MINIMUM NOISE PULSE SLIMMER

Lineu C. Barbosa
IBM Research Laboratory
Monterey and Cottle Rds., San Jose, Ca.

Pulse slimming is a technique commonly used to reduce intersymbol interference in magnetic recording, communication, radar and image processing. This technique in general has an adverse effect on the signal to noise ratio and therefore a limitation on the amount of pulse slimming is dictated by the noise deterioration associated with it. Different pulse slimming equalizers can be designed for a given amount of slimming, each one having a different effect on the total noise deterioration.

This paper introduces a method of designing a pulse slimming equalizer with the property that, among all possible equalizers of a given class of linear systems, this one maximizes the fraction of the output energy (hereon called alpha) within a pre-established time window. The noise deterioration introduced is constrained below a given level. Alternatively, for a given amount alpha of pulse slimming the present equalizer minimizes, within its class, a certain measure of noise deterioration. Control over the amount of slimming and over the noise deterioration is extremely important in face of the above considerations. This control permits tradoffs to be considered. Also extremely important is the fact that the equalizer takes into account the physical constraints of the hardware.

The above technique was used to design equalizers for a magnetic recording channel using a tapped delay line with 10 equally spaced taps separated by 25 ns. For a maximum transition density of 6T (where T is half the clock window) and no intersymbol interference one should have 100% of the energy of the single transition pulse within a 12T time window. The digitized pulse had about 90% of its energy within the 12T window.

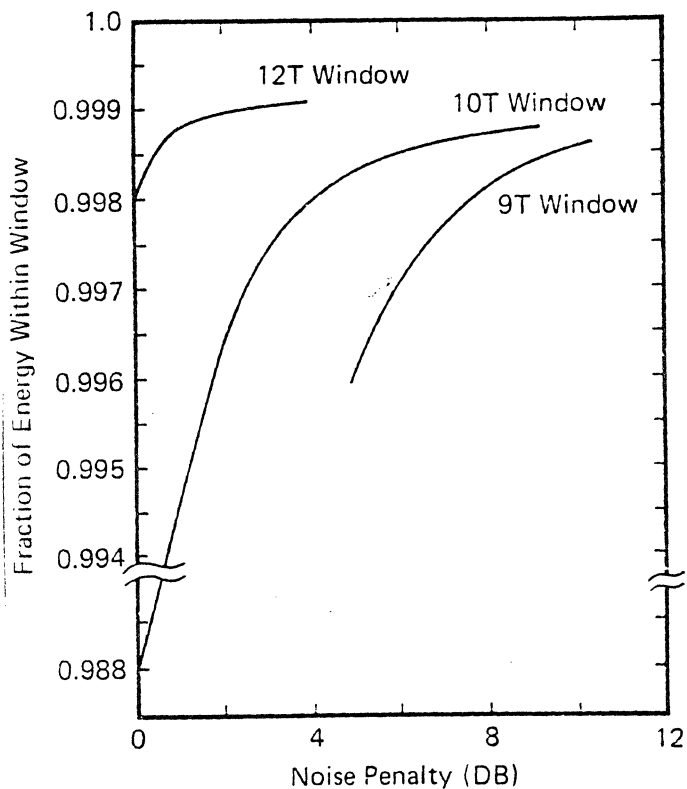

FIG1: Tradoffs between the fraction of the output energy within a given window and the equalizer's noise penalty. 0db = same noise variance before and after equalization when gain is adjusted for equal input and output signal's energies.

Fig. 1 shows the computed tradoffs between alpha and the minimized noise deterioration for several time windows. Notice that even with 0db noise penalty a substantial amount of slimming is possible.

Fig. 2 shows the effect of the 4db-noise-penalty equalizer on the resolution of a complex signal: it brings the resolution from below the 55% level to above the 95% level (resolution=ratio of min. peak amplitude and max. peak amplitude).

Fig. 3 shows the effect of the equalizers on peakshifts occurring when a dibit (double transition) separated by 6T is written: notice the substantial reduction of the peakshift variance for low noise penalties and the gains in the average as well as in the variance of the peakshifts introduced by the 4db-noise-penalty equalizer. The unequalized dibit is also shown in the picture.

Pulse slimming

Let $|X(\omega)| > 0$ for all ω

(a) Specify any $y(t)$ (as slim as desired)

and compute $Y(\omega) = \mathcal{F}[y(t)]$

(b) Compute equalizer $H(\omega) = \frac{Y(\omega)}{X(\omega)}$

Observation: no matter how fat $x(t)$ is, one can equalize it so as to be as slim as wanted.

However ...

The effect of equalizers on the variance of the background noise

• General equalizers :

$$n_y(t) = \int_{-\infty}^{\infty} n_x(t-z) h(z) dz$$

$$\begin{aligned} \therefore \sigma_y^2 &= \overline{n_y(t)^2} = \iint_{-\infty}^{\infty} n_x(t-z) n_x(t-z') h(z) h(z') dz dz' \\ &= \iint_{-\infty}^{\infty} R_x(z-z') h(z) h(z') dz dz' = \|h\|_{R_x}^2 \end{aligned}$$

• TDL equalizers :

$$n_y(t) = \sum_i n_x(t-z_i) w_i$$

$$\sigma_y^2 = \sum_{i,j} R_x(z_i - z_j) w_i w_j$$

white noise + low pass filter :

$$R_x(z_i - z_j) = \delta_{ij} \sigma_x^2$$

$$\therefore \sigma_y^2 = \sigma_x^2 \sum_i w_i^2 = \sigma_x^2 \|w\|^2$$

Deterioration on the S/N due to TDL equalizers

$$\text{Input } S/N = \frac{\|x\|_T^2}{\|m_x\|_T^2} = \frac{\|x\|_T^2}{\sigma_x^2 \cdot T} = \frac{\|x\|_T^2}{2N_0 F_M T}$$

$$(\sigma_x^2 = 2N_0 F_M) \text{ (low pass filter)}$$

$$\text{Output } S/N = \frac{\|y\|_T^2}{\|m_y\|_T^2} = \frac{\|y\|_T^2}{\sigma_y^2 \cdot T} = \frac{\|y\|_T^2}{2N_0 F_M \|w\|^2 T}$$

$$(\text{T.D.L. equ. } \sigma_y^2 = 2F_M N_0 \|w\|^2)$$

$$\therefore S/N \text{ deterioration} \triangleq \frac{(S/N)_{\text{input}}}{(S/N)_{\text{output}}} = \frac{\|x\|_T^2 \|w\|^2}{\|y\|_T^2}$$

Slimming & noise deterioration compromises

P1: Find the equalizer that performs the most "squeezing" in x with a noise penalty not greater than a fixed (tolerable) amount N .

Let :

$$\begin{aligned} (Ty)(t) &= y(t) \quad \text{if } t \in W \\ &= 0 \quad \text{if } t \notin W \end{aligned}$$

Then,
$$\boxed{\text{Max}_{h \in \mathcal{H}} \frac{\|Ty\|^2}{\|y\|^2} \triangleq \alpha^2 / \frac{\|h\|^2 \|x\|^2}{\|y\|^2} \leq N, \quad y = h * x}$$

P2: Among all equalizers that achieve a certain amount of "squeezing" α^2 on x , find the one that pays the least noise penalty :

$$\boxed{\text{Min}_{h \in \mathcal{H}} \frac{\|h\|^2 \|x\|^2}{\|y\|^2} \triangleq N / \frac{\|Ty\|^2}{\|y\|^2} \geq \alpha^2, \quad y = h * x}$$

Some problems with Peak Detection

1) Intersymbol Interference (ISI) :

Ex.: For a symmetric dibit :

$$\text{Peak shift: } sh = \frac{1}{2} (B - A)$$

$$\text{Resolution: } r = \frac{D}{C}$$

2) Noise (S/N ratio) :

What really matters (for peak detectors)

- Must have "reasonable" resolution
- Low detection probability of error

$$\begin{aligned} \text{Total peak shift} &= (\text{ISI shift}) + \text{noise} + \text{others} \\ &\approx sh_{\text{ISI}} + \text{noise} \end{aligned}$$

$$\begin{aligned} \text{Prob}[\text{error}] &= \text{Prob}[\text{Peak fall out of the window}] \\ &= \text{Prob}[\text{noise} > \text{margin} = \text{clock "edge"} - sh_{\text{ISI}}] \\ &= 1 - Q\left\{\frac{\text{margin}}{\sigma}\right\} \end{aligned}$$

965-IBM-08

5-IBM-08

How to choose the equalizer

- In general, ISI decreases at expense of noise deterioration:

- Peak shift noise increases with background noise:

As a result

ABSTRACT

Two approaches in implementing adaptive equalization are presented in this talk.

The basic functional block in the first approach is a programmable transversal filter whose tap weights are adjusted according to an error correction algorithm which is a modified version of the mean square estimation. It is explained why the hybrid approach is proposed to implement in a LSI form the transversal filter which performs the convolution using a CCD tap delay line and multiplying DAC's, one for each tap. Due to the stringent cost requirement for the project at hand, it is found necessary to approximate the linear correlation required by the mean square estimation. The effects of such approximation on the convergence time and the adaptivity (to be defined later) are investigated using APL simulation.

A design for the equalizer discussed above is presented for a discrete realization.

Another approach* is given as an alternative to the transversal filter equalizer, which is especially suitable for a discrete implementation. This approach is based on three

assumptions made on the isolated pulse. They are:

- (1) The pulse is spread over not more than four bit cells
- (2) The pulse is symmetric
- (3) The pulse peak amplitude is predetermined.

In other words, an AGC loop precedes this equalizer.

It is noted that the latter can be described as a simplified version of the former, as evidenced by comparing two respective designs.

* Richard Schneider in Tucson is the originator of this approach.

Abstract: "Equalization and S/N Ratio"

January 14, 1981

D. P. Turner

Our early work in equalization has been based on the frequency domain equalizer programs developed by Jud McDowell in Tuscon. We have attempted to design an equalizer to operate the 3380 head-disk combination at 1.25 times the 3380 data rate. The equalizer design involved measuring the unequalized channel frequency response and deriving an equalizer which would match the desired "sine channel". The equalizer so designed resulted in reduced on track bit shift compared to the unequalized channel. However, when tested on a precision test stand the equalized channel, although it was a better performer than the unequalized channel, did not perform adequately for a product.

We are very concerned that future programs are going to be faced with serious signal to noise ratio problems. We have made experiments which show error rates dropping very rapidly with increased noise levels. Scaling exercises predict Frontier signal-noise ratios of 13 to 26 dB. These signal-noise ratios may make equalizer design extremely difficult.

We have recently discovered three papers on equalization by Kameyama, MacIntosh, and Taub which treat equalization in the time domain and which all come up with similar results predicting limits to which equalization may be gainfully employed. The pulse width reduction obtainable by reasonable equalizers indicates that doubling the data rate would be possible, but further detailed analysis of dibit bitshift and tribit amplitude loss indicates that the potential gains are considerably less, say a 20 - 30 % improvement in linear density. Kameyama even shows a case where if the initial signal-noise ratio is high enough the linear density obtainable with equalization is less than that obtainable without. We are presently working to verify some of these results using 3380 components.

SUMMARY

The objective of this talk is to demonstrate how one can achieve write equalization by shaping the write current transition in the saturate type recording.

Before presenting a novel technique for the write equalization, we will first characterize an 18-track double-gap head manufactured by Nortronics. Then, we will proceed to demonstrate the effectiveness of the proposed technique in terms of the pulse slimming and the peak shift improvement using a test set-up with this head. It is mentioned that this Nortronics head has been highly publicized as a major innovation in the recording field.

For a given test set-up, the maximum flux density one can achieve with this head is obtained by taking into account the following:

- (1) The signal-to-noise ratio is 25dB at minimum.
- (2) The peak shift with a worst case pattern is 50% at maximum.
- (3) The amplitude variation from $3f_1$ to f_1 with the same pattern in (2) is 4:1 at maximum.

The results show the maximum flux density is 17.2kfc/i with the test set-up previously discussed.

