the clipboard's list of formats.	
Parameters	<i>lpszFormatName</i> Points to a null-terminated string that names the new format.	
Return Value	The return value indicates the newly registered format. If the identical format name has been registered before, even by a different application, the format's refer- ence count is incremented (increased by one) and the same value is returned as when the format was originally registered. The return value is zero if the format cannot be registered.	
Comments	The format value returned by the RegisterClipboardFormat function is within the range 0xC000 through 0xFFFF.	
See Also	CountClipboardFormats, EnumClipboardFormats, GetClipboardFormat- Name, GetPriorityClipboardFormat, IsClipboardFormatAvailable	

RegisterWindowMessage

UINT RegisterWindowMessage(*lpsz*)

LPCSTR lpsz;	/* address of message string */
	The RegisterWindowMessage function defines a new window message that is guaranteed to be unique throughout the system. The returned message value can be used when calling the SendMessage or PostMessage function.
Parameters	<i>lpsz</i> Points to a null-terminated string that specifies the message to be registered.
Return Value	The return value is an unsigned short integer in the range 0xC000 through 0xFFFF if the message is successfully registered. Otherwise, the return value is 0.
Comments	RegisterWindowMessage is typically used to register messages for communicat- ing between two cooperating applications.
	If two different applications register the same message string, the applications re- turn the same message value. The message remains registered until the Windows session ends.
	Use the RegisterWindowMessage function only when more than one application must process the same message. For sending private messages within a window class, an application can use any integer in the range WM_USER through 0x7FFF. (Messages in this range are private to a window class, not to an application. For example, such predefined control classes as BUTTON, EDIT, LISTBOX, and COMBOBOX may use values in this range.)
See Also	PostAppMessage, PostMessage, SendMessage

RegOpenKey

#include <shellapi.h>

LONG RegOpenKey(hkey, lp	pszSubKey, lphkResult)	
HKEY hkey;	/* handle of an open key	*/
LPCSTR lpszSubKey;	/* address of string for subkey to open	*/
HKEY FAR* lphkResult;	/* address of handle of open key	*/

The **RegOpenKey** function opens the specified key.

Parameters	<i>hkey</i> Identifies an open key (which can be HKEY_CLASSES_ROOT). The key opened by the RegOpenKey function is a subkey of the key identified by this parameter. This value should not be NULL.
	<i>lpszSubKey</i> Points to a null-terminated string specifying the name of the subkey to open.
	<i>lphkResult</i> Points to the handle of the key that is opened.
Return Value	The return value is ERROR_SUCCESS if the function is successful. Otherwise, it is an error value.
Comments	Unlike the RegCreateKey function, the RegOpenKey function does not create the specified key if the key does not exist in the database.
Example	The following example uses the RegOpenKey function to retrieve the handle of the StdFileEditing subkey, calls the RegQueryValue function to retrieve the name of an object handler, and then calls the RegDeleteKey function to delete the key if its value is nwappobj.dll:
	char szBuff[80]; LONG cb; HKEY hKStdFileEditing;
	<pre>if (RegOpenKey(HKEY_CLASSES_ROOT,</pre>
	<pre>cb = sizeof(szBuff); if (RegQueryValue(hkStdFileEditing,</pre>

See Also

RegCreateKey

RegQueryValue

#include <shellapi.h>

LONG RegQueryVa HKEY hkey; LPCSTR lpszSubKe LPSTR lpszValue; LONG FAR* lpcb;	alue(hkey, lpszSubKey, lpszValue, lpcb) */ /* handle of key to query */ y; /* address of string for subkey to query */ /* address of buffer for returned string */ /* address of buffer for size of returned string */
	The RegQueryValue function retrieves the text string associated with a specified key.
Parameters	<i>hkey</i> Identifies a currently open key (which can be HKEY_CLASSES_ROOT). This value should not be NULL.
	<i>lpszSubKey</i> Points to a null-terminated string specifying the name of the subkey of the <i>hkey</i> parameter for which a text string is retrieved. If this parameter is NULL or points to an empty string, the function retrieves the value of the <i>hkey</i> parameter.
	<i>lpszValue</i> Points to a buffer that contains the text string when the function returns.
	<i>lpcb</i> Points to a variable specifying the size, in bytes, of the buffer pointed to by the <i>lpszValue</i> parameter. When the function returns, this variable contains the size of the string copied to <i>lpszValue</i> , including the null-terminating character.
Return Value	The return value is ERROR_SUCCESS if the function is successful. Otherwise, it is an error value.
Example	The following example uses the RegOpenKey function to retrieve the handle of the StdFileEditing subkey, calls the RegQueryValue function to retrieve the name of an object handler and then calls the RegDeleteKey function to delete the key if its value is nwappobj.dll:
	char szBuff[80]; LONG cb; HKEY hkStdFileEditing;
	<pre>if (RegOpenKey(HKEY_CLASSES_ROOT, "NewAppDocument\\protocol\\StdFileEditing", &hkStdFileEditing) == ERROR_SUCCESS) {</pre>
	<pre>cb = sizeof(szBuff);</pre>

See Also

RegEnumKey

RegSetValue

#include <shellapi.h>

LONG RegSetValue HKEY hkey; LPCSTR lpszSubKe DWORD fdwType; LPCSTR lpszValue; DWORD cb;	/* must be REG_SZ */
	The RegSetValue function associates a text string with a specified key.
Parameters	<i>hkey</i> Identifies a currently open key (which can be HKEY_CLASSES_ROOT). This value should not be NULL.
	<i>lpszSubKey</i> Points to a null-terminated string specifying the subkey of the <i>hkey</i> parameter with which a text string is associated. If this parameter is NULL or points to an empty string, the function sets the value of the <i>hkey</i> parameter.
	<i>fdwType</i> Specifies the string type. For Windows version 3.1, this value must be REG_SZ.
	<i>lpszValue</i> Points to a null-terminated string specifying the text string to set for the given key.
	<i>cb</i> Specifies the size, in bytes, of the string pointed to by the <i>lpszValue</i> parameter. For Windows version 3.1, this value is ignored.
Return Value	The return value is ERROR_SUCCESS if the function is successful. Otherwise, it is an error value.

Comments If the key specified by the *lpszSubKey* parameter does not exist, the **RegSetValue** function creates it. Example The following example uses the RegSetValue function to register a filename extension and its associated class name: RegSetValue(HKEY CLASSES ROOT. /* root */ ".XXX", /* string for filename extension */ REG_SZ, /* required */ "NewAppDocument". /* class name for extension */ /* size of text string 14): */ RegSetValue(HKEY_CLASSES_ROOT, /* root */ "NewAppDocument", /* string for class-definition key */ REG_SZ, /* required */ /* text description of class "New Application", */ /* size of text string */ 15);

RegCreateKey, RegQueryValue

ReleaseCapture

void ReleaseCapture(void)

	The ReleaseCapture function releases the mouse capture and restores normal input processing. A window with the mouse capture receives all mouse input regardless of the position of the cursor.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
Comments	An application calls this function after calling the SetCapture function.
See Also	SetCapture

ReleaseDC

	<pre>vnd, hdc) /* handle of window with device context */ /* handle of device context */</pre>
	The ReleaseDC function releases the given device context, freeing it for use by other applications.
Parameters	<i>hwnd</i> Identifies the window whose device context is to be released.
	<i>hdc</i> Identifies the device context to be released.
Return Value	The return value is 1 if the function is successful. Otherwise, it is 0.
Comments	The effect of ReleaseDC depends on the type of device context. It frees only common and window device contexts. It has no effect on class or private device contexts.
	The application must call the ReleaseDC function for each call to the Get-WindowDC function and for each call to the GetDC function that retrieves a common device context.
See Also	BeginPaint, EndPaint, GetDC, GetWindowDC

RemoveFontResource

BOOL RemoveFontResource(*lpszFile*)

LPCSTR *lpszFile*; /* address of string for filename */

The **RemoveFontResource** function removes an added font resource from the specified file or from the Windows font table.

 Parameters
 lpszFile

 Points to a string that names the font resource file or contains a handle of a loaded module. If this parameter points to the font resource file, the string must be null-terminated and have the MS-DOS filename format. If the parameter contains a handle, the handle must be in the low-order word and the high-order word must be zero.

Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Any application that adds or removes fonts from the Windows font table should send a WM_FONTCHANGE message to all top-level windows in the system by using the SendMessage function with the <i>hwnd</i> parameter set to 0xFFFF.
	In some cases, the RemoveFontResource function may not remove the font re- source immediately. If there are outstanding references to the resource, it remains loaded until the last logical font using it has been removed (deleted) by using the DeleteObject function.
Example	The following example uses the AddFontResource function to add a font re- source from a file, notifies other applications by using the SendMessage function, then removes the font resource by calling the RemoveFontResource function:
	AddFontResource("fontres.fon"); SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0);
	. /* Work with the font. */
	<pre>if (RemoveFontResource("fontres.fon")) { SendMessage(HWND_BROADCAST, WM_FONTCHANGE, 0, 0); return TRUE;</pre>
	} else
	return FALSE;
See Also	AddFontResource, DeleteObject, SendMessage

RemoveMenu

HMENU hmenu;	/* handle of menu	*/
UINT <i>idItem</i> ;	/* menu item to delete	*/
UINT fuFlags;	/* menu flags	*/
	The RemoveMenu functi	on deletes a menu
	from a menu but does not	destroy the hand

The **RemoveMenu** function deletes a menu item with an associated pop-up menu from a menu but does not destroy the handle of the pop-up menu, allowing the menu to be reused. Before calling this function, an application should call the **Get-SubMenu** function to retrieve the pop-up menu handle.

3.0

Parameters

hmenu

Identifies the menu to be changed.

2.x

	fuFlags	m to be removed, as determined by the <i>fuFlags</i> parameter. <i>em</i> parameter is to be interpreted. This parameter can be alues:
	Value	Meaning
	MF_BYCOMMAND MF_BYPOSITION	The <i>idItem</i> parameter specifies the menu-item identifier. The <i>idItem</i> parameter specifies the zero-based position of the menu item.
Return Value	The return value is nonze	ro if the function is successful. Otherwise it is zero.
Comments		es (whether or not it is in a window that is displayed), the e DrawMenuBar function.
See Also	AppendMenu, CreateM InsertMenu	lenu, DeleteMenu, DrawMenuBar, GetSubMenu,

RemoveProp

	veProp(hwnd, lpsz)/* handle of window*//* atom or address of string*/
	The RemoveProp function removes an entry from the property list of the given window. The RemoveProp function returns a data handle so that the application can free the data associated with the handle.
Parameters	<i>hwnd</i> Identifies the window whose property list is to be changed.
	<i>lpsz</i> Points to a null-terminated string or an atom that identifies a string. If an atom is given, it must be a global atom created by a previous call to the GlobalAdd - Atom function. The atom, a 16-bit value, must be placed in the low-order word of this parameter; the high-order word must be zero.
Return Value	The return value is the handle of the given string if the function is successful. Otherwise, it is NULL—for example, if the string cannot be found in the given property list.

CommentsAn application can remove only those properties it has added. It should not remove properties added by other applications or by Windows itself.An application must free the data handles associated with entries removed from a property list. The application should remove only those properties it added to the property list.See AlsoGetProp, GlobalAddAtom

ReplaceText 3.1 #include <commdlg.h> HWND ReplaceText(lpfr) */ **FINDREPLACE FAR*** *lpfr*: /* address of structure with initialization data The **ReplaceText** function creates a system-defined modeless dialog box that makes it possible for the user to find and replace text within a document. The application must perform the actual find and replace operations. **Parameters** lpfr Points to a FINDREPLACE structure that contains information used to initialize the dialog box. When the user makes a selection in the dialog box, the system fills this structure with information about the user's selection and then sends a message to the application. This message contains a pointer to the FINDREPLACE structure. The **FINDREPLACE** structure has the following form: #include <commdlg.h> typedef struct tagFINDREPLACE { /* fr */ DWORD 1StructSize; hwnd0wner; HWND HINSTANCE hInstance; Flags: DWORD LPSTR lpstrFindWhat: LPSTR lpstrReplaceWith; wFindWhatLen; UINT UINT wReplaceWithLen; LPARAM 1CustData; (CALLBACK* lpfnHook)(HWND, UINT, WPARAM, LPARAM); UINT LPCSTR lpTemplateName: } FINDREPLACE;

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

- **Return Value** The return value is the window handle of the dialog box, or it is NULL if an error occurs. An application can use this handle to communicate with or to close the dialog box.
- **Errors** Use the **CommDlgExtendedError** function to retrieve the error value, which may be one of the following:

CDERR_FINDRESFAILURE CDERR_INITIALIZATION CDERR_LOADRESFAILURE CDERR_LOADSTRFAILURE CDERR_LOCKRESFAILURE CDERR_MEMALLOCFAILURE CDERR_MEMLOCKFAILURE CDERR_NOHINSTANCE CDERR_NOHOOK CDERR_NOTEMPLATE CDERR_STRUCTSIZE FRERR BUFFERLENGTHZERO

CommentsThe dialog box procedure for the ReplaceText function passes user requests to the
application through special messages. The *lParam* parameter of each of these mes-
sages contains a pointer to a FINDREPLACE structure. The procedure sends the
messages to the window identified by the hwndOwner member of the FIND-
REPLACE structure. An application can register the identifier for these messages
by specifying the commdlg_FindReplace string in a call to the RegisterWindow-
Message function.

For the TAB key to function correctly, any application that calls the **ReplaceText** function must also call the **IsDialogMessage** function in its main message loop. (The **IsDialogMessage** function returns a value that indicates whether messages are intended for the Replace dialog box.)

Example This example initializes a **FINDREPLACE** structure and calls the **ReplaceText** function to display the Replace dialog box:

static FINDREPLACE fr; char szFindWhat[256] = ""; /* string to find */ char szReplaceWith[256] = ""; /* string to replace */ /* Set all structure fields to zero. */ memset(&fr, 0, sizeof(FINDREPLACE));

```
fr.lStructSize = sizeof(FINDREPLACE);
fr.hwndOwner = hwnd;
fr.lpstrFindWhat = szFindWhat;
fr.wFindWhatLen = sizeof(szFindWhat);
fr.lpstrReplaceWith = szReplaceWith;
fr.wReplaceWithLen = sizeof(szReplaceWith);
```

```
hDlg = ReplaceText(&fr);
```

In addition to initializing the members of the **FINDREPLACE** structure and calling the **ReplaceText** function, an application must register the special FINDMSGSTRING message and process messages from the dialog box. Refer to the description of the **FindText** function for an example that shows how an application registers and processes a message.

2.x

See Also FindText, IsDialogMessage, RegisterWindowMessage

ReplyMessage

void ReplyMessage(LRESULT lResult;	(<i>lResult</i>) /* message-dependent reply */
	The ReplyMessage function is used to reply to a message sent through the Send-Message function without returning control to the function that called Send-Message .
Parameters	<i>lResult</i> Specifies the result of the message processing. The possible values depend on the message sent.
Return Value	This function does not return a value.
Comments	By calling this function, the window procedure that receives the message allows the task that called SendMessage to continue to run as though the task that re- ceived the message had returned control. The task that calls ReplyMessage also continues to run.
	Usually, a task that calls SendMessage to send a message to another task will not continue running until the window procedure that Windows calls to receive the message returns. However, if a task that is called to receive a message must perform some type of operation that might yield control (such as calling the Message-Box or DialogBox function), Windows could be deadlocked, as when the sending task must run and process messages but cannot because it is waiting for

SendMessage to return. An application can avoid this problem if the task receiving the message calls **ReplyMessage** before performing any operation that could cause the task to yield.

The **ReplyMessage** function has no effect if the message was not sent through the **SendMessage** function or if the message was sent by the same task.

See Also DialogBox, MessageBox, SendMessage

ResetDC			3.1
#include <print.h></print.h>			
HDC ResetDC(hdc, HDC hdc; const DEVMODE F		/* handle of device context /* address of DEVMODE structure	*/ */
		function updates the given device context, d DEVMODE structure.	based on the information
Parameters	<i>hdc</i> Identifies tl	he device context to be updated.	
		DEVMODE structure containing informate the DEVMODE structure has the following	
	#include <	(print.h>	
	char UINT UINT UINT UINT	<pre>ruct tagDEVMODE { /* dm */ dmDeviceName[CCHDEVICENAME]; dmSpecVersion; dmDriverVersion; dmSize; dmDriverExtra; dmFields; dmOrientation; dmPaperSize; dmPaperLength; dmPaperWidth; dmScale; dmCopies; dmDefaultSource; dmPrintQuality;</pre>	

	<pre>int dmColor; int dmDuplex; int dmYResolution; int dmTTOption; } DEVMODE;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is the handle of the original device context if the function is successful. Otherwise, it is NULL.
Comments	An application will typically use the ResetDC function when a window receives a WM_DEVMODECHANGE message. ResetDC can also be used to change the paper orientation or paper bins while printing a document.
	The ResetDC function cannot be used to change the driver name, device name or the output port. When the user changes the port connection or device name, the ap- plication must delete the original device context and create a new device context with the new information.
	Before calling ResetDC , the application must ensure that all objects (other than stock objects) that had been selected into the device context have been selected out.
See Also	DeviceCapabilities, Escape, ExtDeviceMode

ResizePalette

BOOL ResizePalet	tte(hpal, cEntries)	
HPALETTE hpal;	/* handle of palette */	
UINT cEntries;	/* number of palette entries after resizing */	
	The ResizePalette function changes the size of the given logic	al palette.
Parameters	<i>hpal</i> Identifies the palette to be changed.	
	<i>cEntries</i> Specifies the number of entries in the palette after it has bee	en resized.
Return Value	The return value is nonzero if the function is successful. Other	wise, it is zero.
Comments	If an application calls the ResizePalette function to reduce the the entries remaining in the resized palette are unchanged. If the	

3.0

ResizePalette to enlarge the palette, the additional palette entries are set to black (the red, green, and blue values are all zero) and the flags for all additional entries are set to zero.

RestoreDC

	(<i>hdc</i> , <i>nSavedDC</i>) /* handle of device context /* integer identifying device context to restore	*/ */
	The RestoreDC function restores the given device The device context is restored by popping state info earlier calls to the SaveDC function.	
Parameters	 hdc Identifies the device context. nSavedDC Specifies the device context to be restored. This turned by a previous SaveDC function. If the pasaved device context is restored. 	
Return Value	The return value is nonzero if the function is succe	ssful. Otherwise, it is zero.
Comments	The stack can contain the state information for severence text. If the context specified by the <i>nSavedDC</i> para stack, RestoreDC deletes all state information betwee <i>nSavedDC</i> and the top of the stack.	meter is not at the top of the
Example	The following example uses the GetMapMode fur mode for the current device context, uses the Save the device context, changes the mapping mode, res device context by using the RestoreDC function, a again. The final mapping mode is the same as the r to the SaveDC function.	DC function to save the state of tores the previous state of the and retrieves the mapping mode
	HDC hdcLocal; int MapMode; char *aModes[] = {"ZERO", "MM_TEXT", "MM_LOM "MM_LOENGLISH", "MM_HIENGLISH", "MM_TWIP "MM_ISOTROPIC", "MM_ANISOTROPIC" };	ETRIC", "MM_HIMETRIC", S",
	hdcLocal = GetDC(hwnd); MapMode = GetMapMode(hdcLocal);

SaveDC

RoundRect

BOOL RoundRect(*hdc*, *nLeftRect*, *nTopRect*, *nRightRect*, *nBottomRect*, *nEllipseWidth*, *nEllipseHeight*)

HDC hdc;	/* handle of device context	*/
int nLeftRect;	/* x-coordinate upper-left corner	*/
int nTopRect;	/* y-coordinate upper-left corner	*/
int nRightRect;	/* x-coordinate lower-right corner	*/
int nBottomRect;	/* y-coordinate lower-right corner	*/
int nEllipseWidth;	/* width of ellipse for rounded corners	*/
int nEllipseHeight;	/* height of ellipse for rounded corners	*/

The **RoundRect** function draws a rectangle with rounded corners, using the current pen. The interior of the rectangle is filled by using the current brush.

Parameters

hdc

Identifies the device context.

nLeftRect

Specifies the logical x-coordinate of the upper-left corner of the rectangle.

nTopRect

Specifies the logical y-coordinate of the upper-left corner of the rectangle.

nRightRect

Specifies the logical x-coordinate of the lower-right corner of the rectangle.

	<i>nBottomRect</i> Specifies the logical y-coordinate of the lower-right corner of the rectangle.
	<i>nEllipseWidth</i> Specifies the width, in logical units, of the ellipse used to draw the rounded corners.
	<i>nEllipseHeight</i> Specifies the height, in logical units, of the ellipse used to draw the rounded corners.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The figure this function draws extends up to but does not include the right and bottom coordinates. This means that the height of the figure is $nBottomRect - nTopRect$ and the width of the figure is $nRightRect - nLeftRect$.
	Both the width and the height of a rectangle must be greater than 2 units and less than 32,767 units.
Example	The following example uses a RECT structure to store the coordinates used by the RoundRect function:
	HDC hdc;
	RECT rc = { 10, 10, 180, 140 }; int iEllipseWidth, iEllipseHeight;
	iEllipseWidth = 20; iEllipseHeight = 40;
	RoundRect(hdc, rc.left, rc.top, rc.right, rc.bottom, iEllipseWidth, iEllipseHeight);
See Also	Rectangle

SaveDC

2.x

int SaveDC(hdc)
HDC hdc; /* handle of device context */

The **SaveDC** function saves the current state of the given device context by copying state information (such as clipping region, selected objects, and mapping mode) to a context stack. The saved device context can later be restored by using the **RestoreDC** function.

Parameters	<i>hdc</i> Identifies the device context to be saved.
Return Value	The return value is an integer identifying the saved device context if the function is successful. This integer can be used to restore the device context by calling the RestoreDC function. The return value is zero if an error occurs.
Comments	The SaveDC function can be used any number of times to save any number of device-context states.
Example	The following example uses the GetMapMode function to retrieve the mapping mode for the current device context, uses the SaveDC function to save the state of the device context, changes the mapping mode, restores the previous state of the device context by using the RestoreDC function, and retrieves the mapping mode again. The final mapping mode is the same as the mapping mode prior to the call to the SaveDC function.
	HDC hdcLocal; int MapMode; char *aModes[] = {"ZERO", "MM_TEXT", "MM_LOMETRIC", "MM_HIMETRIC", "MM_LOENGLISH", "MM_HIENGLISH", "MM_TWIPS", "MM_ISOTROPIC", "MM_ANISOTROPIC" };
	hdcLocal = GetDC(hwnd); MapMode = GetMapMode(hdcLocal); TextOut(hdc, 100, 100, (LPSTR) aModes[MapMode], lstrlen(aModes[MapMode]));
	SaveDC(hdcLocal);
	SetMapMode(hdcLocal, MM_LOENGLISH); MapMode = GetMapMode(hdcLocal); TextOut(hdc, 100, 120, (LPSTR) aModes[MapMode], lstrlen(aModes[MapMode]));
	RestoreDC(hdcLocal, -1);
	<pre>MapMode = GetMapMode(hdcLocal); TextOut(hdc, 100, 140, (LPSTR) aModes[MapMode], lstrlen(aModes[MapMode]));</pre>
	ReleaseDC(hwnd, hdcLocal);
See Also	RestoreDC

ScaleViewportExt

DWORD ScaleV	iewportExt(hdc, nXNum, nXDenom, nYNum, nYDenom)
HDC hdc;	/* handle of device context */
int nXNum;	/* amount by which current x-extent is multiplied */
int nXDenom;	/* amount by which current x-extent is divided */
int nYNum;	/* amount by which current y-extent is multiplied */
int nYDenom;	/* amount by which current y-extent is divided */
	The ScaleViewportExt function modifies the viewport extents relative to the current values.
Parameters	hdc
	Identifies the device context.
	nXNum
	Specifies the amount by which to multiply the current x-extent.
	nXDenom
	Specifies the amount by which to divide the result of multiplying the current x-extent by the value of the <i>nXNum</i> parameter.
	nYNum
	Specifies the amount by which to multiply the current y-extent.
	<i>nYDenom</i> Specifies the amount by which to divide the result of multiplying the current y-extent by the value of the <i>nYNum</i> parameter.
Return Value	The low-order word of the return value contains the x-extent, in device units, of the previous viewport if the function is successful; the high-order word contains the y-extent.
Comments	The new viewport extents are calculated by multiplying the current extents by the given numerator and then dividing by the given denominator, as shown in the following formulas:
	nXNewVE = (nXOldVE * nXNum) / nXDenom nYNewVE = (nYOldVE * nYNum) / nYDenom
Example	The following example draws a rectangle that is 4 logical units high and 4 logical units wide. It then calls the ScaleViewportExt function and draws a rectangle that is 8 units by 8 units. Because of the viewport scaling, the second rectangle is the same size as the first.

```
HDC hdc;
RECT rc;
GetClientRect(hwnd, &rc);
hdc = GetDC(hwnd);
SetMapMode(hdc, MM_ANISOTROPIC);
SetWindowExt(hdc, 10, 10);
SetViewportExt(hdc, rc.right, rc.bottom);
Rectangle(hdc, 3, 3, 7, 7);
ScaleViewportExt(hdc, 1, 2, 1, 2);
Rectangle(hdc, 6, 6, 14, 14);

ScaleViewportExtEx

HDC hdc; int nXnum; int nXdenom; int nYnum;	/* amount by which current y-extent is multiplied /* amount by which current y-extent is divided	*/ */ */ */
	The ScaleViewportExtEx function modifies the viewport e current values. The formulas are written as follows:	extents relative to the
	xNewVE = (xOldVE * Xnum) / Xdenom yNewVE = (yOldVE * Ynum) / Ydenom	
	The new extent is calculated by multiplying the current extended numerator and then dividing by the given denominator.	ents by the given
Parameters	<i>hdc</i> Identifies the device context.	
	<i>nXnum</i> Specifies the amount by which to multiply the current x-	extent.
	<i>nXdenom</i> Specifies the amount by which to divide the current x-ex	tent.

3.1

2.x

	<i>nYnum</i> Specifies the amount by which to multiply the current y-extent.
	<i>nYdenom</i> Specifies the amount by which to divide the current y-extent.
	<i>lpSize</i> Points to a SIZE structure. The previous viewport extents, in device units, are placed in this structure. If <i>lpSize</i> is NULL, nothing is returned.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

ScaleWindowExt

DWORD Scale	WindowExt(hdc, nXNum, nXDenom, nYNum, nYDenom)
HDC hdc;	/* handle of device context	*/
int nXNum;	/* amount by which current x-extent is multiplied	*/
int nXDenom;	/* amount by which current x-extent is divided	*/
int nYNum;	/* amount by which current y-extent is multiplied	*/
int nYDenom;	/* amount by which current y-extent is divided	*/
	The ScaleWindowExt function modifies the windorent values.	ow extents relative to the cur-
Parameters	hdc	
	Identifies the device context.	
	<i>nXNum</i> Specifies the amount by which to multiply the cu	urrent x-extent.
	<i>nXDenom</i> Specifies the amount by which to divide the resu x-extent by the value of the <i>nXNum</i> parameter.	Ilt of multiplying the current
	<i>nYNum</i> Specifies the amount by which to multiply the cu	urrent y-extent.
	<i>nYDenom</i> Specifies the amount by which to divide the resu y-extent by the value of the <i>nYNum</i> parameter.	It of multiplying the current
Return Value	The low-order word of the return value contains the the previous window, if the function is successful; the y-extent.	

Comments	The new window extents are calculated by multiplying the current extents by the given numerator and then dividing by the given denominator, as shown in the following formulas:
	nXNewWE = (nXOldWE * nXNum) / nXDenom nYNewWE = (nYOldWE * nYNum) / nYDenom
Example	The following example draws a rectangle that is 4 logical units high and 4 logical units wide. It then calls the ScaleWindowExt function and draws a rectangle that is 8 units by 8 units. Because of the window scaling, the second rectangle is the same size as the first.
	HDC hdc; RECT rc;
	GetClientRect(hwnd, &rc); hdc = GetDC(hwnd); SetMapMode(hdc, MM_ANISOTROPIC);
	SetWindowExt(hdc, 10, 10); SetViewportExt(hdc, rc.right, rc.bottom); Rectangle(hdc, 3, 3, 7, 7);
	ScaleWindowExt(hdc, 2, 1, 2, 1); Rectangle(hdc, 6, 6, 14, 14);
	ReleaseDC(hwnd, hdc);
See Also	GetWindowExt

ScaleWindowExtEx

3.1

BOOL ScaleWindow	ExtEx(hdc, nXnum, nXdenom, nYnum, nYdenom, lpSize)	
HDC hdc;	/* handle of device context	*/
int nXnum;	/* amount by which current x-extent is multiplied	*/
int nXdenom;	/* amount by which current x-extent is divided	*/
int nYnum;	/* amount by which current y-extent is multiplied	*/
int nYdenom;	/* amount by which current y-extent is divided	*/
SIZE FAR* lpSize;	/* address of SIZE structure	*/

The **ScaleWindowExtEx** function modifies the window extents relative to the current values. The formulas are written as follows:

xNewWE = (xOldWE * Xnum) / Xdenom
yNewWE = (yOldWE * Ynum) / Ydenom

	The new extent is calculated by multiplying the current extents by the given numerator and then dividing by the given denominator.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXnum</i> Specifies the amount by which to multiply the current x-extent.
	<i>nXdenom</i> Specifies the amount by which to divide the current x-extent.
	<i>nYnum</i> Specifies the amount by which to multiply the current y-extent.
	<i>nYdenom</i> Specifies the amount by which to divide the current y-extent.
	<i>lpSize</i> Points to a SIZE structure. The previous window extents, in logical units, are placed in this structure. If <i>lpSize</i> is NULL, nothing is returned.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

Screen1	oClient
---------	---------

void ScreenToClien	t(hwnd, lppt)	
HWND hwnd;	/* window handle for source coordinates	*/
POINT FAR* <i>lppt</i> ;	/* address of structure with coordinates	*/
	The ScreenToClient function converts the screen to client coordinates.	en coordinates of a given point on
Parameters	hwnd	
i ulullotoio	Identifies the window whose client area is to	be used for the conversion.
	lppt	
	Points to a POINT structure that contains the verted. The POINT structure has the following the following the following the following structure has the following stru	
	typedef struct tagPOINT { /* pt */ int x;	
	int y;	
	} POINT;	
	For a full description of this structure, see the <i>mer's Reference</i> , Volume 3.	e Microsoft Windows Program-

Return Value This function does not return a value.

Comments The **ScreenToClient** function replaces the screen coordinates in the **POINT** structure with client coordinates. The new coordinates are relative to the upper-left corner of the given window's client area.

Example The following example uses the **GetWindowRect** function to retrieve the screen coordinates for a specified window, calls the **ScreenToClient** function to convert the upper-left and lower-right corners of the window rectangle to client coordinates, and then reports the results in a message box:

```
RECT rc:
                    /* window's screen coordinates
                                                        */
POINT ptUpperLeft: /* client coordinate of upper left */
POINT ptLowerRight; /* client coordinate of lower right */
char szText[128]; /* char buffer for wsprintf
                                                        */
GetWindowRect(hwnd, &rc);
ptUpperLeft.x
               = rc.left:
ptUpperLeft.y = rc.top:
ptLowerRight.x = rc.right;
ptLowerRight.y = rc.bottom;
ScreenToClient(hwnd, &ptUpperLeft );
ScreenToClient(hwnd, &ptLowerRight);
wsprintf(szText,
    "S: (%d,%d)-(%d,%d) --> C: (%d,%d)-(%d,%d)",
    rc.left, rc.top, rc.right, rc.bottom,
    ptUpperLeft.x, ptUpperLeft.y, ptLowerRight.x, ptLowerRight.y);
MessageBox(hwnd, szText, "ScreenToClient", MB_OK);
```

ScrollDC

BOOL ScrollDC (<i>hdc</i> , <i>dx</i> , <i>dy</i> , <i>lprcS</i>)	croll, lprcClip, hrgnUpdate, lprcUpdate)	
HDC hdc;	/* handle of device context	*/
int dx ;	/* horizontal scroll units	*/
int dy;	/* vertical scroll units	*/
<pre>const RECT FAR* lprcScroll;</pre>	/* address of scrolling rectangle	*/
const RECT FAR* <i>lprcClip</i> ;	/* address of clipping rectangle	*/
HRGN hrgnUpdate;	/* handle of scrolling region	*/
RECT FAR* <i>lprcUpdate</i> ;	/* address of structure for update rect.	*/

	The ScrollDC function scrolls a rectangle of bits horizontally and vertically.
Parameters	 <i>hdc</i> Identifies the device context that contains the bits to be scrolled. <i>dx</i> Specifies the number of horizontal scroll units. <i>dy</i> Specifies the number of vertical scroll units. <i>lprcScroll</i> Points to the RECT structure that contains the coordinates of the scrolling rectangle. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lprcClip</i> Points to the RECT structure that contains the coordinates of the clipping rectangle. When this rectangle is smaller than the original one pointed to by the <i>lprcScroll</i> parameter, scrolling occurs only in the smaller rectangle.
	<i>hrgnUpdate</i> Identifies the region uncovered by the scrolling process. The ScrollDC function defines this region; it is not necessarily a rectangle.
	<i>lprcUpdate</i> Points to the RECT structure that receives the coordinates of the rectangle that bounds the scrolling update region. This is the largest rectangular area that re- quires repainting. The values in the structure when the function returns are in client coordinates, regardless of the mapping mode for the given device context.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	If the <i>lprcUpdate</i> parameter is NULL, Windows does not compute the update rectangle. If both the <i>hrgnUpdate</i> and <i>lprcUpdate</i> parameters are NULL, Windows does not compute the update region. If <i>hrgnUpdate</i> is not NULL, Windows assumes that it contains a valid handle of the region uncovered by the scrolling process (defined by the ScrollDC function).
	When the ScrollDC function returns, the values in the structure pointed to by the <i>lprcUpdate</i> parameter are in client coordinates. This allows applications to use the update region in a call to the InvalidateRgn function, if required.

An application should use the **ScrollWindow** function when it is necessary to scroll the entire client area of a window; otherwise, it should use **ScrollDC**.

See Also InvalidateRgn, ScrollWindow, ScrollWindowEx

ScrollWindow

HWND hwnd;	<i>p</i> , <i>lprcScroll</i> , <i>lprcClip</i>) /* handle of window to scroll	*/
int dx;	/* amount of horizontal scrolling	*/
int dy;	/* amount of vertical scrolling	*/
<pre>const RECT FAR* lprcScroll;</pre>	/* address of structure with scroll rect.	*/
const RECT FAR* <i>lprcClip</i> ;	/* address of structure with clip rect.	*/

The ScrollWindow function scrolls the contents of a window's client area.

Parameters

hwnd

Identifies the window to be scrolled.

dx

Specifies the amount, in device units, of horizontal scrolling. This parameter must be a negative value to scroll to the left.

dy

Specifies the amount, in device units, of vertical scrolling. This parameter must be a negative value to scroll up.

lprcScroll

Points to a **RECT** structure that specifies the portion of the client area to be scrolled. If this parameter is NULL, the entire client area is scrolled. The caret is repositioned if the cursor rectangle intersects the scroll rectangle.

The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

lprcClip

Points to a **RECT** structure that specifies the clipping rectangle to scroll. This structure takes precedence over the rectangle pointed to by *lprcScroll*. Only bits

	inside this rectangle are scrolled. Bits outside this rectangle are not scrolled, even if they are in the <i>lprcScroll</i> rectangle. If this parameter is NULL, no clipping is performed on the scroll rectangle.
Return Value	This function does not return a value.
Comments	If the caret is in the window being scrolled, ScrollWindow automatically hides the caret to prevent it from being erased, then restores the caret after the scroll is finished. The caret position is adjusted accordingly.
	The area uncovered by the ScrollWindow function is not repainted, but it is combined into the window's update region. The application will eventually receive a WM_PAINT message notifying it that the region needs repainting. To repaint the uncovered area at the same time the scrolling is done, call the UpdateWindow function immediately after calling ScrollWindow .
	If the <i>lprcScroll</i> parameter is NULL, the positions of any child windows in the window are offset by the amount specified by the <i>dx</i> and <i>dy</i> parameters, and any invalid (unpainted) areas in the window are also offset. ScrollWindow is faster when <i>lprcScroll</i> is NULL.
	If the <i>lprcScroll</i> parameter is not NULL, the positions of child windows are not changed and invalid areas in the window are not offset. To prevent updating problems when <i>lprcScroll</i> is not NULL, call the UpdateWindow function to repaint the window before calling ScrollWindow .
See Also	ScrollDC, ScrollWindowEx, UpdateWindow

ScrollWindowEx

3.1

int ScrollWindowEx(hwnd, dx, dy,	lprcScroll, lprcClip, hrgnUpdate, lprcUpdate,	fuScroll)
HWND hwnd;	/* handle of window to scroll	*/
int dx ;	/* amount of horizontal scrolling	*/
int dy;	/* amount of vertical scrolling	*/
<pre>const RECT FAR* lprcScroll;</pre>	/* address of structure with scroll rect.	*/
const RECT FAR* lprcClip;	/* address of structure with clip rect.	*/
HRGN hrgnUpdate;	/* handle of update region	*/
RECT FAR* <i>lprcUpdate</i> ;	/* address of structure for update rect.	*/
UINT fuScroll;	/* scrolling flags	*/

The **ScrollWindowEx** function scrolls the contents of a window's client area. This function is similar to the **ScrollWindow** function, with some additional features.

Parameters

hwnd

Identifies the window to be scrolled.

dx

Specifies the amount, in device units, of horizontal scrolling. This parameter must be a negative value to scroll to the left.

dy

Specifies the amount, in device units, of vertical scrolling. This parameter must be a negative value to scroll up.

lprcScroll

Points to a **RECT** structure that specifies the portion of the client area to be scrolled. If this parameter is NULL, the entire client area is scrolled. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

lprcClip

Points to a **RECT** structure that specifies the clipping rectangle to scroll. This structure takes precedence over the rectangle pointed to by the *lprcScroll* parameter. Only bits inside this rectangle are scrolled. Bits outside this rectangle are not affected even if they are in the *lprcScroll* rectangle. If this parameter is NULL, no clipping is performed on the scroll rectangle.

hrgnUpdate

Identifies the region that is modified to hold the region invalidated by scrolling. This parameter may be NULL.

lprcUpdate

Points to a **RECT** structure that will receive the boundaries of the rectangle invalidated by scrolling. This parameter may be NULL.

fuScroll

Specifies flags that control scrolling. This parameter can be one of the following values:

	Value	Meaning
	SW_ERASE	When specified with SW_INVALIDATE, erases the newly invalidated region by sending a WM_ERASEBKGND message to the window.
	SW_INVALIDATE	Invalidates the region identified by the <i>hrgnUpdate</i> parameter after scrolling.
	SW_SCROLLCHILDREN	Scrolls all child windows that intersect the rectangle pointed to by <i>lprcScroll</i> by the number of pixels specified in the <i>dx</i> and <i>dy</i> parameters. Windows sends a WM_MOVE message to all child windows that intersect <i>lprcScroll</i> , even if they do not move. The caret is repositioned when a child window is scrolled and the cursor rectangle intersects the scroll rectangle.
Return Value	COMPLEXREGION (nonrecta	EGION (rectangular invalidated region), angular invalidated region; overlapping rectangles), ated region), if the function is successful. Other- R.
Comments	not invalidate the area that is so ScrollWindowEx invalidates t tion calls the UpdateWindow	Y_ERASE are not specified, ScrollWindowEx does crolled away from. If either of these flags is set, his area. The area is not updated until the applica- function, calls the RedrawWindow function (speci- r RDW_ERASENOW), or retrieves the e application queue.
	hrgnUpdate and lprcUpdate re	PCHILDREN style, the returned areas specified by present the total area of the scrolled window that areas in child windows that need qupdating.
	date the screen if part of a child window that lies outside the so redrawn properly in its new dea	EN flag is specified, Windows will not properly up- d window is scrolled. The part of the scrolled child urce rectangle will not be erased and will not be stination. Use the DeferWindowPos function to of lie completely within the <i>lprcScroll</i> rectangle.
	<i>hrgnUpdate</i>) are assumed to be window has the CS_OWNDC	es (for <i>lprcScroll</i> , <i>lprcClip</i> , <i>lprcUpdate</i> , and e in client coordinates, regardless of whether the or CS_CLASSDC class style. Use the LPtoDP and o and from logical coordinates, if necessary.
See Also	RedrawWindow, ScrollDC, S	ScrollWindow, UpdateWindow

SelectClipRgn

int SelectClipRg	n(hdc, hrgn)
HDC hdc; HRGN hrgn;	/* handle of device context */ /* handle of region */
	The SelectClipRgn function selects the given region as the current clipping region for the given device context.
Parameters	<i>hdc</i> Identifies the device context.
	<i>hrgn</i> Identifies the region to be selected. If this value is NULL, the entire client area is selected and output is still clipped to the window.
Return Value	The return value is SIMPLEREGION (region has no overlapping borders), COMPLEXREGION (region has overlapping borders), or NULLREGION (region is empty), if the function is successful. Otherwise, the return value is ERROR.
Comments	The SelectClipRgn function selects only a copy of the specified region. Because SelectClipRgn uses only a copy, the region can be selected for any number of other device contexts or it can be deleted.
	The coordinates for the specified region should be specified in device units.
	Some printer devices support text output at a higher resolution than graphics output in order to retain the precision needed to express text metrics. These devices report device units at the higher resolution—that is, text units. These devices then scale coordinates for graphics so that several reported device units map to only one graphics unit. Applications should always call the SelectClipRgn function using the text unit. Applications that must take the scaling of graphics objects in the graphics device interface (GDI) can use the GETSCALINGFACTOR printer escape to determine the scaling factor. This scaling factor affects clipping. If a region is used to clip graphics, GDI divides the coordinates by the scaling factor. (If the region is used to clip text, however, GDI makes no scaling adjustment.) A scaling factor of 1 causes the coordinates to be divided by 2; a scaling factor of 2 causes the coordinates to be divided by 4; and so on.
Example	The following example uses the GetClipBox function to determine the size of the current clipping region and the GetTextExtent function to determine the width of a line of text. If the text will not fit in the clipping region, the SelectClipRgn is used to make the region wide enough for the text. The output is clipped to the window regardless of the size of the region specified in the second parameter of SelectClipRgion .