The effectiveness of write equalization depends on dominance of linearity over nonlinearity associated with the write process. For a given recording channel where the above is true, the write equalization provides SNR enhancement and economical hardware implementation.

A general form of the write equalizer functions to be presented can be represented by a transversal filter structure. The first-order function has been reported in the literature to be very effective as a read equalizer and also as a write equalizer in AC bias recording. If the first-order function is realized as a write equalizer in saturate type recording by shaping the write current transition, the major transition is modified such that two minor transitions are added before and after the transition, respectively.

In order to provide some perception on how to select an optimum minor transition, the plot is obtained from APL simulation, where the effects of the minor transition on the Lorentzian pulse are shown.

The transfer function for the second-order case is plotted and a hardware realization of this function in a transversal filter configuration is given. This realization can be seen as an extension of the first-order realization.

The write equalizers discussed so far are compared in terms of the isolated pulse response and the pattern response. It is shown in this comparison that the pulse was slimmed by the factor of two with the second-order equalizer. The performance of the second-order equalizer is also shown to be most satisfactory in terms of peak shift and maintaining the symmetry property the input pattern possesses. The peak shifts associated with the three bits in the pattern are improved from 53, 53 and 20% to 21, 14 and -21%, respectively.

FOR

FINITE STATE CHANNELS

BY R. ADLER AND M. HASSNER

[RESEARCH, YORKTOWN]

ABSTRACT

WE DESCRIBE AN ALGORITHM FOR GENERATING NONLINEAR CONVOLUTIONAL MAPS, TERMED AS SLIDING BLOCK CODES, THAT MAP UNCONSTRAINED (OR CONSTRAINED) DATA INTO FINITE STATE CHANNELS. THE CHANNELS CONSIDERED ARE BOTH OF FINITE AND INFINITE MEMORY TYPE. FOR THE LATTER THE ALGORITHM PRODUCES SLIDING BLOCK CODES THAT HAVE (CHANNEL) STATE INDEPENDENT DECODERS, THUS AVOIDING INFINITE (CATASTROPHIC) ERROR PROPAGATION. THE SLIDING BLOCK CODES TRANSFER INFORMATION AT A RATE ARBITRARILY CLOSE TO THE CHANNEL CAPACITY (WHICH IS THE MAXIMAL INFORMATION RATE TRANSMISSIBLE OVER THE CHANNEL).

THE MAIN PRACTICAL APPLICATION CONSIDERED IS MAGNETIC RECORDING. THE MAGNETIC MEDIUM LIMITATIONS GIVE RISE TO A VARIETY OF CONSTRAINTS ALL OF WHICH CAN BE REPRESENTED IN THE FORMAT OF FINITE STATE CHANNELS. THE CONSTRAINTS CONSIDERED ARE (d, k) RUN-LENGTH-LIMITS DUE TO INTERSYMBOL INTERFERENCE AND CLOCKING REQUIREMENTS, SPECTRAL NULLS DUE TO A-C COUPLING OR THE NEED FOR PILOT SIGNALS THAT WILL NOT INTERFERE WITH THE DATA, EXCLUDED WORST CASE PEAK SHIFT BIT PATTERNS, ETC.

IN SOME OF THE APPLICATIONS THESE CONSTRAINTS 310
 HAVE TO BE IMPOSED SIMULTANEOUSLY AS WELL AS IN
 CONJUNCTION WITH OTHER PREPROCESSING TECHNIQUES SUCH
 AS PARTIAL RESPONSE (CORRELATIVE) CODING.

THE CONSTRAINTS, PROPERTIES OF THE SLIDING BLOCK CODE
 SOLUTIONS, AS WELL AS THE IBM DIVISIONS THAT
 SUGGESTED THE PROBLEMS WHICH THEY SOLVE ARE
 SUMMARIZED IN THE FOLLOWING TABLE.

d	R	SPECTRAL NULL	W.C. PEAK SHIFT PATTERN EXCLUDED	PARTIAL RESPONSE	CODING RATE	ERROR PROPAG. (BITS)	IBM Division
1	6			NRZI	$2/3$	26	GPD, TUCSON
1	7			NRZI	$2/3$	6	GPD, TUCSON
0	4	$\omega = 0$ $\omega = \pi/6$		NRZI	$4/6$	4	RES., SJ
0	5	$\omega = 0$		INTERLEAVED NRZI	$3/4$	3	GPD, TUCSON
0	2	$\omega = 0$		NRZI	$3/4$	3	GPD, TUCSON
2	7		$10^2 10^7$ $10^7 10^2$	NRZI	$1/2$	4	ISD, ROCHESTER

THE CONSTRAINTS ABOVE AS WELL AS THE CORRESPONDING
 SLIDING BLOCK CODE SOLUTIONS SHOULD BE VIEWED AS
 EXAMPLES THAT DEMONSTRATE THE POWER OF THE ALGORITHM
 PRESENTED. IN OUR VIEWPOINT THIS ALGORITHM WOULD BE
 BETTER EXPLOITED IF USED IN CONJUNCTION WITH A
 SYSTEMATIC ANALYSIS OF THE CHANNEL, EQUALIZATION
 AND DETECTION SCHEME. SUCH AN ANALYSIS SHOULD GIVE
 AS AN OUTPUT MATCHING SETS OF CONSTRAINTS TO OPTIMIZE
 OVERALL SYSTEM PERFORMANCE AND WOULD PROVIDE AN
 INPUT TO OUR ALGORITHM RESULTING IN OPTIMAL SLIDING

NOISELESS SLIDING BLOCK CODES
FOR
FINITE-STATE CHANNELS

ROY ADLER AND MARTIN HASSNER

[RESEARCH, YORKTOWN]

PRACTICAL MOTIVATION

FINITE STATE CHANNELS MODEL PHYSICAL LIMITATIONS OF DIGITAL TRANSMISSION OR STORAGE MEDIA.

FINITE-MEMORY CHANNEL MODELS OF MAGNETIC RECORDING

RUN-LENGTH-LIMITATIONS DESCRIBED BY FINITE-MEMORY CHANNELS OF (d, R) -TYPE MODEL CONSTRAINTS DUE TO INTERSYMBOL INTERFERENCE AND CLOCKING REQUIREMENTS

EXAMPLE :

$$d=1$$

$$R=2$$

FINITE MEMORY PROPERTY : CHANNEL STATES $\{a, b, c\}$ ARE UNIQUELY DETERMINED BY THE NUMBER OF 0'S THAT FOLLOW THE LAST OCCURRENCE OF A 1 (I.E. BY A FINITE NUMBER OF PAST CHANNEL SYMBOLS)

CHANNEL SYMBOL SEQUENCE : 1 0 0 1 0

CHANNEL STATE SEQUENCE : a \rightarrow b \rightarrow c \rightarrow a \rightarrow b

SHANNON'S NOISELESS CODING THEOREM

NECESSARY AND SUFFICIENT CONDITION FOR THE EXISTENCE OF AN INVERTIBLE (NOISELESS) CODE THAT MAPS DATA INTO A CONSTRAINED FORMAT.

MATHEMATICAL FORMULATION

STATE TRANSITION MATRIX REPRESENTATION

$$T = \begin{matrix} & \begin{matrix} a & b & c \end{matrix} \\ \begin{matrix} a \\ b \\ c \end{matrix} & \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \end{matrix}$$

CHANNEL CAPACITY

$$C_T = \log_2 \lambda_T \text{ bps}$$

λ_T IS THE MAXIMAL EIGENVALUE (OR SPECTRAL RADIUS) OF T OBTAINED AS A SOLUTION OF THE CHARACTERISTIC EQUATION $\det(T - \lambda I) =$

OPERATIONAL INTERPRETATION

TRELLIS DESCRIPTION OF T-ADMISSIBLE n-BLOCKS.

$$\Theta_n(T) = \sum_{i,j} T^{(n)}(i,j) = \|T^n\|, \quad i,j = a,b,c$$

(is CARDINALITY OF SET OF n-BLOCKS DESCRIBED BY TRELLIS)

SPECTRAL RADIUS THEOREM

$$\text{GROWTH RATE} = \lim_n \|T^n\|^{1/n} = \lambda_T$$

$$C_T = \log_2 \lambda_T = \lim_n n^{-1} \log \Theta_n(T)$$

CHANNEL CAPACITY C_T IS THE MAXIMUM INFORMATION RATE THAT CAN BE TRANSMITTED OVER CHANNEL BY USING T-ADMISSIBLE BLOCKCODES OF ARBITRARY BLOCKLENGTH.

(UNCONSTRAINED BINARY) DATA SOURCE

$$M = \begin{matrix} & 0 & 1 \\ 0 & \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \\ 1 & \end{matrix}$$

SOURCE ENTROPY

$$H_M = \log_2 \lambda_M \text{ bps}$$

(FOR THIS PARTICULAR CASE $\lambda_M = 2$)

OPERATIONAL INTERPRETATION

$\lambda_M = \lim_n n^{-1} \|M^n\|^{1/n}$ is THE GROWTH
 RATE OF THE SOURCE WORD SETS

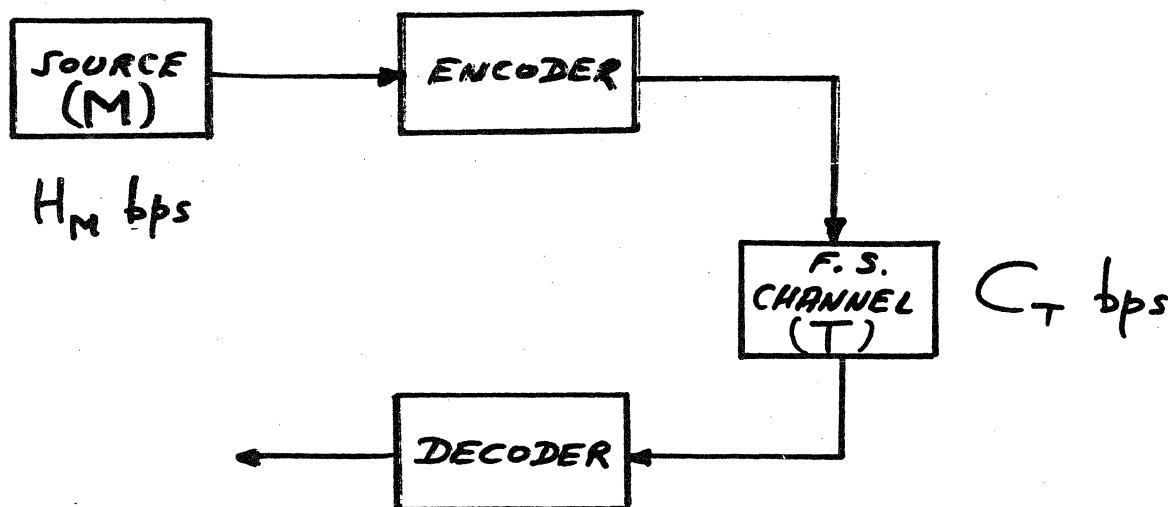

$H_M = \log_2 \lambda_M$ is THE MINIMAL INFORMATION RATE

REQUIRED FOR ERRORLESS TRANSMISSION.

NOISELESS CODING THEOREM

A SOURCE M CAN BE INVERTIBLY CODED INTO
A FINITE STATE CHANNEL T IF AND ONLY IF

$$H_M \leq C_T$$

THE THEOREM IMPLIES THE EXISTENCE OF
ENCODER / DECODER SCHEMES.

BLOCK CODE INTERPRETATION OF THEOREM

FOR LARGE n THERE EXISTS $\Theta_n(T) \approx 2^{nC_T}$ AND
 SINCE THE NUMBER OF n -SOURCE BLOCKS IS 2^{nH_M}
 (FOR OUR PARTICULAR SOURCE $H_M = 1$) THE CONDITION
 $H_M \leq C_T^*$ IMPLIES THE EXISTENCE OF INVERTIBLE
 n -BLOCK MAPS AS FOLLOWS

LIST OF SOURCE n -BLOCKS

$$2^{nH_M} \left\{ \begin{array}{l} x_1^1 \dots x_n^1 \\ x_1^2 \dots x_n^2 \\ \vdots \end{array} \right.$$

LIST OF CHANNEL n -BLOCKS

$$\left. \begin{array}{l} y_1^1 \dots y_n^1 \\ y_1^2 \dots y_n^2 \\ \vdots \end{array} \right\} 2^{nC_T}$$

* IF $H_M > C_T$ WE CAN ENCODE INVERTIBLY AT THE
 EXPENSE OF LOWER INFORMATION RATES

$$m, n : 2^{nH_M} \leq 2^{mC_T}, \quad \frac{n}{m} < 1$$

CRITIQUE OF SHANNON THEORY

THERE IS NO ALGORITHM FOR GENERATING BLOCK
 SCHEMES BUT SEARCH TECHNIQUES.
 2. LARGE BLOCKLENGTHS ARE REQUIRED TO ACHIEVE INFO
 RATES CLOSE TO CHANNEL CAPACITY.

SLIDING BLOCK ALGORITHM

SCHEMATIC DIAGRAM

SEQUENTIAL CODING SCHEME THAT CODES NOISELESSLY (CONSTRAINED OR UNCONSTRAINED) DATA INTO AN ARBITRARY FINITE CONSTRAINT FORMAT AT AN INFORMATION RATE ARBITRARILY CLOSE TO THE CHANNEL CAPACITY.

THE ENCODER f_E AND DECODER f_D ARE DERIVED FROM AN ALGORITHM.

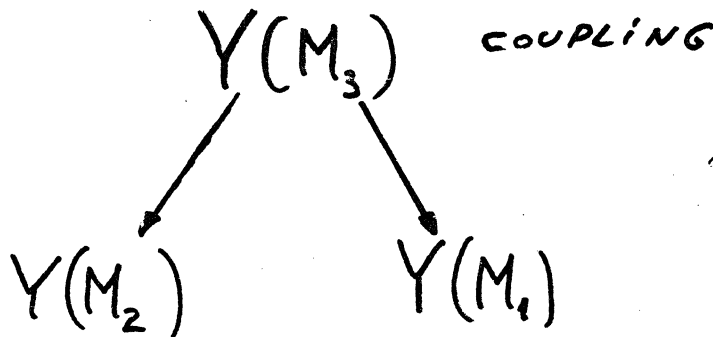

NONPROBABILISTIC ISOMORPHISM THEOREM

(ADLER, GOODWYN, MARCUS AND WEISS)

A SEQUENCE SPACE $Y(M_1)$ THAT CONSISTS OF ALL M_1 -ADMISSIBLE SEQUENCES, WHERE M_1 IS AN (IRREDUCIBLE) 0-1 MATRIX, IS ISOMORPHIC TO A SEQUENCE SPACE $Y(M_2)$ IF AND ONLY IF

$$\lambda_{M_1} = \lambda_{M_2}$$

(THE 0-1 MATRICES M_1 AND M_2 DESCRIBE FINITE EXCLUDED BLOCK LISTS)

$$\lambda_{M_3} = \lambda_{M_2} = \lambda_{M_1}$$

THEOREM

ILLUSTRATION

ENCODER $f_E = \pi_2 \circ \pi_1^{-1}$

DECODER $f_D = \pi_1 \circ \pi_2^{-1}$

FINITE EXCLUDED BLOCK LIST DESCRIPTION

EXAMPLE: $\mathcal{B}_3 = \{101\}$

$$i, j \in \{a_1 = 00, a_2 = 01, a_3 = 10, a_4 = 11\}$$

0-1 MATRIX
REPRESENTATION
OF \mathcal{B}_3

$$M = \begin{matrix} & a_1 & a_2 & a_3 & a_4 \\ \begin{matrix} a_1 \\ a_2 \\ a_3 \\ a_4 \end{matrix} & \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix} \end{matrix}$$

$Y(M)$ IS THE COLLECTION OF M -ADMISSIBLE SEQUENCES

OBSERVATION: A FINITE EXCLUDED BLOCK LIST DESCRIPTION IS EQUIVALENT TO A FINITE MEMORY CHANNEL.

APPLICATION TO MAGNETIC RECORDING - (d, r) CHANNELS (RUN-LENGTH-LIMITED)

EXAMPLE :

FINITE STATE DESCRIPTION OF THE (2, 7) - CHANNEL

STATE TRANSITION MATRIX

$$T = \begin{matrix} & \begin{matrix} a & b & c & d & e & f & g & h \end{matrix} \\ \begin{matrix} a \\ b \\ c \\ d \\ e \\ f \\ g \\ h \end{matrix} & \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \end{matrix}$$

CHANNEL CAPACITY COMPUTATION

THE CHARACTERISTIC EQUATION FOR A (d, k) -CHANNEL
 IS $\lambda^{k+1} - \frac{\lambda^{d+1} - 1}{\lambda - 1}$ [TANG AND BAHL]

FOR THE $(2, 7)$ -CHANNEL $C_T = \log_2 \lambda_T$ WHERE

λ_T IS THE LARGEST ROOT OF THE EQUATION

$$\lambda^8 - \frac{\lambda^6 - 1}{\lambda - 1} = 0 \quad (\sqrt{2} < \lambda_T \approx 1.4314)$$

DATA ENTROPY

$$H_M = \log_2 \lambda_M = 1 \quad \text{SINCE } \lambda_M = 2, \quad M = \begin{matrix} 0 & 1 \\ 0 & \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \\ 1 & \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \end{matrix}$$

SINCE $H_M > C_T$ WE HAVE TO
 LOSE INFORMATION RATE

$$m, n: \lambda_T^m \geq \lambda_M^n$$

$$n = 1$$

$$m = 2$$

CODING RATE CHOSEN IS $\frac{1}{2}$

TWO-STEP STATE TRANSITION MATRIX DESCRIBES
THE CHANNEL IN WHICH EACH STATE TRANSITION IS
LABELLED BY 2 BITS.

$$T^2 = \begin{array}{c} \begin{array}{c} a \\ b \\ c \\ d \\ e \\ f \\ g \\ h \end{array} \begin{array}{c} a \\ b \\ c \\ d \\ e \\ f \\ g \\ h \end{array} \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \end{array}$$

$$\lambda_{T^2} = \lambda_T^2 > 2 = \lambda_M^1$$

GENERALIZED ISOMORPHISM THEOREM (SCHEMATIC DIAGRAM)

π_1 is ONTO 1-1 A.E.

π_2 is ONTO 1-1

MAXIMUM EIGENVALUE- EIGENVECTOR INEQUALITY

$$(T^m \underline{r} \geq \lambda_m^n \underline{r})$$

$$T^2 \underline{r} \geq 2 \underline{r}$$

THERE EXISTS AN INTEGRAL SOLUTION SINCE

T^2 IS AN INTEGRAL MATRIX. \underline{r} IS AN APPROX. POSITIVE EIGENVECTOR

INTEGRAL RIGHT APPROXIMATE EIGENVECTOR SOLUTION

$$\underline{r} = [2, 3, 4, 4, 3, 3, 1, 1]$$

SPLITTING ALGORITHM

THE CHANNEL STATES THAT LABEL THE ROWS AND COLUMNS OF T^2 ARE SPLIT IN A CONTROLLED MANNER AND T^2 IS TRANSFORMED INTO \hat{T}^2 SUCH THAT

$$\hat{T}^2 \underline{r} \geq 2 \underline{r}$$

a. $\hat{r} = [1, \dots, 1]^T$

b. $\dim(\hat{T}^2) = \sum r_i (=21)$

c. row sum $(\hat{T}^2) \geq 2$

d. column sum $(\hat{T}^2) = \text{column sum}(T^2)$

ONE STEP OF ITERATIVE SPLITTING ALGORITHM (GENERAL)

2. CHOOSE STATE i^* SUCH THAT $r_{i^*} \geq r_i$ AND ITS SET OF SUCCESSORS $S(i^*)$ IS OF SIZE $|S(i^*)| > \lambda_M^n$. (THE EXISTENCE OF i^* IS GUARANTEED BY THE IRREDUCIBILITY OF T^m).

3. AMONG ALL SUBSETS $E \subset S(i^*)$ OF SIZE $|E| \leq \lambda_M^n$ THERE IS ONE (OR MANY) SUCH THAT $\sum_{j \in E} r_j \equiv 0 \pmod{\lambda_M^n}$

4. SPLIT AND ASSIGN NEW TRANSITIONS AS FOLLOWS

SUCCESSOR TABLE

a	→	c
b	→	a, d
c	→	a, b, e
d	→	a, b, f
e	→	a, b, g
f	→	a, b, h
g	→	a, b

6 6 1 1 1 1 1 1 1

PROPERTIES OF SPLITTING MAP

THE "OFFSPRING" CHANNEL STATES AND THE "PARENT" STATES HAVE IDENTICAL PREDECESSORS. (THE COLUMN SUMS STAY INVARIANT UNDER SPLITTING). THIS GUARANTEES THAT THE SPLITTING MAP BE INVERTIBLE RESULTING IN A FINITE SLIDING BLOCK DECODER.

FINAL OUTCOME

a_1	→	c_2, c_3
a_2	→	c_1, c_4
b_1	→	d_1, d_2
b_2	→	a_2, a_1
b_3	→	d_3, d_4

SUCCESSOR TABLE REPRESENTATION OF A ROW SUM 2
 MATRIX M_3 (EXCESS TRANSITIONS DELETED)

Π_1 - ASSIGNMENT ("COLORING")