```
HRGN hrgnClip;
RECT rcClip;
LPSTR lpszTest = "Test of clipping region.";
DWORD dwStringLen;
WORD wExtent;
GetClipBox(hdc, &rcClip);
dwStringLen = GetTextExtent(hdc, lpszTest, lstrlen(lpszTest));
wExtent = LOWORD(dwStringLen);
if (rcClip.right < 50 + wExtent) {
    hrgnClip = CreateRectRgn(50, 50, 50 + wExtent, 80);
    SelectClipRgn(hdc, hrgnClip);
}
TextOut(hdc, 50, 60, lpszTest, lstrlen(lpszTest));
DeleteObject(hrgnClip);
```

SelectObject

HGDIOBJ SelectOl HDC hdc; HGDIOBJ hgdiobj;	/* handle	of device context */	
		bject function selects an object into the given device context. The eplaces the previous object of the same type.	
Parameters	<i>hdc</i> Identifies the device context.		
	<i>hgdiobj</i> Identifies the object to be selected. The object can be one of the following and must have been created by using one of the listed functions:		
	Object	Functions	
	Bitmap	CreateBitmap, CreateBitmapIndirect, CreateCompatibleBitmap, CreateDIBitmap	
	Brush	CreateBrushIndirect, CreateDIBPatternBrush, CreateHatchBrush, CreatePatternBrush, CreateSolidBrush	
	Font	CreateFont, CreateFontIndirect	
	Pen	CreatePen, CreatePenIndirect	

	Object	Functions
	Region	CreateEllipticRgn, CreateEllipticRgnIndirect, CreatePolygonRgn, CreateRoundRectRgn, CreateRectRgn, CreateRectRgnIndirect
Return Value		lue is the handle of the object being replaced, if the function is therwise, it is NULL.
	as the Select has no overlap borders), or N is ERROR an	parameter identifies a region, this function performs the same task ClipRgn function and the return value is SIMPLEREGION (region pping borders), COMPLEXREGION (region has overlapping IULLREGION (region is empty). If an error occurs, the return value d the previously selected object of the specified type remains e device context.
Comments	the system all segment space remove each of the application tion can selec	lication uses the SelectObject function to select a font, pen, or brush, ocates space for that object in its data segment. Because data- e is limited, an application should use the DeleteObject function to drawing object that it no longer requires. Before removing the object, n should select it out of the device context. To do this, the applica- t a different object of the same type back into the device context; different object is the original object for the device context.
	function does device contex to a value retu sults. Because	e parameter identifies a metafile device context, the SelectObject not return the handle of the previously selected object. When the t is a metafile, calling SelectObject with the <i>hgdiobj</i> parameter set urned by a previous call to SelectObject can cause unpredictable re- e metafiles perform their own object cleanup, an application need not ilt objects when recording a metafile.
	can select a bit text at a time.	ce contexts are the only device contexts into which an application itmap. A bitmap can be selected into only one memory device con- The format of the bitmap must either be monochrome or be compat- given device; if it is not, SelectObject returns an error.
Example	into a device	g example creates a pen, uses the SelectObject function to select it context, uses the pen to draw a rectangle, selects the previous pen device context, and uses the DeleteObject function to remove the sust created:
	HPEN hpen, h	penOld;
		ePen(PS_SOLID, 6, RGB(0, 0, 255)); electObject(hdc, hpen);
	Rectangle(hd	c, 10, 10, 100, 100);

.

```
SelectObject(hdc, hpenOld);
DeleteObject(hpen);
```

See Also DeleteObject, SelectClipRgn, SelectPalette

SelectPalette

3.0

HPALETTE Select HDC hdc; HPALETTE hpal; BOOL fPalBack;	Palette(hdc, hpal, fPalBack) /* handle of device context */ /* handle of palette */ /* flag for forcing palette to background */
	The SelectPalette function selects the specified logical palette into the given device context. The selected palette replaces the previous palette for that device context.
Parameters	 <i>hdc</i> Identifies the device context. <i>hpal</i> Identifies the logical palette to be selected. <i>fPalBack</i> Specifies whether the logical palette is always to be a background palette. If this parameter is nonzero, the selected palette is always a background palette. If this parameter is zero and the device context is attached to a window, the logical palette is a foreground palette when the window has the input focus. (The device context is attached to a window, the logical palette is a stached to a window if it was obtained by using the GetDC function or if the window-class style is CS_OWNDC.)
Return Value	The return value is the handle of the previous logical palette for the given device context, if the function is successful. Otherwise, it is NULL.
Comments	An application can select a logical palette into more than one device context. However, changes to a logical palette will affect all device contexts for which it is selected. If an application selects a palette into more than one device context, the device contexts must all belong to the same physical device.
Example	The following example calls the SelectPalette function to select a logical palette into a device context and then calls the RealizePalette function to change the palette size:

HPALETTE hpal, hPalPrevious; hdc = GetDC(hwnd); hPalPrevious = SelectPalette(hdc, hpal, FALSE); if (RealizePalette(hdc) == NULL) MessageBox(hwnd, "Can't realize palette", "Error", MB_OK); ReleaseDC(hwnd, hdc);

See Also CreatePalette, GetDC, RealizePalette

SendDlgItemMessage

HWND hwndDlg; int idDlgItem; UINT uMsg;	gItemMessage(hwndDlg, idDlgItem, uMsg, wParam, lParam) /* handle of dialog box */ /* identifier of dialog box item */ /* message */ /* first message parameter */ /* second message parameter */		
	The SendDlgItemMessage function sends a message to a control in a dialog box.		
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the control.		
	<i>idDlgItem</i> Specifies the identifier of the dialog item that will receive the message.		
	<i>uMsg</i> Specifies the message to be sent.		
	<i>wParam</i> Specifies 16 bits of additional message-dependent information.		
	<i>lParam</i> Specifies 32 bits of additional message-dependent information.		
Return Value	The return value specifies the result of the message processing and depends on the message sent.		
Comments	The SendDlgItemMessage function does not return until the message has been processed.		

3.1

Using **SendDlgItemMessage** is identical to retrieving a handle of the given control and calling the **SendMessage** function.

See Also PostMessage, SendMessage

SendDriverMessage

verMessage(hdrvr, msg, lParam1, lParam2)
/* handle of installable driver */
/* message */
/* first message parameter */
/* second message parameter */
The SendDriverMessage function sends the specified message to the given install- able driver.
<i>hdrvr</i> Identifies the installable driver.
<i>msg</i> Specifies the message that the driver must process. The following messages should never be sent by an application directly to the driver; they are sent only by the system:
DRV_CLOSE DRV_DISABLE DRV_ENABLE DRV_EXITAPPLICATION DRV_EXITSESSION DRV_FREE DRV_LOAD DRV_OPEN
<i>lParam1</i> Specifies 32 bits of additional message-dependent information.
<i>lParam2</i> Specifies 32 bits of additional message-dependent information.
The return value is nonzero if the function is successful. Otherwise, it is zero.
DefDriverProc

SendMessage

LRESULT SendMes HWND hwnd; UINT uMsg; WPARAM wParam; LPARAM lParam;	ssage(hwnd, uMsg, wParam, lParam) /* handle of destination window */ /* message to send */ /* first message parameter */ /* second message parameter */	
	The SendMessage function sends the specified message to the given window or windows. The function calls the window procedure for the window and does not return until that window procedure has processed the message. This is in contrast to the PostMessage function, which places (posts) the message in the window's message queue and returns immediately.	
Parameters	<i>hwnd</i> Identifies the window to which the message will be sent. If this parameter is HWND_BROADCAST, the message will be sent to all top-level windows, including disabled or invisible unowned windows.	
	<i>uMsg</i> Specifies the message to be sent.	
	wParam Specifies 16 bits of additional message-dependent information.	
	<i>lParam</i> Specifies 32 bits of additional message-dependent information.	
Return Value	The return value specifies the result of the message processing and depends on the message sent.	
Comments	If the message is being sent to another application and the <i>wParam</i> or <i>lParam</i> parameter is used to pass a handle or pointer to global memory, the memory should be allocated by the GlobalAlloc function using the GMEM_SHARE flag.	
Example	The following example calls the SendMessage function to send an EM_SETSEL message to a multiline edit control, telling it to select all the text. It then calls SendMessage to send a WM_COPY message to copy the selected text to the clipboard.	
	SendMessage(hwndMle, EM_SETSEL, 0, MAKELONG(0, -1)); SendMessage(hwndMle, WM_COPY, 0, 0L);	
See Also	InSendMessage, PostMessage, SendDlgItemMessage	

SetAbortProc

	dc, abrtprc) /* handle of device context */ tprc; /* instance address of abort function */
	The SetAbortProc function sets the application-defined procedure that allows a print job to be canceled during spooling. This function replaces the SETABORTPROC printer escape for Windows version 3.1.
Parameters	 <i>hdc</i> Identifies the device context for the print job. <i>abrtprc</i> Specifies the procedure-instance address of the callback function. The address must have been created by using the MakeProcInstance function. For more information about the callback function, see the description of the AbortProc callback function.
Return Value	The return value is greater than zero if the function is successful. Otherwise, it is less than zero.
See Also	AbortDoc, AbortProc, Escape

SetActiveWindow

HWND SetActive HWND hwnd;	Window (hwnd)/* handle of window to activate*/
	The SetActiveWindow function makes the specified top-level window the active window.
Parameters	<i>hwnd</i> Identifies the top-level window to be activated.
Return Value	The return value identifies the window that was previously active, if the function is successful.

3.1

Comments The **SetActiveWindow** function should be used with care, since it allows an application to arbitrarily take over the active window and input focus. Normally, Windows takes care of all activation.

See Also GetActiveWindow, SetCapture, SetFocus

SetBitmapBits

2.x

HBITMAP hbmp; DWORD cBits;	Bits(hbmp, cBits, lpvBits) /* handle of bitmap /* number of bytes in bitmap array vBits; /* address of array with bitmap bits	*/ */ */
	The SetBitmapBits function sets the bits of the g values.	iven bitmap, to the specified bit
Parameters	<i>hbmp</i> Identifies the bitmap to be set.	
	<i>cBits</i> Specifies the number of bytes pointed to by the <i>lpvBits</i> paramet	
	<i>lpvBits</i> Points to an array of bytes for the bitmap bits.	
Return Value	The return value is the number of bytes used in setting the bitmap bits, if the func- tion is successful. Otherwise, the return value is zero.	
See Also	GetBitmapBits	

SetBitmapDimension

DWORD SetBitmapDimension(hbmp, nWidth, nHeight)HBITMAP hbmp;/* handle of bitmapint nWidth;/* bitmap widthint nHeight;/* bitmap height

The **SetBitmapDimension** function assigns a width and height to a bitmap, in 0.1millimeter units. The graphics device interface (GDI) does not use these values except to return them when an application calls the **GetBitmapDimension** function.

3.1

Parameters	<i>hbmp</i> Identifies the bitmap.
	<i>nWidth</i> Specifies the bitmap width, in 0.1-millimeter units.
	<i>nHeight</i> Specifies the bitmap height, in 0.1-millimeter units.
Return Value	The return value is the dimensions of the previous bitmap, in 0.1-millimeter units, if the function is successful. The low-order word contains the previous width; the high-order word contains the previous height.
See Also	GetBitmapDimension

SetBitmapDimensionEx

	imensionEx(hbm, nX, nY, lpSize)		
HBITMAP hbm;	/* handle of bitmap	*/	
int nX ;	/* bitmap width	*/	
int nY ;	/* bitmap height	*/	
SIZE FAR* lpSize;	/* address of structure for prev. dimensions	*/	
	The SetBitmapDimensionEx function assigns the p 0.1-millimeter units. The graphics device interface (values, except to return them when an application ca DimensionEx function.	GDI) does not use these	
Parameters	hbm		
	Identifies the bitmap.		
	<i>nX</i> Specifies the width of the bitmap, in 0.1-millimeter units. <i>nY</i>		
	Specifies the height of the bitmap, in 0.1-millime	ter units.	
	<i>lpSize</i> Points to a SIZE structure. The previous bitmap of structure. If <i>lpSize</i> is NULL, nothing is returned. lowing form:		
	<pre>typedef struct tagSIZE { int cx; int cy; } SIZE;</pre>		

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

2.x

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

SetBkColor

COLORREF SetBkColor(*hdc*, *clrref*) HDC hdc; /* handle of device context */ **COLORREF** *clrref*; /* color specification */ The **SetBkColor** function sets the current background color to the specified color. **Parameters** hdc Identifies the device context. clrref Specifies the new background color. **Return Value** The return value is the RGB value of the previous background color, if the function is successful. The return value is 0x80000000 if an error occurs. Comments If the background mode is OPAQUE, the system uses the background color to fill the gaps in styled lines, the gaps between hatched lines in brushes, and the background in character cells. The system also uses the background color when converting bitmaps between color and monochrome device contexts. If the device cannot display the specified color, the system sets the background color to the nearest physical color. For information about color-bitmap conversions, see the descriptions of the **BitBlt** and StretchBlt functions. Example The following example uses the **GetBkColor** function to determine whether the current background color is white. If it is, the SetBkColor function sets it to red. DWORD dwBackColor: dwBackColor = GetBkColor(hdc): if (dwBackColor == RGB(255, 255, 255)) { /* if color is white */ SetBkColor(hdc, RGB(255, 0, 0)); /* sets color to red */ TextOut(hdc, 100, 200, "SetBkColor test.", 16);

}

See Also BitBlt, GetBkColor, GetBkMode, SetBkMode, StretchBlt

SetBkMod	е	2. x	
<pre>int SetBkMode(/ HDC hdc; int fnBkMode;</pre>	<i>hdc, fnBkMode)</i> /* handle of device con /* background mode	text */ */	
	mode defines whethe	ction sets the specified background mode. The background r the system removes existing background colors on the draw- awing text, hatched brushes, or any pen style that is not a	
Parameters	<i>hdc</i> Identifies the devic	ce context.	
	<i>fnBkMode</i> Specifies the background mode to be set. This parameter can be one of the fol- lowing values:		
	Value	Meaning	
	OPAQUE	Background is filled with the current background color before the text, hatched brush, or pen is drawn. This is the default background mode.	
	TRANSPARENT	Background is not changed before drawing.	
Return Value	The return value is th	e previous background mode, if the function is successful.	
Example	The following example determines the current background mode by calling the GetBkMode function. If the mode is OPAQUE, the SetBkMode function sets i to TRANSPARENT.		
	int nBackMode;		
	nBackMode = GetBkMo if (nBackMode == OF TextOut(hdc, 90 SetBkMode(hdc, }	PAQUE) {), 100, "This background mode is OPAQUE.", 31);	
See Also	GetBkColor, GetBk	Mode, SetBkColor	

SetBoundsRect

UINT SetBoundsR HDC hdc; const RECT FAR* UINT flags;		/* handle of /* address	of device context of structure for rectangle s information to return	*/ */ */
	The SetBoundsRect function controls the accumulation of bounding-rectangl formation for the specified device context.		of bounding-rectangle in-	
Parameters	<pre>hdc Identifies the device context to accumulate bounding rectangles for. lprcBounds Points to a RECT structure that is used to set the bounding rectangle. Rectangle dimensions are given in logical coordinates. This parameter can be NULL. The RECT structure has the following form: typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>			
	For a full de <i>mer's Refere</i>		this structure, see the <i>Micros</i> $e 3$.	oft Windows Program-
rectangle. This p			ectangle will be combined wi er may be a combination of th	
			Meaning	· · · · · · · · · · · · · · · · · · ·
	DCB_ACCUI	MULATE	Add the rectangle specified by ter to the bounding rectangle (operation).	
	DCB_DISAB	LE	Turn off bounds accumulation	1.
	DCB_ENABI	LE	Turn on bounds accumulation bounds accumulation is disable	
Return Value		e the <i>flags</i> p	rent state of the bounding rect parameter, the return value car	

Value	Meaning
DCB_ACCUMULATE	The bounding rectangle is not empty. (This value will always be set.)

3.1

2.x

	Value	Meaning
	DCB_DISABLE	Bounds accumulation is off.
	DCB_ENABLE	Bounds accumulation is on.
Comments	Windows can maintain a bounding rectangle for all drawing operations. This rectangle can be queried and reset by the application. The drawing bounds are useful for invalidating bitmap caches.	
See Also	GetBoundsRect	

SetBrushOrg

DWORD SetB HDC hdc;	BrushOrg(<i>hdc</i> , <i>nXOrg</i> , <i>nYOrg</i>) /* handle of device context */
int nXOrg; int nYOrg;	/* x-coordinate of new origin */ /* y-coordinate of new origin */
	The SetBrushOrg function specifies the origin that GDI will assign to the next brush an application selects into the specified device context.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXOrg</i> Specifies the x-coordinate, in device units, of the new origin. This value must be in the range 0 through 7.
	<i>nYOrg</i> Specifies the y-coordinate, in device units, of the new origin. This value must be in the range 0 through 7.
Return Value	The return value is the coordinates, in device units, of the previous origin, if the function is successful. The low-order word contains the x-coordinate; the high-order word contains the y-coordinate.
Comments	The default coordinates for the brush origin are $(0, 0)$.
	To alter the origin of a brush, an application should call the UnrealizeObject func- tion, specifying the handle of the brush for which the origin will be set; call SetBrushOrg ; and then call the SelectObject function to select the brush into the device context.
	The SetBrushOrg function should not be used with stock objects.

Example The following example uses the SetBrushOrg function to shift the brush origin vertically by 5 pixels: HBRUSH hbr, hbr01d; SetBkMode(hdc, TRANSPARENT); hbr = CreateHatchBrush(HS_CROSS, RGB(0, 0, 0)); UnrealizeObject(hbr); SetBrushOrg(hdc, 0, 0); hbrOld = SelectObject(hdc, hbr); Rectangle(hdc, 0, 0, 200, 200); hbr = SelectObject(hdc, hbrOld); /* deselects hbr */ UnrealizeObject(hbr); /* resets origin next time hbr selected */ SetBrushOrg(hdc, 3, 5); hbr0ld = SelectObject(hdc, hbr); /* selects hbr again */ Rectangle(hdc, 0, 0, 200, 200); SelectObject(hdc, hbr0ld); DeleteObject(hbr);

See Also GetBrushOrg, SelectObject, UnrealizeObject

SetCa	pture
-------	-------

HWND SetCapt	ure(hwnd)	
HWND hwnd;	/* handle of window to receive all mouse messages */	
	The SetCapture function sets the mouse capture to the specified window. With the mouse capture set to a window, all mouse input is directed to that window, regardless of whether the cursor is over that window. Only one window can have the mouse capture at a time.	
Parameters	<i>hwnd</i> Identifies the window that is to receive all mouse messages.	
Return Value	The return value is the handle of the window that previously received all mouse input, if the function is successful. It is NULL if there is no such window.	
Comments	When the window no longer requires all mouse input, the application should call the ReleaseCapture function so that other windows can receive mouse input.	

See Also ReleaseCapture

SetCaretBlinkTime

void SetCaretBlink' UINT uMSeconds;	Time(uMSeconds)/* blink rate in milliseconds*/
	The SetCaretBlinkTime function sets the caret blink rate. The blink rate is the elapsed time, in milliseconds, between caret flashes.
Parameters	<i>uMSeconds</i> Specifies the new blink rate, in milliseconds.
Return Value	This function does not return a value.
Comments	The caret flashes on or off every <i>uMSeconds</i> milliseconds. One complete flash (off-on) takes twice <i>uMSeconds</i> milliseconds.
	The caret is a shared resource. A window should set the caret blink rate only if it owns the caret. It should restore the previous rate before it loses the input focus or becomes inactive.
See Also	GetCaretBlinkTime

SetCaretPos

<pre>void Set@ int x; int y;</pre>	CaretPos(x, y) /* horizontal position /* vertical position	*/ */
	The SetCar	etPos function sets the position of the caret.
Paramete	Specifies y	the new x-coordinate, in client coordinates, of the caret.
Return V	alue This function	n does not return a value.

2.x

Comments The **SetCaretPos** function moves the caret only if it is owned by a window in the current task. **SetCaretPos** moves the caret whether or not the caret is hidden.

The caret is a shared resource. A window should not move the caret if it does not own the caret.

See Also GetCaretPos

SetClassLong

LONG SetClass HWND hwnd; int nIndex; LONG nVal;	Long(hwnd, nIndex, nVal) /* handle of window */ /* index of value to change */ /* new value */
	The SetClassLong function sets a long value at the specified offset into the extra class memory for the window class to which the specified window belongs. Extra class memory is reserved by specifying a nonzero value in the cbClsExtra member of the WNDCLASS structure used with the RegisterClass function.
Parameters	<i>hwnd</i> Identifies the window.
	<i>nIndex</i> Specifies the zero-based byte offset of the long value to change. Valid values are in the range zero through the number of bytes of class memory, minus four. (For example, if 12 or more bytes of extra class memory were specified, a value of 8 would be an index to the third long integer.) This parameter can also be GCL_WNDPROC, which sets a new long pointer to the window procedure. <i>nVal</i>
	Specifies the replacement value.
Return Value	The return value is the previous value of the specified long integer, if the function is successful. Otherwise, it is zero.
Comments	If the SetClassLong function and GCL_WNDPROC index are used to set a win- dow procedure, the specified window procedure must have the window-procedure form and be exported in the module-definition file. For more information, see the description of the RegisterClass function.
	Calling SetClassLong with the GCL_WNDPROC index creates a subclass of the window class that affects all windows subsequently created by using the class.

Applications should not call **SetClassLong** with the GCL_MENUNAME value.

To access any extra 4-byte values allocated when the window-class structure was created, use a positive byte offset as the index specified by the *nIndex* parameter, starting at 0 for the first 4-byte value in the extra space, 4 for the next 4-byte value, and so on.

See Also GetClassLong, RegisterClass, SetClassWord

SetClassWor	rd	2.x		
WORD SetClassWo HWND hwnd; int nIndex; WORD wNewWord;	ord(<i>hwnd</i> , <i>nIndex</i> , <i>wNewWord</i>) /* handle of window /* index of value to change /* new value	*/ */ */		
	class memory for the window cla class memory is reserved by spec	a word value at the specified offset into the extra ass to which the given window belongs. Extra bifying a nonzero value in the cbClsExtra mem- e used with the RegisterClass function.		
Parameters	<i>hwnd</i> Identifies the window.			
	<i>nIndex</i> Specifies the zero-based byte offset of the word value to change. Valid values are in the range zero through the number of bytes of class memory, minus two (for example, if 10 or more bytes of extra class memory were specified, a value of 8 would be an index to the fifth integer), or one of the following values:			
	Value Meaning			
	GCW_HBRBACKGROUND	Sets a new handle of a background brush.		
	GCW_HCURSOR	Sets a new handle of a cursor.		
	GCW_HICON	Sets a new handle of an icon.		
	GCW_STYLE	Sets a new style bit for the window class.		
	wNewWord Specifies the replacement value	1e.		
Return Value	The return value is the previous successful. Otherwise, it is zero.	value of the specified word, if the function is		

CommentsThe SetClassWord function should be used with care. For example, it is possible
to change the background color for a class by using SetClassWord, but this
change does not cause all windows belonging to the class to be repainted immedi-
ately. Applications should not attempt to set the class word values of any class at-
tribute except those listed for the *nIndex* parameter.To access any extra 2-byte values allocated when the window-class structure was
created, use a positive byte offset as the index specified by the *nIndex* parameter,
starting at 0 for the first 2-byte value in the extra space, 2 for the next 2-byte
value, and so on.See AlsoGetClassWord, RegisterClass, SetClassLong

SetClipboardData

HANDLE SetClipbe UINT uFormat; HANDLE hData;	oardData(uFormat, hData) /* clipboard format */ /* data handle */
	The SetClipboardData function sets the data in the clipboard. The application must have called the OpenClipboard function before calling the SetClipboard-Data function.
Parameters	<i>uFormat</i> Specifies the format of the data. It can be any one of the system-defined for- mats or a format registered by the RegisterClipboardFormat function. For a list of system-defined formats, see the following Comments section.
	<i>hData</i> Identifies the data to be placed in the clipboard. For all formats except CF_BITMAP and CF_PALETTE, this parameter must be a handle of the memory allocated by the GlobalAlloc function. For CF_BITMAP format, the <i>hData</i> parameter is a bitmap handle (see the description of the LoadBitmap function). For the CF_PALETTE format, <i>hData</i> is a palette handle (see the de- scription of the CreatePalette function).
	If this parameter is NULL, the owner of the clipboard will be sent a WM_RENDERFORMAT message when it must supply the data.
Return Value	The return value is a handle of the data, if the function is successful. Otherwise, it is NULL.

Comments

If the *hData* parameter contains a handle of the memory allocated by the **GlobalAlloc** function, the application must not use this handle once it has called the **SetClipboardData** function.

Following are the system-defined clipboard formats:

Value	Meaning
CF_BITMAP	The data is a bitmap.
CF_DIB	The data is a memory object containing a BITMAPINFO structure followed by the bitmap data.
CF_DIF	The data is in Data Interchange Format (DIF).
CF_DSPBITMAP	The data is a bitmap representation of a private format. This data is displayed in bitmap format in lieu of the pri- vately formatted data.
CF_DSPMETAFILEPICT	The data is a metafile representation of a private data format. This data is displayed in metafile-picture format in lieu of the privately formatted data.
CF_DSPTEXT	The data is a textual representation of a private data for- mat. This data is displayed in text format in lieu of the privately formatted data.
CF_METAFILEPICT	The data is a metafile (see the description of the META- FILEPICT structure in the <i>Microsoft Windows Pro-</i> <i>grammer's Reference</i> , <i>Volume 3</i>).
CF_OEMTEXT	The data is an array of text characters in the OEM char- acter set. Each line ends with a carriage return–linefeed (CR–LF) combination. A null character signals the end of the data.
CF_OWNERDISPLAY	The data is in a private format that the clipboard owner must display.
CF_PALETTE	The data is a color palette.
CF_PENDATA	The data is for the pen extensions to the Windows oper- ating system.
CF_RIFF	The data is in Resource Interchange File Format (RIFF).
CF_SYLK	The data is in Microsoft Symbolic Link (SYLK) format.
CF_TEXT	The data is an array of text characters. Each line ends with a carriage return–linefeed (CR–LF) combination. A null character signals the end of the data.
CF_TIFF	The data is in Tag Image File Format (TIFF).
CF_WAVE	The data describes a sound wave. This is a subset of the CF_RIFF data format; it can be used only for RIFF WAVE files.

Private data formats in the range CF_PRIVATEFIRST through CF_PRIVATELAST are not automatically freed when the data is removed from

the clipboard. Data handles associated with these formats should be freed upon receiving a WM_DESTROYCLIPBOARD message.

Private data formats in the range CF_GDIOBJFIRST through CF_GDIOBJLAST will be automatically removed by a call to the **DeleteObject** function when the data is removed from the clipboard.

If Windows Clipboard is running, it will not update its window to show the data placed in the clipboard by the **SetClipboardData** until after the **CloseClipboard** function is called.

See Also CloseClipboard, GetClipboardData, GlobalAlloc, OpenClipboard, RegisterClipboardFormat

SetClipboardViewer

Parameters

HWND SetClipboardViewer(hwnd)

HWND hwnd; /* handle of clipboard viewer */

hwnd

The **SetClipboardViewer** function adds the given window to the chain of windows that are notified (by means of the WM_DRAWCLIPBOARD message) whenever the contents of the clipboard are changed.

Identifies the window to receive clipboard-viewer chain messages.

Return Value The return value is the handle of the next window in the clipboard-viewer chain, if the function is successful.

Comments Applications should save this handle in static memory and use it when responding to clipboard-viewer chain messages.

Windows that are part of the clipboard-viewer chain must respond to WM_CHANGECBCHAIN, WM_DRAWCLIPBOARD, and WM_DESTROY messages.

To remove itself from the clipboard-viewer chain, an application must call the **ChangeClipboardChain** function.

See Also ChangeClipboardChain, GetClipboardViewer

2.x

2.x

SetCommBreak

int SetCommBreak(idComDev)int idComDev;/* device to suspend */		
	The SetCommBreak function suspends character transmission and places the communications device in a break state.	
Parameters	<i>idComDev</i> Specifies the communications device to be suspended. The OpenComm func- tion returns this value.	
Return Value	The return value is zero if the function is successful. Otherwise, it is less than zero.	
Comments	The communications device remains suspended until the application calls the ClearCommBreak function.	
See Also	ClearCommBreak, OpenComm	

SetCommEventMask

UINT FAR* SetCo int idComDev; UINT fuEvtMask;	mmEventMask(<i>idC</i> /* device to enab /* events to enab	le */	
	The SetCommEve specified communi	entMask function enables events in the event word of the ications device.	
Parameters	<i>idComDev</i> Specifies the communications device to be enabled. The OpenComm function returns this value.		
	<i>fuEvtMask</i> Specifies which events are to be enabled. This parameter can be any combina- tion of the following values:		
	Value Meaning		
	EV_BREAK	Set when a break is detected on input.	
	EV_CTS	Set when the CTS (clear-to-send) signal changes state.	
	EV_CTSS	Set to indicate the current state of the CTS signal.	
	EV_DSR	Set when the DSR (data-set-ready) signal changes state.	

	Value	Meaning
	EV_ERR	Set when a line-status error occurs. Line-status errors are CE_FRAME, CE_OVERRUN, and CE_RXPARITY.
	EV_PERR	Set when a printer error is detected on a parallel device. Errors are CE_DNS, CE_IOE, CE_LOOP, and CE_PTO.
	EV_RING	Set to indicate the state of ring indicator during the last modem interrupt.
	EV_RLSD	Set when the RLSD (receive-line-signal-detect) signal changes state.
	EV_RLSDS	Set to indicate the current state of the RLSD signal.
	EV_RXCHAR	Set when any character is received and placed in the receiving queue.
	EV_RXFLAG	Set when the event character is received and placed in the re- ceiving queue. The event character is specified in the device's control block.
	EV_TXEMPTY	Set when the last character in the transmission queue is sent.
Return Value	The return value is a pointer to the event word for the specified communications device, if the function is successful. Each bit in the event word specifies whether a given event has occurred. A bit is 1 if the event has occurred.	
Comments	Only enabled events are recorded. The GetCommEventMask function retrieves and clears the event word.	
See Also	GetCommEventMask, OpenComm	

SetCommState

int SetCommState(<i>l</i> const DCB FAR* <i>lp</i>	
	The SetCommState function sets a communications device to the state specified by a device control block.
Parameters	<i>lpdcb</i> Points to a DCB structure that contains the desired communications settings for the device. The Id member of the DCB structure must identify the device. The DCB structure has the following form:

BYTE Id;			internal device identifier	
UINT BaudRate;			baud rate	
BYTE ByteSize;			number of bits/byte, 4-8	
BYTE Parity;			0–4=none,odd,even,mark,space	
BYTE StopBits;			0,1,2 = 1, 1.5, 2	
UINT RlsTimeout;			timeout for RLSD to be set	
UINT CtsTimeout;			timeout for CTS to be set	
UINT DsrTimeout;		/*	timeout for DSR to be set	
UINT fBinary	:1;		binary mode (skip EOF check)	
UINT fRtsDisable	:1;		don't assert RTS at init time	
UINT fParity	:1;		enable parity checking	
UINT fOutxCtsFlow	:1;		CTS handshaking on output	
UINT fOutxDsrFlow	:1;		DSR handshaking on output	
UINT fDummy	:2;		reserved	
UINT fDtrDisable	:1;	/*	don't assert DTR at init time	
UINT fOutX	:1;		enable output XON/XOFF	
UINT fInX	:1;		enable input XON/XOFF	
UINT fPeChar	:1;		enable parity err replacement	
UINT fNull	:1;		enable null stripping	
UINT fChEvt	:1;		enable Rx character event	
UINT fDtrflow	:1;		DTR handshake on input	
UINT fRtsflow	:1;	/*	RTS handshake on input	
UINT fDummy2	:1;			
char XonChar;		-	Tx and Rx XON character	
char XoffChar;		-	Tx and Rx XOFF character	
UINT XonLim;			transmit XON threshold	
UINT XoffLim;			transmit XOFF threshold	
char PeChar;			parity error replacement char	
char EofChar;			end of Input character	
char EvtChar;		/*	received event character	

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

Return Value The return value is zero if the function is successful. Otherwise, it is less than zero.

Example The following example uses the **BuildCommDCB** and **SetCommState** functions to set up COM1 at 9600 baud, no parity, 8 data bits, and 1 stop bit:

```
idComDev = OpenComm("COM1", 1024, 128);
if (idComDev < 0) {
    ShowError(idComDev, "OpenComm");
    return 0;
}
err = BuildCommDCB("COM1:9600,n,8,1", &dcb);
if (err < 0) {
    ShowError(err, "BuildCommDCB");
    return 0;
}
err = SetCommState(&dcb);
if (err < 0) {
    ShowError(err, "SetCommState");
    return 0;
}
```

Comments

This function reinitializes all hardware and controls as defined by the **DCB** structure, but it does not empty transmission or receiving queues.

See Also GetCommState

SetCursor

HCURSOR SetCur HCURSOR hcur;	rsor(<i>hcur</i>) /* handle of cursor */
	The SetCursor function changes the given cursor.
Parameters	<i>hcur</i> Identifies the cursor resource. The resource must have been loaded by using the LoadCursor function. If this parameter is NULL, the cursor is removed from the screen.
Return Value	The return value is the handle of the previous cursor, if the function is successful. It is NULL if there is no previous cursor.
Comments	The cursor is set only if the new cursor is different from the previous cursor; otherwise, the function returns immediately. The function is quite fast if the new cursor is the same as the old.

The cursor is a shared resource. A window should set the cursor only when the cursor is in the window's client area or when the window is capturing all mouse input. In systems without a mouse, the window should restore the previous cursor before the cursor leaves the client area or before the window relinquishes control to another window.

Any application that must set the cursor while it is in a window must ensure that the class cursor for the given window's class is set to NULL. If the class cursor is not NULL, the system restores the previous shape each time the mouse is moved.

See Also GetCursor, LoadCursor, ShowCursor

SetCursorPo)S		2.x
<pre>void SetCursorPos(x, y) int x; /* horizontal position int y; /* vertical position</pre>		*/ */	
	If the new c ClipCurson	rsorPos function sets the position, in screen coordinates, of the coordinates are not within the screen rectangle set by the most recordination, Windows automatically adjusts the coordinates so that within the rectangle.	cent
Parameters	y	s the new x-coordinate, in screen coordinates, of the cursor.	
Return Value	This function	on does not return a value.	
Comments		is a shared resource. A window should move the cursor only whe	en the

SetDIBits

int SetDIBits(hdc, hbmp, uStartScan, cScanLines, lpvBits, lpbmi, fuColorUse) HDC hdc; /* handle of device context */ **HBITMAP** *hbmp*; /* handle of bitmap */ **UINT** *uStartScan*: /* starting scan line */ **UINT** cScanLines: /* number of scan lines */ const void FAR* *lpvBits*; /* address of array with bitmap bits */ **BITMAPINFO FAR*** *lpbmi*: /* address of structure with bitmap data */ */ **UINT** fuColorUse: /* type of color indices to use

> The **SetDIBits** function sets the bits of a bitmap to the values given in a deviceindependent bitmap (DIB) specification.

Parameters

Identifies the device context.

hbmp

hdc

Identifies the bitmap to set the data in.

uStartScan

Specifies the zero-based scan number of the first scan line in the buffer pointed to by the *lpvBits* parameter.

cScanLines

Specifies the number of scan lines in the *lpvBits* buffer to copy into the bitmap identified by the *hbmp* parameter.

lpvBits

}

Points to the device-independent bitmap bits that are stored as an array of bytes. The format of the bitmap values depends on the **biBitCount** member of the **BITMAPINFOHEADER** structure, which is the first member of the **BITMAPINFO** structure pointed to by the *lpbmi* parameter.

The **BITMAPINFOHEADER** structure has the following form:

```
typedef struct tagBITMAPINFOHEADER { /* bmih */
```

DWORD	biSize;
LONG	biWidth;
LONG	biHeight;
WORD	biPlanes;
WORD	biBitCount;
DWORD	biCompression;
DWORD	biSizeImage;
LONG	biXPelsPerMeter;
LONG	biYPelsPerMeter;
DWORD	biClrUsed;
DWORD	biClrImportant;
BITMAPINF	OHEADER;

3.0

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

lpbmi

Points to a **BITMAPINFO** structure that contains information about the deviceindependent bitmap. The BITMAPINFO structure has the following form:

```
typedef struct tagBITMAPINFO { /* bmi */
   BITMAPINFOHEADER
                        bmiHeader;
   RGBQUAD
                        bmiColors[1];
} BITMAPINFO;
```

For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3.

fuColorUse

Specifies whether the bmiColors member of the BITMAPINFO structure contains explicit RGB values or indices into the currently realized logical palette. This parameter must be one of the following values:

	Value	Meaning
	DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the palette of the device context identified by the <i>hdc</i> parameter.
	DIB_RGB_COLORS	The color table contains literal RGB values.
Return Value	The return value is the nu Otherwise, it is zero.	mber of scan lines copied, if the function is successful.
Comments	 The bitmap identified by the <i>hbmp</i> parameter must not be selected into a device context when the application calls this function. To reduce the amount of memory required to set bits from a large device-independent bitmap on a device surface, an application can band the output by repeatedly calling the SetDIBitsToDevice function, placing a different portion of the entire bitmap into the <i>lpvBits</i> buffer each time. The values of the <i>uStartScan</i> and <i>cScanLines</i> parameters identify the portion of the entire bitmap that is contained in the <i>lpvBits</i> buffer. The origin of a device-independent bitmap is the bottom-left corner of the bitmap, not the top-left corner, which is the origin when the mapping mode is MM_TEXT GDI performs the necessary transformation to display the image correctly. 	
See Also	SetDIBitsToDevice	

SetDIBitsToDevice

int SetDIBitsToDevice(hdc, XDest, YDest, cx, cy, XSrc, YSrc, uStartScan, cScanLines, lpvBits, lpbmi, fuColorUse)

jucolor Use)		
HDC hdc;	/* handle of device context	*/
int XDest;	/* x-coordinate origin of destination rect	*/
int YDest;	/* y-coordinate origin of destination rect	*/
int cx;	/* rectangle width	*/
int cy;	/* rectangle height	*/
int XSrc;	/* x-coordinate origin of source rect	*/
int YSrc;	/* y-coordinate origin of source rect	*/
UINT uStartScan;	/* number of first scan line in array	*/
UINT cScanLines;	/* number of scan lines	*/
void FAR* lpvBits;	/* address of array with DIB bits	*/
BITMAPINFO FAR* lpbmi;	/* address of structure with bitmap info	*/
UINT fuColorUse;	/* RGB or palette indices	*/

The **SetDIBitsToDevice** function sets bits from a device-independent bitmap (DIB) directly on a device surface. The device coordinates specified define a rectangle within the total bitmap. **SetDIBitsToDevice** sets the bits in this rectangle directly on the display surface of the output device associated with the given device context, at the specified logical coordinates.

Parameters

hdc

Identifies the device context.

XDest

Specifies the logical x-coordinate of the origin of the destination rectangle.

YDest

Specifies the logical y-coordinate of the origin of the destination rectangle.

сх

Specifies the x-extent, in device units, of the rectangle in the bitmap.

су

Specifies the y-extent, in device units, of the rectangle in the bitmap.

XSrc

Specifies the x-coordinate, in device units, of the source rectangle in the bitmap.

YSrc

Specifies the y-coordinate, in device units, of the source rectangle in the bitmap.

uStartScan

Specifies the scan-line number of the device-independent bitmap that is contained in the first scan line of the buffer pointed to by the *lpvBits* parameter.

cScanLines

Specifies the number of scan lines in the *lpvBits* buffer to copy to the device.

lpvBits

Points to the DIB bits that are stored as an array of bytes.

lpbmi

Points to a **BITMAPINFO** structure that contains information about the bitmap. The **BITMAPINFO** structure has the following form:

```
typedef struct tagBITMAPINFO { /* bmi */
BITMAPINFOHEADER bmiHeader;
RGBQUAD bmiColors[1];
} BITMAPINFO;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, Volume 3.

fuColorUse

lpvBits buffer.

Specifies whether the **bmiColors** member of the *lpbmi* parameter contains explicit RGB values or indices into the currently realized logical palette. This parameter must be one of the following values:

	Value	Meaning
	DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
	DIB_RGB_COLORS	The color table contains literal RGB values.
Return Value	The return value is the m	umber of scan lines set, if the function is successful.
Comments	The origin of a device-independent bitmap is the bottom-left corner of the bitmap, not the top-left corner, which is the origin when the mapping mode is MM_TEXT. GDI performs the necessary transformation to display the image correctly. To reduce the amount of memory required to set bits from a large device-independent bitmap on a device surface, an application can band the output by repeatedly calling SetDIBitsToDevice , placing a different portion of the entire bitmap into the <i>lpvBits</i> buffer each time. The values of the <i>uStartScan</i> and <i>cScan-Lines</i> parameters identify the portion of the entire bitmap that is contained in the

SetDigitemInt

HWND hwndDlg;	/* identifier of control */		
Parameters	<i>hwndDlg</i> Identifies the dialog box that contains the control.		
	<i>idControl</i> Specifies the control to be changed.		
	<i>uValue</i> Specifies the integer value used to generate the item text.		
	fSigned Specifies whether the <i>uValue</i> parameter is signed or unsigned. If this parameter is TRUE, <i>uValue</i> is signed. If this parameter is TRUE and <i>uValue</i> is less than zero, a minus sign is placed before the first digit in the string. If this parameter is FALSE, <i>uValue</i> is unsigned.		
Return Value	This function does not return a value.		
Comments	SetDlgItemInt sends a WM_SETTEXT message to the given control.		
See Also	GetDlgItemInt, SetDlgItemText		

SetDIgItemText

<pre>void SetDlgItemText(hwndDlg, idControl, lpsz)</pre>			
HWND hwndDlg;	/* handle of dialog box	*/	
int idControl;	/* identifier of control	*/	
LPCSTR lpsz;	/* text to set	*/	
• '			

The SetDlgItemText function sets the title or text of a control in a dialog box.

Parameters

hwndDlg Identifies the dialog box that contains the control. 2.x

2.x

	<i>idControl</i> Identifies the control whose text is to be set.	
	<i>lpsz</i> Points to the null-terminated string that contains the text to be copied to the con- trol.	
Return Value	This function does not return a value.	
Comments	The SetDlgItemText function sends a WM_SETTEXT message to the given control.	
See Also	GetDlgItemText, SetDlgItemInt	

SetDoubleClickTime

void SetDoubleClickTime(uInterval)

UINT uInterval;	/* double-click interval */
	The SetDoubleClickTime function sets the double-click time for the mouse. A double-click is a series of two clicks of the mouse button, the second occurring within a specified time after the first. The double-click time is the maximum number of milliseconds that may occur between the first and second clicks of a double-click.
Parameters	<i>uInterval</i> Specifies the number of milliseconds that can occur between double-clicks.
Return Value	This function does not return a value.
Comments	If the <i>uInterval</i> parameter is zero, Windows uses the default double-click time of 500 milliseconds.
	The SetDoubleClickTime function alters the double-click time for all windows in the system.
See Also	GetDoubleClickTime

SetErrorMode

}

UINT SetErrorMod UINT fuErrorMode;		*/	
	The SetErrorMode function controls whether Windows handles MS-DOS Inter- rupt 24h errors or allows the calling application to handle them.		
Parameters	<i>fuErrorMode</i> Specifies the error-mode flag. The flag can be a combination of the following values:		
	Value	Meaning	
	SEM_FAILCRITICALERRORS	Windows does not display the critical-error- handler message box and returns the error to the calling application.	
	SEM_NOGPFAULTERRORBOX	Windows does not display the general-pro- tection-fault message box. This flag should be set <i>only</i> by debugging applications that handle GP faults themselves.	
	SEM_NOOPENFILEERRORBOX	Windows does not display a message box when it fails to find a file.	
Return Value	The return value is the previous state of the error-mode flag, if the function is successful.		
Example	The following example uses the SetErrorMode function to turn off the file-not-found message box (the application handles this error itself):		
	/* Turn off the "File not found" error box. */		
	<pre>SetErrorMode(SEM_NOOPENFILEERRORBOX);</pre>		
	/* Load the TOOLHELP.DLL library module. */		
	hinstToolHelp = LoadLibrary("TOOLHELP.DLL");		
	if (hinstToolHelp > HINSTANCE_ER	ROR) { /* loaded successfully */	
. /* Use the DLL here. */			

```
else {
    strcpy(szBuf, "LoadLibrary failed");
}
MessageBox(NULL, szBuf, "Library Functions", MB_ICONHAND);
```

SetFocus

HWND SetFocus(hwnd) HWND hwnd; /* handle of window to receive focus */		
	The SetFocus function sets the input focus to the given window. All subsequent keyboard input is directed to this window. The window, if any, that previously had the input focus loses it.	
Parameters	<i>hwnd</i> Identifies the window to receive the keyboard input. If this parameter is NULL, keystrokes are ignored.	
Return Value	The return value identifies the window that previously had the input focus, if the function is successful. It is NULL if there is no such window or if the specified handle is invalid.	
Comments	The SetFocus function sends a WM_KILLFOCUS message to the window that loses the input focus and a WM_SETFOCUS message to the window that receives the input focus. It also activates either the window that receives the focus or the parent of the window that receives the focus.	
	If a window is active but does not have the focus (that is, no window has the focus), any key pressed will produce the WM_SYSCHAR, WM_SYSKEYDOWN, or WM_SYSKEYUP message. If the VK_MENU key is also pressed, the <i>lParam</i> parameter of the message will have bit 30 set. Otherwise, the messages that are produced do <i>not</i> have this bit set.	
See Also	GetActiveWindow, GetFocus, SetActiveWindow, SetCapture	

SetHandleCount

UINT SetHandleCount(cHandles)UINT cHandles;/* number of file handles needed*/	
	The SetHandleCount function changes the number of file handles available to a task.
Parameters	<i>cHandles</i> Specifies the number of file handles the application requires. This count cannot be greater than 255.
Return Value	The return value is the number of file handles available to the application, if the function is successful. This number may be less than the number of handles specified.
Comments	By default, the maximum number of file handles available to a task is 20.
Example	The following example uses the SetHandleCount function to set the number of available file handles to 30:
	UINT cHandles; char szBuf[80];
	cHandles = SetHandleCount(30);
	sprintf(szBuf, "%d handles available", cHandles); MessageBox(hwnd, szBuf, "SetHandleCount", MB_OK);

SetKeyboardState

2.x

void SetKeyboardState(lpbKeyState)
BYTE FAR* lpbKeyState; /* address of array with virtual-key codes */

The **SetKeyboardState** function copies a 256-byte array of keyboard key states into the Windows keyboard-state table.

Parameters

lpbKeyState

Points to a 256-byte array that contains keyboard key states.

2.x

Return Value	This function does not return a value.
Comments	In many cases, an application should call the GetKeyboardState function first to initialize the 256-byte array. The application should then change the desired bytes.
	SetKeyboardState sets the LEDs and BIOS flags for the NUMLOCK, CAPSLOCK, and SCROLL LOCK keys according to the toggle state of the VK_NUMLOCK, VK_CAPITAL, and VK_SCROLL entries of the array.
	For more information, see the description of the GetKeyboardState function.
Example	The following example simulates the pressing of the CTRL key:
	BYTE pbKeyState[256];
	GetKeyboardState((LPBYTE) &pbKeyState); pbKeyState[VK_CONTROL] = 0x80; SetKeyboardState((LPBYTE) &pbKeyState);
See Also	GetKeyboardState

SetMapMode

<pre>int SetMapMode(h HDC hdc; int fnMapMode;</pre>	ndc, fnMapMode) /* handle of device context /* mapping mode to set	*/ */
	The mapping mode defines the device units; it also defines the	ets the mapping mode of the given device context. e unit of measure used to convert logical units to e orientation of the device's x- and y-axes. GDI uses logical coordinates into the appropriate device
Parameters	<i>hdc</i> Identifies the device contex	t.
	<i>fnMapMode</i> Specifies the new mapping ing values:	mode. This parameter can be any one of the follow-

	Value	Meaning
	MM_ANISOTROPIC	Logical units are converted to arbitrary units with arbitrarily scaled axes. Setting the mapping mode to MM_ANISOTROPIC does not change the current win- dow or viewport settings. To change the units, orienta- tion, and scaling, an application should use the SetWindowExt and SetViewportExt functions.
	MM_HIENGLISH	Each logical unit is converted to 0.001 inch. Positive x is to the right; positive y is up.
	MM_HIMETRIC	Each logical unit is converted to 0.01 millimeter. Positive x is to the right; positive y is up.
	MM_ISOTROPIC	Logical units are converted to arbitrary units with equally scaled axes; that is, one unit along the x-axis is equal to one unit along the y-axis. The SetWindowExt and SetViewportExt functions must be used to specify the desired units and the orientation of the axes. GDI makes adjustments as necessary to ensure that the x and y units remain the same size.
	MM_LOENGLISH	Each logical unit is converted to 0.01 inch. Positive x is to the right; positive y is up.
	MM_LOMETRIC	Each logical unit is converted to 0.1 millimeter. Positive x is to the right; positive y is up.
	MM_TEXT	Each logical unit is converted to one device pixel. Posi- tive x is to the right; positive y is down.
	MM_TWIPS	Each logical unit is converted to 1/20 of a point. (Be- cause a point is 1/72 inch, a twip is 1/(1440 inch). Positive x is to the right; positive y is up.
Return Value	The return value is the pre	evious mapping mode, if the function is successful.
Comments		ows applications to work in device pixels, where one The physical size of a pixel varies from device to device.
	MM_LOMETRIC, and M	MM_HIMETRIC, MM_LOENGLISH, IM_TWIPS modes are useful for applications that must ngful units (such as inches or millimeters).
	The MM_ISOTROPIC m important to preserve the	ode ensures a 1:1 aspect ratio, which is useful when it is exact shape of an image.
	The MM_ANISOTROPIC dependently.	C mode allows the x- and y-coordinates to be adjusted in-
Example		ses the SetMapMode function to set the mapping mode uses the CreateFont function to create an 18-point logi-

2.x

HFONT hfont, hfontOld; int MapModePrevious, iPtSize = 18; PSTR pszFace = "MS Serif"; MapModePrevious = SetMapMode(hdc, MM_TWIPS); hfont = CreateFont(-iPtSize * 20, 0, 0, 0, 0, 0, /* specify pt size */ 0, 0, 0, 0, 0, 0, 0, 0, pszFace); /* and face name only */ hfontOld = SelectObject(hdc, hfont); TextOut(hdc, 100, -500, pszFace, strlen(pszFace)); SetMapMode(hdc, MapModePrevious); SelectObject(hdc, hfontOld); DeleteObject(hfont);

See Also GetMapMode, SetViewportExt, SetWindowExt

SetMapperFlags

DWORD SetMapperFlags(*hdc*, *fdwMatch*) HDC hdc: /* handle of device context */ **DWORD** *fdwMatch*; */ /* mapper flag The **SetMapperFlags** function changes the method used by the font mapper when it converts a logical font to a physical font. An application can use **SetMapper**-Flags to cause the font mapper to attempt to choose only a physical font that exactly matches the aspect ratio of the specified device. **Parameters** hdc Identifies a device context. fdwMatch Specifies whether the font mapper attempts to match a font's aspect height and width to the device. When this value is ASPECT FILTERING, the mapper selects only fonts whose x-aspect and y-aspect exactly match those of the specified device, and the remaining bits are ignored. **Return Value** The return value is the previous value of the font-mapper flag, if the function is successful. Comments An application that uses only raster fonts can use the **SetMapperFlags** function to ensure that the font selected by the font mapper is attractive and readable on the specified device. Applications that use scalable (TrueType) fonts typically do not use SetMapperFlags.

If no physical font has an aspect ratio that matches the specifications in the logical font, GDI chooses a new aspect ratio and selects a font that matches this new aspect ratio.

SetMenu

See Also	DestroyMenu, LoadMenuIndirect
	hmenu = LoadMenu(hinst, "My Menu"); SetMenu(hwnd, hmenu);
Example	HMENU hmenu;
	SetMenu will not destroy a previous menu. An application should call the DestroyMenu function to accomplish this task.
Comments	The SetMenu function causes the window to be redrawn to reflect the menu change.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
	<i>hmenu</i> Identifies the new menu. If this parameter is NULL, the window's current menu is removed.
Parameters	<i>hwnd</i> Identifies the window whose menu is to be changed.
	The SetMenu function sets the given window's menu to the specified menu.
	wnd, hmenu) /* handle of window */ /* handle of menu */

SetMenuItemBitmaps

BOOL SetMenuItemBitmaps(hmenu, idItem, fuFlags, hbmUnchecked, hbmChecked)

HMENU hmenu; UINT idItem; UINT fuFlags; HBITMAP hbmUnchecked; HBITMAP hbmChecked;

*/
*/
*/
*/
*/

The **SetMenuItemBitmaps** function associates the given bitmaps with a menu item. Whether the menu item is checked or unchecked, Windows displays the appropriate check-mark bitmap next to the menu item.

Parameters

Identifies the menu.

idItem

hmenu

Specifies the menu item to be changed, as determined by the *fuFlags* parameter.

fuFlags

Specifies how the *idItem* parameter is interpreted. This parameter can be one of the following values:

Value	Meaning
MF_BYCOMMAND	The <i>idItem</i> parameter specifies the menu-item identifier (default value).
MF_BYPOSITION	The <i>idItem</i> parameter specifies the zero-based position of the menu item.

hbmUnchecked

Identifies the check-mark bitmap to display when the menu item is not checked.

hbmChecked

Identifies the check-mark bitmap to display when the menu item is checked.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments If either the *hbmUnchecked* or the *hbmChecked* parameter is NULL, Windows displays nothing next to the menu item for the corresponding attribute. If both parameters are NULL, Windows uses the default check mark when the item is checked and removes the check mark when the item is unchecked.

When the menu is destroyed, these bitmaps are not destroyed; the application must destroy them.

3.0

The **GetMenuCheckMarkDimensions** function retrieves the dimensions of the default check mark used for menu items. The application should use these values to determine the appropriate size for the bitmaps supplied with this function.

See Also GetMenuCheckMarkDimensions

SetMessageQueue

BOOL SetMessageQueue(*cMsg*)

int cMsg; /* size of message queue */

The **SetMessageQueue** function creates a new message queue. It is particularly useful in applications that require a queue that contains more than eight messages (the maximum size of the default queue).

Parameters	<i>cMsg</i> Specifies the maximum number of messages that the new queue may contain. This value must not be larger than 120.
Return Value	The return value is nonzero if the function is successful. If the value specified in the $cMsg$ parameter is larger than 120, the return value is nonzero but the message queue is not created. The return value is zero if an error occurs.
Comments	The function must be called from an application's WinMain function before any windows are created and before any messages are sent. The SetMessageQueue function destroys the old queue, along with messages it might contain.
	If the return value is zero, the application has no queue, because the Set-MessageQueue function deletes the original queue before attempting to create a new one. The application must continue calling SetMessageQueue with a smaller queue size until the function returns nonzero.
See Also	GetMessage, PeekMessage

SetMetaFileBits

HGLOBAL SetMet HMETAFILE hmf;	aFileBits(<i>hmf</i>) /* handle of metafile */
	The SetMetaFileBits function creates a memory metafile from the data in the given global memory object.
Parameters	<i>hmf</i> Identifies the global memory object that contains the metafile data. The object must have been created by a previous call to the GetMetaFileBits function.
Return Value	The return value is the handle of a memory metafile, if the function is successful. Otherwise, it is NULL.
Comments	After the SetMetaFileBits function returns, the metafile handle it returns must be used instead of the <i>hmf</i> handle to refer to the metafile. If SetMetaFileBits is successful, the application should not use or free the memory handle specified by the <i>hmf</i> parameter, because that handle is reused by Windows.
	When the application no longer needs the metafile header, it should free the handle by calling the DeleteMetaFile function.
See Also	GetMetaFileBits, GlobalFree

SetMetaFileBitsBetter

HGLOBAL SetMeta HMETAFILE hmf;	aFileBitsBetter(<i>hmf</i>) /* handle of the metafile */
	The SetMetaFileBitsBetter function creates a memory metafile from the data in the specified global-memory object.
Parameters	<i>hmf</i> Identifies the global-memory object that contains the metafile data. The object must have been created by a previous call to the GetMetaFileBits function.

Return Value The return value is the handle of a memory metafile, if the function is successful. Otherwise, the return value is NULL.

2.x

3.1

CommentsThe global-memory handle returned by SetMetaFileBitsBetter is owned by GDI,
not by the application. This enables applications that use metafiles to support ob-
ject linking and embedding (OLE) to use metafiles that persist beyond the
termination of the application. An OLE application should always use SetMeta-
FileBitsBetter instead of the SetMetaFileBits function.After the SetMetaFileBitsBetter function returns, the metafile handle returned by

After the **SetMetaFileBitsBetter** function returns, the metafile handle returned by the function should be used to refer to the metafile, instead of the handle identified by the *hmf* parameter.

See Also GetMetaFileBits, SetMetaFileBits

SetPaletteEntries

UINT SetPaletteEntries(hpal, iStart, cEntries, lppe)HPALETTE hpal;/* handle of paletteUINT iStart;/* index of first entry to setUINT cEntries;/* number of entries to setconst PALETTEENTRY FAR* lppe;/* address of array of structures

The **SetPaletteEntries** function sets RGB color values and flags in a range of entries in the given logical palette.

Parameters

hpal

Identifies the logical palette.

iStart

Specifies the first logical-palette entry to be set.

cEntries

Specifies the number of logical-palette entries to be set.

lppe

Points to the first member of an array of **PALETTEENTRY** structures containing the RGB values and flags. The **PALETTEENTRY** structure has the following form:

```
typedef struct tagPALETTEENTRY { /* pe */
   BYTE peRed;
   BYTE peGreen;
   BYTE peBlue;
   BYTE peFlags;
} PALETTEENTRY;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

3.0

*/

*/

*/

*/

Return Value	The return value is the number of entries set in the logical palette, if the function is successful. Otherwise, it is zero.
Comments	If the logical palette is selected into a device context when the application calls the SetPaletteEntries function, the changes will not take effect until the application calls the RealizePalette function.
See Also	RealizePalette

SetParent	2.x	
HWND SetParent(HWND hwndChild HWND hwndNewF		
	The SetParent function changes the parent window of the given child window.	
ParametershwndChildIdentifies the child window.		
	hwndNewParent Identifies the new parent window.	
Return Value	The return value is the handle of the previous parent window, if the function is successful.	
Comments	If the window identified by the <i>hwndChild</i> parameter is visible, Windows per- forms the appropriate redrawing and repainting.	
See Also	GetParent, IsChild	

SetPixel

COLORREF SetPixel (<i>hdc</i> , <i>nXPos</i> , <i>nYPos</i> , <i>clrref</i>)			
HDC hdc;	/* handle of device context	*/	
int nXPos;	/* x-coordinate of pixel to set	*/	
int <i>nYPos</i> ;	/* y-coordinate of pixel to set	*/	
COLORREF clrref;	/* color of set pixel	*/	

	The SetPixel function sets the pixel at the specified coordinates to the closest approximation of the given color. The point must be in the clipping region; if it is not, the function does nothing.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nXPos</i> Specifies the logical x-coordinate of the point to be set.
	<i>nYPos</i> Specifies the logical y-coordinate of the point to be set.
	<i>clrref</i> Specifies the color to be used to paint the point.
Return Value	The return value is the RGB value for the color the point is painted, if the function is successful. This value can be different from the specified value if an approximation of that color is used. The return value is -1 if the function fails (if the point is outside the clipping region).
Comments	Not all devices support the SetPixel function. To discover whether a device supports raster operations, an application can call the GetDeviceCaps function using the RC_BITBLT index.
See Also	GetDeviceCaps, GetPixel

SetPolyFillMode

HDC hdc;	Mode (<i>hdc</i> , <i>fnMode</i>) /* handle of device context /* polygon-filling mode	*/ */
	The SetPolyFillMode fur	nction sets the specified polygon-filling mode.
Parameters	<i>hdc</i> Identifies the device co	ontext.
	· ·	ng mode. This value may be either ALTERNATE or lt mode is ALTERNATE.
Return Value	The return value specifies Otherwise, it is zero.	s the previous filling mode, if the function is successful.

Comments When the polygon-filling mode is ALTERNATE, the system fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, the system fills the area between the first and second side, between the third and fourth side, and so on.

When the polygon-filling mode is WINDING, the system uses the direction in which a figure was drawn to determine whether to fill an area. Each line segment in a polygon is drawn in either a clockwise or a counterclockwise direction. Whenever an imaginary line drawn from an enclosed area to the outside of a figure passes through a clockwise line segment, a count is incremented (increased by one); when the line passes through a counterclockwise line segment, the count is decremented (decreased by one). The area is filled if the count is nonzero when the line reaches the outside of the figure.

Example The following example uses winding mode to draw the same figure twice. The figure is a rectangle that completely encloses a triangle. The first time the figure is drawn, both the rectangle and the triangle are drawn clockwise, and both the rectangle and the triangle are filled. The second time, the rectangle is drawn clockwise, but the triangle is drawn counterclockwise; the rectangle is filled, but the triangle is not. (If the figures had been drawn using alternate mode, the rectangle would have been filled and the triangle would not have been filled, in both cases.)