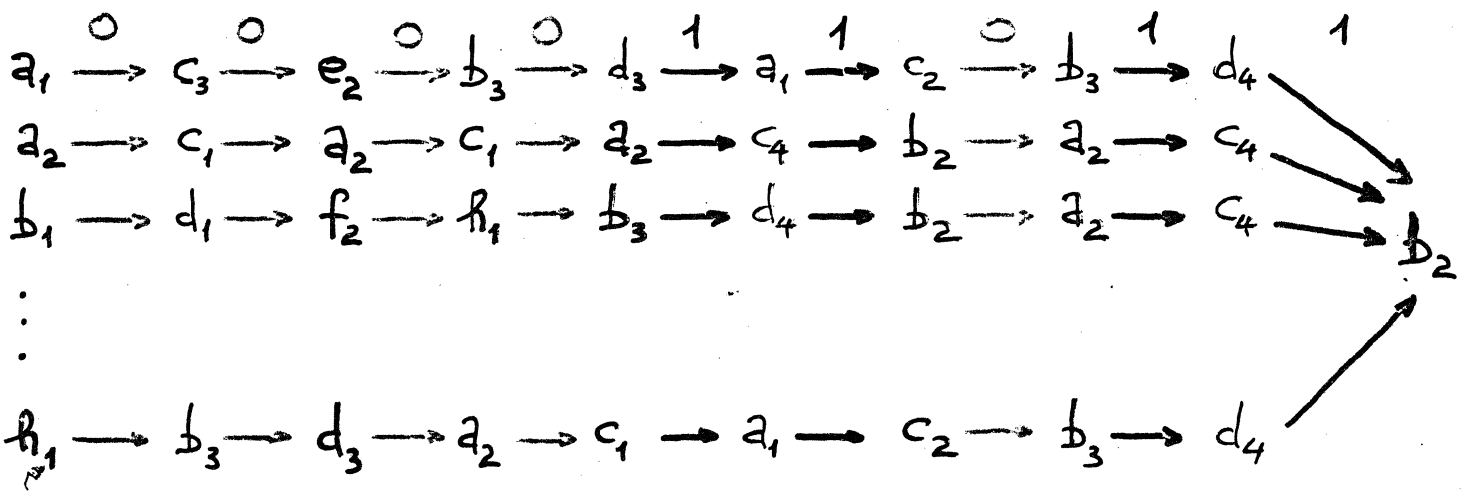

THE "COLORING" IS AN (ARBITRARY) ASSIGNMENT OF DATA SYMBOLS TO (SPLIT) CHANNEL STATE TRANSITIONS

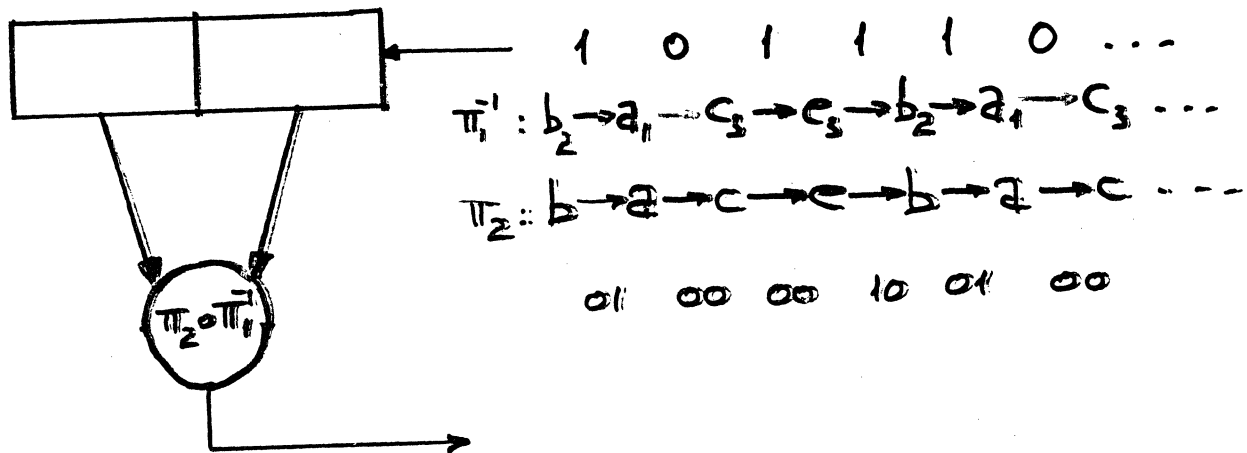

SCHEMATIC DIAGRAM OF ENCODER

RIGHT RESOLVING PROPERTY OF Π_n^{-1}

THE ENCODING AMBIGUITY IS RESOLVED TO THE RIGHT IN A FINITE NUMBER OF STEPS RESULTING IN A FIXED POINT (THE RIGHT END SPLIT CHANNEL STATE IS FIXED INDEPENDENTLY OF THE PARTICULAR "ROAD" CHOSEN)

RIGHT RESOLVING BLOCK $R = 000011011$ RESULT:
IN FIXED POINT b_2

ONE STEP SEQUENTIAL ENCODER

$$f_E = \pi_2 \circ \pi_1^{-1}$$

PREDECESSOR TABLE REPRESENTATION OF M_3

SCHEMATIC DIAGRAM OF DECODER

UNIFORM LEFT RESOLVING PROPERTY OF Π_1^{-1}

EVERY CHANNEL SYMBOL IS UNIQUELY DECODABLE
 GIVEN A FIXED AMOUNT OF "LOOK-AHEAD".
 FOR THE PARTICULAR MATRIX M_3 CHOSEN
 THIS PARAMETER IS 3.

LENGTH 4 DECODING TREE STRUCTURE

4-STEP LOOK-AHEAD SEQUENTIAL DECODER

$$f_D = \pi_1 \circ \pi_2^{-1}$$

RUN-LENGTH-LIMITED CHANNEL APPLICATIONS
CONSIDERED (FOR MAGNETIC RECORDING)

1. SLIDING BLOCK CODE FOR $(1,7)$ -CHANNEL
WITH CODING RATE $\frac{2}{3}$

2. SLIDING BLOCK CODE FOR $(1,6)$ -CHANNEL
WITH CODING RATE $\frac{2}{3}$

APPLICATIONS TO FINITE STATE CHANNELS DEFINED
BY RUN-LENGTH AND SPECTRAL NULL CONSTRAINTS

OBSERVATION

THESE ARE NOT FINITE-MEMORY CHANNELS SINCE THE CHANNEL STATES ARE NOT UNIQUELY DETERMINED BY A FINITE NUMBER OF PAST CHANNEL SYMBOLS.

CHANNEL STATE IDENTIFICATION REQUIRES IN ADDITION (CONSTRAINED) VALUES WHICH ARE CALCULATED FROM CUMULATIVE SPECTRAL SUMS, EVALUATED AT THE FREQUENCIES OF THE SPECTRAL NULLS SPECIFIED.

MAIN PROBLEM

THE OCCURRENCE OF AN ERROR IN THE CHANNEL SYMBOL SEQUENCE CAN BE CATASTROPHIC I.E. IT MAY PROPAGATE INDEFINITELY UNLESS WE USE A STATE INDEPENDENT DECODER.

(STATE DEPENDENT DECODING CAN RESULT IN LARGE HARDWARE COMPLEXITY)

CODE FOR MAGNETIC CHANNEL OF TYPE (a, R)
WITH TWO SPECTRAL NULLS (ONE AT DC)

THIS PROBLEM WAS SUGGESTED BY T. HOWELL (ST RES)
AS APPLICABLE TO THE BURIED SERVO PROJECT.

FINITE STATE CHANNEL REPRESENTATION

A NECESSARY AND SUFFICIENT CONDITION FOR THE
EXISTENCE OF A SPECTRAL ZERO IN THE AVERAGE
POWER SPECTRUM $S_X(\omega)$ OF A $\{-1, 1\}$ -VALUED
SEQUENCE $\{x_R\}$

$$\left| \sum_{R=0}^N x_R e^{j\omega R} \right| \leq C \quad \text{FOR EVERY } N \text{ IS EQUIVALENT}$$

$$\text{TO } S_X(\omega) = 0$$

OBSERVATION

FOR $\omega = 0, \frac{\omega}{4}, \frac{\omega}{6}$ THE VALUES OF $\sum_{R=0}^N x_R e^{j\omega R}$

OCCUR AT SPECIAL POINTS IN THE COMPLEX
PLANE (FOR $\omega = 0$ THESE ARE THE INTEGERS
ON THE REAL LINE).

FOR $\omega = \frac{\omega}{6}$ THESE ARE THE LATTICE POINTS OF A TILING OF THE PLANE BY EQUILATERAL TRIANGLES

STATE DESCRIPTION OF $\{S_X(0)=0, S_X(\frac{\omega}{6})=0\}$

A STATE G IS SPECIFIED BY A TRIPLET (S_1, S_2, S_3)

$$S_1 = \sum_{R=0}^m X_R$$

$$S_2 = \text{Re} \sum_{R=0}^m X_R e^{j \frac{\omega}{6} R}$$

$S_3 =$ VALUE OF COMPONENT OF $\sum_{R=0}^m X_R e^{j \frac{\omega}{6} R}$ IN THE DIRECTION OF $e^{j \frac{\omega}{6}}$

WE CONSTRAIN THE STATE TRIPLETS TO BE INTEGERS IN THE RANGE $(-C, -C+1, \dots, C-1, C)$. FOR EACH VALUE OF C WE COMPUTE THE CHANNEL CAPACITY AS THE MAXIMAL EIGENVALUE OF A STATE TRANSITION MATRIX.

FOR $C=4$ THE FEASIBLE (NOISELESS) CODING RATE IS $\frac{4}{6}$

CODE PROPERTIES

1. THE CODE MAPS 4 UNCONSTRAINED BITS INTO A CHANNEL STATE TRANSITION THAT GENERATES 6 CONSTRAINED (OUTPUT) BITS
2. THE RUNLENGTHS OF 0'S AND 1'S DO NOT EXCEED 5 (EQUIVALENTLY THERE ARE NO MORE THAN 4 ZEROS BETWEEN TWO ONES)
3. THE CODE HAS A SPECTRAL ZERO AT $\omega/2$
4. THE DECODER IS STATE INDEPENDENT AND HENCE DOES NOT PROPAGATE ERRORS. THIS IS ACHIEVED BY ENCODING THE SAME DATA BLOCK INTO STATE TRANSITIONS THAT CORRESPOND TO IDENTICAL BIT PATTERNS (AFTER DROPPING THE STATE LABELS). THIS ENSURES THAT A CHANNEL ERROR WILL NOT PROPAGATE SINCE WE CAN DECODE CORRECTLY EVEN THOUGH THE DECODER MAY BE IN AN ERRONEOUS STATE (WHICH IS INDISTINGUISHABLE FROM THE CORRECT ONE)

FOR OUR PARTICULAR CASE THE MAXIMUM ERROR PROPAGATION IS 4 BITS.

OBSERVATION

THIS CODING STRATEGY TO ACHIEVE STATE INDEPENDENT DECODING IS FEASIBLE PROVIDED THE ROW SUM OF THE STATE TRANSITION MATRIX $\geq \lambda_M^n$. IT ALSO SEEMS THAT FOR THIS CASE STATE INDEPENDENT BLOCK CODING SCHEMES CAN BE FOUND.

IN THE GENERAL CASE STATE INDEPENDENT BLOCK CODING SCHEMES DO NOT EXIST.

(WITHOUT ADDITIONAL OVERHEAD)

STATE INDEPENDENT SLIDING BLOCK CODE SOLUTION

MATHEMATICAL RESULT:

GIVEN A FINITE STATE CHANNEL T OF CAPACITY $C_T > H_M$ WE CAN CONSTRUCT A FINITE MEMORY APPROXIMATION CHANNEL T_A SUCH THAT $C_{T_A} = H_M$ AND A FINITE SLIDING BLOCK CODE THAT HAS THE PROPERTY OF STATE INDEP. DECODING.

UNSOLVED (YET) PROBLEM: $C = H$. (ZERO-MODULATION)

APPLICATIONS

1. $(0, 2)$ DC-FREE CODE AT CODING RATE $\frac{3}{4}$ WITH ERROR PROPAGATION OF 3 BITS

2. R. SCHNEIDER SUGGESTED $(2, 7)$ DC FREE CODE

CODE FOR PARTIAL RESPONSE (CORRELATIVE) CHANNEL
WITH $(0, R)$ RUN-LENGTH CONSTRAINT
AND SPECTRAL ZERO AT DC

THIS PROBLEM WAS SUGGESTED BY R. SCHNEIDER (GPD, TUCSON)
AND WORKED JOINTLY WITH HIM. P. FRANSZEK
(RES. YORKTOWN) HAS EQUIVALENT BLOCK CODE SOLUTION.

FINITE STATE CHANNEL DESCRIPTION

A NECESSARY AND SUFFICIENT CONDITION FOR $S_y(0) = 0$
CAN BE STATED IN TERMS OF THE SPECTRAL PRODUCT
SUMS OF $\{x_R\}$

$$\text{(EVEN SUM)} \quad \sigma_m^e(0) = \sum_{R=0}^m x_0 \cdots x_{2R}$$

$$\text{(ODD SUM)} \quad \sigma_m^o(0) = \sum_{R=0}^m x_1 \cdots x_{2R+1}$$

$$\sigma_m^e(0) + \sigma_m^o(0) = \sum_{R=0}^m y_{-2} y_{2R} + \sum_{R=1}^m y_{-1} y_{2R+1}$$

$$S_y(0) = 0 \iff \left| \sum_{R=0}^m y_R \right| \leq \left| \sigma_m^e(0) + \sigma_m^o(0) \right| \leq C$$

AN EQUIVALENT STATE DESCRIPTION WITH LESS STATES RESULTS IF WE USE "PATEL'S CHARGE RULE"
(A, PATEL, GPD SJ, SEE ZERO MODULATION)

$$z_i(0) \xrightarrow{0} z_i(0) + 1$$

$$z_i(0) \xrightarrow{1} -z_i(0) + 1$$

$$z_m(\omega) = \sum_{k=0}^m x_k \dots x_m e^{j k \omega} + 1 = [v_m(\omega) - v_{m-1}(\omega)] [v_m(\omega) + 1]$$

$$z_m(\omega) = \Delta v_m(\omega) [v_m(\omega) + 1]$$

CODE PROPERTIES

1. CODING RATE IS $\frac{3}{4}$ WHERE 3 BITS ARE ENCODED INTO A CHANNEL STATE TRANSITION THAT OUTPUTS 4 CONSTRAINED BITS
2. IN THE SEQUENCE $\{y_k\}$ AT THE OUTPUT OF THE PARTIAL RESPONSE PRECODER THE RUNLENGTH OF ZEROS BETWEEN TWO ONES DOES NOT EXCEED 5.
3. A CHANNEL ERROR DUE TO RANDOM NOISE WILL NOT PROPAGATE BEYOND 3 BITS OF DECODED DATA
4. PART OF THE ERRORS CAN BE CORRECTED

NOTE: THIS CHANNEL HAS A TRANSITION MATRIX WHOSE ROWSUM $\geq 2^3 (-\lambda_M)$ AND THUS STATE-INDEP DECODING IS ALSO ACHIEVABLE BY BLOCK SCHEMES [FRANASZEK]

CODE FOR $(\frac{1}{2}, \frac{1}{2})$ - CHANNEL THAT ELIMINATES
 WORST CASE PEAK SHIFT BIT PATTERNS

THIS PROBLEM WAS SUGGESTED BY E. CUNNINGHAM (ISD
 R.O.H.)

WORST CASE PEAK-SHIFT FOR $(2,7)$ -CODE IS
 CREATED SHORT-TO-LONG AND LONG-TO-SHORT
 RUNLENGTH TRANSITIONS

PROBLEM: ELIMINATE

10^2	10^7	1
10^7	10^2	1
10^2	10^6	1
10^6	10^2	1
10^2	10^5	1

FINITE MEMORY MODEL

EACH CHANNEL STATE IS DEFINED BY
A TRIPLET (S_1, S_2, S_3)

$S_1 \in \{2, \dots, 7\}$ FIRST ALL

$S_2 \in \{2, \dots, 7\}$ SECOND ALL

$S_3 \in \{0, 1\}$ LAST BIT

FROM STATE TRANSITION MATRIX WE CALCULATE
CHANNEL CAPACITY

PRELIMINARY CONCLUSIONS

1. $10^2 10^7 1$ AND $10^7 10^2 1$ CAN BE ELIMINATED
FROM $(2, 7)$ -CODE WITHOUT LOWERING THE CODING
RATE.
2. IN ADDITION $10^2 10^6 1$ AND $10^6 10^2 1$ CAN
BE ELIMINATED HOWEVER k HAS TO BE
INCREASED FROM 7 TO 8 POSSIBLY 9
3. THE PATTERNS $10^2 10^5 1$ AND $10^5 10^2 1$
CANNOT BE EXCLUDED FROM A $(2, k)$ -
-CODE WITH ARBITRARY UNLESS WE
LOWER THE CODING RATE.

SUMMARY

THIS IS A GENERAL METHOD FOR THE CONSTRUCTION OF MODULATION CODES DEFINED BY AN ARBITRARY FINITE SET OF CONSTRAINTS. THE SLIDING BLOCK CODES FURTHERMORE POSSESS THE PROPERTY OF STATE INDEPENDENT DECODING.

PROBLEMS

1. HOW TO DERIVE CONSTRAINTS OF INTEREST, BESIDES THOSE MENTIONED ((d, R) , SPECTRAL NULLS ETC.)
2. HOW TO QUANTIFY THE IMPROVEMENTS DUE TO CODING.

ERROR CONTROL CODES -- A TUTORIAL -- R. E. Blahut

The attached charts were used as part of a tutorial on error-control codes. The tutorial discussed the nature of the coding problem, solutions, and applications. A description of a simple Hamming (7,4) code illustrates many of the elementary ideas. A discussion of the role of Galois fields in coding follows. Next comes some circuits for decoding simple codes. The tutorial ends with a description of concatenated codes and convolutional codes.

ERROR CONTROL CODES

A TUTORIAL

SHANNON SAYS —

- TO ACHIEVE CHANNEL CAPACITY ONE MUST USE AN ECC
- DIVIDE COMMUNICATION PROBLEM INTO MODULATION AND ECC TO MAKE LIFE SIMPLE
- DESIGN MODULATION AND ECC SIMULTANEOUSLY

APPLICATIONS

- SATELLITE COMMUNICATIONS
> 100 MBPS
- DEEP SPACE COMMUNICATION
(255, 223) $t=16$ REED-SOLOMON (8 BIT-BYTE)
- MILITARY COMMUNICATION
10 MBPS
JAM PROTECTION
- TAPES / DISCS
- DATA BUS
- DIGITAL VIDEO & AUDIO (TV & PHONO)
- VOICE BAND MODEMS
- FACSIMILE

MASSIVE CODES ARE NOW

ECC FOR TAPES AND DISCS -- R. E. Blahut

This presentation is a companion to the following presentation by Steve West. Between the two presentations a proposed universal LSI decoder is described. This decoder will decode any Reed-Solomon code for magnetic tape or disc applications. Very high decoding speed is possible, and any number of errors can be corrected by the decoder. The user need only provide enough redundancy in the recorded message to allow correction of the desired number of errors.

The talk considers the theory upon which the design is based.

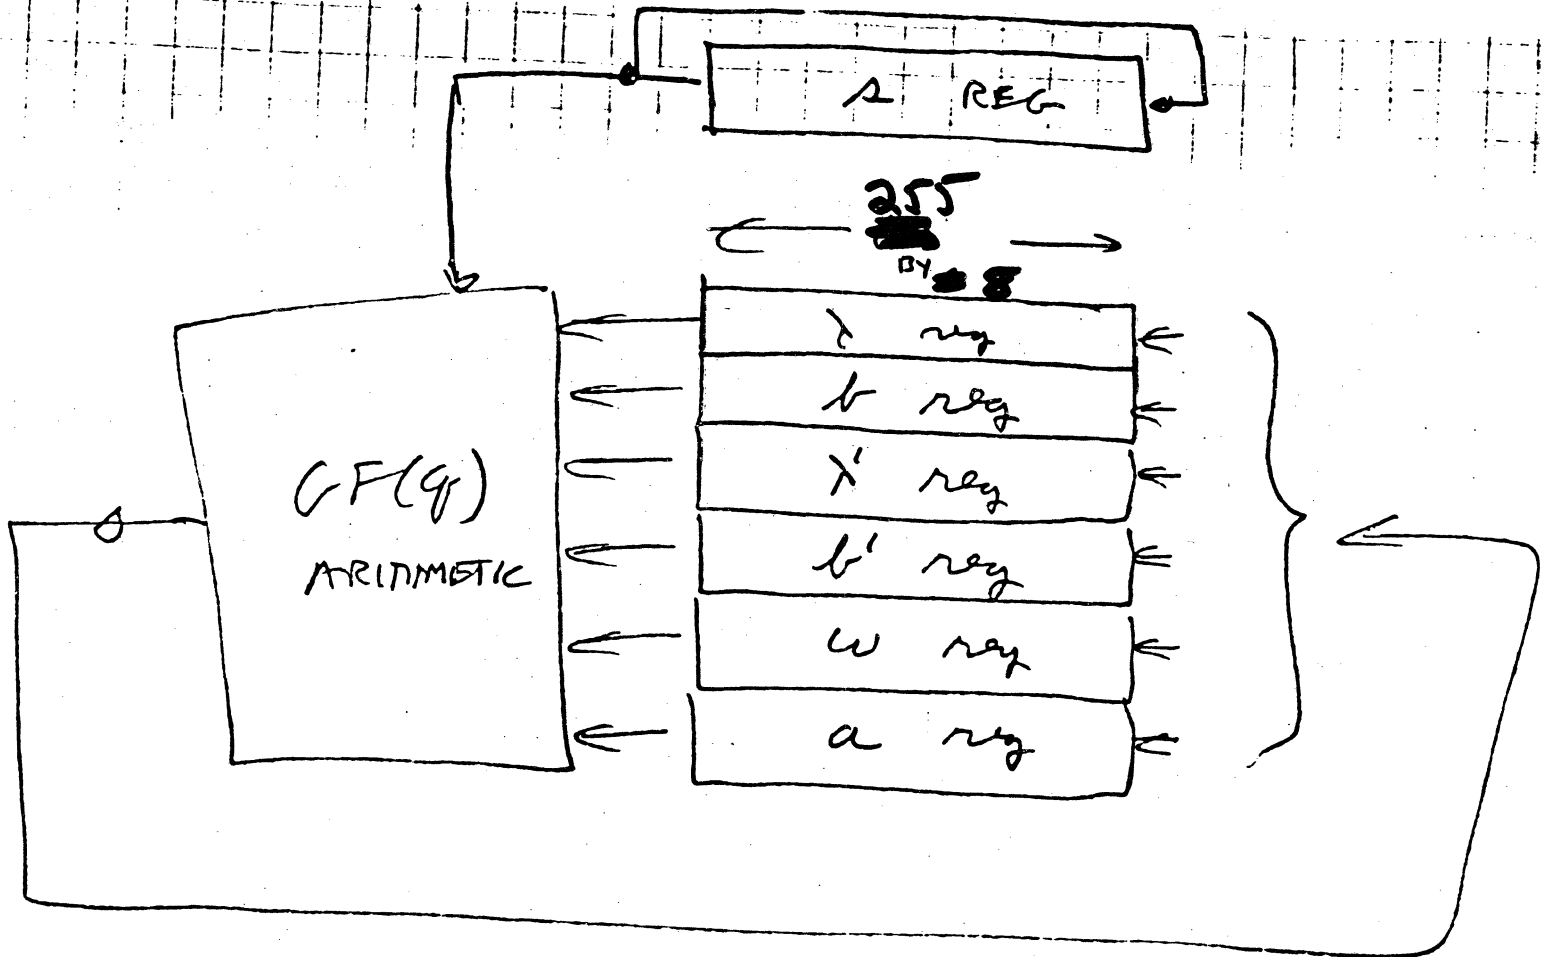

UNIVERSAL LSI DECODER FOR BLOCK CODES

- $m \leq 256$ BYTES
- $q = 2, 4, 8, 16, 32, 64, 128, 256$
(1 to 8 BIT BYTES)
- BCH & REED-SOLOMON CODES
- ERRORS & ERASURES DECODING
- DECODE TIME $m \times 2t$ CLOCKS
- 7 GATES/CLOCK
- CHIP SIZE = ?

PERFORMANCE PREDICTIONS AT A 30 MSEC DECODE CYCLE

BLOCKLENGTH (BYTES)	$2t$	DECODE TIME	DECODE TIME/DIT	# DECODERS FOR 50 MBPS
$n = 256$	20	13 μ SEC	.08 μ SEC	4
$n = 86$	20	50 μ SEC	.08 ^{.08} μ SEC	4
$n = 52$	20	30 μ SEC	.08 μ SEC	4
$n = 18$	4	7 μ SEC	.015 μ SEC	0.8

t ~~is~~ = # BYTE ERRORS
 $2t$ ~~is~~ = # BYTE ERASURES

DECODER

NOW IT GETS HARD

BCH CODES & REED-SOLOMON CODES

- CODES OVER $GF(q)$
- BLOCKLENGTH $n = q^m - 1$ (7, 15, 31, 63, ...)
- IF $m = 1 \Rightarrow$ REED-SOLOMON
 $m \neq 1 \Rightarrow$ BCH
- DEFINE $g(x)$ BY SPECIFYING ROOTS IN $GF(q^m)$
- $g(\alpha^i) = 0$ FOR $i = 1, \dots, 2t$
 α IS AN ELEMENT OF $GF(q^m)$