```
HBRUSH hbrGray, hbrPrevious:
/*
 * Define the points for a clockwise triangle in a clockwise
 * rectangle.
 */
POINT a PolyPoints[9] = \{ \{ 50, 60 \}, \{ 250, 60 \}, \{ 250, 260 \}, \}
    \{50, 260\}, \{50, 60\}, \{150, 80\}, 
    { 230, 240 }, { 70, 240 }, { 150, 80 }}:
int aPolyCount[] = \{5, 4\};
int cValues, i;
hbrGray = GetStockObject(GRAY_BRUSH);
hbrPrevious = SelectObject(hdc, hbrGray);
cValues = sizeof(aPolyCount) / sizeof(int);
SetPolyFillMode(hdc, WINDING);  /* sets winding mode */
PolyPolygon(hdc, aPolyPoints, aPolyCount, cValues);
/* Define the triangle counter-clockwise */
aPolyPoints[6].x = 70; aPolyPoints[6].y = 240;
aPolyPoints[7].x = 230; aPolyPoints[7].y = 240;
```

for (i = 0; i < sizeof(aPolyPoints) / sizeof(POINT); i++)</pre> aPolyPoints[i].x += 300; /* moves figure 300 units right */ PolyPolygon(hdc, aPolyPoints, aPolyCount, cValues); SelectObject(hdc, hbrPrevious); GetPolyFillMode, PolyPolygon

ocurup	2.X
BOOL SetProp(hwn HWND hwnd; LPCSTR lpsz; HANDLE hData;	nd, lpsz, hData) /* handle of window */ /* atom or address of string */ /* handle of data */
	The SetProp function adds a new entry or changes an existing entry in the prop- erty list of the given window. The function adds a new entry to the list if the given character string does not exist already in the list. The new entry contains the string and the handle. Otherwise, the function replaces the string's current handle with the given handle.
Parameters	 hwnd Identifies the window whose property list receives the new entry. <i>lpsz</i> Points to a null-terminated string or an atom that identifies a string. If this parameter is an atom, it must be a global atom created by a previous call to the GlobalAddAtom function. The atom, a 16-bit value, must be placed in the low-order word of <i>lpsz</i>; the high-order word must be zero.
	<i>hData</i> Identifies data to be copied to the property list. The data handle can identify any 16-bit value useful to the application.
Return Value	The return value is nonzero if the data handle and string are added to the property list. Otherwise, it is zero.
Comments	Before destroying a window (that is, before processing the WM_DESTROY mes- sage), an application must remove all entries it has added to the property list. The RemoveProp function must be used to remove entries from a property list.
See Also	GetProp, GlobalAddAtom, RemoveProp

SetRect		2.x
<pre>void SetRect(lprc, n RECT FAR* lprc; int nLeft; int nTop; int nRight; int nBottom;</pre>	<pre>Left, nTop, nRight, nBottom) /* address of structure with rectangle to set /* left side /* top side /* right side /* bottom side</pre>	*/ */ */ */
	The SetRect function sets rectangle coordinates. The quivalent to assigning the left, top, right, and both members of the RECT structure.	
Parameters	<i>lprc</i> Points to the RECT structure that contains the structure has the following form:	rectangle to be set. The RECT
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>	
	For a full description of this structure, see the <i>M mer's Reference</i> , <i>Volume 3</i> .	Aicrosoft Windows Program-
	<i>nLeft</i> Specifies the x-coordinate of the upper-left cor	ner.
	<i>nTop</i> Specifies the y-coordinate of the upper-left cor	ner.
	<i>nRight</i> Specifies the x-coordinate of the lower-right co	orner.
	<i>nBottom</i> Specifies the y-coordinate of the lower-right co	orner.
Return Value	This function does not return a value.	
Comments	The width of the rectangle, specified by the absolution of exceed 32,767 units. This limit also applies to	
See Also	CopyRect, SetRectEmpty	

SetRectEmpty

<pre>void SetRectEmpty RECT FAR* lprc;</pre>	(<i>lprc</i>) /* address of struct. with rectangle to set to empty */
	The SetRectEmpty function creates an empty rectangle (all coordinates set to zero).
Parameters	<i>lprc</i> Points to the RECT structure that contains the rectangle to be set to empty. The RECT structure has the following form:
	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT; For a full description of this structure, see the Microsoft Windows Program-</pre>
	mer's Reference, Volume 3.
Return Value	This function does not return a value.
See Also	CopyRect, SetRect

SetRectRgn

void SetRectRgn(h)	rgn, nLeftRect, nTopRect, nRightRect, nBottomRect)	
HRGN hrgn;	/* handle of region	*/
int nLeftRect;	/* x-coordinate top-left corner of rectangle	*/
int nTopRect;	/* y-coordinate top-left corner of rectangle	*/
int nRightRect;	/* x-coordinate bottom-right corner of rectangle	*/
int nBottomRect;	/* y-coordinate bottom-right corner of rectangle	*/
The SetRectRgn function changes the given region into a rectangular region with the specified coordinates.		
Parameters	hrgn	

Identifies the region.

nLeftRect

Špecifies the x-coordinate of the upper-left corner of the rectangular region.

2.x

	<i>nTopRect</i> Specifies the y-coordinate of the upper-left corner of the rectangular region.
	<i>nRightRect</i> Specifies the x-coordinate of the lower-right corner of the rectangular region.
	<i>nBottomRect</i> Specifies the y-coordinate of the lower-right corner of the rectangular region.
Return Value	This function does not return a value.
Comments	Applications can use this function instead of the CreateRectRgn function to avoid allocating more memory from the GDI heap. Because the memory allocated for the <i>hrgn</i> parameter is reused, no new allocation is performed.
Example	The following example uses the CreateRectRgn function to create a rectangular region and then calls the SetRectRgn function to change the region coordinates:
	HRGN hrgn;
	hrgn = CreateRectRgn(10, 10, 30, 30); PaintRgn(hdc, hrgn);
	SetRectRgn(hrgn, 50, 50, 150, 200); PaintRgn(hdc, hrgn);
	<pre>DeleteObject(hrgn);</pre>
See Also	CreateRectRgn

SetResourceHandler

2.x

RSRCHDLRPROC SetResourceHandler(<i>hinst</i> , <i>lpszType</i> , <i>lpLoadProc</i>)			
HINSTANCE hinst;		/* handle of application instance	*/
LPCSTR lpszType;		/* address of resource-type identifier	*/
RSRCHDLRPROC	lpLoadProc;	/* callback procedure-instance address	*/
	The SetResourc sources.	ceHandler function installs a callback func	tion that loads re-
Parameters	<i>hinst</i> Identifies the source.	instance of the module whose executable	file contains the re-

	<i>lpszType</i> Points to a null-terminated string that specifies a resource type. For predefined resource types, the high-order word should be zero and the low-order word should indicate the resource type.
	<i>lpLoadProc</i> Specifies the procedure-instance address of the application-supplied callback function. For more information, see the description of the LoadProc callback function.
Return Value	The return value is a pointer to the previously installed resource handler, if the function is successful. If no resource handler has been explicitly installed, the return value is a pointer to the default resource handler.
Comments	An application may find this function useful for handling its own resource types, but the use of this function is not required.
	The address passed as the <i>lpLoadProc</i> parameter must be created by using the MakeProcInstance function.
See Also	FindResource, LoadProc, LockResource, MakeProcInstance

SetROP2

<pre>int SetROP2(hdc, f HDC hdc;</pre>	<i>nDrawMode</i>) /* handle of device context	*/
<pre>int fnDrawMode;</pre>	/* new drawing mode	*/
		e current drawing mode. The drawing mode speci- and the interior of filled objects are combined with surface.
Parameters	hdc	
	Identifies the device context	

fnDrawMode

Specifies the new drawing mode. This parameter can be one of the following values:

Value	Meaning
R2_BLACK	Pixel is always black.
R2_WHITE	Pixel is always white.
R2_NOP	Pixel remains unchanged.
R2_NOT	Pixel is the inverse of the screen color.
R2_COPYPEN	Pixel is the pen color.
R2_NOTCOPYPEN	Pixel is the inverse of the pen color.
R2_MERGEPENNOT	Pixel is a combination of the pen color and the inverse of the screen color (final pixel = (~screen pixel) pen).
R2_MASKPENNOT	Pixel is a combination of the colors common to both the pen and the inverse of the screen (final pixel = (~screen pixel) & pen).
R2_MERGENOTPEN	Pixel is a combination of the screen color and the inverse of the pen color (final pixel = $(\sim pen)$ screen pixel).
R2_MASKNOTPEN	Pixel is a combination of the colors common to both the screen and the inverse of the pen (final pixel = (~pen) & screen pixel).
R2_MERGEPEN	Pixel is a combination of the pen color and the screen color (final pixel = pen screen pixel).
R2_NOTMERGEPEN	Pixel is the inverse of the R2_MERGEPEN color (final pixel = ~(pen screen pixel)).
R2_MASKPEN	Pixel is a combination of the colors common to both the pen and the screen (final pixel = pen & screen pixel).
R2_NOTMASKPEN	Pixel is the inverse of the R2_MASKPEN color (final pixel = ~(pen & screen pixel)).
	pixel = (per a seleen pixel)).
R2_XORPEN	Pixel is a combination of the colors that are in the pen and in the screen, but not in both (final pixel = pen ^ screen pixel).

Drawing modes are binary raster-operation codes representing all possible Boolean combinations of two variables. These values are created by using the binary operations AND, OR, and XOR (exclusive OR) and the unary operation NOT.

SetScrollPos

<pre>int SetScrollPos(hw HWND hwnd; int fnBar; int nPos; BOOL fRepaint;</pre>	wnd, fnBar, nPos, fRepaint)/* handle of window with scroll bar*//* scroll bar flag*//* new position of scroll box*//* redraw flag*/		
	The SetScrollPos function sets the position of a scroll box (thumb) and, if re- quested, redraws the scroll bar to reflect the new position of the scroll box.		
Parameters	<i>hwnd</i> Identifies the window whose scroll bar is to be set.		
	<i>fnBar</i> Specifies the scroll bar to be set. This parameter can be one of the following values:		
	Value	Meaning	
	SB_CTL	Sets the position of the scroll box in a scroll bar. In this case, the <i>hwnd</i> parameter must be the handle of a scroll bar.	
	SB_HORZ	Sets the position of the scroll box in a window's horizontal scroll bar.	
	SB_VERT	Sets the position of the scroll box in a window's vertical scroll bar.	
	<i>nPos</i> Specifies the new position of the scroll box. It must be within the scrolling range.		
	box position	ether the scroll bar should be repainted to reflect the new scroll . If this parameter is TRUE, the scroll bar is repainted. If it is scroll bar is not repainted.	
Return Value		e is the previous position of the scroll box, if the function is erwise, it is zero.	
Comments		Setting the <i>fRepaint</i> parameter to FALSE is useful whenever the scroll bar will be redrawn by a subsequent call to another function.	
See Also	GetScrollPos,	GetScrollRange, ScrollWindow, SetScrollRange	

2.x

SetScrollRange

<pre>void SetScrollRang HWND hwnd; int fnBar; int nMin; int nMax; BOOL fRedraw;</pre>		rolling position */
		Cange function sets minimum and maximum position values for the . It can also be used to hide or show standard scroll bars.
Parameters	<i>hwnd</i> Identifies a window or a scroll bar, depending on the value of <i>fnBar</i> .	
	<i>fnBar</i> Specifies the values:	scroll bar to be set. This parameter can be one of the following
	Value	Meaning
	SB_CTL	Sets the range of a scroll bar. In this case, the <i>hwnd</i> parameter must be the handle of a scroll bar.
	SB_HORZ SB_VERT	Sets the range of a window's horizontal scroll bar. Sets the range of a window's vertical scroll bar.
	<i>nMin</i> Specifies the	minimum scrolling position.
	<i>nMax</i> Specifies the	maximum scrolling position.
		ether the scroll bar should be redrawn to reflect the change. If this TRUE, the scroll bar is redrawn. If it is FALSE, the scroll bar is
Return Value	This function de	oes not return a value.
Comments	An application scroll-bar notifi	should not call this function to hide a scroll bar while processing a cation message.
	function, the fR	tScrollRange immediately follows the call to the SetScrollPos edraw parameter in SetScrollPos should be zero, to prevent the being drawn twice.
		ge for a standard scroll bar is 0 through 100. The default range control is empty (both the <i>nMin</i> and <i>nMax</i> values are zero). The

difference between the values specified by the *nMin* and *nMax* parameters must not be greater than 32,767.

See Also GetScrollPos, GetScrollRange, ScrollWindow, SetScrollPos

SetSelectorBase

UINT SetSelectorBase(selector, dwBase) */ **UINT** selector; /* new selector **DWORD** *dwBase*: /* new base */ The SetSelectorBase function sets the base and limit of a selector. **Parameters** selector Specifies the selector value to modify. dwBase Specifies the new base value. This value is the starting linear address that selector will reference. **Return Value** The return value is the selector value, or zero if an error occurs. See Also GetSelectorBase, GetSelectorLimit, SetSelectorLimit

SetSelectorLimit

UINT SetSelectorL UINT selector; DWORD dwBase;	imit(selector, dwBase)/* new selector*//* current base*/
	The SetSelectorLimit function sets the limit of a selector.
Parameters	<i>selector</i> Specifies the selector to modify.
	<i>dwBase</i> Specifies the new limit value for <i>selector</i> . For an 80286 processor, this value must be less than 0x10000.
Return Value	The return value is always zero.

3.1

3.1

See Also GetSelectorBase, GetSelectorLimit, SetSelectorBase

SetSoundNoise

int SetSoundNoise(fnSource, nDuration) int fnSource; /* source of noise */ int nDuration; /* duration of noise */

> This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about audio functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

SetStretchBltMode

int SetStretchBltMode(hdc, fnStretchMode) HDC hdc; /* handle of device context */ int fnStretchMode; /* bitmap-stretching mode */

The **SetStretchBltMode** function sets the bitmap-stretching mode. The bitmapstretching mode defines how information is removed from bitmaps that are compressed by using the **StretchBlt** function.

Parameters

Identifies the device context.

fnStretchMode

hdc

Specifies the new bitmap-stretching mode. This parameter can be one of the following values:

Value	Meaning
STRETCH_ANDSCANS	Uses the AND operator to combine eliminated lines with the remaining lines. This mode pre- serves black pixels at the expense of colored or white pixels. It is the default mode.
STRETCH_DELETESCANS	Deletes the eliminated lines. Information in the eliminated lines is not preserved.
STRETCH_ORSCANS	Uses the OR operator to combine eliminated lines with the remaining lines. This mode preserves colored or white pixels at the expense of black pixels.

2.x

Return Value	The return value is the previous stretching mode, if the function is successful. It can be STRETCH_ANDSCANS, STRETCH_DELETESCANS, or STRETCH_ORSCANS.
Comments	The STRETCH_ANDSCANS and STRETCH_ORSCANS modes are typically used to preserve foreground pixels in monochrome bitmaps. The STRETCH_DELETESCANS mode is typically used to preserve color in color bit- maps.
See Also	GetStretchBltMode, StretchBlt, StretchDIBits

2.x

SetSwapAreaSize

LONG SetSwapAreaSize(*cCodeParagraphs*) */ **UINT** *cCodeParagraphs*: /* number of paragraphs for code The **SetSwapAreaSize** function sets the amount of memory that an application uses for its code segments. **Parameters** *cCodeParagraphs* Specifies the number of 16-byte paragraphs requested by the application for use as code segments. If this parameter is zero, the return value specifies the current size of the code-segment space. **Return Value** The return value is the amount of space available for the code segment, if the function is successful. The low-order word specifies the number of paragraphs obtained for use as a code-segment space (or the current size if the *cCodeParagraphs* parameter is zero); the high-order word specifies the maximum size available. Comments If *cCodeParagraphs* specifies a size larger than is available, this function sets the size to the available amount. The maximum amount of memory available is one half the space remaining after Windows is loaded. Calling this function can improve an application's performance by preventing Windows from swapping code segments to the hard disk. However, increasing the code-segment space reduces the amount of memory available for data objects and can reduce the performance of other applications. See Also GetNumTasks, GlobalAlloc

SetSysColor	S		2.x
<pre>int cDspElements; const int FAR* lpnL</pre>	xDspElements, lpnDspEleme DspElements; FAR* lpdwRgbValues;	ents, lpdwRgbValues)/* number of elements to change*//* address of array of elements*//* address of array of RGB values*/	
		n sets the system colors for one or more display ele- re the various parts of a window and the Windows b screen.	
	windows to inform them o	n sends a WM_SYSCOLORCHANGE message to f the change in color. It also directs Windows to rep currently visible windows.	
Parameters	<i>cDspElements</i> Specifies the number of <i>lpnDspElements</i> parame	display elements in the array pointed to by the eter.	
		egers that specify the display elements to be change play elements, see the following Comments sectior	
		signed long integers that contains the new RGB (rea for each display element in the array pointed to by eter.	
Return Value	This function does not retu	rn a value.	
Comments	The SetSysColors function changes the current Windows session only. The new colors are not saved when Windows terminates.		ew
	Following are the display	elements that may be used in the <i>lpnDspElements</i> and	rray:
	Value	Meaning	
	COLOR_ACTIVEBORDER	Active window border.	
	COLOR_ACTIVECAPTION		
	COLOR_APPWORKSPACE	Background color of multiple document interface (MDI) applications.	
	COLOR_BACKGROUND	Desktop.	
	COLOR_BTNFACE	Face shading on push buttons.	
	COLOR_BTNHIGHLIGHT	Selected button in a control.	
	COLOR_BTNSHADOW	Edge shading on push buttons.	
	COLOR_BTNTEXT	Text on push buttons.	

.

	Value	Meaning
	COLOR_CAPTIONTEXT	Text in title bar, size button, scroll-bar arrow button.
	COLOR_GRAYTEXT	Grayed (dimmed) text. This color is zero if the current display driver does not support a solid gray color.
	COLOR_HIGHLIGHT	Background of selected item in a control.
	COLOR_HIGHLIGHTTEXT	Text of selected item in a control.
	COLOR_INACTIVEBORDER	Inactive window border.
	COLOR_INACTIVECAPTION	Inactive window title.
	COLOR_INACTIVECAPTIONTEXT	Color of text in an inactive title.
	COLOR_MENU	Menu background.
	COLOR_MENUTEXT	Text in menus.
	COLOR_SCROLLBAR	Scroll-bar gray area.
	COLOR_WINDOW	Window background.
	COLOR_WINDOWFRAME	Window frame.
	COLOR_WINDOWTEXT	Text in windows.
Example	The following example changes the w the window to green: int aiDspElements[2]; DWORD aRgbValues[2];	vindow background to black and the text in
	<pre>aiDspElements[0] = COLOR_WINDOW; aRgbValues[0] = RGB(</pre>	
See Also	GetSysColor	

SetSysMod	alWindow	2.x
HWND SetSysMo HWND hwnd;	odalWindow(hwnd)/* handle of window to become system modal*/	
	The SetSysModalWindow function makes the given window the system-mo window.	dal
Parameters	<i>hwnd</i> Identifies the window to be made system modal.	
Return Value	The return value is the handle of the window that was previously the system- modal window, if the function is successful.	
Comments	If another window is made the active window (for example, the system-moda dow creates a dialog box that becomes the active window), the active window comes the system-modal window. When the original window becomes active again, it is once again the system-modal window. To end the system-modal sy destroy the system-modal window.	v be-
	If a WH_JOURNALRECORD hook is in place when SetSysModalWindow called, the hook is called with a hook code of HC_SYSMODALON (for turn on the system-modal window) or HC_SYSMODALOFF (for turning off the system-modal window).	
See Also	GetSysModalWindow	

SetSystemPaletteUse

3.0

UINT SetSystemI HDC hdc; UINT fuStatic;	PaletteUse(hdc, fuStatic)/* handle of device context*//* system-palette contents*/
	The SetSystemPaletteUse function sets the use of static colors in the system palette. The default system palette contains 20 static colors, which are not changed when an application realizes its logical palette. An application can use SetSystem-PaletteUse to change this to two static colors (black and white).
Parameters	<i>hdc</i> Identifies the device context. This device context must support color palettes.

fuStatic Specifies the new use of the system palette. This parameter can be either of the following values:

	Tonowing values.		
	Value	Meaning	
	SYSPAL_NOSTATIC	System palette contains no static colors except black and white.	
	SYSPAL_STATIC	System palette contains static colors that will not change when an application realizes its logical palette.	
Return Value	The return value is the pro- if the function is successful SYSPAL_STATIC.	evious setting for the static colors in the system palette, ful. This setting is either SYSPAL_NOSTATIC or	
Comments	An application must call this function only when its window is maximized the input focus.		
	SYSPAL_NOSTATIC, V	SystemPaletteUse with <i>fuStatic</i> set to Vindows continues to set aside two entries in e white and pure black, respectively.	
	After calling this function with <i>fuStatic</i> set to SYSPAL_NOSTATIC, an application must follow these steps:		
		ject function to force the graphics device interface (GDI) lette completely when it is realized.	
	2. Realize the logical palette.		
	3. Call the GetSysColor	function to save the current system-color settings.	
	using black and white.	function to set the system colors to reasonable values For example, adjacent or overlapping items (such as win- rs) should be set to black and white, respectively.	
		DLORCHANGE message to other top-level windows to wn with the new system colors.	
	When the application's w form the following steps:	vindow loses focus or closes, the application must per-	
	1. Call SetSystemPalette SYSPAL_STATIC.	eUse with the <i>fuStatic</i> parameter set to	
	2. Call UnrealizeObject when it is realized.	to force GDI to remap the logical palette completely	
	3. Realize the logical pale	ette.	
	4. Restore the system col	lors to their previous values.	
	5. Send the WM_SYSCO	DLORCHANGE message.

SetTextAlig	jn		2.x
UINT SetTextAli, HDC hdc; UINT fuAlign;	/* handle of device c /* text-alignment flag		ice con-
	text.	renedion sets the text unginnent mugs for the given dev.	
Parameters	<i>hdc</i> Identifies the de	vice context.	
	point and a recta position or coord TextOut function	ignment flags. The flags specify the relationship betwe ingle that bounds the text. The point can be either the cu dinates specified by a text-output function (such as the on). The rectangle that bounds the text is defined by the ells in the text string.	urrent Ext-
	The <i>fuAlign</i> parameter can be one or more flags from the following three gories. Choose only one flag from each category.		
	The first categor	ry affects text alignment in the x-direction:	
	Value	Meaning	
	TA_CENTER	Aligns the point with the horizontal center of the bounding rectangle.	
	TA_LEFT	Aligns the point with the left side of the bounding rectangle is the default setting.	e. This
	TA_RIGHT	Aligns the point with the right side of the bounding rectang	gle.
	The second category affects text alignment in the y-direction:		
	Value	Meaning	
	TA_BASELINE	Aligns the point with the base line of the chosen font.	
	TA_BOTTOM	Aligns the point with the bottom of the bounding rectang	gle.
	TA_TOP	Aligns the point with the top of the bounding rectangle. The default setting.	This is
	The third catego is written:	ry determines whether the current position is updated w	when text

	Value	Meaning
	TA_NOUPDATECP	Does not update the current position after each call to a text-output function. This is the default setting.
	TA_UPDATECP	Updates the current x-position after each call to a text- output function. The new position is at the right side of the bounding rectangle for the text. When this flag is set, the coordinates specified in calls to the TextOut function are ignored.
Return Value	The return value is the previous text-alignment settings, if the function is success- ful. The low-order byte contains the horizontal setting; the high-order byte con- tains the vertical setting. Otherwise, the return value is zero.	
Comments	The text-alignment flags TextOut functions.	set by SetTextAlign are used by the TextOut and Ext-
Example	The following example uses the GetTextFace function to retrieve the name of the current typeface, calls SetTextAlign so that the current position is updated when the TextOut function is called, and then writes some introductory text and the name of the typeface by calling TextOut :	
	int nFaceNameLen; char aFaceName[80];	
	sizeof(aFaceName),	Face(hdc, /* returns length of string */ /* size of face-name buffer */ ; /* address of face-name buffer */
	TextOut(hdc, 0, 0, "This is the curre	<pre>/* updates current position */ /* sets current position */ /* uses current position for text */ ent face name: ", 31); aceName, nFaceNameLen);</pre>

See Also

ExtTextOut, GetTextAlign, TextOut

SetTextCharacterExtra

int SetTextCharacterExtra(hdc, nExtraSpace)			
HDC hdc;	/* handle of device context	*/	
<pre>int nExtraSpace;</pre>	/* extra character spacing	*/	

	The SetTextCharacterExtra function sets the amount of intercharacter spacing. The graphics device interface (GDI) adds this spacing to each character, including break characters, when it writes a line of text to the device context.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nExtraSpace</i> Specifies the amount of extra space, in logical units, to be added to each charac- ter. If the current mapping mode is not MM_TEXT, this parameter is trans- formed and rounded to the nearest pixel.
Return Value	The return value is the previous intercharacter spacing, if the function is successful.
Comments	The default value for the amount of intercharacter spacing is zero.
See Also	GetTextCharacterExtra

2.x
tColor(<i>hdc</i> , <i>clrref</i>) /* handle of device context */ /* new color for text */
The SetTextColor function sets the text color to the specified color. The system uses the text color when writing text to a device context and also when converting bitmaps between color and monochrome device contexts.
<i>hdc</i> Identifies the device context. <i>clrref</i>
Specifies the color of the text. The return value is the RGB (red-green-blue) value for the previous text color, if the function is successful.
If the device cannot represent the specified color, the system sets the text color to the nearest physical color.
The background color for a character is specified by the SetBkColor and SetBk-Mode functions.

Example The following example sets the text color to red if the **GetTextColor** function determines that the current text color is black. The text color is specified by using the **RGB** macro.

```
DWORD dwColor;
```

See Also

GetTextColor, BitBlt, SetBkColor, SetBkMode

SetTextJustification

int SetTextJustific: HDC hdc; int nExtraSpace; int cBreakChars;	ation(hdc, nExtraSpace, cBreakChars) /* handle of device context */ /* space to add to string */ /* number of break characters in the string */
	The SetTextJustification function adds space to the break characters in a string. An application can use the GetTextMetrics function to retrieve a font's break character.
Parameters	<i>hdc</i> Identifies the device context.
	<i>nExtraSpace</i> Specifies the total extra space, in logical units, to be added to the line of text. If the current mapping mode is not MM_TEXT, the value given by this parameter is converted to the current mapping mode and rounded to the nearest device unit.
	<i>cBreakChars</i> Specifies the number of break characters in the line.
Return Value	The return value is 1 if the function is successful. Otherwise, it is zero.
Comments	After the SetTextJustification function is called, a call to a text-output function (for example, TextOut) distributes the specified extra space evenly among the specified number of break characters. The break character is usually the space character (ASCII 32), but it may be defined by a font as some other character.
	The GetTextExtent function is typically used with SetTextJustification . The GetTextExtent function computes the width of a given line before alignment. An

application can determine how much space to specify in the *nExtraSpace* parameter by subtracting the value returned by **GetTextExtent** from the width of the string after alignment.

The **SetTextJustification** function can be used to align a line that contains multiple runs in different fonts. In this case, the line must be created piecemeal by aligning and writing each run separately.

Because rounding errors can occur during alignment, the system keeps a running error term that defines the current error. When aligning a line that contains multiple runs, **GetTextExtent** automatically uses this error term when it computes the extent of the next run, allowing the text-output function to blend the error into the new run. After each line has been aligned, this error term must be cleared to prevent it from being incorporated into the next line. The term can be cleared by calling **SetTextJustification** with the *nExtraSpace* parameter set to zero.

Example The following example writes two lines of text inside a box; one of the lines is aligned, and the other is not. The **GetTextExtent** function determines the width of the unaligned string. The **GetTextMetrics** function determines the break character that is used by the current font; this information is then used to determine how many break characters the string contains. The **SetTextJustification** function specifies the total amount of extra space and the number of break characters to distribute it among. After writing a line of aligned text, **SetTextJustification** is called again, to set the error term to zero.

```
POINT aPoints[5]:
int iLMargin = 10, iRMargin = 10, iBoxWidth;
int cchString:
LPSTR lpszJustified = "Text to be justified in this test.";
DWORD dwExtent;
WORD wTextWidth:
TEXTMETRIC tm:
int j. cBreakChars:

SetTimer

UINT SetTimer (hwnd, idTimer, uTimeout, tmprc)			
HWND hwnd;	/* handle of window for timer messages	*/	
UINT idTimer;	/* timer identifier	*/	
UINT uTimeout;	/* time-out duration	*/	
TIMERPROC tmprc;	/* instance address of timer procedure	*/	

The **SetTimer** function installs a system timer. A time-out value is specified, and every time a time-out occurs, the system posts a WM_TIMER message to the installing application's message queue or passes the message to an application-defined **TimerProc** callback function.

Parameters

hwnd

Identifies the window to be associated with the timer. If the *tmprc* parameter is NULL, the window procedure associated with this window receives the WM_TIMER messages generated by the timer. If this parameter is NULL, no window is associated with the timer.

idTimer

Specifies a nonzero timer identifier. If the *hwnd* parameter is NULL, this parameter is ignored.

uTimeout

Specifies the time-out value, in milliseconds.

tmprc

Specifies the procedure-instance address of the callback function that processes the WM_TIMER messages. If this parameter is NULL, the WM_TIMER messages are placed in the application's message queue and the **hwnd** member of the **MSG** structure contains the window handle specified in *hwnd*. For more information, see the description of the **TimerProc** callback function.

The MSG structure has the following form:

```
/* msg */
                        typedef struct tagMSG {
                            HWND
                                    hwnd:
                            UINT
                                    message:
                            WPARAM wParam;
                            LPARAM 1Param:
                            DWORD time:
                            POINT pt;
                        } MSG:
                       For a full description of this structure, see the Microsoft Windows Program-
                       mer's Reference, Volume 3.
Return Value
                     The return value is the identifier of the new timer if hwnd is NULL and the func-
                     tion is successful. An application passes this value to the KillTimer function to
                     kill the timer. The return value is nonzero if hwnd is a valid window handle and
                     the function is successful. Otherwise, the return value is zero.
Comments
                     Timers are a limited global resource; therefore, it is important that an application
                     check the value returned by the SetTimer function to verify that a timer is avail-
                     able.
                     The tmprc parameter must specify a procedure-instance address of the callback
                     function, and the callback function must be exported in the application's module-
                     definition file. A procedure-instance address can be created by using the Make-
                     ProcInstance function. The callback function must use the Pascal calling
                     convention and must be declared as FAR.
Example
                     The following example installs a system timer. The system will pass WM TIMER
                     messages generated by the timer to the "MyTimerProc" callback function.
                     TIMERPROC lpfnMyTimerProc;
                     lpfnMyTimerProc = (TIMERPROC) MakeProcInstance(MyTimerProc, hinst);
                     SetTimer(hwnd, ID_MYTIMER, 5000, lpfnMyTimerProc);
```

```
See Also KillTimer, MakeProcInstance, TimerProc
```

SetViewportExt

DWORD SetVie HDC hdc; int nXExtent; int nYExtent;	wportExt(hdc, nXExtent, nYExtent)/* handle of device context/* x-extent of viewport/* y-extent of viewport
	The SetViewportExt function sets the x- and y-extents of the viewport of the given device context. The viewport, along with the window, defines how points are converted from logical coordinates to device coordinates.
Parameters	<i>hdc</i> Identifies the device context. <i>nXExtent</i>
	Specifies the x-extent, in device units, of the viewport. <i>nYExtent</i> Specifies the y-extent, in device units, of the viewport.
Return Value	The return value is the previous viewport extents, in device units, if the function is successful. The low-order word contains the previous x-extent; the high-order word contains the previous y-extent. Otherwise, the return value is zero.
Comments	When the following mapping modes are set, calls to the SetWindowExt and SetViewportExt functions are ignored:
	MM_HIENGLISH MM_HIMETRIC MM_LOENGLISH MM_LOMETRIC MM_TEXT MM_TWIPS
	When the mapping mode is MM_ISOTROPIC, an application must call the SetWindowExt function before calling SetViewportExt .
	The x- and y-extents of the viewport define how much the graphics device inter- face (GDI) must stretch or compress units in the logical coordinate system to fit units in the device coordinate system. For example, if the x-extent of the window is 2 and the x-extent of the viewport is 4, GDI converts two logical units (measured from the x-axis) into four device units. Similarly, if the y-extent of the window is 2 and the y-extent of the viewport is -1 , GDI converts two logical units (measured from the y-axis) into one device unit.
	The extents also define the relative orientation of the x- and y-axes in both coordi- nate systems. If the signs of matching window and viewport extents are the same,

3.1

	the axes have the same orientation. If the signs are different, the orientation is reversed. For example, if the y-extent of the window is 2 and the y-extent of the viewport is -1 , GDI converts the positive y-axis in the logical coordinate system to the negative y-axis in the device coordinate system. If the x-extents are 2 and 4, GDI converts the positive x-axis in the logical coordinate system to the positive x-axis in the device coordinate system.
Example	The following example uses the SetMapMode , SetWindowExt , and Set-ViewportExt functions to create a client area that is 10 logical units wide and 10 logical units high, and then draws a rectangle that is 4 logical units wide and 4 logical units high:
	HDC hdc; RECT rc;
	GetClientRect(hwnd, &rc); hdc = GetDC(hwnd); SetMapMode(hdc, MM_ANISOTROPIC); SetWindowExt(hdc, 10, 10); SetViewportExt(hdc, rc.right, rc.bottom); Rectangle(hdc, 3, 3, 7, 7); ReleaseDC(hwnd, hdc);
See Also	GetViewportExt, SetWindowExt

SetViewportExtEx

BOOL SetViewport	t ExtEx (hdc, nX, nY, lpSize)	
HDC hdc;	/* handle of device context	*/
int nX;	/* x-extent of viewport	*/
int nY ;	/* y-extent of viewport	*/
SIZE FAR* lpSize;	/* address of struct. with prev. extents	*/
Parameters	The SetViewportExtEx function sets the x- specified device context. The viewport, alor points are mapped from logical coordinates <i>hdc</i> Identifies the device context.	g with the window, defines how
	<i>nX</i> Specifies the x-extent of the viewport, in <i>nY</i> Specifies the y-extent of the viewport, in	

lpSize

Points to a **SIZE** structure. The previous extents of the viewport, in device units, are placed in this structure. If *lpSize* is NULL, nothing is returned. The **SIZE** structure has the following form:

```
typedef struct tagSIZE {
    int cx;
    int cy;
} SIZE:
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3.*

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments When the following mapping modes are set, calls to the **SetWindowExtEx** and **SetViewportExtEx** functions are ignored:

MM_HIENGLISH MM_HIMETRIC MM_LOENGLISH MM_LOMETRIC MM_TEXT MM_TWIPS

When MM_ISOTROPIC mode is set, an application must call the **SetWindow-ExtEx** function before it calls **SetViewportExtEx**.

See Also SetWindowExtEx

SetViewportOrg

DWORD SetViewportOrg(hdc, nXOrigin, nYOrigin)			
HDC hdc;	/* handle of device context	*/	
int nXOrigin;	/* x-coordinate of new origin	*/	
int nYOrigin;	/* y-coordinate of new origin	*/	

The **SetViewportOrg** function sets the viewport origin of the specified device context. The viewport, along with the window, defines how points are converted from logical coordinates to device coordinates.

Parameters

hdc

Identifies the device context.

3.1

	<i>nXOrigin</i> Specifies the x-coordinate, in device coordinates, of the origin of the viewport. This value must be within the range of the device coordinate system.
	<i>nYOrigin</i> Specifies the y-coordinate, in device coordinates, of the origin of the viewport. This value must be within the range of the device coordinate system.
Return Value	The return value is the coordinates of the previous viewport origin, in device units, if the function is successful. The low-order word contains the previous x-coordinate; the high-order word contains the previous y-coordinate. Otherwise, the return value is zero.
Comments	The viewport origin is the origin of the device coordinate system. The graphics device interface (GDI) converts points from the logical coordinate system to device coordinates. (An application can specify the origin of the logical coordinate system by using the SetWindowOrg function.) GDI converts all points in the logical coordinate system to device coordinates in the same way as it converts the origin.
Example	The following example uses the SetViewportOrg function to set the viewport origin to the center of the client area and then draws a rectangle centered over the origin:
	HDC hdc; RECT rc;
	<pre>GetClientRect(hwnd, &rc); hdc = GetDC(hwnd); SetViewportOrg(hdc, rc.right/2, rc.bottom/2); Rectangle(hdc, -100, -100, 100, 100); ReleaseDC(hwnd, hdc);</pre>
See Also	SetWindowOrg

SetViewportOrgEx

x (hdc, nX, nY, lpPoint)	
/* handle of device context	*/
/* x-coordinate of new origin	*/
/* y-coordinate of new origin	*/
/* address of struct. with prev. origin	*/
	/* handle of device context /* x-coordinate of new origin /* y-coordinate of new origin

	The SetViewportOrgEx function sets the viewport origin of the specified device context. The viewport, along with the window, defines how points are mapped from logical coordinates to device coordinates.
Parameters	 <i>hdc</i> Identifies the device context. <i>nX</i> Specifies the x-coordinate, in device units, of the origin of the viewport. <i>nY</i> Specifies the y-coordinate, in device units, of the origin of the viewport. <i>lpPoint</i> Points to a POINT structure. The previous origin of the viewport, in device coordinates, is placed in this structure. If <i>lpPoint</i> is NULL, nothing is returned.
	<pre>coordinates, is praced in this structure. If <i>ipPoint</i> is NOLL, nothing is returned. The POINT structure has the following form: typedef struct tagPOINT { /* pt */ int x; int y; } POINT; For a full description of this structure, see the <i>Microsoft Windows Program- mer's Reference, Volume 3.</i></pre>
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.

int voice;	/* voice queue	*/
int cNotesThreshold;	/* threshold level	*/

lpwdi

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

SetWinDebugInfo

BOOL SetWinDebugInfo(*lpwdi*) **const WINDEBUGINFO FAR*** *lpwdi*; /* address of **WINDEBUGINFO structure**

The **SetWinDebugInfo** function sets current system-debugging information for the debugging version of the Windows 3.1 operating system.

Parameters

Points to a **WINDEBUGINFO** structure that specifies the type of debugging information to be set. The **WINDEBUGINFO** structure has the following form:

typedef struct tagWINDEBUGINFO {
 UINT flags;
 DWORD dwOptions;
 DWORD dwFilter;

2.x

*/

2.x

	<pre>char achAllocModule[8]; DWORD dwAllocBreak; DWORD dwAllocCount; } WINDEBUGINFO;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. It is zero if the pointer specified in the <i>lpwdi</i> parameter is invalid, the flags member of the WIN-DEBUGINFO structure is invalid, or the function is not called in the debugging version of Windows 3.1.
Comments	The flags member of the WINDEBUGINFO structure specifies which debugging information should be set. Applications need initialize only those members of the WINDEBUGINFO structure that correspond to the flags set in the flags member.
	Changes to debugging information made by calling SetWinDebugInfo apply only until you exit the system or restart your computer.
See Also	GetWinDebugInfo

SetWindowExt

DWORD SetWin HDC <i>hdc</i> ; int <i>nXExtent</i> ; int <i>nYExtent</i> ;	ndowExt(hdc, nXExtent, nYExtent)/* handle of device context*//* x-extent of window*//* y-extent of window*/
	The SetWindowExt function sets the x- and y-extents of the window associated with the given device context. The window, along with the viewport, defines how logical coordinates are converted to device coordinates.
Parameters	<i>hdc</i> Identifies the device context. <i>nXExtent</i> Specifies the x-extent, in logical units, of the window.
	<i>nYExtent</i> Specifies the y-extent, in logical units, of the window.

Return Value	The return value is the window's previous extents, in logical units, if the function is successful. The low-order word contains the previous x-extent; the high-order word contains the previous y-extent. Otherwise, the return value is zero.
Comments	When the following mapping modes are set, calls to the SetWindowExt and

MM_HIENGLISH MM_HIMETRIC MM_LOENGLISH MM_LOMETRIC MM_TEXT MM_TWIPS

SetViewportExt functions are ignored:

When MM_ISOTROPIC mode is set, an application must call the **SetWindowExt** function before calling **SetViewportExt**.

The x- and y-extents of the window define how much the graphics device interface (GDI) must stretch or compress units in the logical coordinate system to fit units in the device coordinate system. For example, if the x-extent of the window is 2 and the x-extent of the viewport is 4, GDI converts two logical units (measured from the x-axis) into four device units. Similarly, if the y-extent of the window is 2 and the y-extent of the viewport is -1, GDI converts two logical units (measured from the y-axis) into one device unit.

The extents also define the relative orientation of the x- and y-axes in both coordinate systems. If the signs of matching window and viewport extents are the same, the axes have the same orientation. If the signs are different, the orientation is reversed. For example, if the y-extent of the window is 2 and the y-extent of the viewport is -1, GDI converts the positive y-axis in the logical coordinate system to the negative y-axis in the device coordinate system. If the x-extents are 2 and 4, GDI converts the positive x-axis in the logical coordinate system to the positive x-axis in the device coordinate system.

Example

The following example uses the **SetMapMode**, **SetWindowExt**, and **Set-ViewportExt** functions to create a client area that is 10 logical units wide and 10 logical units high and then draws a rectangle that is 4 units wide and 4 units high:

```
HDC hdc;
RECT rc;
```

GetClientRect(hwnd, &rc); hdc = GetDC(hwnd); SetMapMode(hdc, MM_ANISOTROPIC); SetWindowExt(hdc, 10, 10); SetViewportExt(hdc, rc.right, rc.bottom); Rectangle(hdc, 3, 3, 7, 7); ReleaseDC(hwnd, hdc); See Also GetWindowExt, SetViewportExt

SetWindowExtEx

3.1

BOOL SetWindow	ExtEx(hdc, nX, nY, lpSize)
HDC hdc;	/* handle of device context */
int nX ;	/* x-extent of window */
int <i>nY</i> ;	/* y-extent of window */
SIZE FAR* <i>lpSize</i> ;	/* address of struct. with prev. extents */
	The SetWindowExtEx function sets the x- and y-extents of the window associated with the specified device context. The window, along with the viewport, defines how points are mapped from logical coordinates to device coordinates.
Parameters	hdc
	Identifies the device context.
	nX
	Specifies the x-extent, in logical units, of the window.
	nY
	Specifies the y-extent, in logical units, of the window.
	lpSize
	Points to a SIZE structure. The previous extents of the window (in logical units) are placed in this structure. If <i>lpSize</i> is NULL nothing is returned. The SIZE structure has the following form:
	<pre>typedef struct tagSIZE { int cx; int cy; } SIZE;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	When the following mapping modes are set, calls to the SetWindowExtEx and SetViewportExt functions are ignored:
	MM_HIENGLISH MM_HIMETRIC MM_LOENGLISH

MM_LOMETRIC MM_TEXT MM_TWIPS

When MM_ISOTROPIC mode is set, an application must call the **SetWindow-ExtEx** function before calling **SetViewportExt**.

See Also SetViewportExtEx

SetWindowLong

LONG SetWindowLong(hwnd, nOffset, nVal) HWND hwnd; /* handle of window */ int nOffset; /* offset of value to set */ LONG nVal; /* new value */ The SetWindowLong function places a long value at the specified offset into the extra window memory of the given window. Extra window memory is reserved by specifying a nonzero value in the cbWndExtra member of the WNDCLASS structure used with the RegisterClass function.

Parameters

hwnd

Identifies the window.

nOffset

Specifies the zero-based byte offset of the value to change. Valid values are in the range zero through the number of bytes of extra window memory, minus four (for example, if 12 or more bytes of extra memory were specified, a value of 8 would be an index to the third long integer), or one of the following values:

Value	Meaning
GWL_EXSTYLE	Extended window style
GWL_STYLE	Window style
GWL_WNDPROC	Long pointer to the window procedure

The following values are also available when the *hwnd* parameter identifies a dialog box:

Value	Meaning
DWL_DLGPROC	Specifies the address of the dialog box procedure.
DWL_MSGRESULT	Specifies the return value of a message processed in the dialog box procedure.

	Value	Meaning
	DWL_USER	Specifies extra information that is private to the applica- tion, such as handles or pointers.
	<i>nVal</i> Specifies the long valu	te to place in the window's reserved memory.
Return Value	The return value is the previous value of the specified long integer, if the function is successful. Otherwise, it is zero.	
Comments	If the SetWindowLong function and the GWL_WNDPROC index are used to set a new window procedure, that procedure must have the window-procedure form and be exported in the module-definition file of the application. For more informa- tion, see the description of the RegisterClass function.	
	the window class used to	g with the GCL_WNDPROC index creates a subclass of create the window. An application should not attempt to for standard Windows controls such as combo boxes and
		t use this function to set the WS_DISABLE style for a lication should use the EnableWindow function.
	created, use a positive by	te values allocated when the window-class structure was te offset as the index specified by the <i>nOffset</i> parameter, -byte value in the extra space, 4 for the next 4-byte
	dialog box procedure's w return TRUE in order for Some messages, however	e DWL_MSGRESULT value to return values from a indow procedure. Typically, a dialog box procedure must a value to be returned to the sender of the message. c, return a value in the Boolean return value of the dialog wing messages return values in the return value of the
	WM_CHARTOITEM WM_COMPAREITEM WM_CTLCOLOR WM_INITDIALOG WM_QUERYDRAGICC WM_VKEYTOITEM	DN
Example	DWL_MSGRESULT val cations often include a sw	hows how to use the SetWindowLong function with the lue to return a value from a dialog box procedure. Appli- vitch statement to handle the messages that return values ue of the dialog box procedure, even when the dialog box

procedure does not process these messages. This practice makes it easy to revise the dialog box procedure to handle the message and has a negligible effect on speed and memory.