EXAMPLE: HAMMING (7, 4) OVER $GF(2)$

$$n = 2^m - 1$$

$$g(x) = x^3 + x + 1$$

BECAUSE IN $GF(8)$, $g(\alpha) = 0$
 $g(\alpha^2) = 0$

SIMPLEST CASE REED-SOLOMON CODES

$$n = q - 1$$

$$k = q - 1 - 2t$$

2 PARITY BYTES
FOR ERROR
CORRECTION

FOURIER TRANSFORMS

- DISCRETE FOURIER TRANSFORM OVER COMPLEX FIELDS

$$P_k = \sum_{i=0}^{n-1} e^{-j2\pi \frac{ik}{N}} P_i \quad k=0, \dots, n-1$$

$$P_i = \sum_{k=0}^{n-1} e^{j2\pi \frac{ik}{N}} P_k$$

- DISCRETE FOURIER TRANSFORM OVER GALOIS FIELDS

$$E_j = \sum_{i=0}^{n-1} \alpha^{ij} e_i \quad j=0, \dots, n-1$$

$$e_i = \frac{1}{(n \text{ mod } p)} \sum_{j=0}^{n-1} \alpha^{-ij} E_j$$

BUT n DIVIDES $q^m - 1$
 α HAS ORDER n

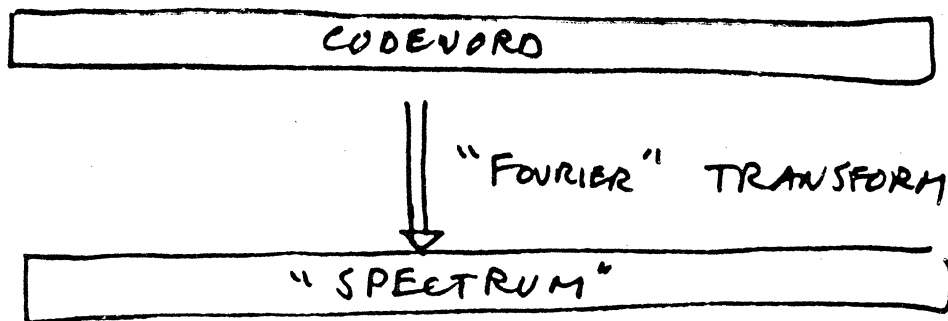

IN GENERAL

$$[GF(q)]^n \xrightarrow{FT} [GF(q^m)]^n$$

$$a_i, b_i \longleftrightarrow A * B$$

FREQUENCY DOMAIN DECODER

- CODES ARE IN $GF(q)$ $m = q^m - 1$
- CODING ALGORITHMS ARE IN $GF(q^m)$
- "FREQUENCY DOMAIN" IS DEFINED BY ANALOGY WITH TRUE FREQUENCY

- "SPECTRUM" IS A SET OF q^m -ARY SYMBOLS
- "SPECTRUM" IS PROCESSED TO FIND ERRORS IN ORIGINAL CODEWORD

Encoding Via the Transform

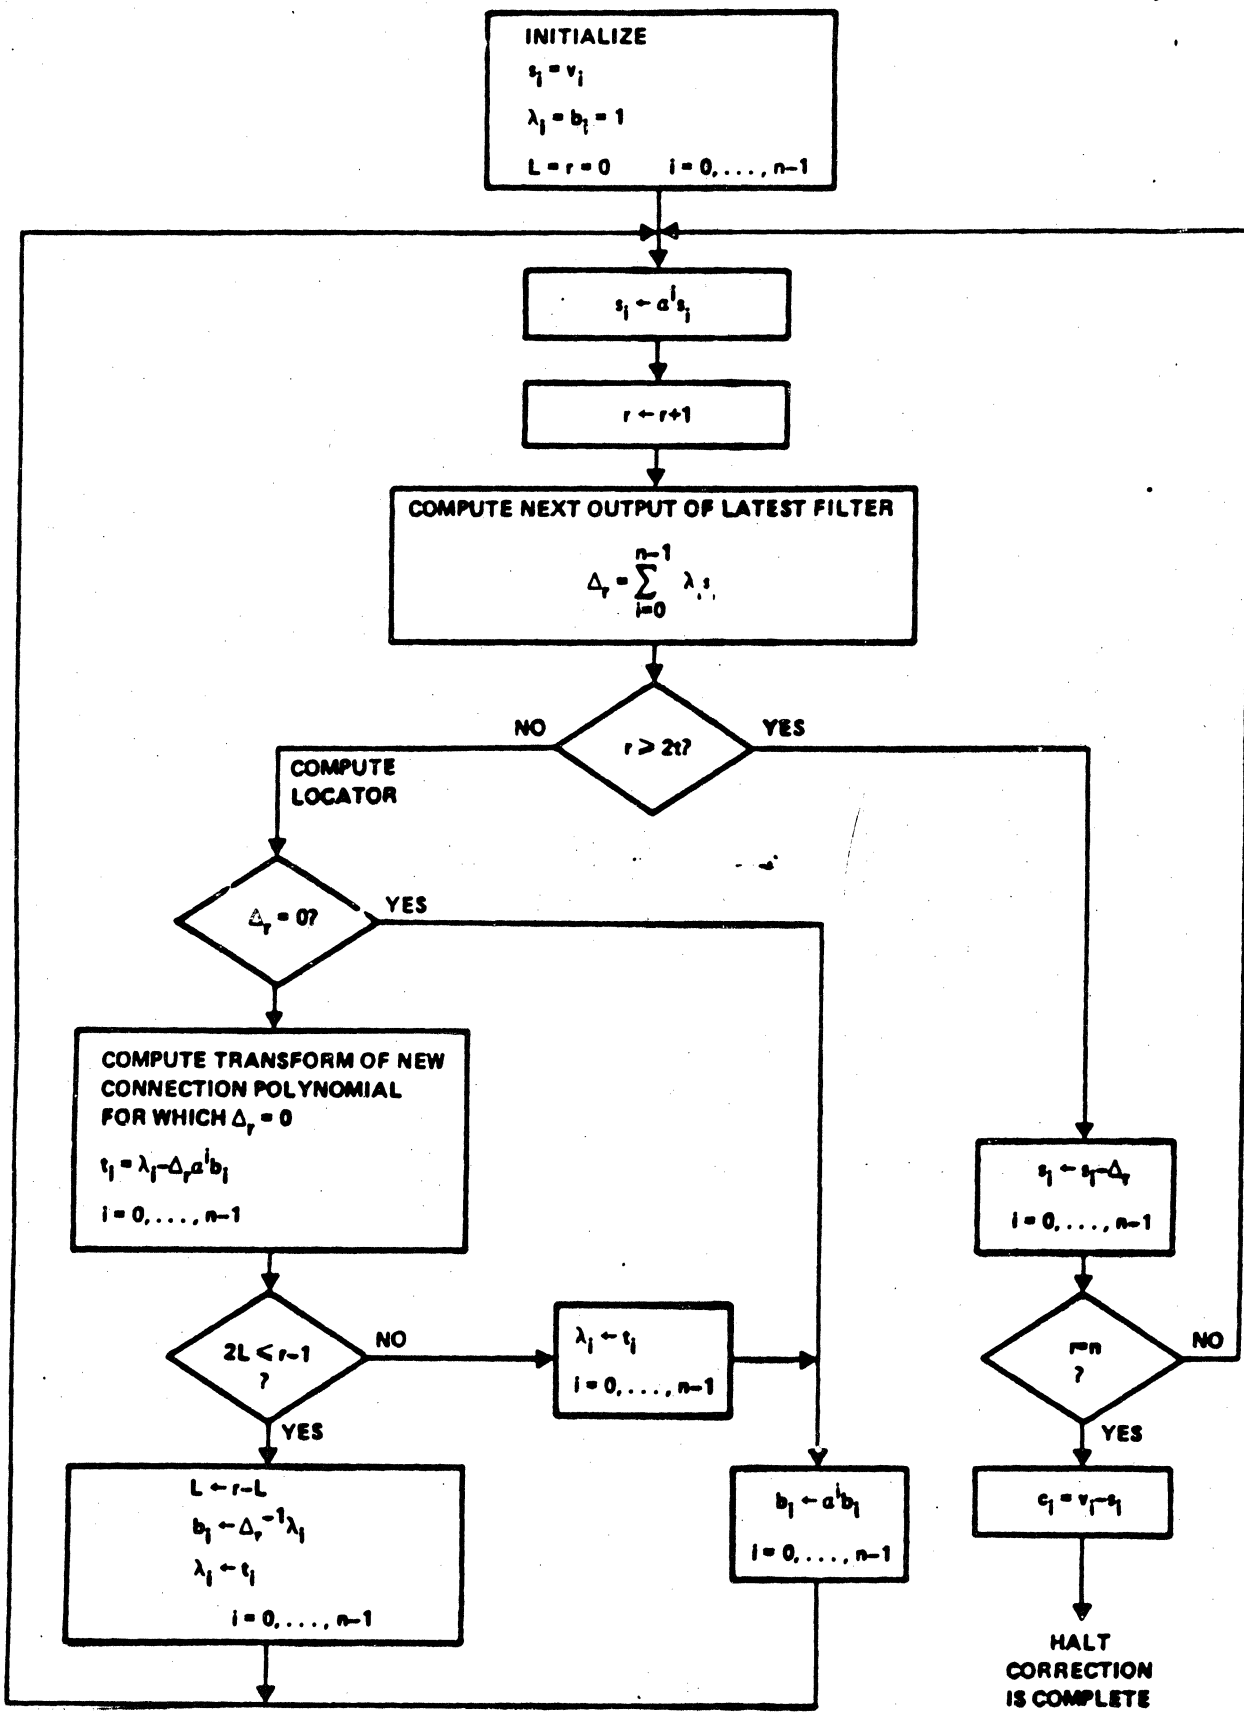

Figure 9.5-3 Time Domain Decoder

Reed-Solomon Time Domain Decoder
Architecture and Galois Field Multipliers

Stephen C. West

GPD Tucson

There is an Advanced Technology effort underway at GPD Tucson to investigate the implementation and performance of a Reed-Solomon error control decoder. This presentation reports on two aspects of the investigation, the decoder architectures being investigated and a recently developed Galois Field multiplier.

Reed-Solomon Decoder Architectures

One of the primary objectives of the current effort is to develop a general purpose Reed-Solomon decoder. The motivation for this objective is two fold: first, to allow selection of the precise code parameters to occur as late as possible in the product development cycle, and second, to support a range of products (low, medium and high end products) within a generation of products.

We are currently trying to put a plan in place to design and build a VTL prototype decoder to be followed by an LSI version.

IBM - TS - 41

The significant features being considered for the VTL decoder are listed in Figure 1.

There are four architectures being examined, all of which are based on two decoding algorithms developed by R. E. Blahut at FSD Owego. The four architectures are summarized in Figure 2. Architectures III and IV are particularly interesting, if multiple LSI chips are required to implement the decoder. A properly partitioned decoder would allow an application, needing only N^2 speed, to purchase and implement a lower cost decoder than an application which required $N \times 2t$ speed.

Figures 3 thru 9 illustrate the algorithms and block diagrams for the four architectures. The algorithm of Figure 3 (Architecture I) is a subset of the algorithm of Figure 5 (Architectures II and III) with the exception of a slight change in the YES branch of the $R > 2t$ check (Architecture II). The algorithm of Architecture III is expanded, over that shown in Figure 5, to include the operations in the YES branch of the $R > 2t$ check as a selectable mode of operation.

The algorithm for Architecture IV (Figure 8) differs from the Architecture I algorithm only in the assignment of the variable used to accumulate the α^i multiplications (S_i versus λ_i). Architecture IV has organized the N^2 decoder

IBM - TS - 41

into two processors:

- o Core Processor - $N \times 2t$ clocks per block decode,
- o Auxillary Processor - $N \times (N - 2t)$ clocks per block decode.

By replicating and multiplexing the Auxillary Processors, the resultant decoder can achieve the $N \times 2t$ speed of Architectures II and III. The Core Processor is also a stand alone N^2 decoder.

Galois Field (GF) Multipliers

One of the more critical elements of the decoder, in terms of delay and chip real estate, is the GF multiplier. A GF multiplier design which has a low circuit count and delay was recently developed at GPD Tucson. A design procedure and implementation for this multiplier, called the Direct GF Multiplier in this presentation, are given in Figures 11 thru 18.

Figure 10 compares a number of different implementations of GF multipliers. The top two configurations use log and anti-log, to the base alpha, look up tables. The second configuration requires the MOD 255 Adder for each multiplier element within the decoder plus a complex GF adder for each adder element within the decoder.

1/19/81

IBM CONFIDENTIAL

IBM
- TS -
41

The apparent choice for an 8-bit LSI decoder implementation would be the Direct GF Multiplier, which has both low circuit count and low delay. A procedure for generating the equations implemented by the Direct GF Multiplier is given in Figure 11 and a GF(8) example of the procedure is given in Figure 12.