```
BOOL CALLBACK MyDlgProc(hwndDlg, msg, wParam, lParam)
HWND hwndDlg;
UINT msq:
WPARAM wParam;
LPARAM 1Param;
{
    BOOL fProcessed = FALSE;
    LRESULT 1Result;
    /*
     * To return a value for a specific message, set lResult to the
     * return value and fProcessed to TRUE.
     */
    switch (msg) {
          /* process messages */
        .
    case WM QUERYENDSESSION:
        /*
         * Example: Do not allow the system to terminate
         * while the dialog box is displayed.
         */
        fProcessed = TRUE;
        IResult = (LRESULT) (UINT) FALSE;
        break:
    default:
        break:
    }
    if (fProcessed) {
        switch (msg) {
        case WM_CTLCOLOR:
        case WM COMPAREITEM:
        case WM_VKEYTOITEM:
        case WM CHARTOITEM:
        case WM_QUERYDRAGICON:
        case WM_INITDIALOG:
            return (BOOL) LOWORD(lResult);
```

```
default:
    SetWindowLong(hwndDlg, DWL_MSGRESULT, (LPARAM) lResult);
  }
}
return fProcessed;
```

SetWindowOrg

}

DWORD SetW HDC hdc; int nXOrigin; int nYOrigin;	/indowOrg(hdc, nXOrigin, nYOrigin) */ /* handle of device context */ /* x-coordinate to map to upper-left window corner */ /* y-coordinate to map to upper-left window corner */	
	The SetWindowOrg function sets the window origin for the given device context.	
Parameters	<i>hdc</i> Identifies the device context.	
	<i>nXOrigin</i> Specifies the logical x-coordinate to map to the upper-left corner of the window.	
	<i>nYOrigin</i> Specifies the logical y-coordinate to map to the upper-left corner of the window.	
Return Value	The return value is the coordinates of the previous window origin, in logical units, if the function is successful. The low-order word contains the x-coordinate of the previous window origin; the high-order word contains the y-coordinate. Otherwise, the return value is zero.	
Comments	The window origin is the origin of the logical coordinate system for a window. By changing the window origin, an application can change the way the graphics device interface (GDI) converts logical coordinates to device coordinates (the viewport). GDI converts logical coordinates to the device coordinates of the view- port in the same way as it converts the origin.	
	To convert points to the right, an application can specify a negative value for the <i>nXOrigin</i> parameter. Similarly, to convert points down (in the MM_TEXT mapping mode), the <i>nYOrigin</i> parameter can be negative.	
Example	The following example uses the CopyMetaFile function to copy a metafile to a specified file, plays the copied metafile, uses the GetMetaFile function to retrieve	

a handle of the copied metafile, uses the **SetWindowOrg** function to change the position at which the metafile is played 200 logical units to the right, and then plays the metafile at the new location:

```
HANDLE hmf, hmfSource, hmfOld;
LPSTR lpszFile1 = "MFTest";
hmf = CopyMetaFile(hmfSource, lpszFile1);
PlayMetaFile(hdc, hmf);
DeleteMetaFile(hmf);
hmfOld = GetMetaFile(lpszFile1);
SetWindowOrg(hdc, -200, 0);
PlayMetaFile(hdc, hmfOld);
DeleteMetaFile(hmfSource);
DeleteMetaFile(hmfOld);
```

SetWindowOrgEx

BOOL SetWindowOrgEx(*hdc*, *nX*, *nY*, *lpPoint*) HDC hdc; /* handle of device context */ /* x-coordinate of window */ int nX: /* y-coordinate of window int nY; */ **POINT FAR*** *lpPoint*; /* address of struct. with prev. origin */ The SetWindowOrgEx function sets the window origin of the specified device context. The window, along with the viewport, defines how points are mapped from logical coordinates to device coordinates. **Parameters** hdc Identifies the device context. nX Specifies the logical x-coordinate of the new origin of the window. nYSpecifies the logical y-coordinate of the new origin of the window. *lpPoint* Points to a **POINT** structure. The previous origin of the window is placed in this structure. If *lpPoint* is NULL nothing is returned. The **POINT** structure has the following form:

3.1

The return value is nonzero if the function is successful. Otherwise, it is zero.	
n-	

SetWindowPlacement

BOOL SetWindowPlacement(*hwnd*, *lpwndpl*) /* handle of the window */ HWND hwnd; const WINDOWPLACEMENT FAR* lpwndpl; */ /* address of structure with position data The SetWindowPlacement function sets the show state and the normal (restored), minimized, and maximized positions for a window. **Parameters** hwnd Identifies the window. lpwndpl Points to a WINDOWPLACEMENT structure that specifies the new show state and positions. The WINDOWPLACEMENT structure has the following form: typedef struct tagWINDOWPLACEMENT { /* wndpl */ UINT length; UINT flags: UINT showCmd; POINT ptMinPosition; POINT ptMaxPosition; RECT rcNormalPosition; } WINDOWPLACEMENT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3. **Return Value** The return value is nonzero if the function is successful. Otherwise, it is zero. GetWindowPlacement See Also

SetWindowPos

BOOL SetWindowPos(*hwnd*, *hwndInsertAfter*, *x*, *y*, *cx*, *cy*, *fuFlags*)

HWND hwnd;	/* handle of window	*/
HWND hwndInsertAfter;	/* placement-order handle	*/
int x;	/* horizontal position	*/
int y;	/* vertical position	*/
int cx;	/* width	*/
int cy;	/* height	*/
UINT fuFlags;	/* window-positioning flags	*/

The **SetWindowPos** function changes the size, position, and Z-order of child, popup, and top-level windows. These windows are ordered according to their appearance on the screen; the window on top receives the highest rank and is the first window in the Z-order.

Parameters

Identifies the window to be positioned.

hwndInsertAfter

hwnd

Identifies the window to precede the positioned window in the Z-order. This parameter must be a window handle or one of the following values:

Value	Meaning
HWND_BOTTOM	Places the window at the bottom of the Z-order. If <i>hwnd</i> identifies a topmost window, the window loses its topmost status; the system places the window at the bottom of all other windows.
HWND_TOP	Places the window at the top of the Z-order.
HWND_TOPMOST	Places the window above all non-topmost windows. The window maintains its topmost position even when it is deactivated.
HWND_NOTOPMOST	Repositions the window to the top of all non-topmost windows (that is, behind all topmost windows). This flag has no effect if the window is already a non- topmost window.

For rules about how this parameter is used, see the following Comments section.

х

Specifies the new position of the left side of the window.

y

Specifies the new position of the top of the window.

cx

Specifies the new width of the window.

сx

Specifies the new width of the window.

су

Return Value

Comments

Specifies the new height of the window.

fuFlags

Specifies the window sizing and positioning options. This parameter can be a combination of the following values:

	-
Value	Meaning
SWP_DRAWFRAME	Draws a frame (defined in the window's class descrip- tion) around the window.
SWP_HIDEWINDOW	Hides the window.
SWP_NOACTIVATE	Does not activate the window. If this flag is not set, the window is activated and moved to the top of either the topmost or non-topmost group (depending on the set- ting of the <i>hwndInsertAfter</i> parameter).
SWP_NOMOVE	Retains the current position (ignores the <i>x</i> and <i>y</i> parameters).
SWP_NOSIZE	Retains the current size (ignores the <i>cx</i> and <i>cy</i> parameters).
SWP_NOREDRAW	Does not redraw changes. If this flag is set, no repaint- ing of any kind occurs. This applies to the client area, the non-client area (including the title and scroll bars), and any part of the parent window uncovered as a re- sult of the moved window. When this flag is set, the ap- plication must explicitly invalidate or redraw any parts of the window and parent window that must be redrawn.
SWP_NOZORDER	Retains the current ordering (ignores the <i>hwnd-InsertAfter</i> parameter).
SWP_SHOWWINDOW	Displays the window.
	o if the function is successful. Otherwise, it is zero. OW or the SWP_HIDEWINDOW flags are set, the win- zed.
ll coordinates for child wi orner of the parent window	indows are client coordinates (relative to the upper-left w's client area).
window can be made a to	opmost window either by setting the hwndInsertAfter

A window can be made a topmost window either by setting the *hwndInsertAfter* parameter to HWND_TOPMOST and ensuring that the SWP_NOZORDER flag is not set, or by setting a window's Z-order so that it is above any existing topmost windows. When a non-topmost window is made topmost, its owned windows are also made topmost. Its owners are not changed.

- -

	If neither SWP_NOACTIVATE nor SWP_NOZORDER is specified (that is, when the application requests that a window be simultaneously activated and placed in the specified Z-order), the value specified in <i>hwndInsertAfter</i> is used only in the following circumstances:
	 Neither HWND_TOPMOST or HWND_NOTOPMOST is specified in the hwndInsertAfter parameter.
	• The window specified in the <i>hwnd</i> parameter is not the active window.
	An application cannot activate an inactive window without also bringing it to the top of the Z-order. Applications can change the Z-order of an activated window without restrictions or activate a window and then move it to the top of the top-most or non-topmost windows.
	A topmost window is no longer topmost if it is repositioned to the bottom (HWND_BOTTOM) of the Z-order or after any non-topmost window. When a topmost window is made non-topmost, all of its owners and its owned windows are also made non-topmost windows.
	A non-topmost window may own a topmost window, but not vice versa. Any win- dow (for example, a dialog box) owned by a topmost window is itself made a top- most window, to ensure that all owned windows stay above their owner.
Example	The following example sets the size of a window equal to one-fourth the size of the desktop and then positions the window in the upper-left corner of the desktop:
	RECT rect;
	<pre>GetWindowRect(GetDesktopWindow(), ▭); SetWindowPos(hwnd, (HWND) NULL, 0, 0, rect.right / 2, rect.bottom / 2, SWP_NOZORDER SWP_NOACTIVATE);</pre>
See Also	BringWindowToTop, GetWindowRect, MoveWindow

SetWindowsHook

2.x

HHOOK SetWindowsHook(*idHook*, *hkprc*)

int idHook; HOOKPROC hkprc; /* type of hook to install */ /* filter function procedure-instance address */

The **SetWindowsHook** function is obsolete but has been retained for backward compatibility with Windows versions 3.0 and earlier. Applications written for Windows version 3.1 should use the **SetWindowsHookEx** function.

The **SetWindowsHook** function installs an application-defined hook function into a hook chain.

Parameters

idHook

Specifies the type of hook to be installed. This parameter can be one of the following values:

Value	Meaning
WH_CALLWNDPROC	Installs a window-procedure filter. For more in- formation, see the description of the CallWnd- Proc callback function.
WH_CBT	Installs a computer-based training (CBT) filter. For more information, see the description of the CBTProc callback function.
WH_DEBUG	Installs a debugging filter. For more information, see the description of the DebugProc callback function.
WH_GETMESSAGE	Installs a message filter. For more information, see the description of the GetMsgProc callback function.
WH_HARDWARE	Installs a nonstandard hardware-message filter. For more information, see the description of the HardwareProc callback function.
WH_JOURNALPLAYBACK	Installs a journaling playback filter. For more in- formation, see the description of the Journal- PlaybackProc callback function.
WH_JOURNALRECORD	Installs a journaling record filter. For more infor- mation, see the description of the Journal- RecordProc callback function.
WH_KEYBOARD	Installs a keyboard filter. For more information, see the description of the KeyboardProc callback function.
WH_MOUSE	Installs a mouse-message filter. For more infor- mation, see the description of the MouseProc callback function.
WH_MSGFILTER	Installs a message filter. For more information, see the description of the MessageProc callback function.
WH_SHELL	Installs a shell-application filter. For more infor- mation, see the description of the ShellProc call- back function.
WH_SYSMSGFILTER	Installs a system-wide message filter. For more information, see the description of the SysMsg-Proc callback function.

	<i>hkprc</i> Specifies the procedure-instance address of the application-defined hook proce- dure to be installed.	
Return Value	The return value is a handle of the installed hook, if the function is successful. Otherwise, it is NULL.	
Comments	Before terminating, an application must call the UnhookWindowsHook function to free system resources associated with the hook.	
	The WH_CALLWNDPROC hook affects system performance. It is supplied for debugging purposes only.	
	The system hooks are a shared resource. Installing a hook affects all applications. Most hook functions must be in libraries. The only exception is WH_MSGFILTER, which is task-specific. System hooks should be restricted to special-purpose applications or to use as a development aid during debugging of an application. Libraries that no longer need the hook should remove the filter function.	
	To install a filter function, the SetWindowsHook function must receive a proce- dure-instance address of the function and the function must be exported in the library's module-definition file. A task must use the MakeProcInstance function to get a procedure-instance address. A dynamic-link library can pass the procedure address directly.	
See Also	DefHookProc, GetProcAddress, MakeProcInstance, MessageBox, PeekMessage, PostMessage, SendMessage, SetWindowsHookEx, UnhookWindowsHook	

SetWindowsHookEx

HHOOK SetWindowsHookEx(idHook, hkprc, hinst, htask)			
int idHook;	/* type of hook to install	*/	
HOOKPROC hkprc;	/* procedure-instance address of filter function	*/	
HINSTANCE hinst;	/* handle of application instance	*/	
HTASK htask;	/* task to install the hook for	*/	

The **SetWindowsHookEx** function installs an application-defined hook function into a hook chain. This function is an extended version of the **SetWindowsHook** function.

Parameters

idHook

Specifies the type of hook to be installed. This parameter can be one of the following values:

Value	Meaning
WH_CALLWNDPROC	Installs a window-procedure filter. For more in- formation, see the description of the CallWnd- Proc callback function.
WH_CBT	Installs a computer-based training (CBT) filter. For more information, see the description of the CBTProc callback function.
WH_DEBUG	Installs a debugging filter. For more information, see the description of the DebugProc callback function.
WH_GETMESSAGE	Installs a message filter. For more information, see the description of the GetMsgProc callback function.
WH_HARDWARE	Installs a nonstandard hardware-message filter. For more information, see the description of the HardwareProc callback function.
WH_JOURNALPLAYBACK	Installs a journaling playback filter. For more in- formation, see the description of the Journal- PlaybackProc callback function.
WH_JOURNALRECORD	Installs a journaling record filter. For more infor- mation, see the description of the Journal- RecordProc callback function.
WH_KEYBOARD	Installs a keyboard filter. For more information, see the description of the KeyboardProc call-back function.
WH_MOUSE	Installs a mouse-message filter. For more infor- mation, see the description of the MouseProc callback function.
WH_MSGFILTER	Installs a message filter. For more information, see the description of the MessageProc callback function.
WH_SYSMSGFILTER	Installs a system-wide message filter. For more information, see the description of the SysMsg-Proc callback function.

hkprc

Specifies the procedure-instance address of the application-defined hook procedure to be installed.

hinst

Identifies the instance of the module containing the hook function.

	<i>htask</i> Identifies the task for which the hook is to be installed. If this parameter is NULL, the installed hook function has system scope and may be called in the context of any process or task in the system.	
Return Value	The return value is a handle of the installed hook, if the function is successful. The application or library must use this handle to identify the hook when it calls the CallNextHookEx and UnhookWindowsHookEx functions. The return value is NULL if an error occurs.	
Comments	An application or library can use the GetCurrentTask or GetWindowTask function to obtain task handles for use in hooking a particular task.	
	Hook procedures used with SetWindowsHookEx must be declared as follows:	
	DWORD CALLBACK HookProc(code, wParam, 1Param) int code; WPARAM wParam; LPARAM 1Param; { if () return CallNextHookEx(hhook, code, wParam, 1Param); }	

Chaining to the next hook procedure (that is, calling the **CallNextHookProc** function) is optional. An application or library can call the next hook procedure either before or after any processing in its own hook procedure.

Before terminating, an application must call the **UnhookWindowsHookEx** function to free system resources associated with the hook.

Some hooks may be set with system scope only, and others may be set only for a specific task, as shown in the following list:

Hook	Scope
WH_CALLWNDPROC	Task or system
WH_CBT	Task or system
WH_DEBUG	Task or system
WH_GETMESSAGE	Task or system
WH_HARDWARE	Task or system
WH_JOURNALRECORD	System only
WH_JOURNALPLAYBACK	System only
WH_KEYBOARD	Task or system
WH_MOUSE	Task or system
WH_MSGFILTER	Task or system

	WH_SYSMSGFILTER Sy	vstem only	
	For a given hook type, task hooks are called first, then system hooks.

Scope

SetWindowText

void SetWindowText(hwnd, lpsz)			
HWND hwnd;	/* handle of window	*/	
LPCSTR lpsz;	/* address of string	*/	

Hook

2.x

	The SetWindowText function sets the given window's title to the specified text.		
Parameters	<i>hwnd</i> Identifies the window or control whose text is to be set.		
	<i>lpsz</i> Points to a null-terminated string to be used as the new title or control text.		
Return Value	This function does not return a value.		
Comments	This function causes a WM_SETTEXT message to be sent to the given window or control.		
	If the window specified by the <i>hwnd</i> parameter is a control, the text within the control is set. If the specified window is a list-box control created with WS_CAPTION style, however, SetWindowText will set the caption for the control, not for the list-box entries.		
Example	The following example sets a window title:		
	char szBuf[64]; char szFileName[64];		
	wsprintf((LPSTR) szBuf, "PrntFile – %s", (LPSTR) szFileName); SetWindowText(hwnd, (LPSTR) szBuf);		
See Also	GetWindowText		

SetWindowWord

WORD SetWind HWND hwnd; int nOffset; WORD nVal;	dowWord(hwnd, nOffset, nVal) /* handle of window */ /* offset of value to set */ /* new value */	
	The SetWindowWord function places a word value extra window memory of the given window. Extra w specifying a nonzero value in the cbWndExtra men structure used with the RegisterClass function.	vindow memory is reserved by
Parameters	hwnd Identifies the window.	

2.x

nOffset

Specifies the zero-based byte offset of the value to change. Valid values are in the range zero through the number of bytes of extra window memory, minus two (for example, if 10 or more bytes of extra memory were specified, a value of 8 would be an index to the fifth integer), or one of the following values:

	Value	Meaning
	GWW_HINSTANCE	Specifies the instance handle of the module that owns the window.
	GWW_ID	Specifies the identifier of the child window.
	<i>nVal</i> Specifies the word value	ue to be placed in the window's reserved memory.
Return Value	The return value is the previous value of the specified word, if the function is successful. Otherwise, it is zero.	
Comments	To access any extra 2-byte values allocated when the window-class structure was created, use a positive byte offset as the index specified by the <i>nOffset</i> parameter, starting at 0 for the first 2-byte value in the extra space, 2 for the next 2-byte value, and so on.	
	An application should call the SetParent function, not the SetWindowWord function, to change a value in the parent of a child window.	
See Also	GetWindowWord, RegisterClass, SetParent, SetWindowLong	

ShellExecute

#include <shellapi.h>

HINSTANCE ShellExecu	te(hwnd, lpszOp, lpszFile, lpszParams, lpszDir, fsSh	owCmd)
HWND hwnd;	/* handle of parent window	*/
LPCSTR lpszOp;	/* address of string for operation to perform	*/
LPCSTR <i>lpszFile</i> ;	/* address of string for filename	*/
LPCSTR lpszParams;	/* address of string for executable-file parameters	*/
LPCSTR <i>lpszDir</i> ;	/* address of string for default directory	*/
int fsShowCmd;	/* whether file is shown when opened	*/

The ShellExecute function opens or prints the specified file.

Parameters

hwnd

Identifies the parent window. This window receives any message boxes an application produces (for example, for error reporting).

lpszOp

Points to a null-terminated string specifying the operation to perform. This string can be "open" or "print". If this parameter is NULL, "open" is the default value.

lpszFile

Points to a null-terminated string specifying the file to open.

lpszParams

Points to a null-terminated string specifying parameters passed to the application when the *lpszFile* parameter specifies an executable file. If *lpszFile* points to a string specifying a document file, this parameter is NULL.

lpszDir

Points to a null-terminated string specifying the default directory.

fsShowCmd

Specifies whether the application window is to be shown when the application is opened. This parameter can be one of the following values:

Value	Meaning
SW_HIDE	Hides the window and passes activation to another window.
SW_MINIMIZE	Minimizes the specified window and activates the top-level window in the system's list.
SW_RESTORE	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_SHOWNORMAL).
SW_SHOW	Activates a window and displays it in its current size and position.
SW_SHOWMAXIMIZED	Activates a window and displays it as a maxi- mized window.
SW_SHOWMINIMIZED	Activates a window and displays it as an icon.
SW_SHOWMINNOACTIVE	Displays a window as an icon. The window that is currently active remains active.
SW_SHOWNA	Displays a window in its current state. The win- dow that is currently active remains active.
SW_SHOWNOACTIVATE	Displays a window in its most recent size and position. The window that is currently active remains active.

	Value		Meaning	
	SW_S	HOWNORMAL	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_RESTORE).	
Return Value	printed, DDE sei	if the function is success over application.) A return	andle of the application that was opened or ful. (This handle could also be the handle of a n value less than or equal to 32 specifies an error. ed in the following Comments section.	
Errors	specified	The ShellExecute function returns the value 31 if there is no association for the specified file type or if there is no association for the specified action within the file type. The other possible error values are as follows:		
	Value	Meaning		
	0	System was out of mem invalid.	ory, executable file was corrupt, or relocations were	
	2	File was not found.		
	3	Path was not found.		
	5	Attempt was made to dy network-protection error	namically link to a task, or there was a sharing or r.	
	6	Library required separat	e data segments for each task.	
	8	There was insufficient n	nemory to start the application.	
	10	Windows version was in	ncorrect.	
	11	Executable file was inva there was an error in the	ilid. Either it was not a Windows application or .EXE image.	
	12	Application was designed	ed for a different operating system.	
	13	Application was designed	ed for MS-DOS 4.0.	
	14	Type of executable file v	was unknown.	
	15	Attempt was made to low version of Windows).	ad a real-mode application (developed for an earlier	
	16		ad a second instance of an executable file contain- nts that were not marked read-only.	
	19	Attempt was made to load decompressed before it of	ad a compressed executable file. The file must be can be loaded.	
	20	Dynamic-link library (D run this application was	LL) file was invalid. One of the DLLs required to corrupt.	
	21	Application requires Mi	crosoft Windows 32-bit extensions.	
Comments			parameter can be a document file or an execu- this function opens or prints it, depending on the	

value of the *lpszOp* parameter. If it is an executable file, this function opens it, even if the string "print" is pointed to by *lpszOp*.

See Also FindExecutable

ShellProc

3.1

LRESULT CALLBACK	X ShellProc (code, wParam, l.	Param)
int code;	/* process-message flag	*/
WPARAM wParam;	/* current-task flag	*/
LPARAM lParam;	/* undefined	*/

The **ShellProc** function is a library-defined callback function that a shell application can use to receive useful notifications from the system.

Parameters

Specifies a shell-notification code. This parameter can be one of the following values:

Value	Meaning
HSHELL_ACTIVATESHELLWINDOW	The shell application should activate its main window.
HSHELL_WINDOWCREATED	A top-level, unowned window was created. The window exists when the system calls a ShellProc function.
HSHELL_WINDOWDESTROYED	A top-level, unowned window is about to be destroyed. The window still exists when the system calls a ShellProc function.

wParam

code

Specifies additional information the shell application may need. The interpretation of this parameter depends on the value of the *code* parameter, as follows:

code	wParam
HSHELL_ACTIVATESHELLWINDOW	Not used.
HSHELL_WINDOWCREATED	Specifies the handle of the window being created.
HSHELL_WINDOWDESTROYED	Specifies the handle of the window being destroyed.

	<i>lParam</i> Reserved; not used.
Return Value	The return value should be zero.
Comments	An application must install this callback function by specifying the WH_SHELL filter type and the procedure-instance address of the callback function in a call to the SetWindowsHook function.
	ShellProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.
See Also	DefHookProc, SendMessage, SetWindowsHook

2.x

void ShowCaret(hwnd)
HWND hwnd; /* handle of window with caret

The **ShowCaret** function shows the caret on the screen at the caret's current position. Once shown, the caret begins flashing automatically.

*/

Parameters	<i>hwnd</i> Identifies the window that owns the caret. This parameter can be set to NULL to indirectly specify the window in the current task that owns the caret.
Return Value	This function does not return a value.
Comments	The ShowCaret function shows the caret only if it has a current shape and has not been hidden two or more times consecutively. If the given window does not own the caret, the caret is not shown. If the <i>hwnd</i> parameter is NULL, the ShowCaret function shows the caret only if it is owned by a window in the current task.
	Hiding the caret is cumulative. If the HideCaret function has been called five times consecutively, ShowCaret must be called five times to show the caret.
	The caret is a shared resource. A window should show the caret only when it has the input focus or is active.
See Also	CreateCaret, GetActiveWindow, GetFocus, HideCaret

ShowCursor

int ShowCursor(fShow) BOOL fShow; /* cursor visibility flag */			
	The ShowCursor function shows or hides the cursor.		
Parameters	<i>fShow</i> Specifies whether the display count is incremented or decremented (increased or decreased by one). If this parameter is TRUE, the display count is incremented; otherwise, it is decremented.		
Return Value	The return value specifies the new display count, if the function is successful.		
Comments	A cursor show-level count is kept internally. It is incremented by a show operation and decremented by a hide operation. The cursor is visible only if the count is greater than or equal to zero. If a mouse exists, the initial setting of the cursor show level is zero; otherwise, it is -1 .		
	The cursor is a shared resource. A window that hides the cursor should show it before the cursor leaves its client area or before the window relinquishes control to another window.		
See Also	SetCursor		

ShowOwnedPopups

void ShowOwned	lPopups(hwnd, fShow)
HWND hwnd.	/* handle of window

HWND hwnd;	/* handle of window	*/
BOOL fShow;	/* window visibility flag	*/

The **ShowOwnedPopups** function shows or hides all pop-up windows owned by the given window.

Parameters

hwnd

Identifies the window that owns the pop-up windows to be shown or hidden.

2.x

	<i>fShow</i> Specifies whether pop-up windows are to be shown or hidden. If this parameter is TRUE, all hidden pop-up windows are shown. If this parameter is FALSE, all visible pop-up windows are hidden.
Return Value	This function does not return a value.
See Also	IsWindowVisible, ShowWindow

ShowScrollBar

2.x

	Bar (<i>hwnd</i> , <i>fnBar</i> , <i>fS</i> /* handle of windo /* scroll-bar flag /* scroll-bar visibi	ow with scroll bar	*/ */ */
	The ShowScrol	IBar function shows or	r hides a scroll bar.
Parameters	 <i>hwnd</i> Identifies a scroll bar or a window that contains a scroll bar in its nonclient area, depending on the value of the <i>fnBar</i> parameter. If <i>fnBar</i> is SB_CTL, <i>hwnd</i> identifies a scroll bar. If <i>fnBar</i> is SB_HORZ, SB_VERT, or SB_BOTH, <i>hwnd</i> identifies a window that has a scroll bar in its nonclient area. <i>fnBar</i> Specifies whether the scroll bar is a control or part of a window's nonclient area. If the scroll bar is part of the nonclient area, <i>fnBar</i> also indicates whether the scroll bar is positioned horizontally, vertically, or both. This parameter can be one of the following values: 		
	Value	Meaning	
	SB_BOTH	Specifies the window's	horizontal and vertical scroll bars.
	SB_CTL	Specifies that the hwnd	parameter identifies a scroll bar control.
	SB_HORZ	Specifies the window's	horizontal scroll bar.
	SB_VERT	Specifies the window's	vertical scroll bar.
	fShow		

Specifies whether the scroll bar is shown or hidden. If this parameter is TRUE, the scroll bar is shown; otherwise, it is hidden.

Return Value	This function does not return a value.
Comments	An application should not call this function to hide a scroll bar while processing a scroll-bar notification message.
See Also	GetScrollPos, GetScrollRange, ScrollWindow, SetScrollPos, SetScrollRange

ShowWindow

BOOL ShowWindow(hwnd, nCmdShow)

HWND hwnd;	/* handle of window	*/
int nCmdShow;	/* window visibility flag	*/

The ShowWindow function sets the given window's visibility state.

Parameters

Identifies the window.

nCmdShow

hwnd

Specifies how the window is to be shown. This parameter can be one of the following values:

Value	Meaning
SW_HIDE	Hides the window and passes activation to another window.
SW_MINIMIZE	Minimizes the specified window and activates the top-level window in the system's list.
SW_RESTORE	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_SHOWNORMAL).
SW_SHOW	Activates a window and displays it in its current size and position.
SW_SHOWMAXIMIZED	Activates a window and displays it as a maxi- mized window.
SW_SHOWMINIMIZED	Activates a window and displays it as an icon.
SW_SHOWMINNOACTIVE	Displays a window as an icon. The window that is currently active remains active.
SW_SHOWNA	Displays a window in its current state. The win- dow that is currently active remains active.

2.x

2.x

	Value	Meaning
	SW_SHOWNOACTIVATE	Displays a window in its most recent size and position. The window that is currently active remains active.
	SW_SHOWNORMAL	Activates and displays a window. If the window is minimized or maximized, Windows restores it to its original size and position (same as SW_RESTORE).
Return Value	The return value is nonzero if the window was previously hidden.	e window was previously visible. It is zero if the
Comments	The ShowWindow function must be called only once per application using the <i>nCmdShow</i> parameter from the WinMain function. Subsequent calls to Show-Window must use one of the values listed in the preceding list, instead of the one specified by the <i>nCmdShow</i> parameter from WinMain .	
See Also	IsWindowVisible, ShowOwned	lPopups

SizeofResource

DWORD SizeofRes HINSTANCE hinst; HRSRC hrsrc;		
	The SizeofResource function returns the size, in bytes, of the given resource.	
Parameters hinst Identifies the instance of the module whose executable file contains the source.		
	<i>hrsrc</i> Identifies the resource. This handle must have been created by using the FindResource function.	
Return Value	The return value specifies the number of bytes in the resource, if the function is successful. It is zero if the resource cannot be found.	
Comments	The value returned may be larger than the resource due to alignment. An applica- tion should not rely upon this value for the exact size of a resource.	
See Also	AccessResource, FindResource	

SpoolFile

HANDLE SpoolFile LPSTR lpszPrinter; LPSTR lpszPort; LPSTR lpszJob; LPSTR lpszFile;	e(lpszPrinter, lpszPort, lpszJob, lpszFile) /* printer name */ /* port name */ /* job name */ /* file name */		
	The SpoolFile function puts a file into the spooler queue. This function is typically used by device drivers.		
Parameters	ers <i>lpszPrinter</i> Points to a null-terminated string specifying the printer name—for example, "HP LasterJet IIP".		
	<i>lpszPort</i> Points to a null-terminated string specifying the local name—for example, "LPT1:". This must be a local port.		
	<i>lpszJob</i> Points to a null-terminated string specifying the name of the print job for the spooler. This string cannot be longer than 32 characters, including the null-terminating character.		
	<i>lpszFile</i> Points to a null-terminated string specifying the path and filename of the file to put in the spooler queue. This file contains raw printer data.		
Return Value	The return value is the global handle that is passed to the spooler, if the function is successful. Otherwise, it is an error value, which can be one of the following:		
	SP_APPABORT SP_ERROR SP_NOTREPORTED SP_OUTOFDISK SP_OUTOFMEMORY SP_USERABORT		
Comments	Applications should ensure that the spooler is enabled before calling the SpoolFile function.		

StackTraceCSIPFirst

#include <toolhelp.h>

BOOL StackTraceCSIPFirst(lpste, wSS	, wCS, wIP, wBP)	
STACKTRACEENTRY FAR * lpste;	/* address of stack-frame structure	*/
WORD wSS;	/* value of SS register	*/
WORD <i>wCS</i> ;	/* value of CS register	*/
WORD wIP;	/* value of IP register	*/
WORD <i>wBP</i> ;	/* value of BP register	*/

The **StackTraceCSIPFirst** function fills the specified structure with information that describes the specified stack frame.

Parameters

Points to a **STACKTRACEENTRY** structure to receive information about the stack. The **STACKTRACEENTRY** structure has the following form:

```
#include <toolhelp.h>
typedef struct tagSTACKTRACEENTRY { /* ste */
    DWORD
            dwSize:
    HTASK
            hTask:
    WORD
            wSS;
    WORD
            wBP;
    WORD
            wCS;
    WORD
            wIP;
    HMODULE hModule;
    WORD
            wSegment:
    WORD
            wFlags;
} STACKTRACEENTRY;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

wSS

lpste

Contains the value in the SS register. This value is used with the *wBP* value to determine the next entry in the stack trace.

wCS

Contains the value in the CS register of the first stack frame.

wIP

Contains the value in the IP register of the first stack frame.

wBP

Contains the value in the BP register. This value is used with the *wSS* value to determine the next entry in the stack trace.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments	The StackTraceFirst function can be used to begin a stack trace of any task except the current task. When a task is inactive, the kernel maintains its state, including its current stack, stack pointer, CS and IP values, and BP value. The kernel does not maintain these values for the current task. Therefore, when a stack trace is done on the current task, the application must use StackTraceCSIPFirst to begin a stack trace. An application can continue to trace through the stack by using the StackTraceNext function.
	Before calling StackTraceCSIPFirst , an application must initialize the STACK-TRACEENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	StackTraceNext, StackTraceFirst

StackTraceFirst

#include <toolhelp.h>

	ExeFirst (<i>lpste</i> , <i>htask</i>) ENTRY FAR* <i>lpste</i> ; /* address of stack-frame structure /* handle of task	*/ */
	The StackTraceFirst function fills the specified structure w describes the first stack frame for the given task.	ith information that
Parameters	<pre>lpste Points to a STACKTRACEENTRY structure to receive task's first stack frame. The STACKTRACEENTRY str ing form: #include <toolhelp.h></toolhelp.h></pre>	
	<pre>typedef struct tagSTACKTRACEENTRY { /* ste */ DWORD dwSize; HTASK hTask; WORD wSS; WORD wBP; WORD wCS; WORD wIP; HMODULE hModule; WORD wSegment; WORD wFlags; } STACKTRACEENTRY;</pre>	

	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>htask</i> Identifies the task whose stack information is to be described.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The StackTraceFirst function can be used to begin a stack trace of any task except the current task. When a task is inactive, the kernel maintains its state, including its current stack, stack pointer, CS and IP values, and BP value. The kernel does not maintain these values for the current task. Therefore, when a stack trace is done on the current task, the application must use the StackTraceCSIPFirst function to begin a stack trace. An application can continue to trace through the stack by using the StackTraceNext function.
	Before calling StackTraceFirst , an application must initialize the STACK- TRACEENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	StackTraceCSIPFirst, StackTraceNext

StackTraceNext

#include <toolhelp.h< th=""><th>1></th><th></th><th></th></toolhelp.h<>	1>		
BOOL StackTraceN STACKTRACEEN		/* address of stack-frame structure	*/
		Next function fills the specified structure wi tack frame in a stack trace.	th information that de-
Parameters	<i>lpste</i> Points to a STACKTRACEENTRY structure to receive information about the next stack frame. The STACKTRACEENTRY structure has the following form:		
	#include <too< td=""><td>olhelp.h></td><td></td></too<>	olhelp.h>	
	DWORD C HTASK H WORD V WORD V	ct tagSTACKTRACEENTRY { /* ste */ dwSize; nTask; vSS; vBP; vCS;	

	WORD wIP;	
	HMODULE hModule;	
	WORD wSegment;	
	WORD wFlags;	
	<pre>} STACKTRACEENTRY;</pre>	
	For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The StackTraceNext function can be used to continue a stack trace started by using the StackTraceFirst or StackTraceCSIPFirst function.	
See Also	StackTraceCSIPFirst, StackTraceFirst, STACKTRACEENTRY	

StartDoc	3.1
int StartDoc(hdc, lpd HDC hdc; DOCINFO FAR* lpd	/* handle of device context */
	The StartDoc function starts a print job. For Windows version 3.1, this function replaces the STARTDOC printer escape.
	 <i>hdc</i> Identifies the device context for the print job. <i>lpdi</i> Points to a DOCINFO structure containing the name of the document file and the name of the output file. The DOCINFO structure has the following form:
	<pre>typedef struct { /* di */ int cbSize; LPCSTR lpszDocName; LPCSTR lpszOutput; } DOCINFO;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is positive if the function is successful. Otherwise, it is SP_ERROR.

2.x

Comments	Applications should call the StartDoc function immediately before beginning a print job. Using this function ensures that documents containing more than one page are not interspersed with other print jobs.
	The StartDoc function should not be used inside metafiles.
See Also	EndDoc, Escape

StartPage

int StartPage(hdc)
HDC hdc; /* handle of device context */

The StartPage function prepares the printer driver to accept data.

Parameters	<i>hdc</i> Identifies the device context for the print job.
Return Value	The return value is greater than zero if the function is successful. It is less than or equal to zero if an error occurs.
Comments	The system disables the ResetDC function between calls to the StartPage and EndPage functions. This means that applications cannot change the device mode except at page boundaries.
See Also	EndPage, Escape, ResetDC

StartSound

int StartSound(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

StopSound

int StopSound(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

StretchBlt

2.x

BOOL StretchBlt(*hdcDest*, *nXOriginDest*, *nYOriginDest*, *nWidthDest*, *nHeightDest*, *hdcSrc*, *nXOriginSrc*, *nYOriginSrc*, *nWidthSrc*, *nHeightSrc*, *fdwRop*)

maonginore, ni o		
HDC hdcDest;	/* destination device-context handle	*/
int nXOriginDest;	/* x-coordinate of origin of destination rectangle	*/
int nYOriginDest;	/* y-coordinate of origin of destination rectangle	*/
int nWidthDest;	/* width of destination rectangle	*/
int nHeightDest;	/* height of destination rectangle	*/
HDC hdcSrc;	/* source device-context handle	*/
int nXOriginSrc;	/* x-coordinate of origin of source rectangle	*/
int nYOriginSrc;	/* y-coordinate of origin of source rectangle	*/
int nWidthSrc;	/* width of source rectangle	*/
int nHeightSrc;	/* height of source rectangle	*/
DWORĎ fdwRop;	/* raster operation	*/

The **StretchBlt** function copies a bitmap from a source rectangle into a destination rectangle, stretching or compressing the bitmap if necessary to fit the dimensions of the destination rectangle. The **StretchBlt** function uses the stretching mode of the destination device context (set by the **SetStretchBltMode** function) to determine how to stretch or compress the bitmap.

Parameters

hdcDest

Identifies the device context to receive the bitmap.

nXOriginDest

Specifies the logical x-coordinate of the upper-left corner of the destination rectangle.

nYOriginDest

Specifies the logical y-coordinate of the upper-left corner of the destination rectangle.

nWidthDest

Specifies the width, in logical units, of the destination rectangle.

2.x

nHeightDest

Specifies the height, in logical units, of the destination rectangle.

hdcSrc

Identifies the device context that contains the source bitmap.

nXOriginSrc

Specifies the logical x-coordinate of the upper-left corner of the source rectangle.

nYOriginSrc

Specifies the logical y-coordinate of the upper-left corner of the source rectangle.

nWidthSrc

Specifies the width, in logical units, of the source rectangle.

nHeightSrc

Specifies the height, in logical units, of the source rectangle.

fdwRop

Specifies the raster operation to be performed. Raster-operation codes define how the graphics device interface (GDI) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. This parameter can be one of the following values:

Code	Description
BLACKNESS	Turns all output black.
DSTINVERT	Inverts the destination bitmap.
MERGECOPY	Combines the pattern and the source bitmap by using the Boolean AND operator.
MERGEPAINT	Combines the inverted source bitmap with the destination bit- map by using the Boolean OR operator.
NOTSRCCOPY	Copies the inverted source bitmap to the destination.
NOTSRCERASE	Inverts the result of combining the destination and source bit- maps by using the Boolean OR operator.
PATCOPY	Copies the pattern to the destination bitmap.
PATINVERT	Combines the destination bitmap with the pattern by using the Boolean XOR operator.
PATPAINT	Combines the inverted source bitmap with the pattern by using the Boolean OR operator. Combines the result of this operation with the destination bitmap by using the Boolean OR operator.
SRCAND	Combines pixels of the destination and source bitmaps by using the Boolean AND operator.
SRCCOPY	Copies the source bitmap to the destination bitmap.
SRCERASE	Inverts the destination bitmap and combines the result with the source bitmap by using the Boolean AND operator.

	Code	Description
	SRCINVERT	Combines pixels of the destination and source bitmaps by using the Boolean XOR operator.
	SRCPAINT	Combines pixels of the destination and source bitmaps by using the Boolean OR operator.
	WHITENESS	Turns all output white.
Return Value	The return value is no	onzero if the function is successful. Otherwise, it is zero.
Comments	The StretchBlt function stretches or compresses the source bitmap in memory and then copies the result to the destination. If a pattern is to be merged with the result it is not merged until the stretched source bitmap is copied to the destination.	
	If a brush is used, it i	s the selected brush in the destination device context.
	 The destination coordinates are transformed according to the destination device context; the source coordinates are transformed according to the source device text. If the destination, source, and pattern bitmaps do not have the same color forma StretchBlt converts the source and pattern bitmaps to match the destination bit maps. The foreground and background colors of the destination device context used in the conversion. If StretchBlt must convert a monochrome bitmap to color, it sets white bits (1) the background color and black bits (0) to the foreground color. To convert color to monochrome, it sets pixels that match the background colors of the destination device (1) and sets all other pixels to black (0). The foreground and background colors of the device context with color are used. 	
	<i>nWidthDest</i> or <i>nHeig</i> <i>nWidthDest</i> have diff along the x-axis. If <i>n</i> .	mirror image of a bitmap if the signs of the <i>nWidthSrc</i> and <i>whSrc</i> and <i>nHeightDest</i> parameters differ. If <i>nWidthSrc</i> and ferent signs, the function creates a mirror image of the bitmap <i>HeightSrc</i> and <i>nHeightDest</i> have different signs, the function ge of the bitmap along the y-axis.
		ort the StretchBlt function. Applications can discover ports StretchBlt by calling the GetDeviceCaps function and ERCAPS index.
Example	create a device conte the example calls the	ble retrieves the handle of the desktop window and uses it to xt. After retrieving the dimensions of the desktop window, StretchBlt function to copy the desktop bitmap into a he destination device context.

```
HWND hwndDesktop;
HDC hdcLocal;
RECT rc;
hwndDesktop = GetDesktopWindow();
hdcLocal = GetDC(hwndDesktop);
GetWindowRect(GetDesktopWindow(), &rc);
StretchBlt(hdc, 10, 10, 138, 106,
hdcLocal, 0, 0, rc.right, rc.bottom, SRCCOPY);
ReleaseDC(hwndDesktop, hdcLocal);
See Also BitBlt, GetDeviceCaps, SetStretchBltMode, StretchDIBits
```

StretchDIBits

int StretchDIBits(hdc, XDest, YDest, cxDest, cyDest, XSrc, YSrc, cxSrc, cySrc, lpvBits, lpbmi, fuColorUse, fdwRop)

jucción osc, junitop)		
HDC hdc;	/* handle of device context	*/
int XDest;	/* x-coordinate of destination rectangle	*/
int YDest;	/* y-coordinate of destination rectangle	*/
int cxDest;	/* width of destination rectangle	*/
int cyDest;	/* height of destination rectangle	*/
int XSrc;	/* x-coordinate of source rectangle	*/
int YSrc;	/* y-coordinate of source rectangle	*/
int cxSrc;	/* width of source rectangle	*/
int cySrc;	/* height of source rectangle	*/
<pre>const void FAR* lpvBits;</pre>	/* address of buffer with DIB bits	*/
LPBITMAPINFO lpbmi;	/* address of structure with bitmap data	*/
UINT fuColorUse;	/* RGB or palette indices	*/
DWORD fdwRop;	/* raster operation	*/

The **StretchDIBits** function moves a device-independent bitmap (DIB) from a source rectangle into a destination rectangle, stretching or compressing the bitmap if necessary to fit the dimensions of the destination rectangle.

Parameters

hdc

Identifies the destination device context for a screen surface or memory bitmap.

XDest

Specifies the logical x-coordinate of the destination rectangle.

YDest

Specifies the logical y-coordinate of the destination rectangle.

cxDest

Specifies the logical x-extent of the destination rectangle.

cyDest

Specifies the logical y-extent of the destination rectangle.

XSrc

Specifies the x-coordinate, in pixels, of the source rectangle in the DIB. *YSrc*

Specifies the y-coordinate, in pixels, of the source rectangle in the DIB.

cxSrc

Specifies the width, in pixels, of the source rectangle in the DIB.

cySrc

Specifies the height, in pixels, of the source rectangle in the DIB.

lpvBits

Points to the DIB bits that are stored as an array of bytes.

lpbmi

Points to a **BITMAPINFO** structure that contains information about the DIB. The **BITMAPINFO** structure has the following form:

```
typedef struct tagBITMAPINFO { /* bmi */
BITMAPINFOHEADER bmiHeader;
RGBQUAD bmiColors[1];
} BITMAPINFO;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

fuColorUse

Specifies whether the **bmiColors** member of the *lpbmi* parameter contains explicit RGB (red-green-blue) values or indices into the currently realized logical palette. The *fuColorUse* parameter can be one of the following values:

Value	Meaning
DIB_PAL_COLORS	The color table consists of an array of 16-bit indices into the currently realized logical palette.
DIB_RGB_COLORS	The color table contains literal RGB values.

fdwRop

Specifies the raster operation to be performed. Raster-operation codes define how the graphics device interface (GDI) combines colors in output operations that involve a current brush, a possible source bitmap, and a destination bitmap. For a list of raster-operation codes, see the description of the **BitBlt** function. For a complete list of the raster operations, see the *Microsoft Windows Programmer's Reference*, *Volume 4*.

Return Value

The return value is the number of scan lines copied, if the function is successful.

Comments The **StretchDIBits** function uses the stretching mode of the destination device context (set by the **SetStretchBltMode** function) to determine how to stretch or compress the bitmap.

The origin of the coordinate system for a device-independent bitmap is the lowerleft corner. The origin of the coordinates of the destination rectangle depends on the current mapping mode of the device context.

StretchDIBits creates a mirror image of a bitmap if the signs of the *cxSrc* and *cxDest* parameters or the *cySrc* and *cyDest* parameters differ. If *cxSrc* and *cxDest* have different signs, the function creates a mirror image of the bitmap along the x-axis. If *cySrc* and *cyDest* have different signs, the function creates a mirror image of the bitmap along the y-axis.

See Also SetMapMode, SetStretchBltMode

SubtractRect

BOOL SubtractRect(*lprcDest*, *lprcSource1*, *lprcSource2*) **RECT FAR*** *lprcDest*; /* pointer to destination rectangle **const RECT FAR*** *lprcSource1*; /* pointer to rect. to subtract from

one rectangle from another.

const RECT FAR* *lprcSource2*; /* pointer to rect. to subtract */ The **SubtractRect** function retrieves the coordinates of a rectangle by subtracting

Parameters

lprcDest

Points to the **RECT** structure to receive the dimensions of the new rectangle. The **RECT** structure has the following form:

*/

*/

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference, Volume 3*.

lprcSource1

Points to the **RECT** structure from which a rectangle is to be subtracted.

	<i>lprcSource2</i> Points to the RECT- structure that is to be subtracted from the rectangle pointed to by the <i>lprcSource1</i> parameter.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The rectangle specified by the <i>lprcSource2</i> parameter is subtracted from the rectangle specified by <i>lprcSource1</i> only when the rectangles intersect completely in either the x- or y-direction. For example, if <i>lprcSource1</i> were (10,10, 100,100) and <i>lprcSource2</i> were (50,50, 150,150), the rectangle pointed to by <i>lprcDest</i> would contain the same coordinates as <i>lprcSource1</i> when the function returned. If <i>lprcSource1</i> were (10,10, 100,100) and <i>lprcSource1</i> were (10,10, 100,100) and <i>lprcSource2</i> were (50,10, 150,150), however, the rectangle pointed to by <i>lprcDest</i> would contain the coordinates (10,10, 50,100) when the function returned.
See Also	IntersectRect, UnionRect

SwapMouseButton

BOOL SwapMouseButton(fSwap)

BOOL *fSwap*; /* reverse or restore buttons

applications.

The **SwapMouseButton** function reverses the meaning of left and right mouse buttons.

2.x

 Parameters fSwap Specifies whether the button meanings are reversed or restored. If this parameter is TRUE, the left button generates right-button mouse messages and the right button generates left-button messages. If this parameter is FALSE, the buttons are restored to their original meanings.
 Return Value The return value specifies the meaning of the mouse buttons immediately before the function is called. It is nonzero if the meaning was reversed. Otherwise, it is zero.
 Comments Button swapping is provided as a convenience to people who use the mouse with their left hands. The SwapMouseButton function is usually called by Control Panel only. Although an application is free to call the function, the mouse is a shared resource and reversing the meaning of the mouse button affects all

*/

Example The following example swaps the mouse buttons, depending on the check state of a check box:

```
BOOL fSwap;
fSwap = (BOOL) SendDlgItemMessage(hdlg, IDD_SWAP,
BM_GETCHECK, 0, 0L);
SwapMouseButton(fSwap);
```

SwapRecording

void SwapRecording(fuFlag)
UINT fuFlag; /* whether to start or stop swap recording */

The **SwapRecording** function starts or stops recording data about memory swapping. Because this function can be used only in real mode, it cannot be used with Windows 3.1.

SwitchStackBack

void SwitchStackBack(void)

	The SwitchStackBack function restores the stack of the current task, canceling the effect of the SwitchStackTo function.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
Comments	SwitchStackBack preserves the contents of the AX:DX registers when it returns.
See Also	SwitchStackTo

3.0

SwitchStackTo

void SwitchStackTo UINT uStackSegmer UINT uStackPointer UINT uStackTop;		
	The SwitchStackTo function changes the stack of the current task to the specified data segment.	
Parameters	 uStackSegment Specifies the data segment to contain the stack. uStackPointer Specifies the offset to the beginning of the stack in the data segment. 	
	<i>uStackTop</i> Specifies the offset to the top of the stack from the beginning of the stack.	
Return Value	This function does not return a value.	
Comments	Dynamic-link libraries (DLLs) do not have private stacks; instead, a DLL uses the stack of the task that calls the library. As a result, a DLL function fails if it treats the contents of the data-segment (DS) and stack-segment (SS) registers as equal. A task can call SwitchStackTo before calling a function in a DLL that treats the SS and DS registers as equal. When the DLL function returns, the task must then call the SwitchStackBack function to redirect its stack to its own data segment.	
	A DLL can also call SwitchStackTo before calling a function that assumes SS and DS to be equal and then call SwitchStackBack before returning to the task that called the DLL function.	
	Calls to SwitchStackTo and SwitchStackBack cannot be nested. That is, after calling SwitchStackTo, an application must call SwitchStackBack before calling SwitchStackTo again.	
See Also	SwitchStackBack	

SyncAllVoices

int SyncAllVoices(void)

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

SysMsgProc	, ,	3.1	
LRESULT CALLB int code; WPARAM wParam LPARAM lParam;	ACK SysMsgProc(<i>code</i> , w /* message type ; /* undefined /* pointer to an MSG	*/ */	
	calls after a dialog box, me	n is a library-defined callback function that the system essage box, or menu has retrieved a message, but before The callback function can process or modify messages system.	
Parameters	<i>code</i> Specifies the type of message being processed. This parameter can be one of the following values:		
	Value	Meaning	
	MSGF_DIALOGBOX	Messages inside a dialog box or message box procedure are being processed.	
	MSGF_MENU	Keyboard and mouse messages in a menu are being processed.	
	If the <i>code</i> parameter is less than zero, the callback function must pass the sage to the CallNextHookEx function without further processing and retuvalue returned by CallNextHookEx .		
<i>wParam</i> Must be NULL.			
	<i>lParam</i> Points to the MSG structure to contain the message. The MSG structure has the following form:		

2.x

	typedef struct tagMSG { /* msg */
	HWND hwnd; UINT message;
	WPARAM wParam;
	LPARAM 1Param;
	DWORD time;
	POINT pt;
	} MSG;
	For a full description of this structure, see the <i>Microsoft Windows Program</i> - mer's Reference, Volume 3.
Return Value	The return value should be nonzero if the function processes the message. Otherwise, it should be zero.
Comments	This callback function must be in a dynamic-link library (DLL).
	An application must install this callback function by specifying the WH_SYSMSGFILTER filter type and the procedure-instance address of the callback function in a call to the SetWindowsHookEx function.
	SysMsgProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an EXPORTS statement in the library's module-definition file.
See Also	CallNextHookEx, MessageBox, SetWindowsHookEx

SystemHeapInfo

#include <toolhelp.h>

BOOL SystemHeapInfo(lpshi)SYSHEAPINFO FAR* lpshi;/* address of heap-info structure*/

The **SystemHeapInfo** function fills the specified structure with information that describes the USER.EXE and GDI.EXE heaps.

3.1

Parameters

lpshi

Points to a **SYSHEAPINFO** structure to receive information about the USER and GDI heaps. The **SYSHEAPINFO** structure has the following form:

```
#include <toolhelp.h>
                       typedef struct tagSYSHEAPINFO { /* shi */
                           DWORD dwSize;
                           WORD wUserFreePercent;
                           WORD
                                  wGDIFreePercent;
                           HGLOBAL hUserSegment;
                           HGLOBAL hGDISegment:
                       } SYSHEAPINFO;
                      For a full description of this structure, see the Microsoft Windows Program-
                      mer's Reference, Volume 3.
Return Value
                    The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments
                    This function is included for advisory purposes. Before calling SystemHeapInfo,
                    an application must initialize the SYSHEAPINFO structure and specify its size,
                    in bytes, in the dwSize member.
```

SystemParametersInfo

uAction

BOOL SystemParamete UINT <i>uAction</i> ;	ersInfo(uAction, uParam, lpvParam, fuV /* system parameter to query or set	VinIni) */
UINT uParam;	/* depends on system parameter	*/
void FAR* lpvParam;	/* depends on system parameter	*/
UINT fuWinIni;	/* WIN.INI update flag	*/
Th	e SystemParametersInfo function queri	es or set

The **SystemParametersInfo** function queries or sets system-wide parameters. This function can also update the WIN.INI file while setting a parameter.

Parameters

Specifies the system-wide parameter to query or set. This parameter can be one of the following values:

Value	Meaning
SPI_GETBEEP	Retrieves a BOOL value that indicates whether the warning beep is on or off.
SPI_GETBORDER	Retrieves the border multiplying factor that determines the width of a window's sizing border.
SPI_GETFASTTASKSWITCH	Determines whether fast task switching is on or off.

Value	Meaning
SPI_GETGRIDGRANULARITY	Retrieves the current granularity value of the desktop sizing grid.
SPI_GETICONTITLELOGFONT	Retrieves the logical-font information for the current icon-title font.
SPI_GETICONTITLEWRAP	Determines whether icon-title wrapping is on or off.
SPI_GETKEYBOARDDELAY	Retrieves the keyboard repeat-delay setting.
SPI_GETKEYBOARDSPEED	Retrieves the keyboard repeat-speed setting.
SPI_GETMENUDROPALIGNMENT	Determines whether pop-up menus are left-aligned or right-aligned relative to the corresponding menu-bar item.
SPI_GETMOUSE	Retrieves the mouse speed and the mouse threshold values, which Windows uses to calculate mouse acceleration.
SPI_GETSCREENSAVEACTIVE	Retrieves a BOOL value that indicates whether screen saving is on or off.
SPI_GETSCREENSAVETIMEOUT	Retrieves the screen-saver time-out value
SPI_ICONHORIZONTALSPACING	Sets the width, in pixels, of an icon cell.
SPI_ICONVERTICALSPACING	Sets the height, in pixels, of an icon cell.
SPI_LANGDRIVER	Forces the user to load a new language driver.
SPI_SETBEEP	Turns the warning beep on or off.
SPI_SETBORDER	Sets the border multiplying factor that de termines the width of a window's sizing border.
SPI_SETDESKPATTERN	Sets the current desktop pattern to the value specified in the Pattern entry in the WIN.INI file or to the pattern specified by the <i>lpvParam</i> parameter.
SPI_SETDESKWALLPAPER	Specifies the filename that contains the bitmap to be used as the desktop wall-paper.
SPI_SETDOUBLECLKHEIGHT	Sets the height of the rectangle within which the second click of a double-click must fall for it to be registered as a double-click.
SPI_SETDOUBLECLICKTIME	Sets the double-click time for the mouse. The double-click time is the maximum number of milliseconds that may occur between the first and second clicks of a double-click.

Value	Meaning
SPI_SETDOUBLECLKWIDTH	Sets the width of the rectangle in which the second click of a double-click must fall to be registered as a double-click.
SPI_SETFASTTASKSWITCH	Turns fast task switching on or off.
SPI_SETGRIDGRANULARITY	Sets the granularity of the desktop sizing grid.
SPI_SETICONTITLELOGFONT	Sets the font that is used for icon titles.
SPI_SETICONTITLEWRAP	Turns icon-title wrapping on or off.
SPI_SETKEYBOARDDELAY	Sets the keyboard repeat-delay setting.
SPI_SETKEYBOARDSPEED	Sets the keyboard repeat-speed setting.
SPI_SETMENUDROPALIGNMENT	Sets the alignment value of pop-up menus.
SPI_SETMOUSE	Sets the mouse speed and the x and y mouse-threshold values.
SPI_SETMOUSEBUTTONSWAP	Swaps or restores the meaning of the left and right mouse buttons.
SPI_SETSCREENSAVEACTIVE	Sets the state of the screen saver.
SPI_SETSCREENSAVETIMEOUT	Sets the screen-saver time-out value.

uParam

Depends on the *uAction* parameter. For more information, see the following Comments section.

lpvParam

Depends on the *uAction* parameter. For more information, see the following Comments section.

fuWinIni

If a system parameter is being set, specifies whether the WIN.INI file is updated, and if so, whether the WM_WININICHANGE message is broadcast to all top-level windows to notify them of the change. This parameter can be a combination of the following values:

Value	Meaning
SPIF_UPDATEINIFILE	Writes the new system-wide parameter setting to the WIN.INI file.
SPIF_SENDWININICHANGE	Broadcasts a WM_WININICHANGE message after WIN.INI is updated. This flag has no ef- fect if SPIF_UPDATEINIFILE is not specified.

Return Value The return value is nonzero if the function is successful. Otherwise, it is zero.

Comments The **SystemParameterInfo** function is intended for applications, such as Control Panel, that allow the user to customize the Windows environment.

Constant	uParam	lpvParam
SPI_GETBEEP	0	Points to a BOOL variable that receives TRUE if the beep is on, FALSE if it is off.
SPI_GETBORDER	0	Points to an integer variable that receives the border multiplying factor.
SPI_GETFASTTASKSWITCH	0	Points to a BOOL variable that receives TRUE if fast task switching is on, FALSE if it is off.
SPI_GETGRIDGRANULARITY	0	Points to an integer variable that receives the grid-granularity value.
SPI_GETICONTITLELOGFONT	Size of LOGFONT structure	Points to a LOGFONT structure that receives the logical-font information.
SPI_GETICONTITLEWRAP	0	Points to a BOOL variable that receives TRUE if wrapping is on, FALSE if wrapping is off.
SPI_GETKEYBOARDDELAY	0	Points to an integer variable that receives the keyboard repeat-delay setting.
SPI_GETKEYBOARDSPEED	0	Points to a WORD variable that receives the current keyboard repeat-speed setting.
SPI_GETMENUDROPALIGNMENT	0	Points to a BOOL variable that receives TRUE if pop-up menus are right-aligned, FALSE if they are left-aligned.
SPI_GETMOUSE	0	Points to an integer array name lpiMouse, where lpiMouse[0] receives the WIN.INI entry MouseThreshold1 , lpiMouse[1] re- ceives the entry MouseThreshold2 , and lpiMouse[2] receives the entry MouseSpeed .
SPI_GETSCREENSAVEACTIVE	0	Points to a BOOL variable that receives TRUE if the screen saver is active, FALSE if it is not.
SPI_GETSCREENSAVETIMEOUT	0	Points to an integer variable that receives the screen-saver time-out value, in milliseconds.
SPI_ICONHORIZONTALSPACING	New width, in pixels, for horizontal spacing of icons	Is NULL if the icon cell width, in pixels, is returned in <i>uParam</i> . If this value is a pointer to an integer, the current horizontal spacing is returned in that variable and <i>uParam</i> is ignored.
SPI_ICONVERTICALSPACING	New height, in pixels, for vertical spacing of icons	Is NULL if the icon cell height, in pixels, is returned in <i>uParam</i> . If this value is a pointer to an integer, the current vertical spacing is returned in that variable and <i>uParam</i> is ignored.

The following table describes the *uParam* and *lpvParam* parameters for each SPI_ constant:

Constant	uParam	lpvParam
SPI_LANGDRIVER	0	Points to a string containing the new lan- guage driver filename. The application should make sure that all other international settings remain consistent when changing the language driver.
SPI_SETBEEP	TRUE = turn the beep on; FALSE = turn the beep off	Is NULL.
SPI_SETBORDER	Border multiplying factor	Is NULL.
SPI_SETDESKPATTERN	0 or –1	Specifies the desktop pattern. If this value is NULL and the <i>uParam</i> parameter is -1, the value is reread from the WIN.INI file. This value can also be a null-terminated string (LPSTR) containing a sequence of 8 num- bers that represent the new desktop pattern; for example, "170 85 170 85 170 85 170 85" represents a 50% gray pattern.
SPI_SETDESKWALLPAPER	0	Points to a string that specifies the name of the bitmap file.
SPI_SETDOUBLECLKHEIGHT	Double-click height, in pixels	Is NULL.
SPI_SETDOUBLECLICKTIME	Double-click time, in milliseconds	Is NULL.
SPI_SETDOUBLECLKWIDTH	Double-click width, in pixels	Is NULL.
SPI_SETFASTTASKSWITCH	TRUE = turn on fast task switching; FALSE = turn it off	Is NULL.
SPI_SETGRIDGRANULARITY	Grid granularity,	
SPI_SETICONTITLELOGFONT	Size of the LOG- FONT structure	Points to a LOGFONT structure that defines the font to use for icon titles. If <i>uParam</i> is set to zero and <i>lParam</i> is set to NULL, Windows uses the icon-title font and spacings that were in effect when Windows was started.
SPI_SETICONTITLEWRAP	TRUE = turn wrap- ping on; FALSE = turn wrapping off	Is NULL.
SPI_SETKEYBOARDDELAY	Keyboard-delay setting	Is NULL.
SPI_SETKEYBOARDSPEED	Repeat-speed setting	Is NULL.

Constant		uParam	lpvParam
SPI_SETMENUDRO	PALIGNMENT	TRUE = right- alignment; FALSE = left-alignment	Is NULL.
SPI_SETMOUSE		0	Points to an integer array named lpiMouse, where lpiMouse[0] receives the WIN.INI entry xMouseThreshold , lpiMouse[1] re- ceives the entry yMouseThreshold , and lpiMouse[2] receives the entry MouseSpeed .
SPI_SETMOUSEBU	TTONSWAP	TRUE = reverse the meaning of the left and right mouse buttons; FALSE = restore the buttons to their original meanings	Is NULL.
SPI_SETSCREENSA	WEACTIVE	TRUE = activate screen saving; FALSE = deactivate screen saving	Is NULL.
SPI_SETSCREENSAVETIMEOUT		Idle time-out dura- tion, in seconds, before screen is saved	Is NULL.
Example	the WIN.INI f while the WM	ile and uses the value to COMMAND messag om the edit control and	value for the DoubleClickSpeed entry from o initialize an edit control. In this example, e is being processed, the user-specified value used to set the double-click time.
	case WM_INIT	DIALOG:	
	/* Initi	alize edit control to	a the current double-click time */

/* Initialize edit control to the current double-click time. */

iResult = GetProfileInt("windows", "DoubleClickSpeed", 550); itoa(iResult, szBuf, 10); SendDlgItemMessage(hdlg, IDD_DCLKTIME, WM_SETTEXT, 0, (DWORD) (LPSTR) szBuf);

. /* Initialize any other controls. */

return FALSE;

TabbedTextOut

LONG TabbedTextOut(*hdc*, *xPosStart*, *yPosStart*, *lpszString*, *cbString*, *cTabStops*, *lpnTabPositions*, *nTabOrigin*)

maconging		
HDC hdc;	/* handle of device context	*/
int xPosStart;	/* x-coordinate of starting position	*/
int yPosStart;	/* y-coordinate of starting position	*/
LPCSTR lpszString;	/* address of string	*/
int cbString;	/* number of characters in string	*/
int cTabStops;	/* number of tabs in array	*/
int FAR* lpnTabPositions;	/* address of array with tab positions	*/
int nTabOrigin;	/* x-coordinate for tab expansion	*/

The **TabbedTextOut** function writes a character string at the specified location, expanding tabs to the values specified in the array of tab-stop positions. The function writes text in the currently selected font.

Parameters

hdc

Identifies the device context.

xPosStart

Specifies the logical x-coordinate of the starting point of the string.

yPosStart

Specifies the logical y-coordinate of the starting point of the string.

	<i>lpszString</i> Points to the character string to be drawn.
	<i>cbString</i> Specifies the number of characters in the string.
	<i>cTabStops</i> Specifies the number of values in the array of tab-stop positions.
	<i>lpnTabPositions</i> Points to an array containing the tab-stop positions, in device units. The tab stops must be sorted in increasing order; the smallest x-value should be the first item in the array.
	<i>nTabOrigin</i> Specifies the logical x-coordinate of the starting position from which tabs are expanded.
Return Value	The return value is the dimensions of the string, in logical units, if the function is successful. The low-order word contains the string width; the high-order word contains the string height. Otherwise, the return value is zero.
Comments	If the <i>cTabStops</i> parameter is zero and the <i>lpnTabPositions</i> parameter is NULL, tabs are expanded to eight times the average character width.
	If <i>cTabStops</i> is 1, the tab stops are separated by the distance specified by the first value in the <i>lpnTabPositions</i> array.
	If the <i>lpnTabPositions</i> array contains more than one value, a tab stop is set for each value in the array, up to the number specified by <i>cTabStops</i> .
	The <i>nTabOrigin</i> parameter allows an application to call the TabbedTextOut function several times for a single line. If the application calls TabbedTextOut more than once with the <i>nTabOrigin</i> set to the same value each time, the function expands all tabs relative to the position specified by <i>nTabOrigin</i> .
	By default, the current position is not used or updated by the TabbedTextOut function. If an application must update the current position when calling Tabbed-TextOut , it can call the SetTextAlign function with the <i>wFlags</i> parameter set to TA_UPDATECP. When this flag is set, Windows ignores the <i>xPosStart</i> and <i>yPosStart</i> parameters on subsequent calls to the TabbedTextOut function, using the current position instead.
Example	The following example expands tabs from the same x-coordinate as the string's starting point:
	LPSTR lpszTabbedText = "Column 1\tColumn 2\tTest of TabbedTextOut"; int aTabs[2] = { 150, 300 }; int iStartXPos = 100; int iStartYPos = 100:

```
TabbedTextOut(hdc.
                                /* handle of device context
                                                              */
    iStartXPos, iStartYPos, /* starting coordinates
                                                              */
    lpszTabbedText,
                                /* address of text
                                                              */
    lstrlen(lpszTabbedText), /* number of characters
                                                              */
    sizeof(aTabs) / sizeof(int), /* number of tabs in array
                                                              */
                                /* array for tab positions
    aTabs.
                                                              */
    iStartXPos):
                                /* x-coord. for tab expanding */
```

TaskFindHandle

#include <toolhelp.h>

BOOL TaskFindHandle (<i>lpte</i>	, htask)	
TASKENTRY FAR* <i>lpte</i> ;	/* address of TASKENTRY structure	*/
HTASK htask;	/* handle of task	*/

The **TaskFindHandle** function fills the specified structure with information that describes the given task.

Parameters

Points to a **TASKENTRY** structure to receive information about the task. The **TASKENTRY** structure has the following form:

;

#include <toolhelp.h>

lpte

unadof struct	tagTASKENTRY { /* te */
•	dwSize:
HTASK	hTask;
HTASK	hTaskParent;
HINSTANCE	hInst;
HMODULE	hModule;
WORD	wSS;
WORD	wSP;
WORD	wStackTop;
WORD	wStackMinimum;
WORD	wStackBottom;
WORD	wcEvents;
HGLOBAL	hQueue;
char	<pre>szModule[MAX_MODULE_NAME + 1]</pre>
WORD	wPSPOffset;
HANDLE	hNext;
TASKENTRY;	
	HINSTANCE HMODULE WORD WORD WORD WORD WORD HGLOBAL char WORD HANDLE

	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	htask Identifies the task to be described.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The TaskFindHandle function can be used to begin a walk through the task queue. An application can examine subsequent entries in the task queue by using the TaskNext function.
	Before calling TaskFindHandle , an application must initialize the TASKENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	TaskFirst, TaskNext

TaskFirst

3.1

#include <toolhelp.h>

BOOL TaskFirst(<i>l</i> TASKENTRY FA		ess of TASKENTRY structure */
	The TaskFirst fur first task on the tas	nction fills the specified structure with information about the sk queue.
Parameters		SKENTRY structure to receive information about the first task. TRY structure has the following form:
	∦ include <too`< td=""><td>lhelp.h></td></too`<>	lhelp.h>
	typedef struct	t tagTASKENTRY { /* te */
	DWORD	dwSize;
	HTASK	hTask;
	HTASK	hTaskParent;
	HINSTANCE	hInst;
	HMODULE	hModule;
	WORD	wSS;
	WORD	wSP;
	WORD	wStackTop;
	WORD	wStackMinimum;
	WORD	wStackBottom;
	WORD	wcEvents;

3.1

	HGLOBAL hQueue; char szModule[MAX_MODULE_NAME + 1]; WORD wPSPOffset; HANDLE hNext; } TASKENTRY;
	For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The TaskFirst function can be used to begin a walk through the task queue. An application can examine subsequent entries in the task queue by using the TaskNext function.
	Before calling TaskFirst , an application must initialize the TASKENTRY structure and specify its size, in bytes, in the dwSize member.
See Also	TaskFindHandle, TaskNext

TaskGetCSIP

#include <toolhelp< th=""><th>).h></th></toolhelp<>).h>
DWORD TaskGet HTASK htask;	CSIP(<i>htask</i>) /* handle of task */
	The TaskGetCSIP function returns the next CS:IP value of a sleeping task. This function is useful for applications that must "know" where a sleeping task will begin execution upon awakening.
Parameters	<i>htask</i> Identifies the task whose CS:IP value is being examined. This task must be sleeping when the application calls TaskGetCSIP .
Return Value	The return value is the next CS:IP value, if the function is successful. If the <i>htask</i> parameter is invalid, the return value is NULL.
Comments	TaskGetCSIP should not be called if <i>htask</i> identifies the current task.
See Also	DirectedYield, TaskSetCSIP, TaskSwitch

TaskNext

#include <toolhelp.h>

BOOL TaskNext(*lpte*) **TASKENTRY FAR*** *lpte*: /* address of TASKENTRY structure */ The TaskNext function fills the specified structure with information about the next task on the task queue. **Parameters** lpte Points to a **TASKENTRY** structure to receive information about the next task. The **TASKENTRY** structure has the following form: #include <toolhelp.h> typedef struct tagTASKENTRY { /* te */ DWORD dwSize: HTASK hTask; hTaskParent; HTASK HINSTANCE hInst; HMODULE hModule: WORD wSS: WORD wSP; WORD wStackTop; WORD wStackMinimum; WORD wStackBottom; WORD wcEvents: HGLOBAL hOueue: char szModule[MAX_MODULE_NAME + 1]; WORD wPSPOffset; HANDLE hNext; } TASKENTRY; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3. **Return Value** The return value is nonzero if the function is successful. Otherwise, it is zero.

CommentsThe TaskNext function can be used to continue a walk through the task queue.
The walk must have been started by the TaskFirst or TaskFindHandle function.

See Also TaskFindHandle, TaskFirst

TaskSetCSIP

#include <toolhelp.h>

HTASK htask;	CSIP(htask, wCS, wIP) /* handle of task */ /* value in CS register */ /* value in IP register */
	The TaskSetCSIP function sets the CS:IP value of a sleeping task. When the task is yielded to, it will begin execution at the specified address.
Parameters	 htask Identifies the task to be assigned the new CS:IP value. wCS Contains the new value of the CS register. wIP Contains the new value of the IP register.
Return Value	The return value is the previous CS:IP value for the task. The TaskSwitch function uses this value. The return value is NULL if the <i>htask</i> parameter is invalid.
Comments	TaskSetCSIP should not be called if <i>htask</i> identifies the current task.
See Also	Directed Yield, TaskGetCSIP, TaskSwitch

TaskSwitch

#include <toolhelp.h>

BOOL TaskSwitch(htask,	dwNewCSIP)	
HTASK htask;	/* handle of task	*/
DWORD dwNewCSIP;	/* execution address within task	*/

The **TaskSwitch** function switches to the given task. The task begins executing at the specified address.

Parameters *htask* Identifies the new task. 3.1

	<i>dwNewCSIP</i> Identifies the address within the given task at which to begin execution. Be very careful that this address is not in a code segment owned by the given task.
Return Value	The return value is nonzero if the task switch is successful. Otherwise, it is zero.
Comments	When the task identified by the <i>htask</i> parameter yields, TaskSwitch returns to the calling application.
	TaskSwitch changes the CS:IP value of the task's stack frame to the value specified by the <i>dwNewCSIP</i> parameter and then calls the DirectedYield function.
See Also	DirectedYield, TaskSetCSIP, TaskGetCSIP

TerminateApp

#include <toolhelp.h>

void	Termi	inateApp)(htask,	wFlags)	

HTASK htask;	/* handle of task	*/
WORD wFlags;	/* termination flags	*/

The **TerminateApp** function ends the given application instance (task).

Parameters

htask

Identifies the task to be ended. If this parameter is NULL, it identifies the current task.

wFlags

Indicates how to end the task. This parameter can be one of the following values:

Value	Meaning
UAE_BOX	Calls the Windows kernel to display the Application Error mes- sage box and then ends the task.
NO_UAE_BOX	Calls the Windows kernel to end the task but does not display the Application Error message box. The application's interrupt or notification callback function should have displayed an error message, a warning, or both.

Return Value This function returns only if *htask* is not NULL and does not identify the current task.

Comments	The TerminateApp function unregisters all callback functions registered with the Tool Help functions and then ends the application as if the given task had produced a general-protection (GP) fault or other error.
	TerminateApp should be used only by debugging applications, because the function may not free not all objects owned by the ended application.

TextOut

BOOL TextOut(hdc	, nXStart, nYStart, lpszString, cbString)		
HDC hdc;	/* handle of device context	*/	
int nXStart;	/* x-coordinate of starting position	*/	
int nYStart;	/* y-coordinate of starting position	*/	
LPCSTR lpszString;		*/	
int cbString;	/* number of bytes in string	*/	
	The TextOut function writes a character structure currently selected font.	ing at the specified location, using the	
Parameters	hdc		
	Identifies the device context.		
	<i>nXStart</i> Specifies the logical x-coordinate of the	starting point of the string.	
	<i>nYStart</i> Specifies the logical y-coordinate of the starting point of the string.		
	<i>lpszString</i> Points to the character string to be drawn	l.	
	<i>cbString</i> Specifies the number of bytes in the strin	ıg.	
Return Value	The return value is nonzero if the function i	s successful. Otherwise, it is zero.	
Comments	Character origins are at the upper-left corner of the character cell.		
	By default, the TextOut function does not application must update the current position SetTextAlign function with the <i>wFlags</i> part this flag is set, Windows ignores the <i>nXStat</i> sequent calls to the TextOut function, using	when calling TextOut , it can call the ameter set to TA_UPDATECP. When <i>t</i> and <i>nYStart</i> parameters on sub-	

 Example
 The following example uses the GetTextFace function to retrieve the face name of the current font, calls SetTextAlign so that the current position is updated when the TextOut function is called, and then writes some introductory text and the face name by calling TextOut:

 int nFaceNameLen;
 char aFaceName[80];

 nFaceNameLen
 CatTextFace(hde (th nature) length of string th)

nfaceNameLen = GetlextFace	(hdc, /* returns length of string	*/
sizeof(aFaceName),	<pre>/* size of face-name buffer</pre>	*/
(LPSTR) aFaceName);	<pre>/* address of face-name buffer</pre>	*/
SetTextAlign(hdc,		
TA_UPDATECP);	<pre>/* updates current position</pre>	*/
MoveTo(hdc, 100, 100);	<pre>/* sets current position</pre>	*/
TextOut(hdc, 0, 0,	<pre>/* uses current position for text</pre>	*/
"This is the current f	ace name: ", 31);	
TextOut(hdc, 0, 0, aFaceNa	me, nFaceNameLen);

ExtTextOut, GetTextExtent, SetTextAlign, SetTextColor, TabbedTextOut

Throw

. .

const int FAR* lpCa int nErrorReturn;	
	The Throw function restores the execution environment to the values saved in the specified array. Execution then transfers to the Catch function that copied the environment to the array.
Parameters	<i>lpCatchBuf</i> Points to a CATCHBUF array that contains the execution environment. This array must have been set by a previous call to the Catch function.
	<i>nErrorReturn</i> Specifies the value to be returned to the Catch function. The meaning of the value is determined by the application. The value should be nonzero, so that the call to the Catch function can distinguish between a return from Catch (which returns zero) and a return from Throw .
Return Value	This function does not return a value.
Comments	The Throw function is similar to the C run-time function longjmp .

The function that calls **Catch** must free any resources allocated between the time **Catch** was called and the time **Throw** was called.

Do not use the **Throw** function across messages. For example, if an application calls **Catch** while processing a WM_CREATE message and then calls **Throw** while processing a WM_PAINT message, the application will terminate.

Example The following example calls the **Catch** function to save the current execution environment before calling a recursive sort function. The first return from **Catch** is zero. If the doSort function calls the **Throw** function, execution will again return to the **Catch** function. This time, **Catch** returns the STACKOVERFLOW error passed by the doSort function. The doSort function is recursive—that is, it calls itself. It maintains a variable, wStackCheck, that is used to check the amount of stack space used. If more than 3K of the stack has been used, doSort calls **Throw** to drop out of all the nested function calls back into the function that called **Catch**.