Figure 13 lists the equations for GF(2) thru GF(128) multipliers, and Figure 14 lists the equations for the GF(256) multiplier.

Figure 15 shows the block diagram of the Direct GF Multiplier. The three basic operations (blocks) in the multiplier are:

- o "AND" Product Array - "AND" each bit of one input with each bit of the second input
- o Product Compression - generation of the Y variables shown in Figure 14
- o Final Selection - collecting the Y's into the final output equations.

Figures 16, 17 and 18 illustrate the implementations of the three blocks of Figure 15. This particular implementation employs 64 2-input "AND" circuits and 76 2-input "XOR" circuits.

ON THE FLY ERROR CORRECTION FOR DISK FILES

BY William Bliss 208/050-1 Rochester, Mn.

Jan. 10, 1981

Present error correcting systems for disk files typically can only correct a single error burst in a block and require the system to 'hickup' to achieve correction. The decoding of multiple burst error correcting codes can be implemented at a minimal expense by using slower software techniques instead of dedicated hardware solutions. Methods do exist to utilize the encoder hardware/standard syndrome generator to assist in the calculations of the syndrome components (fig. 1&2). If throughput degradation is acceptable then no special high speed circuitry is required. The software does utilize a modest amount of hardware

As the need for multiple burst correction becomes greater the soft error rate will worsen until an unacceptable level is reached. At this raw error rate on the fly correction of single error bursts will become cost effective. This will necessitate an additional block of buffering to store data while it is checked for correctibility under the constraint of one burst (fig. 3). The system will be allowed to hickup if more than one burst error occurs in a block. In the time of one data block the syndrome components must be calculated, the error solved for under the assumption of only one occurrence, and that solution checked for validity (fig. 4). We are probably in the realm of 'special Galois processor hardware' to achieve these goals. A hardware syndrome component calculator could be used to ease these high speed calculation constraints and also to speed up multiple burst correction (fig. 5). Alternately, a duplicate encoder/standard syndrome generator could be used with a traditional burst error trapping method (fig. 6).

For systems with even higher raw error probabilities it may be desirable to achieve on the fly double burst error correction with Reed-Solomon codes. The solution is similar to that of single burst correction except that a lookup table is used to solve for the roots of the error location polynomial (fig. 7).

On the fly correction of three bursts in a block is more difficult for all B.C.H. codes. A Chien root searcher (hardware) is needed in all cases. The root searcher can operate synchronously with the appropriate output buffer but the validity of the correction is not known until tested after the fact. A Reed-Solomon code requires additional data buffering to allow time for calculation of the values of the errors at the locations indicated by the reciprocals of the roots of the error location polynomial.

418

$r(x)$ is received word, degree $< n$

$g(x)$ is generator polynomial, degree $= r$

S_j is the j th Syndrome component, $\in GF(2^m)$

$$S_j = r(\alpha^j) \quad n-1 \text{ multiplications}$$

The encoder hardware can easily generate an 'overall syndrome' $S^o(x)$

$$S^o(x) = \text{Rem} \left[\frac{r(x)}{g(x)} \right] \quad \begin{array}{l} S_i \in GF(2) \text{ binary BCH} \\ \in GF(2^m) \text{ R-S} \end{array}$$

$$r(x) = q(x)g(x) + S^o(x)$$

$$S_j = r(\alpha^j) = q(\alpha^j) \cdot 0 + S^o(\alpha^j) = S^o(\alpha^j)$$

which is $n-1$ multiplications

$$\text{Reduction by } \frac{n-1}{n-1} \approx \frac{r}{n}$$

Syndrome Component Calculation Using
Standard Syndrome Remainder

Fig 1

SYNDROME COMPONENT CALCULATIONS for Binary BCH codes

$$S_i = S(d^i) = \sum_{r=1}^r d^{(r-1)i} + \sum_{r=2}^r d^{(r-2)i} + \dots + \sum_1 d^i + S_0$$

$$= (\dots ((\sum_{r-1}) d^i + \sum_{r-2}) d^i + \dots \sum_1) d^i + S_0$$

$$= \left[\dots \left[\left(\sum_{r-1} d^{i(b-1)} + \sum_{r-2} d^{i(b-2)} + \dots + \sum_{r-b} d^{i(b-b)} \right) d^{ib} + \left(\sum_{r-b-1} d^{i(b-1)} + \sum_{r-b-2} d^{i(b-2)} + \dots + \sum_{r-2b} d^0 \right) d^{ib} + \right. \right.$$

⋮

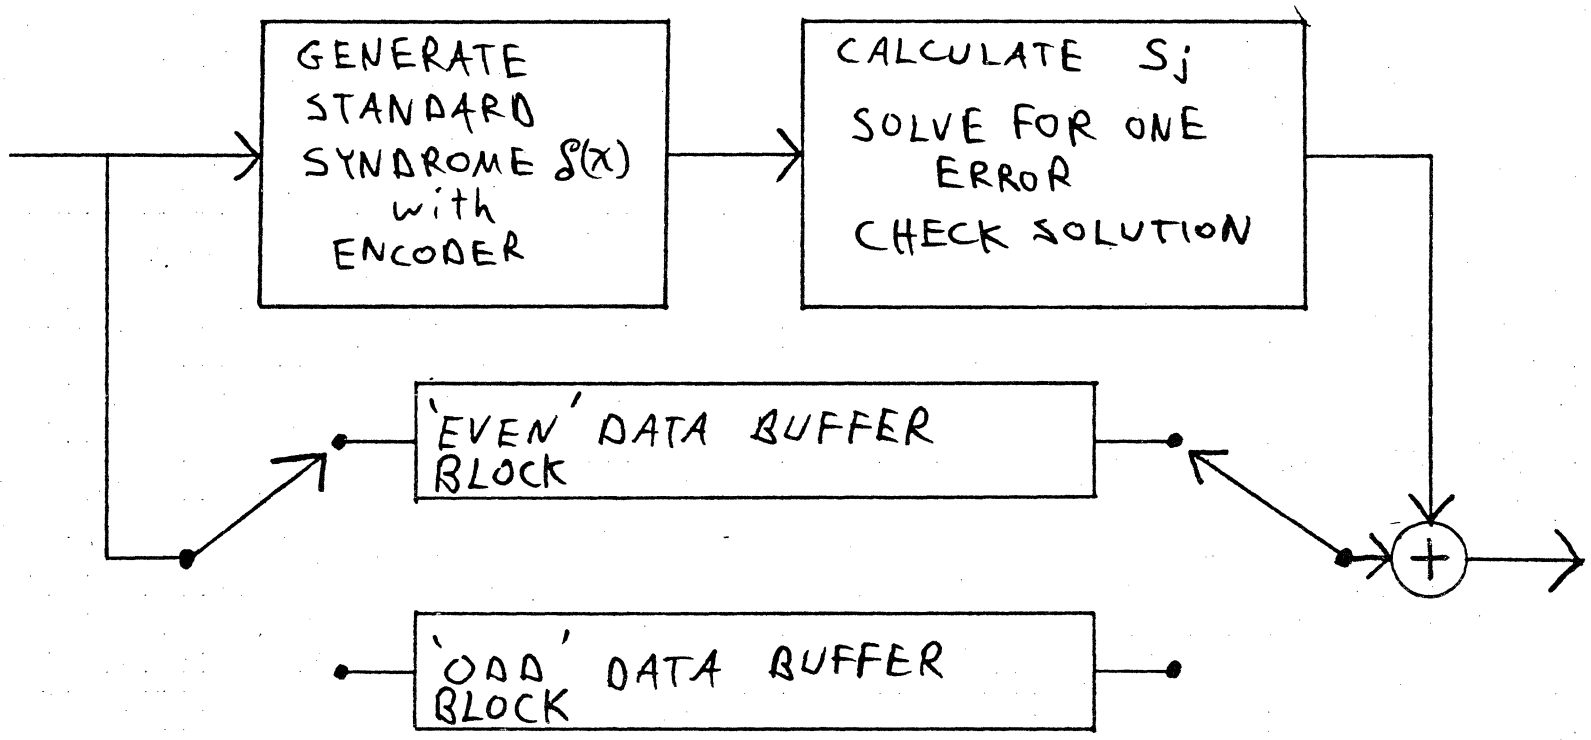

$$\left. \left(\sum_{2b-1} d^{i(b-1)} + \sum_{2b-2} d^{i(b-2)} + \dots + \sum_b \right) \right] d^{ib} +$$

$$\left(\sum_{b-1} d^{i(b-1)} + \sum_{b-2} d^{i(b-2)} + \dots + \sum_0 \right)$$

Let $\frac{r}{b} = R$ (an integer) # of multiplies over $GF(2^m)$.
 $d^{i(b-1)}, d^{i(b-2)}, \dots, d^i$ are pre-computed constants.

On the Fly Correction of Single Bursts
with Duplicate Encoder and Simple Error
Trapping Decoding

Fig. 6

$$\sigma'(x) = x^2 + \sigma_1 x + \sigma_2 = 0$$

where $\sigma_1 = \frac{s_2 s_3 + s_1 s_4}{s_2^2 + s_1 s_3}$

$$\sigma_2 = \frac{s_3^2 + s_2 s_4}{s_2^2 + s_1 s_3}$$

Let $x = y \sigma_1$

$$\sigma_1^2 y^2 + \sigma_1^2 y = \sigma_2$$

$$y^2 + y = \frac{\sigma_2}{\sigma_1^2} = d$$

Look-up d to get
a root ' y_p '

$y_p + 1$ is other root

$$X_1 = \sigma_1 y_p$$

$$X_2 = \sigma_1 (y_p + 1)$$

Look-up Table to Find Roots of Second Degree Equation

IBM CONFIDENTIAL 12/16/68

WHITNEY : ERROR CORRECTION CODE

- Each Area Count has 12 check bytes ECC.
Key
DATA (WORD = 13 bytes to 47476 bytes)

- Correct one group of 3 consecutive bytes
(50% of 4 byte groups)

- High degree of Error Detection.

- Syndrome Computation in Whitney.

Syndrome Decoding in Storage Control.

Error correction in Host Memory.

- ECC Uncorrectable Error → Reread with Offsets.
Upto. 37 reread operations in ERP

- Unrecoverable Error → Track flagged Unusable
Alternate Track assigned.

$\frac{12 \times 3}{1000} \xrightarrow{\text{CKD}} \begin{matrix} 3.6\% \text{ for } 1000 \text{ byte record} \\ 1.8\% \text{ for } 2000 \text{ " " } \\ .36\% \text{ for } 10000 \text{ byte " } \end{matrix}$