```
#define STACKOVERFLOW 1
UINT uStackCheck:
CATCHBUF catchbuf:
ſ
    int iReturn;
    char szBuf[80];
    if ((iReturn = Catch((int FAR*) catchbuf)) != 0) {
        . /* Error processing goes here. */
    }
    else {
        uStackCheck = 0:
                             /* initializes stack-usage count */
        doSort(1, 100);
                             /* calls sorting function
                                                                 */
    }
    break:
}
void doSort(int sLeft, int sRight)
ſ
    int sLast:
    /*
     * Determine whether more than 3K of the stack has been
     * used, and if so, call Throw to drop back into the
     * original calling application.
     * The stack is incremented by the size of the two parameters,
     * the two local variables, and the return value (2 for a near
     * function call).
     */
```

```
uStackCheck += (sizeof(int) * 4) + 2;
if (uStackCheck > (3 * 1024))
Throw((int FAR*) catchbuf, STACKOVERFLOW);
.
. /* A sorting algorithm goes here. */
.
doSort(sLeft, sLast - 1); /* note recursive call */
uStackCheck -= 10; /* updates stack-check variable */
}
See Also Catch
```

TimerCount

#include <toolhelp.l< th=""><th>n></th></toolhelp.l<>	n>
BOOL TimerCount TIMERINFO FAR	
	The TimerCount function fills the specified structure with the execution times of the current task and VM (virtual machine).
Parameters	<i>lpti</i> Points to the TIMERINFO structure that will receive the execution times. The TIMERINFO structure has the following form:
	#include <toolhelp.h></toolhelp.h>
	<pre>typedef struct tagTIMERINFO { /* ti */ DWORD dwSize; DWORD dwmsSinceStart; DWORD dwmsThisVM; } TIMERINFO;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The TimerCount function provides a consistent source of timing information, accurate to the millisecond. In enhanced mode, TimerCount uses the VTD (virtual timer device) to obtain accurate execution times.

In standard mode, **TimerCount** calls the **GetTickCount** function, which returns information accurate to one clock tick (approximately 55 ms). **TimerCount** then reads the hardware timer to estimate how many milliseconds remain until the next clock tick. The resulting time is accurate to 1 ms.

Before calling **TimerCount**, an application must initialize the **TIMERINFO** structure and specify its size, in bytes, in the **dwSize** member.

See Also GetTickCount

TimerProc

void CALLBACK	TimerProc (<i>hwnd</i> , <i>msg</i> , <i>idTimer</i> , <i>dwTime</i>)	
HWND hwnd;	/* handle of window for timer messages	*/
UINT msg;	/* WM_TIMER message	*/
UINT idTimer;	/* timer identifier	*/
DWORD dwTime;	/* current system time	*/
	The TimerProc function is an application-de WM_TIMER messages.	fined callback function that processes
Parameters	<i>hwnd</i> Identifies the window associated with the	imer
	msg	
	Specifies the WM_TIMER message.	
	<i>idTimer</i> Specifies the timer's identifier.	
	<i>dwTime</i> Specifies the current system time.	
Return Value	This function does not return a value.	
Comments	TimerProc is a placeholder for the application name must be exported by including it in an I tion's module-definition file.	
See Also	KillTimer, SetTimer	

ToAscii

int ToAscii(uVirtKe	ey, uScanC	ode, lpbKeyState, lpdwTransKey, fuState)		
UINT uVirtKey;		/* virtual-key code	*/	
UINT uScanCode;		/* scan code	*/	
BYTE FAR* lpbK	evState:	/* address of key-state array	*/	
DWORD FAR * <i>lp</i>			*/	
UINT fuState;		/* active-menu flag	*/	
		Ascii function translates the specified virtua rresponding Windows character or characte		
Parameters	uVirtKey Speci	, fies the virtual-key code to be translated.		
	Speci	<i>uScanCode</i> Specifies the hardware scan code of the key to be translated. The high-order bit of this value is set if the key is not pressed (is up).		
	<i>lpbKeyState</i> Points to a 256-byte array that contains the current keyboard state. Each ele- ment (byte) in the array contains the state of one key. If the high-order bit of a byte is set, the key is pressed (is down).			
	<i>lpdwTransKey</i> Points to a doubleword buffer to receive the translated Windows character or characters.			
		fies whether a menu is active. This parameter or zero otherwise.	ter must be 1 if a menu is ac-	
Return Value		rn value is a negative value if the specified of the following values:	key is a dead key. Otherwise,	
	Value	Meaning		
	2	Two characters were copied to the buffer. The dead-key character, when the dead key cannot		
	1	One Windows character was copied to the bu	uffer.	
	0	The specified virtual key has no translation f board.		
Comments		ious dead key is stored in the keyboard driv scii function might not be sufficient to trans		

Typically, **ToAscii** performs the translation based on the virtual-key code. In some cases, however, the *uScanCode* parameter may be used to distinguish between a key press and a key release. The scan code is used for translating ALT+*number* key combinations.

TrackPopupMenu

BOOL TrackPopupMenu (hmenu, fuFlags, x, y, nReserved, hwnd, lprc)		
HMENU hmenu;	/* handle of menu	*/
UINT fuFlags;	/* screen-position and mouse-button flags	*/
int x;	/* horizontal screen position	*/
int y;	/* vertical screen position	*/
int nReserved;	/* reserved	*/
HWND hwnd;	/* handle of owner window	*/
<pre>const RECT FAR* lprc;</pre>	/* address of structure with rectangle	*/

The **TrackPopupMenu** function displays the given floating pop-up menu at the specified location and tracks the selection of items on the pop-up menu. A floating pop-up menu can appear anywhere on the screen.

Parameters

hmenu

Identifies the pop-up menu to be displayed. The application retrieves this handle by calling the **CreatePopupMenu** function to create a new pop-up menu or by calling the **GetSubMenu** function to retrieve the handle of a pop-up menu associated with an existing menu item.

fuFlags

Specifies the screen-position and mouse-button flags. The screen-position flag can be one of the following:

Value	Meaning
TPM_CENTERALIGN	Centers the pop-up menu horizontally relative to the coordinate specified by the <i>x</i> parameter.
TPM_LEFTALIGN	Positions the pop-up menu so that its left side is aligned with the coordinate specified by the <i>x</i> parameter.
TPM_RIGHTALIGN	Positions the pop-up menu so that its right side is aligned with the coordinate specified by the <i>x</i> parameter.

The mouse-button flag can be one of the following:

Value	Meaning
TPM_LEFTBUTTON	Causes the pop-up menu to track the left mouse button.
TPM_RIGHTBUTTON	Causes the pop-up menu to track the right mouse but-
	ton instead of the left.

х

Specifies the horizontal position, in screen coordinates, of the pop-up menu. Depending on the value of the *fuFlags* parameter, the menu can be left-aligned, right-aligned, or centered relative to this position.

y

Specifies the vertical position, in screen coordinates, of the top of the menu on the screen.

nReserved

Reserved; must be zero.

hwnd

Identifies the window that owns the pop-up menu. This window receives all WM_COMMAND messages from the menu. The window will not receive WM_COMMAND messages until **TrackPopupMenu** returns.

lprc

Points to a **RECT** structure that contains the screen coordinates of a rectangle in which the user can click without dismissing the pop-up menu. If this parameter is NULL, the pop-up menu is dismissed if the user clicks outside the pop-up menu. The **RECT** structure has the following form:

```
typedef struct tagRECT { /* rc */
    int left;
    int top;
    int right;
    int bottom;
} RECT;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Return Value

The return value is nonzero if the function is successful. Otherwise, it is zero.

Example

The following example creates and tracks a pop-up menu when the user clicks the left mouse button:

```
POINT ptCurrent;
HMENU hmenu;
```

ptCurrent = MAKEPOINT(lParam); hmenu = CreatePopupMenu();

```
AppendMenu(hmenu, MF_ENABLED, IDM_ELLIPSE, "Ellipse");
AppendMenu(hmenu, MF_ENABLED, IDM_SQUARE, "Square");
AppendMenu(hmenu, MF_ENABLED, IDM_TRIANGLE, "Triangle");
ClientToScreen(hwnd, &ptCurrent);
TrackPopupMenu(hmenu, TPM_LEFTALIGN, ptCurrent.x,
ptCurrent.y, 0, hwnd, NULL);
```

See Also CreatePopupMenu, GetSubMenu

TranslateAccelerator

	rator(hwnd, haccl, lpmsg) /* handle of window */
	/* handle of accelerator table */ /* address of structure with message information */
	The TranslateAccelerator function processes accelerator keys for menu com- mands. The function translates WM_KEYUP and WM_KEYDOWN messages to WM_COMMAND or WM_SYSCOMMAND messages if there is an entry for the accelerator key in the application's accelerator table.
Parameters	<i>hwnd</i> Identifies the window whose messages are to be translated.
	<i>haccl</i> Identifies an accelerator table (loaded by using the LoadAccelerators function).
	<i>lpmsg</i> Points to an MSG structure retrieved by a call to the GetMessage or Peek-Message function. The structure contains message information from the application's message queue. The MSG structure has the following form:
	typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the message is translated. Otherwise, it is zero.

Comments The high-order word of the *lParam* parameter of the WM_COMMAND or WM_SYSCOMMAND message contains the value 1, to differentiate the message from messages sent by menus or controls.

WM_COMMAND or WM_SYSCOMMAND messages are sent directly to the window, rather than being posted to the application queue. The **Translate**-**Accelerator** function does not return until the message is processed.

Accelerator keystrokes that are defined to select items from the System menu are translated into WM_SYSCOMMAND messages; all other accelerator keystrokes are translated into WM_COMMAND messages.

When **TranslateAccelerator** returns a nonzero value (meaning that the message is translated), the application should *not* process the message again by using the **TranslateMessage** function.

Keystrokes in accelerator tables need not correspond to menu items.

If the accelerator keystroke does correspond to a menu item, the application is sent WM_INITMENU and WM_INITMENUPOPUP messages, just as if the user were trying to display the menu. However, these messages are not sent if any of the following conditions are present:

- The window is disabled.
- The menu item is disabled.
- The accelerator keystroke does not correspond to an item on the System menu and the window is minimized.
- A mouse capture is in effect (for more information, see the description of the **SetCapture** function).

If the window is the active window and there is no keyboard focus (generally the case if the window is minimized), WM_SYSKEYUP and WM_SYSKEYDOWN messages are translated instead of WM_KEYUP and WM_KEYDOWN messages.

If an accelerator keystroke that corresponds to a menu item occurs when the window that owns the menu is minimized, no WM_COMMAND message is sent. However, if an accelerator keystroke that does not match any of the items on the window's menu or the System menu occurs, a WM_COMMAND message is sent, even if the window is minimized.

TranslateMD	ISysAccel 3.0
BOOL TranslateMI HWND hwndClient; MSG FAR* lpmsg;	DISysAccel(hwndClient, lpmsg) /* handle of parent MDI client window */ /* address of structure with message data */
	The TranslateMDISysAccel function processes accelerator keystrokes for the given multiple document interface (MDI) child window. The function translates WM_KEYUP and WM_KEYDOWN messages to WM_SYSCOMMAND messages.
Parameters	hwndClient Identifies the parent MDI client window.
	<i>lpmsg</i> Points to an MSG structure retrieved by a call to the GetMessage or Peek-Message function. The structure contains message information from the application's message queue. The MSG structure has the following form:
	typedef struct tagMSG { /* msg */ HWND hwnd; UINT message; WPARAM wParam; LPARAM 1Param; DWORD time; POINT pt; } MSG;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The high-order word of the <i>lParam</i> parameter of the WM_SYSCOMMAND mes- sage contains the value 1, to differentiate the message from messages sent by menus or controls.
See Also	GetMessage, PeekMessage

TranslateMessage

BOOL TranslateMessage(*lpmsg*)

lpmsg

const MSG FAR* *lpmsg*; /* address of MSG structure */

The **TranslateMessage** function translates virtual-key messages into character messages, as follows:

- WM_KEYDOWN/WM_KEYUP combinations produce a WM_CHAR or WM_DEADCHAR message.
- WM_SYSKEYDOWN/WM_SYSKEYUP combinations produce a WM_SYSCHAR or WM_SYSDEADCHAR message.

The character messages are posted to the application's message queue, to be read the next time the application calls the **GetMessage** or **PeekMessage** function.

Parameters

Points to an **MSG** structure retrieved by a call to the **GetMessage** or **Peek-Message** function. The structure contains message information from the application's message queue. The **MSG** structure has the following form:

```
typedef struct tagMSG { /* msg */
HWND hwnd;
UINT message;
WPARAM wParam;
LPARAM 1Param;
DWORD time;
POINT pt;
} MSG;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

Return Value The return value is nonzero if the message is WM_KEYDOWN, WM_KEYUP, WM_SYSKEYDOWN, or WM_SYSKEYUP, regardless of whether the key that was pressed or released generates a WM_CHAR message. Otherwise, the return value is zero.

Comments The **TranslateMessage** function does not modify the message pointed to by the *lpmsg* parameter.

TranslateMessage produces WM_CHAR messages only for keys that are mapped to ASCII characters by the keyboard driver.

An application should not call **TranslateMessage** if the application processes virtual-key messages for some other purpose. For instance, an application should not call **TranslateMessage** if the **TranslateAccelerator** function returns nonzero.

2.x

llso GetMessage, PeekMessage, TranslateAccelerator

TransmitCommChar

<pre>int TransmitComm int idComDev; char chTransmit;</pre>	Char(idComDev, chTransmit)/* communications device*//* character to transmit*/		
	The TransmitCommChar function places the specified character at the head of the transmission queue for the specified device.		
Parameters	<i>idComDev</i> Specifies the communications device to transmit the character. The Open- Comm function returns this value.		
	<i>chTransmit</i> Specifies the character to be transmitted.		
Return Value	The return value is zero if the function is successful. It is less than zero if the char- acter cannot be transmitted.		
Comments	The TransmitCommChar function cannot be called repeatedly if the device is not transmitting. Once TransmitCommChar places a character in the transmis- sion queue, the character must be transmitted before the function can be called again. TransmitCommChar returns an error if the previous character has not yet been sent.		
Example	The following example uses the TransmitCommChar function to send characters from the keyboard to the communications port:		
	case WM_CHAR:		
	ch = (char)wParam; TransmitCommChar(idComDev, ch);		
	/* Add a linefeed for every carriage return. */		
	<pre>if (ch == 0x0d) TransmitCommChar(idComDev, 0x0a);</pre>		
	break;		
See Also	OpenComm, WriteComm		

See Also

UnAllocDiskSpace

#include <stress.h>

void UnAllocDiskSpace(drive) UINT drive;

The **UnAllocDiskSpace** function deletes the STRESS.EAT file from the root directory of the specified drive. This frees the disk space previously consumed by the **AllocDiskSpace** function.

Parameters	<i>drive</i> Specifies the disk partition on which to delete the STRESS.EAT file. This can be one of the following values:			
	Value Meaning			
	EDS_WIN	Deletes the file on the Windows partition.		
	EDS_CUR	Deletes the file on the current partition.		
	EDS_TEMP	Deletes the file on the partition that contains the TEMP directory.		
Return Value	This function does not return a value.			
See Also	AllocDiskSpace			

UnAllocFileHandles

#include <stress.h>

void UnAllocFileHandles(void)

The **UnAllocFileHandles** function frees all file handles allocated by the **AllocFile-Handles** function.

- **Parameters** This function has no parameters.
- **Return Value** This function does not return a value.
- See Also AllocFileHandles

3.1

2.x

UndeleteFile

#include <wfext.h>

int FAR PASCAL U HWND hwndParent LPSTR lpszDir;	; /* handle	ondParent, lpszDir) of File Manager window */ s of name of initial directory */
		File function is an application-defined callback function that File when the user chooses the Undelete command from the File menu.
Parameters	<i>hwndParent</i> Identifies the File Manager window. An "undelete" dynamic-link library (DLL) should use this handle to specify the parent window for any dialog box or mes- sage box the DLL may display.	
	<i>lpszDir</i> Points to a p	null-terminated string that contains the name of the initial directory.
Return Value	The return value is one of the following, if the function is successful:	
	Value	Meaning
	–l IDOK IDCANCEL	An error occurred. A file was undeleted. File Manager will repaint its windows. No file was undeleted.

UngetCommChar

int UngetComm(C har (idComDev, chUnget)	
int idComDev;	/* communications device	*/
char chUnget;	/* character to place in queue	*/
Parameters	ing queue. The next read opera <i>idComDev</i>	on places the specified character back in the receiv- tion will return this character first.
	<i>chUnget</i> Specifies the character to be	placed in the receiving queue.

Return ValueThe return value is zero if the function is successful. Otherwise, it is less than zero.CommentsConsecutive calls to the UngetCommChar function are not permitted. The character placed in the queue must be read before this function can be called again.

2.x

UnhookWindowsHook

BOOL UnhookWind int idHook; HOOKPROC hkprc;	owsHook(<i>idHook</i> , <i>hkprc</i>) /* type of hook function to re /* hook function procedure-i	
,	ward compatibility with Windows	ction is obsolete but has been retained for back- s versions 3.0 and earlier. Applications written use the UnhookWindowsHookEx function.
1	tion from a chain of hook function	ction removes an application-defined hook func- ns. A hook function processes events before they ge loop in the WinMain function.
Parameters	<i>idHook</i> Specifies the type of function t following values:	to be removed. This parameter can be one of the
	Value	Meaning
	WH_CALLWNDPROC	Removes a window-procedure filter. For more in- formation, see the description of the CallWnd- Proc callback function.
	WH_CBT	Removes a computer-based training (CBT) filter. For more information, see the description of the CBTProc callback function.
	WH_DEBUG	Removes a debugging filter. For more informa- tion, see the description of the DebugProc call- back function.
	WH_GETMESSAGE	Removes a message filter. For more information, see the description of the GetMsgProc callback function.
	WH_HARDWARE	Removes a nonstandard hardware-message filter. For more information, see the description of the HardwareProc callback function.
	WH_JOURNALPLAYBACK	Removes a journaling playback filter. For more information, see the description of the Journal-PlaybackProc callback function.

3.1

	Value	Meaning
	WH_JOURNALRECORD	Removes a journaling record filter. For more in- formation, see the description of the Journal- RecordProc callback function.
	WH_KEYBOARD	Removes a keyboard filter. For more informa- tion, see the description of the KeyboardProc callback function.
	WH_MOUSE	Removes a mouse-message filter. For more infor- mation, see the description of the MouseProc callback function.
	WH_MSGFILTER	Removes a message filter. For more information, see the description of the MessageProc callback function.
	WH_SYSMSGFILTER	Removes a system-wide message filter. For more information, see the description of the SysMsg-Proc callback function.
	<i>hkprc</i> Specifies the procedure-insta tion to remove.	ance address of the application-defined filter func-
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	The UnhookWindowsHook function calls the hook chain, causing the hook func- tion to receive a negative value for the <i>idHook</i> parameter. The hook function must then call the DefHookProc function, which removes the hook function from the chain.	
See Also	SetWindowsHook	

UnhookWindowsHookEx

	ndowsHookEx(<i>hhook</i>) /* handle of hook function to remove */
	The UnhookWindowsHookEx function removes an application-defined hook function from a chain of hook functions. A hook function processes events before they are sent to an application's message loop in the WinMain function.
Parameters	<i>hhook</i> Identifies the hook function to be removed. This is the value returned by the SetWindowsHookEx function when the hook was installed.

Return Value	The return value is nonzero if the function is successful. It is zero if the hook cannot be found.
Comments	The UnhookWindowsHookEx function must be used in combination with the SetWindowsHookEx function.
Example	The following example uses the UnhookWindowsHookEx function to remove a message filter that was used to provide context-sensitive help for a dialog box:
	DLGPROC lpfnAboutProc; HOOKPROC lpfnFilterProc; HHOOK hhook;
	<pre>case IDM_ABOUT:</pre>
	<pre>DialogBox(hinst, "AboutBox", hwnd, lpfnAboutProc);</pre>
	UnhookWindowsHookEx(hhook); FreeProcInstance((FARPROC) lpfnFilterProc); FreeProcInstance((FARPROC) lpfnAboutProc);
	break;
See Also	CallNextHookEx, SetWindowsHookEx

UnionRect

BOOL UnionRect(<i>l</i> RECT FAR* <i>lprcDs</i> const RECT FAR* <i>l</i> const RECT FAR*	st; lprcSrc1;	<i>rc1, lprcSrc2</i>) /* address of structure for union /* address of structure with 1st rect. /* address of structure with 2nd rect.	*/ */ */
		Rect function creates the union of two r tangle that contains both source rectang	
Parameters	pointed to	a RECT structure to receive a rectangl b by the <i>lprcSrc1</i> and <i>lprcSrc2</i> paramet ving form:	

2.x

	<pre>typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom; } RECT;</pre>
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	<i>lprcSrc1</i> Points to a RECT structure that contains the first source rectangle.
	<i>lprcSrc2</i> Points to a RECT structure that contains the second source rectangle.
Return Value	The return value is nonzero if the function is successful—that is, if the <i>lprcDst</i> parameter contains a nonempty rectangle. It is zero if the rectangle is empty or an error occurs.
Comments	Windows ignores the dimensions of an empty rectangle—that is, a rectangle that has no height or no width.
See Also	InflateRect, IntersectRect, OffsetRect, SubtractRect

UnlockSegment

void UnlockSegme UINT uSegment;	ent(uSegment) /* specifies segment to unlock */
	The UnlockSegment function unlocks the specified discardable memory segment. The function decrements (decreases by one) the segment's lock count. The seg- ment is completely unlocked and subject to discarding when the lock count reaches zero.
Parameters	<i>uSegment</i> Specifies the segment address of the segment to be unlocked. If this parameter is -1, the UnlockSegment function unlocks the current data segment.
Return Value	The return value is the lock count for the segment, if the function is successful. This function returns its result in the CX register. When the CX register contains zero, the segment is completely unlocked.

The value returned when the function is called in C should be ignored, because the return value can be checked only in assembly language.

Comments An application should not rely on the return value to determine the number of times it must subsequently call **UnlockSegment** for the segment.

Other functions also can affect the lock count of a memory object. For a list of these functions, see the description of the **GlobalFlags** function.

Each time an application calls **LockSegment** for a segment, it must eventually call **UnlockSegment** for the segment.

See Also

GlobalFlags, LockSegment, UnlockData

UnrealizeObject

BOOL UnrealizeOb HGDIOBJ hgdiobj;	
	The UnrealizeObject function resets the origin of a brush or resets a logical palette. If the <i>hgdiobj</i> parameter identifies a brush, UnrealizeObject directs the system to reset the origin of the brush the next time it is selected. If the <i>hgdiobj</i> parameter identifies a logical palette, UnrealizeObject directs the system to realize the palette as though it had not previously been realized. The next time the application calls the RealizePalette function for the specified palette, the system completely remaps the logical palette to the system palette.
Parameters	<i>hgdiobj</i> Identifies the object to be reset.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	The UnrealizeObject function should not be used with stock objects.
	The UnrealizeObject function must be called whenever a new brush origin is set (by using the SetBrushOrg function).
	A brush identified by the <i>hgdiobj</i> parameter must not be the currently selected brush of any device context.
	A palette identified by <i>hgdiobj</i> can be the currently selected palette of a device context.

3.0

Example The following example uses the **SetBrushOrg** function to set the origin coordinates of the current brush to (3,5), uses the **SelectObject** function to remove that brush from the device context, uses the **UnrealizeObject** function to force the system to reset the origin of the specified brush, and then calls **SelectObject** again to select the brush into the device context with the new brush origin:

```
HBRUSH hbr, hbr01d;
SetBkMode(hdc, TRANSPARENT);
hbr = CreateHatchBrush(HS_CROSS, RGB(0, 0, 0));
UnrealizeObject(hbr):
SetBrushOrg(hdc, 0, 0);
hbr0ld = SelectObject(hdc, hbr);
Rectangle(hdc, 0, 0, 200, 200);
hbr = SelectObject(hdc, hbrOld);
                                              /* deselects hbr */
UnrealizeObject(hbr); /* resets origin next time hbr selected */
SetBrushOrg(hdc, 3, 5);
hbrOld = SelectObject(hdc, hbr);
                                         /* selects hbr again */
Rectangle(hdc, 0, 0, 200, 200);
SelectObject(hdc, hbr0ld);
DeleteObject(hbr);
```

See Also RealizePalette, SelectObject, SetBrushOrg

UnregisterClass

BOOL UnregisterCla LPCSTR lpszClassNa HINSTANCE hinst;	ass(lpszClassName, hinst) ame; /* address of class-name string */ /* handle of application instance */
	The UnregisterClass function removes a window class, freeing the storage re- quired for the class.
Parameters <i>L</i>	<i>IpszClassName</i> Points to a null-terminated string containing the class name. This class name must have been registered by a previous call to the RegisterClass function with a valid hinstance member of the WNDCLASS structure. Predefined classes, such as dialog box controls, cannot be unregistered. The WNDCLASS struc- ture has the following form:

	<pre>typedef struct tagWNDCLASS { /* wc */ UINT style;</pre>
	WNDPROC lpfnWndProc;
	int cbClsExtra:
	int cbWndExtra:
	HINSTANCE hInstance:
	HICON hIcon;
	HCURSOR hCursor;
	HBRUSH hbrBackground;
	LPCSTR 1pszMenuName;
	LPCSTR lpszClassName;
	} WNDCLASS;
	For a full description of this structure, see the <i>Microsoft Windows Programmer's Reference</i> , Volume 3.
	hinst
	Identifies the instance of the module that created the class.
Return Value	The return value is nonzero if the function successful. It is zero if the class could
	not be found or if a window exists that was created with the class.
Comments	Before calling this function, an application should destroy all windows that were
	created with the specified class.
See Also	RegisterClass

UpdateColors

int UpdateColors(hdc)
HDC hdc; /* handle of device context */

The **UpdateColors** function updates the client area of the given device context by matching the current colors in the client area, pixel by pixel, to the system palette. An inactive window with a realized logical palette may call **UpdateColors** as an alternative to redrawing its client area when the system palette changes.

3.0

ParametershdcIdentifies the device context.Return ValueThe return value is not used.

Comments Using **UpdateColors** to update a client area is typically faster than redrawing the area. However, because **UpdateColors** performs the color translation based on the color of each pixel before the system palette changed, each call to this function results in the loss of some color accuracy.

UpdateWindow

2.x

void UpdateWindow(hwnd)HWND hwnd;/* handle of window*/	
	The UpdateWindow function updates the client area of the given window by sending a WM_PAINT message to the window if the update region for the window is not empty. The function sends a WM_PAINT message directly to the window procedure of the given window, bypassing the application queue. If the update region is empty, no message is sent.
Parameters	<i>hwnd</i> Identifies the window to be updated.
Return Value	This function does not return a value.
See Also	ExcludeUpdateRgn, GetUpdateRect, GetUpdateRgn, InvalidateRect, InvalidateRgn

ValidateCodeSegments

3.0

void ValidateCodeSegments(void)

The **ValidateCodeSegments** function tests all code segments for random memory overwrites. The function works only in real mode (for Windows versions earlier than 3.1) and only with the debugging version of Windows.

Parameters This function has no parameters.

Return Value This function does not return a value.

Comments Because code segments are not writable in protected mode (standard or enhanced), this function does nothing in Windows 3.1.

See Also ValidateFreeSpaces

ValidateFreeSpaces

void ValidateFreeSpaces(void)

	The ValidateFreeSpaces function checks free segments in memory for valid con- tents. This function is available only in the debugging version of Windows.
Parameters	This function has no parameters.
Return Value	This function does not return a value.
Comments	In the debugging version of Windows, the kernel fills all the bytes in free seg- ments with the hexadecimal value 0x0CC. This function begins checking for valid contents in the free segment with the lowest address; it continues checking until it finds an invalid byte or until it has determined that all free space contains valid contents. Before calling this function, put the following lines in the WIN.INI file:
	[KERNEL] EnableFreeChecking=1 EnableHeapChecking=1
	Windows sends debugging information to the debugging terminal if an invalid byte is encountered, and then it performs a fatal exit.
	The [KERNEL] entries in WIN.INI cause automatic checking of free memory. Before returning a memory object to the application in response to a call to the GlobalAlloc function, Windows checks that memory to make sure it is filled with 0x0CC. Before a call to the GlobalCompact function, all free memory is checked. Note that using this function slows Windows system-wide by about twenty per- cent.
See Also	GlobalAlloc, GlobalCompact, ValidateCodeSegments

ValidateRect 2.x void ValidateRect(hwnd, lprc) HWND hwnd: /* handle of window */ const RECT FAR* lprc: /* address of structure with validation rect. */ The ValidateRect function validates the client area within the given rectangle by removing the rectangle from the update region of the given window. **Parameters** hwnd Identifies the window whose update region is to be modified. lprc Points to a **RECT** structure that contains the client coordinates of the rectangle to be removed from the update region. If this parameter is NULL, the entire client area is removed. The **RECT** structure has the following form: typedef struct tagRECT { /* rc */ int left; int top; int right; int bottom: } RECT; For a full description of this structure, see the Microsoft Windows Programmer's Reference, Volume 3. **Return Value** This function does not return a value. Comments The **BeginPaint** function automatically validates the entire client area. Neither the ValidateRect nor the ValidateRgn function should be called if a portion of the update region needs to be validated before the next WM_PAINT message is generated. Windows continues to generate WM PAINT messages until the current update region is validated. See Also BeginPaint, InvalidateRect, InvalidateRgn, ValidateRgn

ValidateRgn

void ValidateRgn			
HWND hwnd; HRGN hrgn;	/* handle of window */ /* handle of valid region */		
	The ValidateRgn function validates the client area within the given region by removing the region from the current update region of the specified window.		
Parameters	<i>hwnd</i> Identifies the window whose update region is to be modified.		
	<i>hrgn</i> Identifies a region that defines the area to be removed from the update region. If this parameter is NULL, the entire client area is removed.		
Return Value	This function does not return a value.		
Comments	The given region must have been created by a region function. The region coordi- nates are assumed to be client coordinates.		
	The BeginPaint function automatically validates the entire client area. Neither the ValidateRect nor the ValidateRgn function should be called if a portion of the update region must be validated before the next WM_PAINT message is generated.		
See Also	BeginPaint, InvalidateRect, InvalidateRgn, ValidateRect		

VerFindFile

#include <ver.h>

UINT VerFindFile(*flags*, *lpszFilename*, *lpszWinDir*, *lpszAppDir*, *lpszCurDir*, *lpuCurDirLen*, *lpszDestDir*, *lpuDestDirLen*)

(p s = c s = i , p i = c s = i = d = i)		
UINT flags;	/* source-file flags	*/
LPCSTR lpszFilename;	/* address of buffer for file	*/
LPCSTR lpszWinDir;	/* address of Windows directory	*/
LPCSTR lpszAppDir;	/* address of application directory	*/
LPSTR lpszCurDir;	/* address of buffer for current directory	*/
UINT FAR * lpuCurDirLen;	/* address of buffer size for directory	*/
LPSTR lpszDestDir;	/* address of buffer for dest. directory	*/
UINT FAR * lpuDestDirLen;	/* address of size for dest. directory	*/

2.x

The **VerFindFile** function determines where to install a file based on whether it locates another version of the file in the system. The values **VerFindFile** returns are used in a subsequent call to the **VerInstallFile** function.

Parameters

flags

Contains a bitmask of flags. This parameter can be VFFF_ISSHAREDFILE, which indicates that the source file may be shared by multiple applications. **VerFindFile** uses this information to determine where the file should be copied. All other values are reserved for future use.

lpszFilename

Points to a null-terminated string specifying the name of the file to be installed. This name should include only the filename and extension, not a path.

lpszWinDir

Points to a null-terminated string specifying the Windows directory. This string is returned by the **GetWindowsDir** function. The dynamic-link library (DLL) version of **VerFindFile** ignores this parameter.

lpszAppDir

Points to a null-terminated string specifying the drive letter and directory where the installation program is installing a set of related files. If the installation program is installing an application, this is the directory where the application will reside. This directory will also be the application's working directory unless you specify otherwise.

lpszCurDir

Points to a buffer that receives the path to a current version of the file being installed. The path is a null-terminated string. If a current version is not installed, the buffer will contain the source directory of the file being installed. The buffer must be at least _MAX_PATH bytes long.

lpuCurDirLen

Points to a null-terminated string specifying the length, in bytes, of the buffer pointed to by *lpszCurDir*. On return, *lpuCurDirLen* contains the size, in bytes, of the data returned in *lpszCurDir*, including the terminating null character. If the buffer is too small to contain all the data, *lpuCurDirLen* will be greater than the actual size of the buffer.

lpszDestDir

Points to a buffer that receives the path to the installation directory recommended by **VerFindFile**. The path is a null-terminated string. The buffer must be at least _MAX_PATH bytes long.

lpuDestDirLen

Points to the length, in bytes, of the buffer pointed to by *lpszDestDir*. On return, *lpuDestDirLen* contains the size, in bytes, of the data returned in *lpszDestDir*, including the terminating null character. If the buffer is too small to contain all the data, *lpuDestDirLen* will be greater than the actual size of the buffer.

Return Value The return value is a bitmask that indicates the status of the file, if the function is successful. This value may be one or more of the following:

	Error	Meaning	
	VFF_CURNEDEST	Indicates that the currently installed version of the file is not in the recommended destination.	
	VFF_FILEINUSE	Indicates that Windows is using the currently installed version of the file; therefore, the file cannot be overwritten or deleted.	
	VFF_BUFFTOOSMALL	Indicates that at least one of the buffers was too small to contain the corresponding string. An application should check the <i>lpuCurDirLen</i> and <i>lpuDestDirLen</i> parameters to determine which buffer was too small.	
	All other values are reserv	red for future use.	
Comments The dynamic-link library (DLL) version of VerFindFile searches specified file by using the OpenFile function. In the LIB version, searches for the file in the Windows directory, the system director directories specified by the PATH environment variable.		OpenFile function. In the LIB version, the function Windows directory, the system directory, and then the	
	VerFindFile determines the system directory from the specified Wind directory, or it searches the path.		
	If the <i>flags</i> parameter indicates that the file is private to this application (not VFFF_ISSHAREDFILE), VerFindFile recommends installing the file in the application's directory. Otherwise, if the system is running a shared copy of Windows, the function recommends installing the file in the Windows directory. If the system is running a private copy of Windows, the function recommends installing the file in the system directory.		
See Also	VerInstallFile		

VerInstallFile

#include <ver.h>

lpszCurDir, lpszTmpFile, lpwTmpFileLen)				
UINT flags;	/* source-file flags	*/		
LPCSTR lpszSrcFilename;	/* address of source filename	*/		
LPCSTR lpszDestFilename;	/* address of destination filename	*/		
LPCSTR lpszSrcDir;	/* address of buffer for source dir. name	*/		
LPCSTR lpszDestDir;	/* address of buffer for dest. dir. name	*/		
LPCSTR lpszCurDir;	/* address of buffer for preexisting dir.	*/		
LPSTR lpszTmpFile;	/* address of buffer for temp. filename	*/		
UINT FAR* <i>lpwTmpFileLen</i> ;	/* address of buffer for temp. file size	*/		

DWORD VerInstallFile(*flags*, *lpszSrcFilename*, *lpszDestFilename*, *lpszSrcDir*, *lpszDestDir*,

The **VerInstallFile** function attempts to install a file based on information returned from the **VerFindFile** function. **VerInstallFile** decompresses the file with the **LZCopy** function and checks for errors, such as outdated files.

Parameters

flags

Contains a bitmask of flags. This parameter can be a combination of the following values:

Value	Meaning	
VIFF_FORCEINSTALL	Installs the file regardless of mismatched version numbers. The function will check only for physical errors during installation.	
	If <i>flags</i> includes VIFF_FORCEINSTALL and <i>lpszTmpFileLen</i> is not a pointer to zero, VerInstall-File will skip all version checks of the temporary file and the destination file and rename the temporary file to the name specified by <i>lpszSrcFilename</i> , as long as the temporary file exists in the destination directory, the destination file is not in use, and the user has privileges to delete the destination file and rename the temporary file. The return value from VerInstallFile should be checked for any errors.	
VIFF_DONTDELETEOLD	Installs the file without deleting the previously in- stalled file, if the previously installed file is not in the destination directory. If the previously installed file is in the destination directory, VerInstallFile re- places it with the new file upon successful installa- tion.	

All other values are reserved for future use.

lpszSrcFilename

Points to the name of the file to be installed. This is the filename in the directory pointed to by *lpszSrcDir*; the filename should include only the filename and extension, not a path. **VerInstallFile** opens the source file by using the **LZOpenFile** function. This means it can handle both files as specified and files that have been compressed and renamed by using the */r* option with COMPRESS.EXE.

lpszDestFilename

Points to the name **VerInstallFile** will give the new file upon installation. This filename may be different than the filename in the directory pointed to by *lpszSrcFilename*. The new name should include only the filename and extension, not a path.

lpszSrcDir

Points to a buffer that contains the directory name where the new file is found.

lpszDestDir

Points to a buffer that contains the directory name where the new file should be installed. The **VerFindFile** function returns this value in the *lpszDestDir* parameter.

lpszCurDir

Points to a buffer that contains the directory name where the preexisting version of this file is found. **VerFindFile** returns this value in the *lpszCurDir* parameter. If the filename specified in *lpszDestFilename* already exists in the *lpszCurDir* directory and *flags* does not include VIFF_DONTDELETEOLD, the existing file will be deleted. If *lpszCurDir* is a pointer to NULL, a previous version of the file does not exist on the system.

lpszTmpFile

Points to a buffer that should be empty upon the initial call to **VerInstallFile**. The function fills the buffer with the name of a temporary copy of the source file. The buffer must be at least _MAX_PATH bytes long.

lpwTmpFileLen

Points to the length of the buffer pointed to by *lpszTmpFile*. On return, *lpwTmpFileLen* contains the size, in bytes, of the data returned in *lpszTmpFile*, including the terminating null character. If the buffer is too small to contain all the data, *lpwTmpFileLen* will be greater than the actual size of the buffer.

If *flags* includes VIFF_FORCEINSTALL and *lpwTmpFileLen* is not a pointer to zero, **VerInstallFile** will rename the temporary file to the name specified by *lpszSrcFilename*.

Return Value

The return value is a bitmask that indicates exceptions, if the function is successful. This value may be one or more of the following:

Value	Meaning
VIF_TEMPFILE	Indicates that the temporary copy of the new file is in the destination directory. The cause of failure is re- flected in other flags. Applications should always check whether this bit is set and delete the temporary file, if required.
VIF_MISMATCH	Indicates that the new and preexisting files differ in one or more attributes. This error can be overridden by calling VerInstallFile again with the VIFF_FORCEINSTALL flag.
VIF_SRCOLD	Indicates that the file to install is older than the preexisting file. This error can be overridden by calling VerInstallFile again with the VIFF_FORCEINSTALL flag.
VIF_DIFFLANG	Indicates that the new and preexisting files have different language or code-page values. This error can be overridden by calling VerInstallFile again with the VIFF_FORCEINSTALL flag.
VIF_DIFFCODEPG	Indicates that the new file requires a code page that cannot be displayed by the currently running version of Windows. This error can be overridden by calling VerInstallFile with the VIFF_FORCEINSTALL flag.
VIF_DIFFTYPE	Indicates that the new file has a different type, sub- type, or operating system than the preexisting file. This error can be overridden by calling VerInstall- File again with the VIFF_FORCEINSTALL flag.
VIF_WRITEPROT	Indicates that the preexisting file is write-protected. The installation program should reset the read-only bit in the destination file before proceeding with the installation.
VIF_FILEINUSE	Indicates that the preexisting file is in use by Win- dows and cannot be deleted.
VIF_OUTOFSPACE	Indicates that the function cannot create the tem- porary file due to insufficient disk space on the desti- nation drive.
VIF_ACCESSVIOLATION	Indicates that a create, delete, or rename operation failed due to an access violation.
VIF_SHARINGVIOLATION	Indicates that a create, delete, or rename operation failed due to a sharing violation.
VIF_CANNOTCREATE	Indicates that the function cannot create the tem- porary file. The specific error may be described by another flag.

Value	Meaning		
VIF_CANNOTDELETE	Indicates that the function cannot delete the destination file or cannot delete the existing version of the file located in another directory. If the VIF_TEMPFILE bit is set, the installation failed and the destination file probably cannot be deleted.		
VIF_CANNOTRENAME	Indicates that the function cannot rename the tem- porary file but already deleted the destination file.		
VIF_OUTOFMEMORY	Indicates that the function cannot complete the re- quested operation due to insufficient memory. Gener ally, this means the application ran out of memory attempting to expand a compressed file.		
VIF_CANNOTREADSRC	Indicates that the function cannot read the source file. This could mean that the path was not specified properly, that the file does not exist, or that the file is a compressed file that has been corrupted. To distin- guish these conditions, use LZOpenFile to deter- mine whether the file exists. (Do not use the OpenFile function, because it does not correctly translate filenames of compressed files.) Note that VIF_CANNOTREADSRC does not cause either the VIF_ACCESSVIOLATION or VIF_SHARINGVIOLATION bit to be set.		
VIF_CANNOTREADDST	Indicates that the function cannot read the destina- tion (existing) files. This prevents the function from examining the file's attributes.		
VIF_BUFFTOOSMALL	Indicates that the <i>lpszTmpFile</i> buffer was too small to contain the name of the temporary source file. On return, <i>lpwTmpFileLen</i> contains the size of the buffer required to hold the filename.		
All other values are reserved	l for future use.		

Comments

VerInstallFile is designed for use in an installation program. This function copies a file (specified by *lpszSrcFilename*) from the installation disk to a temporary file in the destination directory. If necessary, **VerInstallFile** expands the file by using the functions in LZEXPAND.DLL.

If a preexisting copy of the file exists in the destination directory, **VerInstallFile** compares the version information of the temporary file to that of the preexisting file. If the preexisting file is more recent than the new version, or if the files' attributes are significantly different, **VerInstallFile** returns one or more error values. For example, files with different languages would cause **VerInstallFile** to return VIF_DIFFLANG.

VerInstallFile leaves the temporary file in the destination directory. If all of the errors are recoverable, the installation program can override them by calling **Ver**-

InstallFile again with the VIFF_FORCEINSTALL flag. In this case, *lpszSrcFilename* should point to the name of the temporary file. Then, **VerInstall-File** deletes the preexisting file and renames the temporary file to the name specified by *lpszSrcFilename*. If the VIF_TEMPFILE bit indicates that a temporary file exists and the application does not force the installation by using the VIFF_FORCEINSTALL flag, the application must delete the temporary file.

If an installation program attempts to force installation after a nonrecoverable error, such as VIF_CANNOTREADSRC, **VerInstallFile** will not install the file.

VerQueryValue

#include <ver.h>

BOOL VerQueryValue(lpvBlock, const void FAR* lpvBlock; LPCSTR lpszSubBlock; VOID FAR* FAR* lplpBuffer; UINT FAR* lpcb;		<i>lpszSubBlock, lplpBuffer, lpcb)</i> /* address of buffer for version resource /* address of value to retrieve /* address of buffer for version pointer /* address of buffer for version-value length	*/ */ */
		cryValue function returns selected version information resource. To obtain the appropriation	tion from the
-		sionInfo function must be called before VerQuery	
		the buffer containing the version-information resou ersionInfo function.	rce returned by the
		k a zero-terminated string specifying which version-i e. The string consists of names separated by backsla	

have one of the following forms:

3.1

	Form		Description
	l		Specifies the root block. The func- tion retrieves a pointer to the VS_FIXEDFILEINFO structure for the version-information resource.
	\VarFileInfo\Tran	slation	Specifies the translation table in the variable information block. The function retrieves a pointer to an array of language and character-set identifiers. An application uses these identifiers to create the name of an language-specific block in the version-information resource.
	\StringFileInfo\ <i>lar</i>	ng-charset\string-name	Specifies a value in a language- specific block. The <i>lang-charset</i> name is a concatenation of a lan- guage and character-set identifier pair found in the translation table for the resource. The <i>lang-charset</i> name must be specified as a hex- adecimal string. The <i>string-name</i> name is one of the predefined strings described in the following Comments section.
	<i>lplpBuffer</i> Points to a buffer	that receives a pointer to	o the version-information value.
	<i>lpcb</i> Points to a buffer value.	that receives the length,	in bytes, of the version-information
Return Value	is available. If <i>lpcb</i> is zero, no value is available for the specified version- information name. The return value is zero if the specified name does not exist or the resource pointed to by <i>lpvBlock</i> is not valid.		
Comments			eter can be one of the following prede-
	Name	Value	
	Comments	Specifies additional info diagnostic purposes.	rmation that should be displayed for
	CompanyName	Specifies the company the "Microsoft Corporation" tion, Inc.". This string is	nat produced the file—for example, ' or "Standard Microsystems Corpora- required.

Name	Value
FileDescription	Specifies a file description to be presented to users. This string may be displayed in a list box when the user is choosing files to install—for example, "Keyboard Driver for AT-Style Keyboards" or "Microsoft Word for Windows". This string is required.
FileVersion	Specifies the version number of the file—for example, "3.10" or "5.00.RC2". This string is required.
InternalName	Specifies the internal name of the file, if one exists—for ex- ample, a module name if the file is a dynamic-link library. If the file has no internal name, this string should be the original filename, without extension. This string is required.
LegalCopyright	Specifies all copyright notices that apply to the file. This should include the full text of all notices, legal symbols, copyright dates, and so on—for example, "Copyright Microsoft Corporation 1990–1991". This string is optional.
LegalTrademarks	Specifies all trademarks and registered trademarks that apply to the file. This should include the full text of all notices, legal symbols, trademark numbers, and so on—for example, "Windows(TM) is a trademark of Microsoft Corporation". This string is optional.
OriginalFilename	Specifies the original name of the file, not including a path. This information enables an application to determine whether a file has been renamed by a user. The format of the name de- pends on the file system for which the file was created. This string is required.
PrivateBuild	Specifies information about a private version of the file—for example, "Built by TESTER1 on \TESTBED". This string should be present only if the VS_FF_PRIVATEBUILD flag is set in the dwFileFlags member of the VS_FIXEDFILEINFO structure of the root block.
ProductName	Specifies the name of the product with which the file is dis- tributed—for example, "Microsoft Windows". This string is re- quired.
ProductVersion	Specifies the version of the product with which the file is dis- tributed—for example, "3.10" or "5.00.RC2". This string is re- quired.
SpecialBuild	Specifies how this version of the file differs from the standard version—for example, "Private build for TESTER1 solving mouse problems on M250 and M250E computers". This string should be present only if the VS_FF_SPECIALBUILD flag is set in the dwFileFlags member of the VS_FIXEDFILEINFO structure in the root block.

Example The following example loads the version information for a dynamic-link library and retrieves the company name:

```
BYTE abData[512];
DWORD handle;
DWORD dwSize;
LPBYTE lpBuffer;
char szName[512];
dwSize = GetFileVersionInfoSize("c:\\dll\\sample.dll", &handle));
GetFileVersionInfo("c:\\dll\\sample.dll", handle, dwSize, abData));
VerQueryValue(abData, "\\VarFileInfo\\Translation", &lpBuffer,
&dwSize));
if (dwSize!=0) {
    wsprintf(szName, "\\StringFileInfo\\%81x\\CompanyName", &lpBuffer);
    VerQueryValue(abData, szName, &lpBuffer, &dwSize);
}
```

GetFileVersionInfo

VkKeyScan

UINT VkKeyScan(*uChar*) **UINT** *uChar*; /* character to translate */ The VkKeyScan function translates a Windows character to the corresponding virtual-key code and shift state for the current keyboard. **Parameters** uChar Specifies the character to be translated to a virtual-key code. **Return Value** The return value is the virtual-key code and shift state, if the function is successful. The low-order byte contains the virtual-key code; the high-order byte contains the shift state, which can be one of the following: Value Meaning 1 Character is shifted. 2 Character is a control character. 3-5 Shift-key combination that is not used for characters. 6 Character is generated by the CTRL+ALT key combination. 7 Character is generated by the SHIFT+CTRL+ALT key combination.

	If no key is found that translates to the passed Windows code, the return value is -1 .
Comments	Translations for the numeric keypad (VK_NUMPAD0 through VK_DIVIDE) are ignored. This function is intended to force a translation for the main keyboard only.
	Applications that send characters by using the WM_KEYUP and WM_KEYDOWN messages use this function.
See Also	OemKeyScan

WaitMessage

void WaitMessage(void)

	The WaitMessage function yields control to other applications when an applica- tion has no other tasks to perform. The WaitMessage function suspends the appli- cation and does not return until a new message is placed in the application's queue.	
Parameters	This function has no parameters.	
Return Value	This function does not return a value.	
Comments	The WaitMessage function normally returns immediately if there is a message in the queue. If an application has used the PeekMessage function but not removed the message, however, WaitMessage does not return until the message is re- ceived. Applications that use the PeekMessage function should remove any retrieved messages from the queue before calling WaitMessage .	
	The GetMessage , PeekMessage , and WaitMessage functions yield control to other applications. Using these functions is the only way to allow other applications to run. Applications that do not call any of these functions for long periods prevent other applications from running.	
See Also	GetMessage, PeekMessage	

2.x

WaitSoundState

int WaitSoundState(fnState)

int fnState; /* state to wait for

*/

This function is obsolete. Use the Microsoft Windows multimedia audio functions instead. For information about these functions, see the *Microsoft Windows Multimedia Programmer's Reference*.

WEP

<pre>int CALLBACK ` int nExitType;</pre>	WEP(<i>nExitType</i>) /* type of exit */
	The WEP (Windows exit procedure) callback function performs cleanup for a dynamic-link library (DLL) before the library is unloaded. This function is called by Windows. Although a WEP function was required for every dynamic-link library in previous versions of the Windows operating system, for version 3.1 the WEP function is optional. Most dynamic-link libraries use the WEP function.
Parameters	<i>nExitType</i> Specifies whether all of Windows is shutting down or only the individual library. This parameter can be either WEP_FREE_DLL or WEP_SYSTEM_EXIT.
Return Value	The return value should be 1 if the function is successful.
Comments	For Windows version 3.1, WEP is called on the stack of the application that is ter- minating. This enables WEP to call Windows functions. In Windows version 3.0, however, WEP is called on a KERNEL stack that is too small to process most calls to Windows functions. These calls, including calls to global-memory func- tions, should be avoided in a WEP function for Windows 3.0. Calls to MS-DOS functions go through a KERNEL intercept and can also overflow the stack in Win- dows 3.0. There is no general reason to free memory from the global heap in a WEP function, because the kernel frees this kind of memory automatically.
	In some low-memory conditions, WEP can be called before the library initializa- tion function is called and before the library's DGROUP data-segment group has been created. A WEP function that relies on the library initialization function should verify that the initialization function has been called. Also, WEP functions that rely on the validity of DGROUP should check for this. The following

procedure is recommended for dynamic-link libraries in Windows 3.0; for Windows 3.1, only step 3 is necessary.

- 1. Verify that the data segment is present by using a **lar** instruction and checking the present bit. This will indicate whether DS has been loaded. (The DS register always contains a valid selector.)
- 2. Set a flag in the data segment when the library initialization is performed. Once the **WEP** function has verified that the data segment exists, it should test this flag to determine whether initialization has occurred.
- 3. Declare **WEP** in the **EXPORTS** section of the module-definition file for the DLL. Following is an example declaration:
 - WEP @1 RESIDENTNAME

The keyword **RESIDENTNAME** makes the name of the function (**WEP**) resident at all times. (It is not necessary to use the ordinal reference 1.) The name listed in the **LIBRARY** statement of the module-definition file must be in uppercase letters and must match the name of the DLL file.

Windows calls the **WEP** function by name when it is ready to remove the DLL. Under low-memory conditions, it is possible for the DLL's nonresident-name table to be discarded from memory. If this occurs, Windows must load the table to determine whether a **WEP** function was declared for the DLL. Under lowmemory conditions, this method could fail, causing a fatal exit. Using the **RESIDENTNAME** option forces Windows to keep the name entry for **WEP** in memory whenever the DLL is in use.

In Windows 3.0, **WEP** must be placed in a fixed code segment. If it is placed instead in a discardable segment, under low-memory conditions Windows must load the **WEP** segment from disk so that the **WEP** function can be called before the DLL is discarded. Under certain low-memory conditions, attempting to load the segment containing **WEP** can cause a fatal exit. When **WEP** is in a fixed segment, this situation cannot occur. (Because fixed DLL code is also page-locked, you should minimize the amount of fixed code.)

If a DLL is explicitly loaded by calling the **LoadLibrary** function, its **WEP** function is called when the DLL is freed by a call to the **FreeLibrary** function. (The **FreeLibrary** function should not be called from within a **WEP** function.) If the DLL is implicitly loaded, **WEP** is also called, but some debugging applications will indicate that the application has been terminated before **WEP** is called.

The **WEP** functions of dependent DLLs can be called in any order. This order depends on the order in which the usage counts for the DLLs reach zero.

WindowFromPoint

HWND WindowFi POINT <i>pt</i> ; /* s	romPoint(<i>pt</i>) tructure with point */
	The WindowFromPoint function retrieves the handle of the window that contains the specified point.
Parameters	<i>pt</i> Specifies a POINT structure that defines the screen coordinates of the point to be checked. The POINT structure has the following form:
	<pre>typedef struct tagPOINT { /* pt */ int x; int y; } POINT;</pre>
	For a full description of this structure, see the Microsoft Windows Program- mer's Reference, Volume 3.
Return Value	The return value is the handle of the window in which the point lies, if the func- tion is successful. The return value is NULL if no window exists at the specified point.
Comments	The WindowFromPoint function does not retrieve the handle of a hidden, dis- abled, or transparent window, even if the point is within the window. An applica- tion should use the ChildWindowFromPoint function for a nonrestrictive search.
See Also	ChildWindowFromPoint

WindowProc

LRESULT CALLBACK WindowProc (<i>hwnd</i> , <i>msg</i> , <i>wParam</i> , <i>lParam</i>)			
HWND hwnd;	/* handle of window	*/	
UINT msg;	/* message	*/	
WPARAM wParam;	/* first message parameter	*/	
LPARAM lParam;	/* second message parameter	*/	

The **WindowProc** function is an application-defined callback function that processes messages sent to a window.

3.0

Parameters	<i>hwnd</i> Identifies the window.		
	<i>msg</i> Specifies the message.		
	<i>wParam</i> Specifies 16 bits of additional message-dependent information.		
	<i>lParam</i> Specifies 32 bits of additional message-dependent information.		
Return Value	The return value is the result of the message processing. The value depends on the message being processed.		
Comments	The WindowProc name is a placeholder for the application-defined function name. The actual name must be exported by including it in an EXPORTS statement in the application's module-definition file.		
See Also	DefWindowProc, RegisterClass		

WinExec

UINT WinExec(*lpszCmdLine*, *fuCmdShow*) **LPCSTR** *lpszCmdLine*; /* address of command line */ **UINT** fuCmdShow; /* window style for new app. */ The WinExec function runs the specified application. **Parameters** *lpszCmdLine* Points to a null-terminated Windows character string that contains the command line (filename plus optional parameters) for the application to be run. If the string does not contain a path, Windows searches the directories in this order: 1. The current directory. 2. The Windows directory (the directory containing WIN.COM); the Get-**WindowsDirectory** function retrieves the path of this directory. 3. The Windows system directory (the directory containing such system files as GDI.EXE); the **GetSystemDirectory** function retrieves the path of this directory. 4. The directory containing the executable file for the current task; the **Get-**ModuleFileName function retrieves the path of this directory.

Return Value	 5. The directories listed in the PATH environment variable. 6. The directories mapped in a network. <i>fuCmdShow</i> Specifies how a Windows application window is to be shown. See the description of the ShowWindow function for a list of the acceptable values for the <i>fuCmdShow</i> parameter. For a non-Windows application, the programinformation file (PIF), if any, for the application determines the window state. 		
	The return value identifies the instance of the loaded module, if the function is successful. Otherwise, the return value is an error value less than 32.		
Errors		value may be one of the following:	
	Value	Meaning	
	0	System was out of memory, executable file was corrupt, or relocations were invalid.	
	2	File was not found.	
	3	Path was not found.	
	5	Attempt was made to dynamically link to a task, or there was a sharing or network-protection error.	
	6	Library required separate data segments for each task.	
	8	There was insufficient memory to start the application.	
	10	Windows version was incorrect.	
	11	Executable file was invalid. Either it was not a Windows application or there was an error in the .EXE image.	
	12	Application was designed for a different operating system.	
	13	Application was designed for MS-DOS 4.0.	
	14	Type of executable file was unknown.	
	15	Attempt was made to load a real-mode application (developed for an earlier version of Windows).	
	16	Attempt was made to load a second instance of an executable file contain- ing multiple data segments that were not marked read-only.	
	19	Attempt was made to load a compressed executable file. The file must be decompressed before it can be loaded.	
	20	Dynamic-link library (DLL) file was invalid. One of the DLLs required to run this application was corrupt.	
	21	Application requires Microsoft Windows 32-bit extensions.	
Comments	The LoadModule function provides an alternative method for running an applica- tion.		
Example	The following example uses the WinExec function to run DRAW.EXE:		

```
WORD wReturn;
char szMsg[80];
wReturn = WinExec("draw", SW_SHOW);
if (wReturn < 32) {
    sprintf(szMsg, "WinExec failed; error code = %d", wReturn);
    MessageBox(hwnd, szMsg, "Error", MB_ICONSTOP);
}
else {
    sprintf(szMsg, "WinExec returned %d", wReturn);
    MessageBox(hwnd, szMsg, "", MB_OK);
}
```

WinHelp		3.0
HWND hwnd;	nd, lpszHelpFile, fuCommand, dwData) /* handle of window requesting help le; /* address of directory-path string /* type of help /* additional data	*/ */ */ */
	The WinHelp function starts Windows Help (tional data indicating the nature of the help rec cation specifies the name and, where required. Help application is to display. For information see <i>Microsoft Windows Programming Tools</i> .	quested by the application. The appli- , the path of the help file that the
Parameters	<i>hwnd</i> Identifies the window requesting Help. The to keep track of which applications have rea <i>lpszHelpFile</i>	
	Points to a null-terminated string containing name of the help file that the Help application	
	The filename may be followed by an angle ondary window if the topic is to be displayed than in the primary window. The name of t been defined in the [WINDOWS] section o	ed in a secondary window rather he secondary window must have

	<i>fuCommand</i> Specifies the type of help requested. For a list of possible values and how they affect the value to place in the <i>dwData</i> parameter, see the following Comments section.	
	<i>dwData</i> Specifies additional data. The value used depends on the value of the <i>fuCommand</i> parameter. For a list of possible values, see the following Comments section.	
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.	
Comments	Before closing the window that requested the help, the application must call Win-Help with <i>fuCommand</i> set to HELP_QUIT. Until all applications have done this, Windows Help does not terminate.	
	The following table shows the possible values for the <i>fuCommand</i> parameter and the corresponding formats of the <i>dwData</i> parameter:	

fuCommand	dwData	Action
HELP_CONTEXT	An unsigned long integer contain- ing the context number for the topic.	Displays Help for a particular topic iden- tified by a context number that has been defined in the [MAP] section of the .HPJ file.
HELP_CONTENTS	Ignored; applications should set to 0L.	Displays the Help contents topic as de- fined by the Contents option in the [OPTIONS] section of the .HPJ file.
HELP_SETCONTENTS	An unsigned long integer contain- ing the context number for the topic the application wants to designate as the Contents topic.	Determines which Contents topic Help should display when a user presses the F1 key.
HELP_CONTEXTPOPUP	An unsigned long integer contain- ing the context number for a topic.	Displays in a pop-up window a particular Help topic identified by a context number that has been defined in the [MAP] sec- tion of the .HPJ file.
HELP_KEY	A long pointer to a string that con- tains a keyword for the desired topic.	Displays the topic found in the keyword list that matches the keyword passed in the <i>dwData</i> parameter if there is one exact match. If there is more than one match, displays the Search dialog box with the topics listed in the Go To list box. If there is no match, displays the Search dialog box.

fuCommand	dwData	Action
HELP_PARTIALKEY	A long pointer to a string that con- tains a keyword for the desired topic.	Displays the topic found in the keyword list that matches the keyword passed in the <i>dwData</i> parameter if there is one exact match. If there is more than one match, displays the Search dialog box with the topics found listed in the Go To list box. If there is no match, displays the Search dialog box. If you just want to bring up the Search dialog box without passing a keyword (the third result), you should use a long pointer to an empty string.
HELP_MULTIKEY	A long pointer to the MULTI- KEYHELP structure, as defined in WINDOWS.H. This structure specifies the table footnote charac- ter and the keyword.	Displays the Help topic identified by a keyword in an alternate key word table.
HELP_COMMAND	A long pointer to a string that con- tains a Help macro to be executed.	Executes a Help macro.
HELP_SETWINPOS	A long pointer to the HELPWININFO structure, as de- fined in WINDOWS.H. This struc- ture specifies the size and position of the primary Help window or a secondary window to be displayed.	Displays the Help window if it is min- imized or in memory, and positions it according to the data passed.
HELP_FORCEFILE	Ignored; applications should set to 0L.	Ensures that WinHelp is displaying the correct Help file. If the correct Help file is currently displayed, there is no action. If the incorrect Help file is displayed, WinHelp opens the correct file.
HELP_HELPONHELP	Ignored; applications should set to 0L.	Displays the Contents topic of the desig- nated Using Help file.
HELP_QUIT	Ignored; applications should set to 0L.	Informs the Help application that Help is no longer needed. If no other applications have asked for Help, Windows closes the Help application.

The **MULTIKEYHELP** structure has the following form:

```
typedef struct tagMULTIKEYHELP { /* mkh */
 UINT mkSize;
 BYTE mkKeylist;
 BYTE szKeyphrase[1];
} MULTIKEYHELP;
```

For a full description of this structure, see the *Microsoft Windows Programmer's Reference*, *Volume 3*.

WNetAddConnection

}

UINT WNetAddConnection(*lpszNetPath*, *lpszPassword*, *lpszLocalName*) **LPSTR** *lpszNetPath*; /* address of network device */ LPSTR *lpszPassword*; /* address of password */ LPSTR *lpszLocalName*; /* address of local device */ The WNetAddConnection function redirects the specified local device (either a disk drive or a printer port) to the given shared device or remote server. **Parameters** *lpszNetPath* Points to a null-terminated string specifying the shared device or remote server. *lpszPassword* Points to a null-terminated string specifying the network password for the given device or server. *lpszLocalName* Points to a null-terminated string specifying the local drive or device to be redirected. All lpszLocalName strings (such as LPT1) are case-independent. Only the drive names A through Z and the device names LPT1 through LPT3 are used. **Return Value** The return value is one of the following: Value Meaning WN_SUCCESS The function was successful. WN_NOT_SUPPORTED The function was not supported. WN OUT OF MEMORY The system was out of memory. WN_NET_ERROR An error occurred on the network. WN_BAD_POINTER The pointer was invalid.

WN_BAD_NETNAME

The network resource name was invalid.

3.1

Value	Meaning
WN_BAD_LOCALNAME	The local device name was invalid.
WN_BAD_PASSWORD	The password was invalid.
WN_ACCESS_DENIED	A security violation occurred.
WN_ALREADY_CONNECTED	The local device was already connected to a remote resource.

WNetGetConnection

UINT WNetGetCo LPSTR lpszLocalN LPSTR lpszRemote UINT FAR* cbRen	<i>Tame</i> ; /* address of <i>Pame</i> ; /* address of /* address of	szRemoteName, cbRemoteName) local device name */ remote device name */ per of bytes in buffer */
	The WNetGetConnection sociated with the specified	function returns the name of the network resource as- redirected local device.
Parameters	rs <i>lpszLocalName</i> Points to a null-terminated string specifying the name of the redirected local device.	
	<i>lpszRemoteName</i> Points to the buffer to re resource.	ceive the null-terminated name of the remote network
		ifying the maximum number of bytes the buffer <i>eName</i> can hold. The function sets this variable to the to the buffer.
Return Value	The return value is one of t	he following:
	Value	Meaning
	WN_SUCCESS	The function was successful.
	WN_NOT_SUPPORTED	The function was not supported.
	WN_OUT_OF_MEMORY	The system was out of memory.
	WN_NET_ERROR	An error occurred on the network.
	WN_BAD_POINTER	The pointer was invalid.
	WN_BAD_VALUE	The <i>szLocalName</i> parameter was not a valid local device.

	Value	Meaning
	WN_NOT_CONNECTED	The <i>szLocalName</i> parameter was not a redirected local device.
	WN_MORE_DATA	The buffer was too small.

WordBreakProc

<pre>int CALLBACK We LPSTR lpszEditText; int ichCurrentWord; int cbEditText; int action;</pre>		point */
		inction is an application-defined callback function that the line of text in a multiline edit control must be broken.
Parameters	<i>lpszEditText</i> Points to the text of th	ne edit control.
		a word in the buffer of text that identifies the point at ould begin checking for a word break.
	<i>cbEditText</i> Specifies the number	of bytes in the text.
	action Specifies the action to one of the following w	b be taken by the callback function. This parameter can be values:
	Value	Action
	WB_LEFT	Look for the beginning of a word to the left of the current position.
	WB_RIGHT	Look for the beginning of a word to the right of the current position.
	WB_ISDELIMITER	Check whether the character at the current position is a delimiter.
Return Value		pecifies WB_ISDELIMITER, the return value is non-zero at the current position is a delimiter, or zero if it is not.

Otherwise, the return value is an index to the begining of a word in the buffer of text.

Comments A carriage return (CR) followed by a linefeed (LF) must be treated as a single word by the callback function. Two carriage returns followed by a linefeed also must be treated as a single word.

An application must install the callback function by specifying the procedureinstance address of the callback function in a EM_SETWORDBREAKPROC message.

WordBreakProc is a placeholder for the library-defined function name. The actual name must be exported by including it in an **EXPORTS** statement in the library's module-definition file.

WriteComm

int WriteComm(*idComDev*, *lpvBuf*, *cbWrite*) int idComDev: /* identifier of comm. device */ const void FAR* *lpvBuf*; /* address of data buffer */ */ int cbWrite; /* number of bytes to write The WriteComm function writes to the specified communications device. **Parameters** idComDev Specifies the device to receive the bytes. The **OpenComm** function returns this value. lpvBuf Points to the buffer that contains the bytes to be written. cbWrite Specifies the number of bytes to be written. **Return Value** The return value specifies the number of bytes written, if the function is successful. The return value is less than zero if an error occurs, making the absolute value of the return value the number of bytes written. Comments To determine what caused an error, use the GetCommError function to retrieve the error value and status.

For serial ports, the **WriteComm** function deletes data in the transmission queue if there is not enough room in the queue for the additional bytes. Before calling **WriteComm**, applications should check the available space in the transmission queue by using the **GetCommError** function. Also, applications should use the **OpenComm** function to set the size of the transmission queue to an amount no smaller than the size of the largest expected output string.

See Also GetCommError, OpenComm, TransmitCommChar

WritePrivateProfileString

BOOL WritePrivate	eProfileString(lpszSection, lpszEntry, lpszString, lpszFilename)
LPCSTR lpszSection	<i>i</i> ; /* address of section */
LPCSTR <i>lpszEntry</i> ;	
LPCSTR lpszString;	
LPCSTR lpszFilena	<i>me</i> ; /* address of initialization filename */
	The WritePrivateProfileString function copies a character string into the specified section of the specified initialization file.
Parameters	lpszSection
	Points to a null-terminated string that specifies the section to which the string will be copied. If the section does not exist, it is created. The name of the section is case-independent; the string may be any combination of uppercase and lowercase letters.
	<i>lpszEntry</i> Points to the null-terminated string containing the entry to be associated with the string. If the entry does not exist in the specified section, it is created. If this parameter is NULL, the entire section, including all entries within the section, is deleted.
	<i>lpszString</i> Points to the null-terminated string to be written to the file. If this parameter is NULL, the entry specified by the <i>lpszEntry</i> parameter is deleted.
	<i>lpszFilename</i> Points to a null-terminated string that names the initialization file.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	To improve performance, Windows keeps a cached version of the most-recently accessed initialization file. If that filename is specified and the other three parameters are NULL, Windows flushes the cache.

Sections in the initialization file have the following form: [section] entry=string . If *lpszFilename* does not contain a fully qualified path and filename for the file, WritePrivateProfileString searches the Windows directory for the file. If the file does not exist, this function creates the file in the Windows directory. If *lpszFilename* contains a fully qualified path and filename and the file does not exist, this function creates the file. The specified directory must already exist. An application should use a private (application-specific) initialization file to record information that affects only that application. This improves the performance of both the application and Windows itself by reducing the amount of information that Windows must read when it accesses the initialization file. The exception to this is that device drivers should use the SYSTEM.INI file, to reduce the number of initialization files Windows must open and read during the startup process. An application can use the **WriteProfileString** function to add a string to the WIN.INI file. Example The following example uses the WritePrivateProfileString function to add the string "testcode.c" to the LastFile entry in the [MyApp] section of the **TESTCODE.INI** initialization file: BOOL fSuccess: DebugBreak(); fSuccess = WritePrivateProfileString("MyApp", "LastFile", "testcode.c", "testcode.ini"); if (fSuccess) MessageBox(hwnd, "String added successfully". "WritePrivateProfileString", MB_OK); else MessageBox(hwnd, "String could not be added", "WritePrivateProfileString", MB_ICONSTOP); WriteProfileString

See Also

WriteProfileString

BOOL WriteProfile LPCSTR lpszSection LPCSTR lpszEntry; LPCSTR lpszString;	/* address of entry */
	The WriteProfileString function copies a string into the specified section of the Windows initialization file, WIN.INI.
Parameters	<i>lpszSection</i> Points to a null-terminated string that specifies the section to which the string is to be copied. If the section does not exist, it is created. The name of the section is case-independent; the string may be any combination of uppercase and lower-case letters.
	<i>lpszEntry</i> Points to the null-terminated string containing the entry to be associated with the string. If the entry does not exist in the specified section, it is created. If this parameter is NULL, the entire section, including all entries within the section, is deleted.
	<i>lpszString</i> Points to the null-terminated string to be written to the file. If this parameter is NULL, the entry specified by the <i>lpszEntry</i> parameter is deleted.
Return Value	The return value is nonzero if the function is successful. Otherwise, it is zero.
Comments	Windows keeps a cached version of WIN.INI to improve performance. If all three parameters are NULL, Windows flushes the cache.
	Sections in the WIN.INI initialization file have the following form:
	[section] entry=string
Example	The following example calls the GetWindowRect function to retrieve the dimensions of the current window, converts the dimensions of a string, and writes the string to WIN.INI by using the WriteProfileString function. The next time the application is run, it could call the GetProfileString function to read the string, convert it to numbers, and pass the numbers as parameters to the CreateWindow function, thereby creating the window again with the same dimensions it had when the application terminated.

wsprintf

int _cdecl wsprintf(lpszOutput, lpszFormat,)
	/* address of string for output */
LPSTR lpszFormat;	/* address of format-control string */
	The wsprintf function formats and stores a series of characters and values in a buffer. Each argument (if any) is converted according to the corresponding format specified in the format string.
Parameters	<i>lpszOutput</i> Points to a null-terminated string to receive the string formatted as specified in the <i>lpszFormat</i> parameter.
	<i>lpszFormat</i> Points to a null-terminated string that contains the format-control string. In addition to the standard ASCII characters, a format specification for each argument appears in this string. For more information about the format specification, see the following Comments section.
	Specifies zero or more optional arguments. The number and type of the optional arguments depend on the corresponding format-control character sequences specified in the <i>lpszFormat</i> parameter.

Return Value The return value is the number of bytes stored in the *lpszOutput* string, not counting the terminating null character, if the function is successful.

Comments The largest buffer that **wsprintf** can create is 1K.

Unlike most Windows functions, **wsprintf** uses the C calling convention (**_cdecl**) rather than the Pascal calling convention. As a result, the calling function must pop arguments off the stack. Also, arguments must be pushed on the stack from right to left. In C-language modules, the C compiler performs this task. (The **wvsprintf** function uses the Pascal calling convention.)

The format-control string contains format specifications that determine the output format for the arguments that follow the *lpszFormat* parameter. Format specifications always begin with a percent sign (%). If a percent sign is followed by a character that has no meaning as a format field, the character is not formatted. For example, %% produces a single percent-sign character.

The format-control string is read from left to right. When the first format specification is encountered, it causes the value of the first argument after the formatcontrol string to be converted according to the format specification. The second format specification causes the second argument to be converted, and so on. If there are more arguments than there are format specifications, the extra arguments are ignored. The results are undefined if there are not enough arguments for all of the format specifications.

A format specification has the following form:

%[-][#][0][width][.precision]type

Each field of the format specification is a single character or number signifying a particular format option. The *type* characters, for example, determine whether the associated argument is interpreted as a character, a string, or a number. The simplest format specification contains only the percent sign and a *type* character (for example, %s). The optional fields (in brackets) control other aspects of the formatting. Following are the optional and required fields and their meanings:

Field	Meaning
-	Pad the output value with blanks or zeros to the right to fill the field width, aligning the output value to the left. If this field is omitted, the output value is padded to the left, aligning it to the right.
#	Prefix hexadecimal values with 0x (lowercase) or 0X (uppercase).
0	Pad the output value with zeros to fill the field width. If this field is omitted, the output value is padded with blank spaces.

Field	Meaning	· · · · · · · · · · · · · · · · · · ·		
width	Convert the specified minimum number of characters. The <i>width</i> field is a nonnegative integer. The width specification never causes a value to be truncated; if the number of characters in the output value is greater than the specified width, or if the <i>width</i> field is not present, all characters of the value are printed, subject to the value of the <i>precision</i> field.			
precision	Convert the specified minimum number of digits. If there are fewer digits in the argument than the specified value, the output value is padded on the left with zeros. The value is not truncated when the number of digits exceeds the specified precision. If the specified precision is zero or omitted entirely, or if the period (.) appears without a number following it, the precision is set to 1.			
	For strings, co	onvert the specified maximum number of characters.		
type	Format the corresponding argument as a character, a string, or a number. This field may be any of the following character sequences:			
	Sequence	Meaning		
	c	Insert a single character argument. The wsprintf func- tion ignores character arguments with a numeric value of zero.		
	d, i	Insert a signed decimal integer argument.		
	ld, li	Insert a long signed decimal integer argument.		
	u	Insert an unsigned integer argument.		
	lu	Insert a long unsigned integer argument.		
	lx, lX	Insert a long unsigned hexadecimal integer argument in lowercase or uppercase.		
	S	Insert a string.		

See Also wvsprintf

wvsprintf

int wvsprintf(lpszOutput, lpszFormat, lpvArglist)				
LPSTR lpszOutput;	/* address of output destination	*/		
LPCSTR lpszFormat;	/* address of format string	*/		
const void FAR* lpvArglist;	/* address of array of arguments	*/		

The **wvsprintf** function formats and stores a series of characters and values in a buffer. The items pointed to by the argument list are converted according to the corresponding format specification in the format string.

Parameters	 <i>lpszOutput</i> Points to a null-terminated string to receive the string formatted as specified in the <i>lpszFormat</i> parameter. <i>lpszFormat</i> Points to a null-terminated string that contains the format-control string. In addi-
	tion to the standard ASCII characters, a format specification for each argument appears in this string. For more information about the format specification, see the description of the wsprintf function.
	 <i>lpvArglist</i> Points to an array of 16-bit values, each of which specifies an argument for the format-control string. The number, type, and interpretation of the arguments depend on the corresponding format-control character sequences specified in the <i>lpszFormat</i> parameter. Each character or 16-bit integer (%c, %d, %x, %i) requires one word in <i>lpvArglist</i>. Long integers (%ld, %li, %lx) require two words, the low-order word of the integer followed by the high-order word. A string (%s) requires two words, the offset followed by the segment (which together make up a far pointer).
Return Value	The return value is the number of bytes stored in the <i>lpszOutput</i> string, not counting the terminating null character, if the function is successful.
See Also	wsprintf

Yield

2.x

void Yield(void)The Yield function stops the current task and starts any waiting task.ParametersThis function has no parameters.Return ValueThis function does not return a value.CommentsUse the Yield function only when the application will not receive any messages.
Applications that contain windows should use a DispatchMessage, PeekMessage,
or TranslateMessage loop rather than call the Yield function directly. The message-loop functions handle message synchronization properly and yield at the appropriate times.See AlsoDispatchMessage, PeekMessage, TranslateMessage