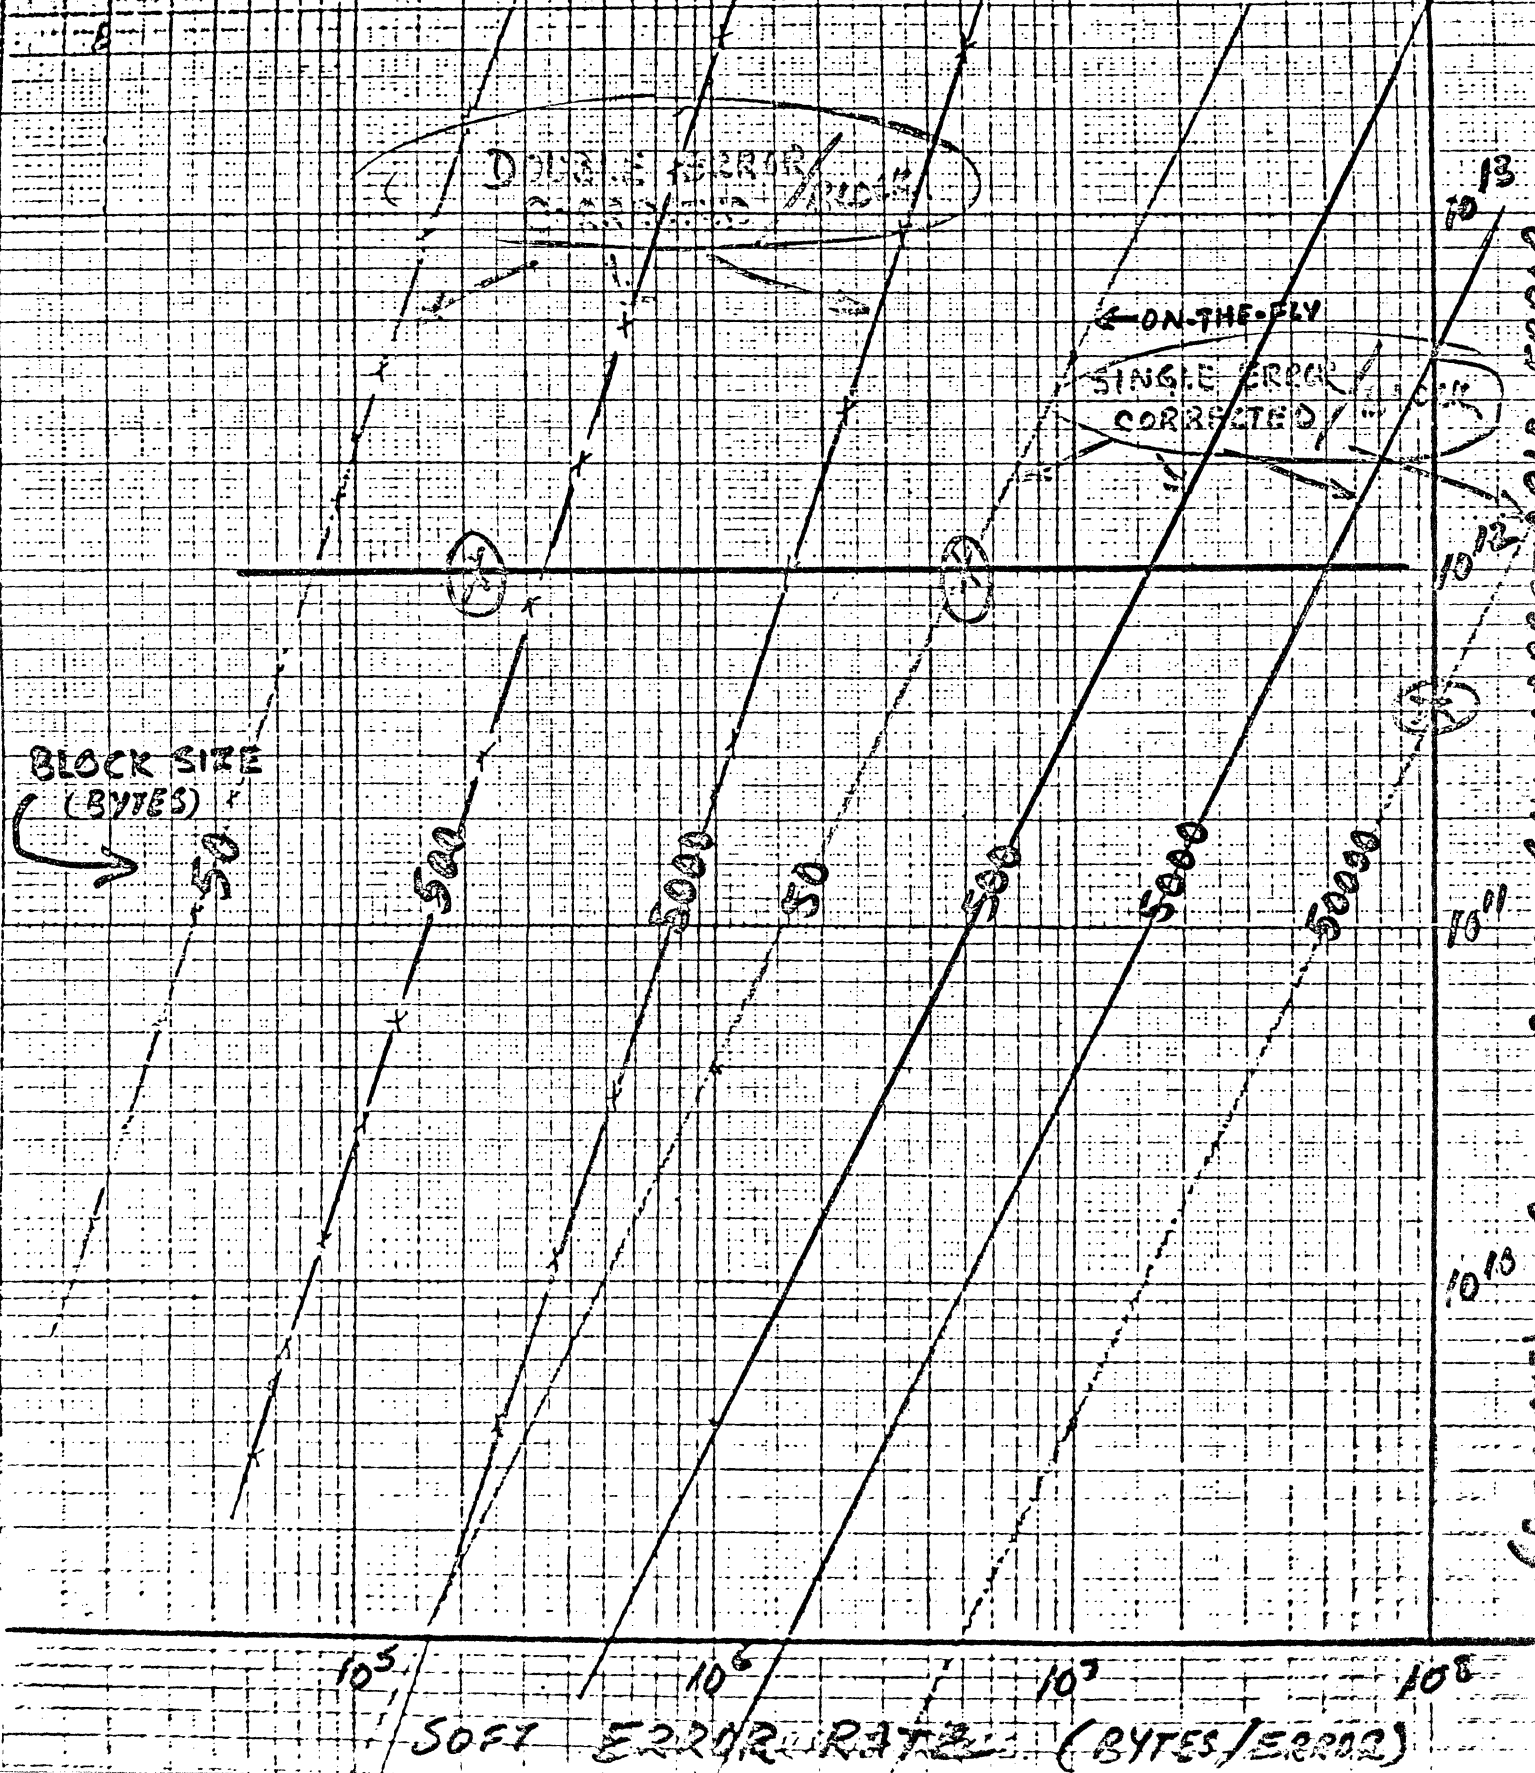

FUTURE ENVIRONMENT.

- = HIGHER DENSITY / DATA RATE.
 - SHORT MULTIPLE ERRORS.
- = DEMAND * FOR HIGHER RELIABILITY / DATA INTEGRITY.
- = RELIABILITY AWARENESS OF CUSTOMER.
 - RELIABILITY +
- = IBM'S EMPHASIS ON QUALITY.
- = COST OF UNSCHEDULED MAINTENANCE IS HIGH and INCREASING.
- = IMPACT OF HIGHER SOFT ERROR RATE.
 - ON PERFORMANCE
 - CUSTOMER ACCEPTANCE.

RATIONALE AND DESIGN POINT.

- COST OF ECC IS IN
 - DECODING HARDWARE
 - DECODING TIME
- REDUNDANCY IS NOT COST. (≈5%)
 - BUY BACK WITH DENSITY.
 - REDUCE DECODING COST. - HARDWARE
- TIME
- ON-THE-FLY CORRECTION OF MOST ERRORS
 - WITHOUT CPU INVOLVEMENT
 - NO EFFECT ON THRU-PUT
 - NO NEED TO LOG ERRORS.
- PLAN ON CORRECTING LOT OF ERRORS.
 - INCREASE DENSITY
 - TRADE-OFF IN HEAD-DISK TOLERANCES.
 - PARTIAL COVERAGE FOR SMALL DEFECTS
- RESERVE CAPABILITY TO COVER WEAKER DEVICE
 - SIGNAL WEAKER DEVICE
 - AVOID UNSCHEDULED SERVICE CALLS.

10¹⁰

SOFT ERROR RATE (BYTES/ERROR)

430

TWO LEVEL CODING SCHEME

- SEPERABLE CODING STRUCTURE WITH
TWO LEVEL CAPABILITY
- PRIMARY CAPABILITY ON-THE-FLY.
- SECONDARY CAPABILITY ON FURTHER PROCESSING
- SIMPLE CHECK AND EASY TRANSITION FROM
PRIMARY TO SECONDARY
- BYTE PROCESSING AND BYTE CORRECTION.
- INTERLEAVED FOR BURST CORRECTION.
- FLEXIBILITY ON BLOCK SIZE.

IBM CONFIDENTIAL

AMP 1/12/81.

TRACK

BLOCK

2x

2x

SECONDARY CHECK BYTES.

TWO INTERLEAVED WORDS.

SUBBLOCK

2x

PRIMARY CHECK BYTES.

ECC DATA FORMAT.

PRIMARY WORD (SUB BLOCK)

432
REDUNDANCY \approx 3%

$$\begin{array}{r} 64 \\ \text{DATA} \end{array} + \begin{array}{r} 2 \\ \text{CHECK} \end{array} = 66 \text{ BYTES/WORD}$$

- CORRECT ONE BYTE/WORD (BYTE ERROR)
- MAXIMUM DECODE TIME \approx 66 SHIFTS.
- ON-THE-FLY CORRECTION (~~66~~¹³² BYTE BUFFER)
- INTERLEAVE TWO WORDS (BURST 9-bit MIN)
- MORE INTERLEAVING FOR LONGR BURST. (\Rightarrow BUFFER)

SECONDARY WORD (BLOCK)

REDUNDANCY \approx 1%

$$4 \text{ SUBBLOCK} + 2 \text{ CHECK BYTES} = 266 \text{ BYTES/BLOCK}$$

- SIMPLE CHECK DETECTS DOUBLE ERROR
- CORRECTS TWO BYTE ERROR IN ONE SUBBLOCK
- DECODING VIA MICROCODE PROCESSING
- PROVIDES RESERVE CAPABILITY FOR WEAKER DEVICES
- SIGNALS WEAKER DEVICE
- (WILL WORK ON ANY NUMBER OF SUBBLOCKS)

END-OF-RECORD CHECK. (Optional, 2 bytes) IBM CONFIDENTIAL

- INVOKES REREAD

AMP 11/13/80

CONCLUSIONS & COMMENTS

- ✓ DESIGN FOR HIGH, SOFT ERROR RATE.
- ✓ TWO LEVEL CAPABILITY
 - FIRST LEVEL \iff AVERAGE DEVICE ?
 - SECOND LEVEL \iff WEAKER DEVICE ?
- ✓ OPTIMAL USEAGE OF REDUNDACY.
- ✓ ON-THE-FLY CORRECTION OF MOST ERRORS.
- ✓ FLEXIBILITY OF DESIGN TO FIT ERROR MODES.
(INCLUDING MOST DEFECTS).
- ✓ SECOND LEVEL PROCESSING CAN BE ELIMINATED
LATER AND/OR IN ALTERNATE OFFERING.
- ✓ USE SUBBLOCK CODE AS INDEPENDENT CODE ON
SMALL FIELDS (COUNT, KEY etc)
- ✓ TRUNCATE (OR PAD) SUBBLOCK A/O BLOCK IN CKD.
- ✓ NEW CONCEPT IN ERROR PROCESSING IN DASD.
